Preface

If you're contemplating whether to devote some time to this book, read this:

- MariaDB Server is a general-purpose, open source, relational database management system, optimised for performance and easy usability; it has its roots in MySQL Server, and is an alternative to Postgres, Oracle Database and other relational and NoSQL databases
- This book is the full documentation on MariaDB Server, a “Reference Manual Plus” which includes aspects of a User's Guide; it is based on the contents of the MariaDB Knowledge base (<https://mariadb.com/kb/> ) , an open, community-edited site contributed to since the inception of MariaDB in 2009
- This edition is not specific to any version of MariaDB Server, but includes functionality up to the latest version of MariaDB at the time of generation

This preface describes the goals, structure and contents of the documentation. Reading it is intended as a helpful step in understanding how to best use the manual to improve productivity in using MariaDB Server.

This Book's “Prehistory”

As noted, MariaDB Server has its roots in MySQL Server. It started as a fork of MySQL Server, using the same GPLv2 license. However, although the MySQL Server documentation was always publicly available, it was never released using a free documentation license. This means that the documentation of MariaDB Server was created from scratch. Or rather, from the online help texts, which had a compatible open licence that made them usable as a starting point.

The place to which documentation was written was labelled the “Knowledge Base”, by MySQL and MariaDB creator Michael “Monty” Widenius. The Knowledge Base was – and remains – a community effort. As with many community efforts, there are core contributors around whom the work is centered. This is where Daniel Bartholomew loaded the online help text, as a first seed. For roughly the last ten years, the core editor of the MariaDB Knowledge Base has been Ian Gilfillan, working for MariaDB Foundation and based in South Africa. Hence, his name is on the cover of the book. However, there are a large number of other contributors, many of whom come from MariaDB Corporation – both as developers of code and as documentation writers. They are listed on <https://mariadb.com/kb/stats/users/> .

With now some 3000 pages in this book, most of the initial holes in the documentation have been filled. There should now be no reason to do as in the very early days of MariaDB Server – namely look up MariaDB features in the MySQL documentation. On the contrary, the functionality of the two databases have diverged considerably, so you would be ill advised not to use this MariaDB Server specific documentation.

The First Edition

The first edition of the MariaDB Server Documentation as a PDF file was released in April 2022. Prior to this, the contents were accessible as individual Knowledge Base (KB) articles. But already in 2014 – over seven years before – the user base requested a PDF version, as seen by MariaDB's Jira entry <https://jira.mariadb.org/browse/MDEV-6881>  MariaDB Documentation improvements. There, user Stoykov pointed out that MariaDB documentation already had search capabilities and a way to mirror the KB in an offline version – but lacked downloadable PDF and EPUB versions,

Fast forward some seven years and a number of upvotes and watchers, we decided to devote resources to it. Creating a PDF from an HTML file is something Python is good at, and Dorje Gilfillan did all the tweaking necessary to merge the individual KB pages into one huge HTML file for PDF conversion.

This Book's Structure

We had to impose a chapter structure on the book which is only indirectly visible from a collection of KB articles on the web. This means that the work in compiling the PDF isn't just about merging many KB pages in an order that could be derived from the hierarchical pointers between the articles. It also involves cleaning up that structure.

As a result, you will see two tables of contents. One is a one-pager overview with just the two top levels of hierarchy. The other is over 30 pages long. True to the Open Source mantra of “release early, release often”, we believe that the structure can still be improved upon – but it is a good starting point. We have seven overall chapters, and the structures below them all make sense at some level.

To get the most out of the book, we recommend you to spend time making yourself familiar with the table of contents. It will give you an idea of existing functionality. Just browsing it through may give you ideas of commands you didn't know existed.

This Book's Format

There is currently just one version of the book. It's delivered in the PDF format, and in the 1 / sqrt(2) aspect ratio, meaning A4. As we envision it to be read mostly on-screen anyway, we wanted to avoid the additional complexity of also providing a US Letter format. If we meet demand for further versions, doing US Letter is of course an option; however, given there are many ways to improve the documentation, we would also like to understand how adding another aspect ratio of the PDF would benefit the users in practice.

We don't yet provide the ePub format. Again, if you desire ePub, please educate us as to what added benefits you expect of ePub on top of PDF.

Use Cases For This Book

We expect the main use case for the PDF version of the book to be offline access. Offline may be imposed by a flaky or non-existent internet, but also by self-imposed abstinence from the many distractions of being online.

We expect that browsing the PDF will enable concentrated time to be spent on learning about MariaDB Server. The search functionality of PDF browsers helps in finding out about commands and syntax you already know of; browsing through a PDF – in particular the clickable Table of Contents – will hopefully provide you with an educational overview better than the online KB does.

We expect downloading the manual into laptops, tablets and phones will make sense. If you have the MariaDB Server Documentation on your phone, you can turn waiting time into something productive, perhaps even fun.

What we should work on

We have lots of room for improvement. That said, our foremost goal now is to get the book out, to get it used. User feedback will help us determine the right priority for our already existing ideas for improvements. We will likely get other requests beyond what we currently have in mind.

In the area of basic usability, an index has been spoken about. Looking up commands through searches or through browsing the table of contents is ok, but an index also has use cases. Our plan here starts from automatic indexing based on keywords of the headers of individual articles.

In the area of layout, we are looking at finding icons that make the PDF look more like a book, and less like a web page. We already solved the first issue, which was to find a clearer visual distinction between links within the PDF and links to the web.

In the area of structure, the length of individual chapters varies a lot. It may make sense to move around chapters in the TOC tree, to be more balanced. It may be that the reader expects another ordering based on experiences from other databases. It may even be that we lack entire topics. For instance, we eliminated the Release Notes for unsupported versions of MariaDB, even though these are still accessible on the KB.

In the area of accessibility, there may be places we should publish the PDF to make it easier to find, download, and use.

The common denominator for all of the above is that we need your feedback on what makes sense for you as a user of MariaDB Server.

Give Us Feedback

We would like to pick the brains of individual users. At conferences, asking open-ended questions is easy and feels productive for both parties, when meeting in the corridors between talks. Replicating the same productive discussion on-line is much harder. It takes effort from both parties. It feels like work.

We are still looking for the best way for you to give us meaningful feedback. Feel free to approach us over Zulip (<https://mariadb.zulipchat.com/> – the Documentation topic). Also email to foundation@mariadb.org will find its way to us.

When you find individual bugs, please enter them into Jira using the guidelines mentioned in the KB article <https://mariadb.com/kb/en/reporting-documentation-bugs/>.

Acknowledgements

Compiling any book requires more effort than expected by the authors, and more than visible to the readers. This book is no exception. It has been over ten years in the making.

The primary thanks go to Ian Gilfillan, as the overall editor of the book and as the individually most productive author.

Close to Ian, we have Daniel Bartholomew. Daniel even beats Ian when it comes to articles created, and comes second on articles edited.

Among the community contributors, we want to highlight Federico Razzoli. He has two accounts, totalling 4488, at the time of writing – making him rank third amongst personal contributors.

When it comes to organisational contributors, the largest one is MariaDB Corporation. With them coding most of the features, they also stand for the lion's share of their documentation. As writers, besides Daniel Bartholomew whom we already mentioned several times, we want to highlight Russell Dyer, Kenneth Dyer, Geoff Montee, and Jacob Moorman.

As the developer of the KB software itself, Bryan Alsdorf deserves special acknowledgement.

A special thanks goes to Michael "Monty" Widenius, the creator of MariaDB. Monty has always understood the importance of documentation. He is leading by example, with a large number of personal edits. In fact, Monty has the second highest number of edits amongst developers, after Sergei Golubchik and followed by Sergey Petrunia – all of which have over a thousand edits.

Amongst the prolific contributors within the MariaDB Corporation Engineering team, the Connectors team stands out, with Diego Dupin, Georg Richter, and Lawrin Novitzky ranking near the top. However, we have decided not to include Connectors documentation in this first edition; we are contemplating whether it should be a separate PDF manual.

Other past and present Engineering team members, in decreasing order of number of edits, are David Hill, Dipti Joshi, David

Thompson, Massimiliano Pinto, Kolbe Kegel, Vladislav Vaintroub, Ralf Gebhardt, Markus Mäkelä, Sunanda Menon, the late Rasmus Johansson, Todd Stoffel, Elena Stepanova, Julien Fritsch, and Alexander Barkov. They all have more than one hundred edits, which is a lot.

As a true Open Source project, MariaDB Server documentation attracts attention and plentiful contributions also from outside the MariaDB Corporation Documentation and Engineering teams. We want to highlight those with over a hundred edits: Colin Charles and Stephane Varoqui, both of MariaDB Corporation, and Daniel Black, of MariaDB Foundation.

Amongst community contributors in the over-a-hundred-edits category, we want to mention especially Alena Subotina, with edits related to the dbforge documentation tool, and Juan Telleria, with edits often related to R Statistical Programming. Prolific contributors whose contributions are not visible in this English manual are Esper Ecyan (Japanese) and Hector Stredel (French); Federico Razzoli (Italian) has many edits also in English.

We also want to extend a thank you to the code developers who make work easy for the documentation team through thoroughly prepared, reusable texts in Jira; in this category, Marko Mäkelä and Oleksandr Byelkin come to mind.

As for the PDF manual, it has been teamwork between Ian and his son Dorje Gilfillan. Ian has done what editors do, Dorje has coded the Python code that compiles the KB pages into one.

All in all, thank you to everyone who has contributed to this book! We hope compiling it into one volume is of use for you, and we would love to hear what you think about the end result.

Munich, Germany, October 2022, updated October 2024

Kaj Arnö, CEO, MariaDB Foundation

Chapter Contents

Chapter 1 Using MariaDB Server	49
1.1 SQL Statements & Structure.....	49
1.2 Built-in Functions.....	909
1.3 Clients & Utilities.....	1302
Chapter 2 MariaDB Administration	1458
2.1 Getting, Installing, and Upgrading MariaDB.....	1458
2.2 User & Server Security.....	1919
2.3 Backing Up and Restoring Databases.....	1981
2.4 Server Monitoring & Logs.....	2051
2.5 Partitioning Tables.....	2078
2.6 MariaDB Audit Plugin.....	2105
2.7 Variables and Modes.....	2105
2.8 Copying Tables Between Different MariaDB Databases and MariaDB Servers.....	2246
Chapter 3 High Availability & Performance Tuning	2248
3.1 MariaDB Replication.....	2248
3.2 MariaDB Galera Cluster.....	2368
3.3 Optimization and Tuning.....	2444
3.4 Connection Redirection Mechanism in the MariaDB Client/Server Protocol.....	2738
Chapter 4 Programming & Customizing MariaDB	2739
4.1 Programmatic & Compound Statements.....	2740
4.2 Stored Routines.....	2740
4.3 Triggers & Events.....	2764
4.4 Views.....	2773
4.5 User-Defined Functions.....	2776

Chapter 2 MariaDB Administration	1458
2.1 Getting, Installing, and Upgrading MariaDB	1458
2.1.1 Where to Download MariaDB	1459
2.1.2 MariaDB Binary Packages	1460
2.1.2.1 Installing MariaDB RPM Files	1461
2.1.2.1.1 About the MariaDB RPM Files	1461
2.1.2.1.2 Installing MariaDB with yum/dnf	1463
2.1.2.1.3 Installing MariaDB with zypper	1468
2.1.2.1.4 Installing MariaDB With the rpm Tool	1472
2.1.2.1.5 Checking MariaDB RPM Package Signatures	1474
2.1.2.1.6 Troubleshooting MariaDB Installs on Red Hat/CentOS	1475
2.1.2.1.7 MariaDB for DirectAdmin Using RPMs	1475
2.1.2.1.8 MariaDB Installation (Version 10.1.21) via RPMs on CentOS 7	1476
2.1.2.1.9 Why Source RPMs (SRPMs) Aren't Packaged For Some Platforms	1477
2.1.2.1.10 Building MariaDB from a Source RPM	1477
2.1.2.2 Installing MariaDB .deb Files	1478
2.1.2.3 Installing MariaDB MSI Packages on Windows	1485

2.1.2.4 Installing MariaDB Server PKG packages on macOS	1493
2.1.2.5 Installing MariaDB Binary Tarballs	1493
2.1.2.6 Installing MariaDB Server on macOS Using Homebrew	1496
2.1.2.7 Installing MariaDB Windows ZIP Packages	1497
2.1.2.8 Compiling MariaDB From Source	1497
2.1.2.8.1 Get, Build and Test Latest MariaDB the Lazy Way	1498
2.1.2.8.2 MariaDB Source Code	1499
2.1.2.8.3 Build Environment Setup for Linux	1500
2.1.2.8.4 Generic Build Instructions	1501
2.1.2.8.5 Compiling MariaDB with Extra Modules/Options	1504
2.1.2.8.5.1 Using MariaDB with TCMalloc or jemalloc	1504
2.1.2.8.5.2 Specifying Which Plugins to Build	1507
2.1.2.8.6 Creating the MariaDB Source Tarball	1507
2.1.2.8.7 Creating the MariaDB Binary Tarball	1507
2.1.2.8.8 Build Environment Setup for Mac	1508
2.1.2.8.9 Building MariaDB From a Source RPM	1508
2.1.2.8.10 Building MariaDB on CentOS	1508
2.1.2.8.11 Building MariaDB on Fedora	1510
2.1.2.8.12 Building MariaDB on Debian	1511
2.1.2.8.13 Building MariaDB on FreeBSD	1512
2.1.2.8.14 Building MariaDB on Gentoo	1514
2.1.2.8.15 Building MariaDB on Solaris and OpenSolaris	1514
2.1.2.8.16 Building MariaDB on Ubuntu	1515
2.1.2.8.17 Building MariaDB on Windows	1516
2.1.2.8.18 Creating a Debian Repository	1518
2.1.2.8.19 Building MariaDB From Source Using musl-based GNU/Linux	1519
2.1.2.8.20 Compiling MariaDB for Debugging	1520
2.1.2.8.21 Cross-compiling MariaDB	1522
2.1.2.8.22 MariaDB Source Configuration Options	1523
2.1.2.8.23 Building RPM Packages From Source	1523
2.1.2.8.24 Compile and Using MariaDB with Sanitizers (ASAN, UBSAN, TSAN, MSAN)	1523
2.1.2.9 Distributions Which Include MariaDB	1526
2.1.2.10 Running Multiple MariaDB Server Processes	1527
2.1.2.11 Installing MariaDB Alongside MySQL	1528
2.1.2.12 GPG	1531
2.1.2.13 MariaDB Platform Deprecation Policy	1532
2.1.2.14 Automated MariaDB Deployment and Administration	1536
2.1.2.14.1 Why to Automate MariaDB Deployments and Management	1537
2.1.2.14.2 A Comparison Between Automation Systems	1538
2.1.2.14.3 Ansible and MariaDB	1540
2.1.2.14.3.1 Ansible Overview for MariaDB Users	1541
2.1.2.14.3.2 Deploying to Remote Servers with Ansible	1543
2.1.2.14.3.3 Deploying Docker Containers with Ansible	1545
2.1.2.14.3.4 Existing Ansible Modules and Roles for MariaDB	1545
2.1.2.14.3.5 Installing MariaDB .deb Files with Ansible	1547
2.1.2.14.3.6 Running mariadb-tzinfo-to-sql with Ansible	1549
2.1.2.14.3.7 Managing Secrets in Ansible	1550
2.1.2.14.4 Puppet and MariaDB	1551
2.1.2.14.4.1 Puppet Overview for MariaDB Users	1551
2.1.2.14.4.2 Bolt Examples	1554
2.1.2.14.4.3 Puppet hiera Configuration System	1556
2.1.2.14.4.4 Deploying Docker Containers with Puppet	1557
2.1.2.14.4.5 Existing Puppet Modules for MariaDB	1559
2.1.2.14.5 Vagrant and MariaDB	1559
2.1.2.14.5.1 Vagrant Overview for MariaDB Users	1560
2.1.2.14.5.2 Creating a Vagrantfile	1563
2.1.2.14.5.3 Vagrant Security Concerns	1567
2.1.2.14.5.4 Running MariaDB ColumnStore containers on Linux, Windows and MacOS	1568
2.1.2.14.6 MariaDB Containers	1569
2.1.2.14.6.1 Benefits of Managing MariaDB Containers with Orchestration Software	1570
2.1.2.14.6.2 Installing and Using MariaDB via Docker	1572
2.1.2.14.6.3 Container Backup and Restoration	1577
2.1.2.14.6.4 Container Security Concerns	1579
2.1.2.14.6.5 Adding Plugins to the MariaDB Docker Official Image	1580
2.1.2.14.6.6 Setting Up a LAMP Stack with Docker Compose	1581
2.1.2.14.6.7 Creating a Custom Container Image	1584
2.1.2.14.6.8 MariaDB Server Docker Official Image Environment Variables	1587

2.1.2.14.6.9 Running MariaDB ColumnStore Docker containers on Linux, Windows and MacOS	1589
2.1.2.14.6.10 Docker Official Image Frequently Asked Questions	1589
2.1.2.14.6.11 MariaDB Container Cheat Sheet	1594
2.1.2.14.6.12 Using Healthcheck.sh.....	1596
2.1.2.14.6.13 Docker and AWS EC2	1599
2.1.2.14.6.14 Docker and Google Cloud	1601
2.1.2.14.6.15 Docker and Microsoft Azure	1606
2.1.2.14.7 Kubernetes and MariaDB	1611
2.1.2.14.8 Kubernetes Overview for MariaDB Users	1611
2.1.2.14.9 Kubernetes Operators for MariaDB	1613
2.1.2.14.10 Automating Upgrades with MariaDB.Org Downloads REST API	1614
2.1.2.14.11 HashiCorp Vault and MariaDB	1616
2.1.2.14.12 Orchestrator Overview.....	1617
2.1.2.14.13 Rotating Logs on Unix and Linux	1619
2.1.2.14.14 Automating MariaDB Tasks with Events	1619
2.1.2.15 MariaDB Package Repository Setup and Usage	1620
2.1.3 Upgrading MariaDB	1625
2.1.3.1 Upgrading Between Major MariaDB Versions	1626
2.1.3.2 Upgrading Between Minor Versions on Linux	1628
2.1.3.3 Upgrading from MariaDB 11.4 to MariaDB 11.8	1629
2.1.3.4 Upgrading from MariaDB 10.11 to MariaDB 11.4	1630
2.1.3.5 Upgrading from MariaDB 11.3 to MariaDB 11.4	1632
2.1.3.6 Upgrading from MariaDB 11.2 to MariaDB 11.3	1633
2.1.3.7 Upgrading from MariaDB 11.1 to MariaDB 11.2	1634
2.1.3.8 Upgrading from MariaDB 11.0 to MariaDB 11.1	1635
2.1.3.9 Upgrading from MariaDB 10.11 to MariaDB 11.0	1637
2.1.3.10 Upgrading from MariaDB 10.6 to MariaDB 10.11	1638
2.1.3.11 Upgrading from MariaDB 10.5 to MariaDB 10.6	1641
2.1.3.12 Upgrading from MariaDB 10.4 to MariaDB 10.5	1643
2.1.3.13 Upgrading from MariaDB 10.3 to MariaDB 10.4	1646
2.1.3.14 Upgrading MariaDB on Windows.....	1648
2.1.3.15 Upgrading Galera Cluster.....	1649
2.1.3.15.1 Upgrading Between Minor Versions with Galera Cluster	1650
2.1.3.15.2 Upgrading from MariaDB 10.4 to MariaDB 10.5 with Galera Cluster	1650
2.1.3.15.3 Upgrading from MariaDB 10.3 to MariaDB 10.4 with Galera Cluster	1652
2.1.3.16 Upgrading from MySQL to MariaDB	1653
2.1.3.16.1 Upgrading from MySQL to MariaDB	1653
2.1.3.16.2 Moving from MySQL to MariaDB in Debian 9	1657
2.1.3.16.3 Screencast for Upgrading MySQL to MariaDB (Obsolete)	1661
2.1.4 Downgrading between Major Versions of MariaDB	1661
2.1.5 Compiling MariaDB From Source	1662
2.1.6 Starting and Stopping MariaDB	1662
2.1.6.1 Starting and Stopping MariaDB Server	1663
2.1.6.2 Configuring MariaDB with Option Files	1665
2.1.6.3 mariadb Configuration Files and Groups	1674
2.1.6.4 mariadb Options	1674
2.1.6.5 What to Do if MariaDB Doesn't Start	1720
2.1.6.6 Running MariaDB from the Build Directory	1724
2.1.6.7 mysql.server	1726

2.1.7.4 Configuring Swappiness	1761
2.1.8 Troubleshooting Installation Issues	1762
2.1.8.1 Troubleshooting Connection Issues	1763
2.1.8.2 Installation issues on Windows	1763
2.1.8.3 Troubleshooting MariaDB Installs on Red Hat/CentOS	1763
2.1.8.4 Installation issues on Debian and Ubuntu	1764
2.1.8.4.1 Differences in MariaDB in Debian (and Ubuntu)	1764
2.1.8.4.2 Upgrading from MySQL to MariaDB	1765
2.1.8.4.3 Creating a Debian Repository	1765
2.1.8.4.4 apt-upgrade Fails, But the Database is Running	1765
2.1.8.5 What to Do if MariaDB Doesn't Start	1766
2.1.8.6 Installing on an Old Linux Version	1766
2.1.8.7 Error: symbol mysql_get_server_name, version libmysqlclient_16 not defined	1767
2.1.9 Installing System Tables (mysql_install_db)	1767
2.1.10 mariadb-install-db.exe	1767
2.1.11 Configuring MariaDB with Option Files	1769
2.1.12 MariaDB Environment Variables	1769
2.1.13 MariaDB on Amazon AWS	1769
2.1.14 Migrating to MariaDB	1770
2.1.14.1 Migrating to MariaDB from MySQL	1771
2.1.14.1.1 MySQL vs MariaDB: Performance	1772
2.1.14.1.2 MariaDB versus MySQL: Compatibility	1775
2.1.14.1.3 Upgrading from MySQL to MariaDB	1780
2.1.14.1.4 Incompatibilities and Feature Differences Between MariaDB Rolling and MySQL 8.0	1780
2.1.14.1.5 Incompatibilities and Feature Differences Between MariaDB 11.4 and MySQL 8.0	1783
2.1.14.1.6 Incompatibilities and Feature Differences Between MariaDB 10.11 and MySQL 8.0	1786
2.1.14.1.7 Incompatibilities and Feature Differences Between MariaDB 10.6 and MySQL 8.0	1789
2.1.14.1.8 Incompatibilities and Feature Differences Between MariaDB 10.5 and MySQL 8.0	1792
2.1.14.1.9 Replication Compatibility Between MariaDB and MySQL	1795
2.1.14.1.10 Function Differences Between MariaDB and MySQL	1797
2.1.14.1.10.1 Function Differences Between MariaDB Rolling and MySQL 8.0	1797
2.1.14.1.10.2 Function Differences Between MariaDB 11.4 and MySQL 8.0	1801
2.1.14.1.10.3 Function Differences Between MariaDB 10.11 and MySQL 8.0	1804
2.1.14.1.10.4 Function Differences Between MariaDB 10.6 and MySQL 8.0	1808
2.1.14.1.10.5 Function Differences Between MariaDB 10.5 and MySQL 8.0	1811
2.1.14.1.11 System Variable Differences between MariaDB and MySQL	1814
2.1.14.1.11.1 System Variable Differences Between MariaDB 11.4 and MySQL 8.0	1815
2.1.14.1.11.2 System Variable Differences Between MariaDB 10.11 and MySQL 8.0	1826
2.1.14.1.11.3 System Variable Differences Between MariaDB 10.6 and MySQL 8.0	1837
2.1.14.1.11.4 System Variable Differences Between MariaDB 10.5 and MySQL 8.0	1847
2.1.14.1.12 Upgrading from MySQL 5.7 to MariaDB 10.2	1857
2.1.14.1.13 Installing MariaDB Alongside MySQL	1857
2.1.14.1.14 Moving from MySQL to MariaDB in Debian 9	1857
2.1.14.2 Migrating to MariaDB from SQL Server	1857
2.1.14.2.1 Understanding MariaDB Architecture	1858
2.1.14.2.2 SQL Server Features Not Available in MariaDB	1865
2.1.14.2.3 SQL Server Features Implemented Differently in MariaDB	1866
2.1.14.2.4 MariaDB Features Not Available in SQL Server	1867
2.1.14.2.5 Setting Up MariaDB for Testing for SQL Server Users	1869
2.1.14.2.6 Syntax Differences between MariaDB and SQL Server	1870
2.1.14.2.7 SQL Server and MariaDB Types Comparison	1875
2.1.14.2.8 MariaDB Transactions and Isolation Levels for SQL Server Users	1879
2.1.14.2.9 MariaDB Authorization and Permissions for SQL Server Users	1886
2.1.14.2.10 Repairing MariaDB Tables for SQL Server Users	1889
2.1.14.2.11 MariaDB Backups Overview for SQL Server Users	1891
2.1.14.2.12 MariaDB Replication Overview for SQL Server Users	1893
2.1.14.2.13 Moving Data Between SQL Server and MariaDB	1899
2.1.14.2.14 SQL_MODE=MSSQL	1902
2.1.14.3 Migrating to MariaDB from PostgreSQL	1902
2.1.14.3.1 SQL_MODE=ORACLE	1905
2.1.14.4 Installing MariaDB on IBM Cloud	1909
2.1.14.5 mysqld Configuration Files and Groups	1919
2.2 User & Server Security	1919
2.2.1 Securing MariaDB	1919
2.2.1.1 Encryption	1919
2.2.1.1.1 Data-in-Transit Encryption	1920

2.2.1.1.1.1	Secure Connections Overview	1920
2.2.1.1.1.2	Certificate Creation with OpenSSL	1925
2.2.1.1.1.3	Securing Connections for Client and Server	1927
2.2.1.1.1.4	Replication with Secure Connections	1930
2.2.1.1.1.5	Securing Communications in Galera Cluster	1933
2.2.1.1.1.6	SSL/TLS System Variables	1934
2.2.1.1.1.7	SSL/TLS Status Variables	1937
2.2.1.1.1.8	Using TLSv1.3	1940
2.2.1.1.2	Data-at-Rest Encryption	1941
2.2.1.1.2.1	Data-at-Rest Encryption Overview	1941
2.2.1.1.2.2	Why Encrypt MariaDB Data?	1943
2.2.1.1.2.3	Key Management and Encryption Plugins	1944
2.2.1.1.2.4	Encrypting Binary Logs	1944

2.3.4.7	Setting up a Replica with Mariabackup	2029
2.3.4.8	Files Backed Up By Mariabackup	2031
2.3.4.9	Files Created by Mariabackup	2032
2.3.4.10	Using Encryption and Compression Tools With Mariabackup	2036

2.3.4.11 How Mariabackup Works	2038
2.3.4.12 Mariabackup and BACKUP STAGE Commands.....	2039
2.3.4.13 mariabackup SST Method	2042
2.3.4.14 Manual SST of Galera Cluster Node with Mariabackup	2047
2.3.4.15 Individual Database Restores with MariaBackup from Full Backup	2047
2.3.5 mariadb-hotcopy.....	2051
2.4 Server Monitoring & Logs.....	2051
2.4.1 Overview of MariaDB Logs.....	2051
2.4.2 Error Log	2052
2.4.3 Setting the Language for Error Messages	2059
2.4.4 General Query Log.....	2061
2.4.5 Slow Query Log.....	2063
2.4.5.1 Slow Query Log Overview.....	2063
2.4.5.2 Slow Query Log Extended Statistics	2069
2.4.5.3 mariadb-dumpslow.....	2069
2.4.5.4 EXPLAIN in the Slow Query Log	2069
2.4.5.5 log_slow_always_query_time System Variable	2069
2.4.5.6 mariadb-dumpslow_log Table	2070
2.4.6 Rotating Logs on Unix and Linux.....	2070
2.4.7 Binary Log.....	2074
2.4.8 InnoDB Redo Log	2074
2.4.9 InnoDB Undo Log	2074
2.4.10 MyISAM Log.....	2074
2.4.11 Transaction Coordinator Log.....	2074
2.4.11.1 Transaction Coordinator Log Overview	2075
2.4.11.2 Heuristic Recovery with the Transaction Coordinator Log	2077
2.4.12 SQL Error Log Plugin.....	2078
2.4.13 Writing Logs Into Tables.....	2078
2.4.14 Performance Schema	2078
2.4.15 MariaDB Audit Plugin.....	2078
2.5 Partitioning Tables	2078
2.5.1 Partitioning Overview.....	2079
2.5.2 Partitioning Types	2091
2.5.2.1 Partitioning Types Overview.....	2092
2.5.2.2 LIST Partitioning Type	2092
2.5.2.3 RANGE Partitioning Type	2093
2.5.2.4 HASH Partitioning Type.....	2095
2.5.2.5 KEY Partitioning Type	2096
2.5.2.6 LINEAR HASH Partitioning Type	2098
2.5.2.7 LINEAR KEY Partitioning Type.....	2098
2.5.2.8 RANGE COLUMNS and LIST COLUMNS Partitioning Types.....	2098
2.5.3 Partition Pruning and Selection	2100
2.5.4 Partition Maintenance.....	2100
2.5.5 Partitioning Limitations with MariaDB	2104
2.5.6 Partitions Files	2104
2.5.7 Partitions Metadata.....	2105
2.5.8 Information Schema PARTITIONS Table	2105
2.6 MariaDB Audit Plugin	2105
2.7 Variables and Modes.....	2105
2.7.1 Full List of MariaDB Options, System and Status Variables	2106
2.7.2 Server System Variables.....	2159
2.7.3 OLD_MODE	2238
2.7.4 SQL_MODE.....	2240
2.7.5 SQL_MODE-MSSQL.....	2246
2.8 Copying Tables Between Different MariaDB Databases and MariaDB Servers	2246
Chapter 3 High Availability & Performance Tuning	2248
3.1 MariaDB Replication.....	2248
3.1.1 Replication Overview.....	2250
3.1.2 Replication Commands.....	2255
3.1.3 Setting Up Replication.....	2255
3.1.4 Setting up a Replica with Mariabackup.....	2258
3.1.5 Read-Only Replicas	2258
3.1.6 Replication as a Backup Solution.....	2258
3.1.7 Multi-Source Replication.....	2259
3.1.8 Multi-Master Ring Replication	2262
3.1.9 Replication Threads	2267
3.1.10 Global Transaction ID	2269

3.1.11 Parallel Replication	2282
3.1.12 Replication and Binary Log System Variables	2287
3.1.13 Replication and Binary Log Status Variables	2309
3.1.14 Binary Log	2315
3.1.14.1 Overview of the Binary Log	2316
3.1.14.2 Activating the Binary Log	2317
3.1.14.3 Using and Maintaining the Binary Log	2318
3.1.14.4 Binary Log Formats	2320
3.1.14.5 Binary Logging of Stored Routines	2323
3.1.14.6 SHOW BINLOG LOGS	2324
3.1.14.7 PURGE BINLOG LOGS	2324
3.1.14.8 SHOW BINLOG EVENTS	2324
3.1.14.9 SHOW MASTER STATUS	2324
3.1.14.10 Binlog Event Checksums	2324
3.1.14.11 Binlog Event Checksum Interoperability	2324
3.1.14.12 Group Commit for the Binary Log	2325
3.1.14.13 mariadb-binlog	2328
3.1.14.14 Transaction Coordinator Log	2328
3.1.14.15 Compressing Events to Reduce Size of the Binary Log	2328
3.1.14.16 Encrypting Binary Logs	2328
3.1.14.17 Flashback	2328
3.1.14.18 Relay Log	2329
3.1.14.19 Replication and Binary Log System Variables	2330
3.1.15 Unsafe Statements for Statement-based Replication	2330
3.1.16 Replication and Foreign Keys	2331
3.1.17 Relay Log	2333
3.1.18 Group Commit for the Binary Log	2333
3.1.19 Selectively Skipping Replication of Binlog Events	2333
3.1.20 Binlog Event Checksums	2334
3.1.21 Annotate_rows_log_event	2335
3.1.22 Row-based Replication With No Primary Key	2335
3.1.23 Replication Filters	2336
3.1.24 Running Triggers on the Replica for Row-based Events	2343
3.1.25 Semisynchronous Replication	2345
3.1.26 Using MariaDB Replication with MariaDB Galera Cluster	2350
3.1.26.1 Using MariaDB Replication with MariaDB Galera Cluster	2351
3.1.26.2 Using MariaDB GTIDs with MariaDB Galera Cluster	2352
3.1.26.3 Configuring MariaDB Replication between MariaDB Galera Cluster and MariaDB Server	2353
3.1.26.4 Configuring MariaDB Replication between Two MariaDB Galera Clusters	2357
3.1.27 Delayed Replication	2361
3.1.28 Replication When the Primary and Replica Have Different Table Definitions	2362
3.1.29 Restricting Speed of Reading Binlog from Primary by a Replica	2366
3.1.30 Changing a Replica to Become the Primary	2366
3.1.31 Replication with Secure Connections	2368
3.2 MariaDB Galera Cluster	2368
3.2.1 What is MariaDB Galera Cluster?	2370
3.2.2 About Galera Replication	2371
3.2.3 Galera Use Cases	2373
3.2.4 MariaDB Galera Cluster - Known Limitations	2374
3.2.5 Tips on Converting to Galera	2375
3.2.6 Getting Started with MariaDB Galera Cluster	2379
3.2.7 Configuring MariaDB Galera Cluster	2384
3.2.8 State Snapshot Transfers (SSTs) in Galera Cluster	2386
3.2.8.1 Introduction to State Snapshot Transfers (SSTs)	2386
3.2.8.2 mariabackup SST Method	2390
3.2.8.3 Manual SST of Galera Cluster Node With Mariabackup	2390
3.2.8.4 Knowledge Base	2392
3.2.8.5 Knowledge Base	2393
3.2.9 Galera Cluster Status Variables	2394
3.2.10 Galera Cluster System Variables	2401
3.2.11 Building the Galera wsrep Package on Ubuntu and Debian	2415
3.2.12 Building the Galera wsrep Package on Fedora	2415
3.2.13 Installing Galera from Source	2418
3.2.14 Galera Test Repositories	2420
3.2.15 wsrep_provider_options	2421
3.2.16 Galera Cluster Address	2432
3.2.17 Galera Load Balancer	2433

3.2.18 Upgrading Galera Cluster.....	2433
3.2.19 Using MariaDB Replication with MariaDB Galera Cluster	2433
3.2.20 Securing Communications in Galera Cluster	2433
3.2.21 Installing MariaDB Galera on IBM Cloud	2433
3.3 Optimization and Tuning	2444
3.3.1 Hardware Optimization	2445
3.3.2 Operating System Optimizations	2446
3.3.2.1 Configuring Linux for MariaDB	2446
3.3.2.2 Configuring Swappiness	2446
3.3.2.3 Filesystem Optimizations	2446
3.3.3 Optimization and Indexes	2447
3.3.3.1 The Essentials of an Index	2448
3.3.3.2 Getting Started with Indexes	2448
3.3.3.3 Full-Text Indexes	2452
3.3.3.3.1 Full-Text Index Overview	2452
3.3.3.3.2 Full-Text Index Stopwords	2456
3.3.3.3.3 MATCH AGAINST	2459
3.3.3.3.4 myisam_ftdump	2459
3.3.3.4 ANALYZE TABLE	2460
3.3.3.5 Building the best INDEX for a given SELECT	2460
3.3.3.6 Compound (Composite) Indexes	2468
3.3.3.7 EXPLAIN	2472
3.3.3.8 Foreign Keys	2472
3.3.3.9 Ignored Indexes	2476
3.3.3.10 Index Statistics	2479
3.3.3.11 Latitude/Longitude Indexing	2480
3.3.3.12 Primary Keys with Nullable Columns	2487
3.3.3.13 SHOW EXPLAIN	2488

5.3.14 MyRocks	3359
5.3.14.1 About MyRocks for MariaDB	3360
5.3.14.2 Getting Started with MyRocks	3361
5.3.14.3 Building MyRocks in MariaDB	3364
5.3.14.4 Loading Data Into MyRocks	3365
5.3.14.5 MyRocks Status Variables	3365
5.3.14.6 MyRocks System Variables	3380
5.3.14.7 MyRocks Transactional Isolation	3408
5.3.14.8 MyRocks and Replication	3408
5.3.14.9 MyRocks and Group Commit with Binary log	3409
5.3.14.10 Optimizer Statistics in MyRocks	3410
5.3.14.11 Differences Between MyRocks Variants	3411
5.3.14.12 MyRocks and Bloom Filters	3412
5.3.14.13 MyRocks and CHECK TABLE	3414
5.3.14.14 MyRocks and Data Compression	3414
5.3.14.15 MyRocks and Index-Only Scans	3416
5.3.14.16 MyRocks and START TRANSACTION WITH CONSISTENT SNAPSHOT	3417
5.3.14.17 MyRocks Column Families	3417
5.3.14.18 MyRocks in MariaDB 10.2 vs MariaDB 10.3	3418
5.3.14.19 MyRocks Performance Troubleshooting	3419
5.3.15 OQGRAPH	3420
5.3.15.1 Installing OQGRAPH	3420
5.3.15.2 OQGRAPH Overview	3421
5.3.15.3 OQGRAPH Examples	3423
5.3.15.4 Compiling OQGRAPH	3427
5.3.15.5 Building OQGRAPH Under Windows	3427
5.3.15.6 OQGRAPH System and Status Variables	3427
5.3.16 S3 Storage Engine	3428
5.3.16.1 Using the S3 Storage Engine	3429
5.3.16.2 Testing the Connections to S3	3434
5.3.16.3 S3 Storage Engine Internals	3436

5.3.16.4 aria_s3_copy	3437
5.3.16.5 S3 Storage Engine Status Variables	3439
5.3.16.6 S3 Storage Engine System Variables	3439
5.3.17 Sequence Storage Engine	3444
5.3.18 SphinxSE	3447
5.3.18.1 About SphinxSE	3448
5.3.18.2 Installing Sphinx	3452
5.3.18.3 Configuring Sphinx	3453
5.3.18.4 Installing and Testing SphinxSE with MariaDB	3454
5.3.18.5 Sphinx Status Variables	3454
5.3.19 Spider	3454
5.3.19.1 Spider Storage Engine Overview	3456
5.3.19.2 Spider Installation	3471
5.3.19.3 Spider Storage Engine Core Concepts	3475
5.3.19.4 Spider Use Cases	3476
5.3.19.5 Spider Cluster Management	3480
5.3.19.6 Spider Feature Matrix	3483
5.3.19.7 Spider System Variables	3484
5.3.19.8 Spider Table Parameters	3513
5.3.19.9 Spider Status Variables	3519
5.3.19.10 Spider Functions	3520
5.3.19.10.1 SPIDER_BG_DIRECT_SQL	3520
5.3.19.10.2 SPIDER_COPY_TABLES	3520
5.3.19.10.3 SPIDER_DIRECT_SQL	3520
5.3.19.10.4 SPIDER_FLUSH_TABLE_MON_CACHE	3520
5.3.19.11 Spider mysql Database Tables	3521
5.3.19.11.1 mysqlspider_link_failed_log Table	3521
5.3.19.11.2 mysqlspider_link_mon_servers Table	3521
5.3.19.11.3 mysqlspider_tables Table	3521
5.3.19.11.4 mysqlspider_table_crdr Table	3521
5.3.19.11.5 mysqlspider_table_position_for_recovery Table	3521
5.3.19.11.6 mysqlspider_table_sts Table	3521
5.3.19.11.7 mysqlspider_xa Table	3521
5.3.19.11.8 mysqlspider_xa_failed_log Table	3521
5.3.19.11.9 mysqlspider_xa_member Table	3521
5.3.19.12 Information Schema SPIDER_ALLOC_MEM Table	3521
5.3.19.13 Information Schema SPIDER_WRAPPER_PROTOCOLS Table	3521
5.3.19.14 Spider Differences Between SpiderForMySQL and MariaDB	3521
5.3.19.15 Spider Case Studies	3521
5.3.19.16 Spider Benchmarks	3522
5.3.19.17 Spider FAQ	3523
5.3.20 Information Schema ENGINES Table	3524
5.3.21 PERFORMANCE_SCHEMA Storage Engine	3524
5.3.22 Storage Engine Development	3524
5.3.22.1 Storage Engine FAQ	3525
5.3.22.2 Engine-defined New Table/Field/Index Attributes	3525
5.3.22.3 Table Discovery	3527
5.3.23 Converting Tables from MyISAM to InnoDB	3530
5.3.24 Machine Learning with MindsDB	3533
5.4 Plugins	3534
5.4.1 Plugin Overview	3535
5.4.2 Information on Plugins	3541
5.4.2.1 List of Plugins	3541
5.4.2.2 Information Schema PLUGINS Table	3543
5.4.2.3 Information Schema ALL_PLUGINS Table	3543
5.4.3 Plugin SQL Statements	3543
5.4.4 Creating and Building Plugins	3543
5.4.4.1 Specifying Which Plugins to Build	3543
5.4.4.2 Writing Plugins for MariaDB	3543
5.4.5 MariaDB Audit Plugin	3545
5.4.5.1 MariaDB Audit Plugin - Installation	3546
5.4.5.2 MariaDB Audit Plugin - Configuration	3547
5.4.5.3 MariaDB Audit Plugin - Log Settings	3548
5.4.5.4 MariaDB Audit Plugin - Location and Rotation of Logs	3551
5.4.5.5 MariaDB Audit Plugin - Log Format	3552
5.4.5.6 MariaDB Audit Plugin - Versions	3553
5.4.5.7 MariaDB Audit Plugin Options and System Variables	3554

5.4.5.8 MariaDB Audit Plugin - Status Variables	3558
5.4.6 Authentication Plugins	3559
5.4.6.1 Pluggable Authentication Overview	3560
5.4.6.2 Authentication Plugin - mysql_native_password	3568
5.4.6.3 Authentication Plugin - mysql_old_password	3570
5.4.6.4 Authentication Plugin - ed25519	3571
5.4.6.5 Authentication Plugin - GSSAPI	3575
5.4.6.6 Authentication with Pluggable Authentication Modules (PAM)	3582
5.4.6.6.1 Authentication Plugin - PAM	3582
5.4.6.6.2 User and Group Mapping with PAM	3593
5.4.6.6.3 Configuring PAM Authentication and User Mapping with Unix Authentication	3598
5.4.6.6.4 Configuring PAM Authentication and User Mapping with LDAP Authentication	3601
5.4.6.7 Authentication Plugin - Unix Socket	3611
5.4.6.8 Authentication Plugin - Named Pipe	3615
5.4.6.9 Authentication Plugin - SHA-256	3617
5.4.6.10 Authentication Plugin - PARSEC	3619
5.4.7 Password Validation Plugins	3619
5.4.7.1 Simple Password Check Plugin	3620
5.4.7.2 Cracklib Password Check Plugin	3622
5.4.7.3 Password Reuse Check Plugin	3626
5.4.7.4 Password Validation Plugin API	3627
5.4.7.5 password_reuse_check_interval	3628
5.4.8 Key Management and Encryption Plugins	3629
5.4.8.1 Encryption Key Management	3629
5.4.8.2 File Key Management Encryption Plugin	3631
5.4.8.3 Hashicorp Key Management Plugin	3636
5.4.8.4 AWS Key Management Encryption Plugin	3638
5.4.8.5 Amazon Web Services (AWS) Key Management Service (KMS) Encryption Plugin Setup Guide	3643
5.4.8.6 Amazon Web Services (AWS) Key Management Service (KMS) Encryption Plugin Advanced Usage	3650
5.4.8.7 Eperi Key Management Encryption Plugin	3657
5.4.8.8 Encryption Plugin API	3661
5.4.9 MariaDB Replication & Cluster Plugins	3664
5.4.9.1 Semisynchronous Replication	3665
5.4.9.2 WSREP_INFO Plugin	3665
5.4.10 Storage Engines	3666
5.4.11 Other Plugins	3666
5.4.11.1 Feedback Plugin	3667
5.4.11.2 Locales Plugin	3671
5.4.11.3 METADATA_LOCK_INFO Plugin	3673
5.4.11.4 MYSQL_JSON	3675
5.4.11.5 Query Cache Information Plugin	3675
5.4.11.6 Query Response Time Plugin	3676
5.4.11.7 SQL Error Log Plugin	3682
5.4.11.8 User Statistics	3684
5.4.11.9 User Variables Plugin	3684
5.4.11.10 Disks Plugin	3685
5.4.11.11 Compression Plugins	3687
Chapter 6 Training & Tutorials	3688
6.1 Beginner MariaDB Articles	3688
6.1.1 A MariaDB Primer	3689
6.1.2 MariaDB Basics	3692
6.1.3 Getting Data from MariaDB	3696
6.1.4 Adding and Changing Data in MariaDB	3701
6.1.5 Altering Tables in MariaDB	3704
6.1.6 Changing Times in MariaDB	3709
6.1.7 Doing Time with MariaDB	3712
6.1.8 Importing Data into MariaDB	3718
6.1.9 Making Backups with mariadb-dump	3722
6.1.10 MariaDB String Functions	3724
6.1.11 Restoring Data from Dump Files	3727
6.1.12 Basic SQL Queries: A Quick SQL Cheat Sheet	3728
6.1.13 Connecting to MariaDB	3729
6.1.14 External Tutorials	3733
6.1.15 Useful MariaDB Queries	3733
6.2 Basic MariaDB Articles	3738
6.2.1 Basic SQL Debugging	3739
6.2.2 Configuring MariaDB for Remote Client Access	3742

6.2.3 Creating & Using Views	3745
6.2.4 Getting Started with Indexes	3749
6.2.5 Joining Tables with JOIN Clauses	3749
6.2.6 The Essentials of an Index	3750
6.2.7 Troubleshooting Connection Issues	3751
6.3 Intermediate MariaDB Articles	3754
6.3.1 Database Theory	3754
6.3.1.1 Introduction to Relational Databases	3755
6.3.1.2 Exploring Early Database Models	3755
6.3.1.3 Understanding the Hierarchical Database Model	3756
6.3.1.4 Understanding the Network Database Model	3756
6.3.1.5 Understanding the Relational Database Model	3757
6.3.1.6 Relational Databases: Basic Terms	3757
6.3.1.7 Relational Databases: Table Keys	3758
6.3.1.8 Relational Databases: Foreign Keys	3759
6.3.1.9 Relational Databases: Views	3760
6.3.1.10 Database Design	3761
6.3.1.10.1 Database Design: Overview	3762
6.3.1.10.2 Database Lifecycle	3762
6.3.1.10.3 Database Design Phase 1: Analysis	3763
6.3.1.10.4 Database Design Phase 2: Conceptual Design	3763
6.3.1.10.5 Database Design Phase 2: Logical and Physical Design	3767
6.3.1.10.6 Database Design Phase 3: Implementation	3768
6.3.1.10.7 Database Design Phase 4: Testing	3768
6.3.1.10.8 Database Design Phase 5: Operation	3769
6.3.1.10.9 Database Design Phase 6: Maintenance	3769
6.3.1.10.10 Database Design Example Phase 1: Analysis	3770
6.3.1.10.11 Database Design Example Phase 2: Design	3770
6.3.1.10.12 Database Design Example Phase 3: Implementation	3773
6.3.1.10.13 Database Design Example Phases 4-6: Testing, Operation and Maintenance	3774
6.3.1.11 Database Normalization	3775
6.3.1.11.1 Database Normalization Overview	3775
6.3.1.11.2 Database Normalization: 1st Normal Form	3779
6.3.1.11.3 Database Normalization: 2nd Normal Form	3780
6.3.1.11.4 Database Normalization: 3rd Normal Form	3781
6.3.1.11.5 Database Normalization: Boyce-Codd Normal Form	3783
6.3.1.11.6 Database Normalization: 4th Normal Form	3785
6.3.1.11.7 Database Normalization: 5th Normal Form and Beyond	3786
6.3.1.11.8 Understanding Denormalization	3788
6.3.1.12 ACID: Concurrency Control with Transactions	3788
6.3.2 Starting and Stopping MariaDB	3789
6.4 Advanced MariaDB Articles	3789
6.4.1 Development Articles	3789
6.4.1.1 MariaDB Internals Documentation	3790
6.4.1.1.1 Query Optimizer	3791
6.4.1.1.1.1 Optimizer Trace	3791
6.4.1.1.1.1.1 Optimizer Trace Overview	3792
6.4.1.1.1.1.2 Optimizer Trace Guide	3793
6.4.1.1.1.1.3 Basic Optimizer Trace Example	3798
6.4.1.1.1.1.4 How to Collect Large Optimizer Traces	3800
6.4.1.1.1.1.5 Optimizer Trace for Developers	3800
6.4.1.1.1.2 Optimizer Development	3801
6.4.1.1.1.3 optimizer_max_sel_arg_weight	3802
6.4.1.1.1.4 Range Optimizer	3804
6.4.1.1.1.5 The Optimizer Cost Model from MariaDB 11.0	3807
6.4.1.1.2 Using MariaDB with Your Programs (API)	3811
6.4.1.1.2.1 Error Codes	3811
6.4.1.1.2.1.1 MariaDB Error Code Reference	3812
6.4.1.1.2.1.2 Operating System Error Codes	3864
6.4.1.1.2.1.3 SQLSTATE	3869
6.4.1.1.2.1.4 MariaDB Error Codes 1000 to 1099	3869
6.4.1.1.2.1.4.1 Error 1044: Access denied for user	3874
6.4.1.1.2.1.4.2 Error 1045: Access denied for user (using password)	3874
6.4.1.1.2.1.4.3 Error 1068: Multiple primary key defined	3875
6.4.1.1.2.1.4.4 Error 1075: Incorrect table definition; there can be only one auto column and it must be defined as a key	3875
6.4.1.1.2.1.5 MariaDB Error Codes 1100 to 1199	3876
6.4.1.1.2.1.5.1 Error 1142: command denied to user for table	3881

6.4.1.1.2.1.5.2 Error 1149: You have an error in your SQL syntax	3881
6.4.1.1.2.1.6 MariaDB Error Codes 1200 to 1299	3883
6.4.1.1.2.1.6.1 Error 1227: Access denied; you need (at least one of) the privilege(s) for this operation	3888
6.4.1.1.2.1.7 MariaDB Error Codes 1300 to 1399	3888
6.4.1.1.2.1.7.1 Error 1305: does not exist	3893
6.4.1.1.2.1.8 MariaDB Error Codes 1400 to 1499	3894
6.4.1.1.2.1.9 MariaDB Error Codes 1500 to 1599	3899
6.4.1.1.2.1.10 MariaDB Error Codes 1600 to 1699	3904
6.4.1.1.2.1.10.1 Error 1698: Access denied for user	3910
6.4.1.1.2.1.11 MariaDB Error Codes 1700 to 1799	3910
6.4.1.1.2.1.12 MariaDB Error Codes 1800 to 1899	3915
6.4.1.1.2.1.13 MariaDB Error Codes 1900 to 1999	3920
6.4.1.1.2.1.14 MariaDB Error Codes 3000 to 3099	3924
6.4.1.1.2.1.14.1 Error 3024: Query execution was interrupted, maximum statement execution time exceeded	3927
6.4.1.1.2.1.14.2 Error 3048: Out of range error	3927
6.4.1.1.2.1.15 MariaDB Error Codes 4000 to 4099	3928
6.4.1.1.2.1.16 MariaDB Error Codes 4100 to 4199	3933
6.4.1.1.2.1.17 MariaDB Error Codes 4200 to 4299	3938
6.4.1.1.2.1.17.1 Error 4200: ORDER BY	3938
6.4.1.1.2.1.17.2 Error 4201: The variable is ignored	3939
6.4.1.1.2.1.17.3 Error 4202: Incorrect column name count for derived table	3939
6.4.1.1.2.2 Progress Reporting	3939
6.4.1.2 EXPLAIN FORMAT=JSON in MySQL	3942
Chapter 7 MariaDB Server Releases	3943
7.0.0.1 MariaDB Server 12.0	3945
7.0.0.2 Changes and Improvements in MariaDB 12.0	3945
7.0.0.3 MariaDB Server 11.8	3946
7.0.0.4 Changes and Improvements in MariaDB 11.8	3946
7.0.0.5 Release Notes - MariaDB 11.8 Series	3950
7.0.0.5.1 MariaDB 11.8.1 Release Notes	3950
7.0.0.5.2 MariaDB 11.8.0 Release Notes	3952
7.0.0.6 MariaDB Server 11.7	3953
7.0.0.7 Changes and Improvements in MariaDB 11.7	3954
7.0.0.8 Release Notes - MariaDB 11.7 Rolling Releases	3955
7.0.0.8.1 MariaDB 11.7.2 Release Notes	3955
7.0.0.8.2 MariaDB 11.7.1 Release Notes	3959
7.0.0.8.3 MariaDB 11.7.0 Release Notes	3961
7.0.0.9 MariaDB Server 11.6	3963
7.0.0.10 Changes and Improvements in MariaDB 11.6	3963
7.0.0.11 Release Notes - MariaDB 11.6 Rolling Releases	3964
7.0.0.12 MariaDB Server 11.5	3964
7.0.0.13 Changes and Improvements in MariaDB 11.5	3965
7.0.0.14 Release Notes - MariaDB 11.5 Rolling Releases	3966
7.0.0.15 MariaDB Server 11.4	3967
7.0.0.16 Changes and Improvements in MariaDB 11.4	3967
7.0.0.17 Release Notes - MariaDB 11.4 Series	3971
7.0.0.17.1 MariaDB 11.4.4 Release Notes	3971
7.0.0.17.2 MariaDB 11.4.3 Release Notes	3973
7.0.0.17.3 MariaDB 11.4.2 Release Notes	3976
7.0.0.17.4 MariaDB 11.4.1 Release Notes	3979
7.0.0.17.5 MariaDB 11.4.0 Release Notes	3983
7.0.0.18 MariaDB Server 11.3	3985
7.0.0.19 Changes and Improvements in MariaDB 11.3	3985
7.0.0.20 Release Notes - MariaDB 11.3 Rolling Releases	3987
7.0.0.21 MariaDB Server 11.2	3987
7.0.0.22 Changes and Improvements in MariaDB 11.2	3987
7.0.0.23 Release Notes - MariaDB 11.2 Series	3989
7.0.0.24 MariaDB Server 11.1	3989
7.0.0.25 Changes and Improvements in MariaDB 11.1	3989
7.0.0.26 Release Notes - MariaDB 11.1 Series	3991
7.0.0.27 MariaDB Server 11.0	3991
7.0.0.28 Changes and Improvements in MariaDB 11.0	3991
7.0.0.29 Release Notes - MariaDB 11.0 Series	3992
7.0.1 MariaDB Server 10.11	3993
7.0.1.1 Changes and Improvements in MariaDB 10.11	3993
7.0.1.2 Release Notes - MariaDB 10.11 Series	3998
7.0.1.2.1 MariaDB 10.11.11 Release Notes	3998

7.0.1.2.2 MariaDB 10.11.10 Release Notes	4001
7.0.1.2.3 MariaDB 10.11.9 Release Notes	4003
7.0.1.2.4 MariaDB 10.11.8 Release Notes	4005
7.0.1.2.5 MariaDB 10.11.7 Release Notes	4009
7.0.1.2.6 MariaDB 10.11.6 Release Notes	4013
7.0.1.2.7 MariaDB 10.11.5 Release Notes	4017
7.0.1.2.8 MariaDB 10.11.4 Release Notes	4020
7.0.1.2.9 MariaDB 10.11.3 Release Notes	4021
7.0.1.2.10 MariaDB 10.11.2 Release Notes	4023
7.0.1.2.11 MariaDB 10.11.1 Release Notes	4024
7.0.1.2.12 MariaDB 10.11.0 Release Notes	4025
7.0.2 MariaDB Server 10.10	4026
7.0.2.1 Changes and Improvements in MariaDB 10.10	4027
7.0.2.2 Release Notes - MariaDB 10.10 Series	4028
7.0.3 MariaDB Server 10.9	4029
7.0.3.1 Changes and Improvements in MariaDB 10.9	4029
7.0.3.2 Release Notes - MariaDB 10.9 Series	4031
7.0.4 MariaDB Server 10.8	4031
7.0.4.1 Changes and Improvements in MariaDB 10.8	4031
7.0.5 MariaDB Server 10.7	4034
7.0.5.1 Changes and Improvements in MariaDB 10.7	4034
7.0.6 MariaDB Server 10.6	4037
7.0.6.1 Changes and Improvements in MariaDB 10.6	4037
7.0.6.2 Release Notes - MariaDB 10.6 Series	4041
7.0.6.2.1 MariaDB 10.6.21 Release Notes	4042
7.0.6.2.2 MariaDB 10.6.20 Release Notes	4045
7.0.6.2.3 MariaDB 10.6.19 Release Notes	4047
7.0.6.2.4 MariaDB 10.6.18 Release Notes	4049
7.0.6.2.5 MariaDB 10.6.17 Release Notes	4053
7.0.6.2.6 MariaDB 10.6.16 Release Notes	4057
7.0.6.2.7 MariaDB 10.6.15 Release Notes	4061
7.0.6.2.8 MariaDB 10.6.14 Release Notes	4063
7.0.6.2.9 MariaDB 10.6.13 Release Notes	4064
7.0.6.2.10 MariaDB 10.6.12 Release Notes	4066
7.0.6.2.11 MariaDB 10.6.11 Release Notes	4068
7.0.6.2.12 MariaDB 10.6.10 Release Notes	4069
7.0.6.2.13 MariaDB 10.6.9 Release Notes	4070
7.0.6.2.14 MariaDB 10.6.8 Release Notes	4073
7.0.6.2.15 MariaDB 10.6.7 Release Notes	4075
7.0.6.2.16 MariaDB 10.6.6 Release Notes	4076
7.0.6.2.17 MariaDB 10.6.5 Release Notes	4078
7.0.6.2.18 MariaDB 10.6.4 Release Notes	4079

1 Using MariaDB Server

New Whitepaper: The Ultimate Guide to High Availability with MariaDB

[Download Now](#)

Documentation on using MariaDB Server.

SQL Statements & Structure

SQL statements, structure, and rules.

Built-in Functions

Functions and procedures in MariaDB.

Clients & Utilities

Client and utility programs for MariaDB.

There are [1 related questions](#).

1.1 SQL Statements & Structure

The letters *SQL* stand for Structured Query Language. As with all languages—even computer languages—there are grammar rules. This includes a certain structure to statements, acceptable punctuation (i.e., operators and delimiters), and a vocabulary (i.e., reserve words).

SQL Statements

Explanations of all of the MariaDB SQL statements.

SQL Language Structure

Explanation of SQL grammar rules, including reserved words and literals.

Geographic & Geometric Features

Spatial extensions for geographic and geometric features.

NoSQL

NoSQL-related commands and interfaces

Operators

Operators for comparing and assigning values.

Sequences

Sequence objects, an alternative to `AUTO_INCREMENT`.

Temporal Tables

MariaDB supports system-versioning, application-time periods and bitemporal tables.

Vectors

Vectors are a feature that allows MariaDB Server to perform as a relational vector database.

Unleashing the Power of Advanced SQL: Joins, Subqueries, and Set Operations

SQL (Structured Query Language) is a highly potent language used in the rea... [↗](#)

There are [24 related questions](#).

1.1.1 SQL Statements

Complete list of SQL statements for data definition, data manipulation, etc.

Account Management SQL Commands

CREATE/DROP USER, GRANT, REVOKE, SET PASSWORD etc.

Administrative SQL Statements

SQL statements for setting, flushing and displaying server variables and resources.

Data Definition

SQL commands for defining data, such as ALTER, CREATE, DROP, RENAME etc.

Data Manipulation

SQL commands for querying and manipulating data, such as SELECT, UPDATE, DELETE etc.

Prepared Statements

Prepared statements from any client using the text based prepared statement interface.

Programmatic & Compound Statements

Compound SQL statements for stored routines and in general.

Stored Routine Statements

SQL statements related to creating and using stored routines.

Table Statements

Documentation on creating, altering, analyzing and maintaining tables.

Transactions

Sequence of statements that are either completely successful, or have no effect on any schemas

HELP Command

The HELP command will retrieve syntax and help within the mariadb client.

Comment Syntax

Comment syntax and style.

Built-in Functions

Functions and procedures in MariaDB.

There are [28 related questions](#)

1.1.1.1 Account Management SQL Commands

CREATE/DROP USER, GRANT, REVOKE, SET PASSWORD etc.

CREATE USER

Create new MariaDB accounts.

ALTER USER

Modify an existing MariaDB account.

DROP USER

Remove one or more MariaDB accounts.

GRANT

Create accounts and set privileges or roles.

RENAME USER

Rename user account.

REVOKE

Remove privileges or roles.

SET PASSWORD

Assign password to an existing MariaDB user.

CREATE ROLE

Add new roles.

DROP ROLE

Drop a role.

SET ROLE

Enable a role.

SET DEFAULT ROLE

Sets a default role for a specified (or current) user.

SHOW GRANTS

View GRANT statements.

SHOW CREATE USER

Show the CREATE USER statement that creates a specified user.

There are [3 related questions](#).

1.1.1.1.1 CREATE USER

Syntax

```

CREATE [OR REPLACE] USER [IF NOT EXISTS]
  user_specification [,user_specification ...]
  [REQUIRE {NONE | tls_option [[AND] tls_option ...] }]
  [WITH resource_option [resource_option ...] ]
  [lock_option] [password_option]

user_specification:
  username [authentication_option]

authentication_option:
  IDENTIFIED BY 'password'
  | IDENTIFIED BY PASSWORD 'password_hash'
  | IDENTIFIED {VIA|WITH} authentication_rule [OR authentication_rule ...]

authentication_rule:
  authentication_plugin
  | authentication_plugin {USING|AS} 'authentication_string'
  | authentication_plugin {USING|AS} PASSWORD('password')

tls_option:
  SSL
  | X509
  | CIPHER 'cipher'
  | ISSUER 'issuer'
  | SUBJECT 'subject'

resource_option:
  MAX_QUERIES_PER_HOUR count
  | MAX_UPDATES_PER_HOUR count
  | MAX_CONNECTIONS_PER_HOUR count
  | MAX_USER_CONNECTIONS count
  | MAX_STATEMENT_TIME time

password_option:
  PASSWORD EXPIRE
  | PASSWORD EXPIRE DEFAULT
  | PASSWORD EXPIRE NEVER
  | PASSWORD EXPIRE INTERVAL N DAY

lock_option:
  ACCOUNT LOCK
  | ACCOUNT UNLOCK
}

```

Description

The `CREATE USER` statement creates new MariaDB accounts. To use it, you must have the global `CREATE USER` privilege or the `INSERT` privilege for the `mysql` database. For each account, `CREATE USER` creates a new row in `mysql.user` (until MariaDB 10.3 this is a table, from MariaDB 10.4 it's a view) or `mysql.global_priv_table` (from MariaDB 10.4) that has no privileges.

If any of the specified accounts, or any permissions for the specified accounts, already exist, then the server returns `ERROR 1396 (HY000)`. If an error occurs, `CREATE USER` will still create the accounts that do not result in an error. Only one error is produced for all users which have not been created:

```
ERROR 1396 (HY000):
  Operation CREATE USER failed for 'u1'@'%','u2'@'%'
```

`CREATE USER`, `DROP USER`, `CREATE ROLE`, and `DROP ROLE` all produce the same error code when they fail.

See [Account Names](#) below for details on how account names are specified.

One can also create users with `GRANT` if `SQL_MODE` does not have `NO_AUTO_CREATE_USER` set.

`NO_AUTO_CREATE_USER` is set by default.

OR REPLACE

If the optional `OR REPLACE` clause is used, it is basically a shortcut for:

```
DROP USER IF EXISTS name;
CREATE USER name ...;
```

For example:

```
CREATE USER foo2@test IDENTIFIED BY 'password';
ERROR 1396 (HY000): Operation CREATE USER failed for 'foo2'@'test'

CREATE OR REPLACE USER foo2@test IDENTIFIED BY 'password';
Query OK, 0 rows affected (0.00 sec)
```

IF NOT EXISTS

When the `IF NOT EXISTS` clause is used, MariaDB will return a warning instead of an error if the specified user already exists.

For example:

```
CREATE USER foo2@test IDENTIFIED BY 'password';
ERROR 1396 (HY000): Operation CREATE USER failed for 'foo2'@'test'

CREATE USER IF NOT EXISTS foo2@test IDENTIFIED BY 'password';
Query OK, 0 rows affected, 1 warning (0.00 sec)

SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message                                     |
+-----+-----+-----+
| Note  | 1973 | Can't create user 'foo2'@'test'; it already exists |
+-----+-----+-----+
```

Authentication Options

If more than one authentication mechanism is declared using the `OR` keyword, the mechanisms are attempted in the order they are declared in the `CREATE USER` statement. As soon as one of the authentication mechanisms is successful, authentication is complete. If none of them is successful, the authentication has failed.

IDENTIFIED BY 'password'

The optional `IDENTIFIED BY` clause can be used to provide an account with a password. The password should be specified in plain text. It will be hashed by the `PASSWORD` function prior to being stored in the `mysql.user/mysql.global_priv_table` table.

For example, if our password is `mariadb`, then we can create the user with:

```
CREATE USER foo2@test IDENTIFIED BY 'mariadb';
```

If you do not specify a password with the `IDENTIFIED BY` clause, the user will be able to connect without a password. A blank password is not a wildcard to match any password. The user must connect without providing a password if no password is set.

The only [authentication plugins](#) that this clause supports are `mysql_native_password` and `mysql_old_password`.

IDENTIFIED BY PASSWORD 'password_hash'

The optional `IDENTIFIED BY PASSWORD` clause can be used to provide an account with a password that has already been hashed. The password should be specified as a hash that was provided by the `PASSWORD` function. It will be stored in the `mysql.user/mysql.global_priv_table` table as-is.

For example, if our password is `mariadb`, then we can find the hash with:

```
SELECT PASSWORD('mariadb');
+-----+
| PASSWORD('mariadb') |
+-----+
| *54958E764CE10E50764C2EECB71D01F08549980 |
+-----+
1 row in set (0.00 sec)
```

And then we can create a user with the hash:

```
CREATE USER foo2@test IDENTIFIED BY PASSWORD '*54958E764CE10E50764C2EECB71D01F08549980';
```

If you do not specify a password with the `IDENTIFIED BY` clause, the user will be able to connect without a password. A blank password is not a wildcard to match any password. The user must connect without providing a password if no password is set.

The only [authentication plugins](#) that this clause supports are `mysql_native_password` and `mysql_old_password`.

IDENTIFIED {VIA|WITH} authentication_plugin

The optional `IDENTIFIED VIA authentication_plugin` allows you to specify that the account should be authenticated by a specific [authentication plugin](#). The plugin name must be an active authentication plugin as per `SHOW PLUGINS`. If it doesn't show up in that output, then you will need to install it with `INSTALL PLUGIN` or `INSTALL SONAME`.

`VIA` and `WITH` are synonyms.

For example, this could be used with the [PAM authentication plugin](#):

```
CREATE USER foo2@test IDENTIFIED VIA pam;
```

Some authentication plugins allow additional arguments to be specified after a `USING` or `AS` keyword. For example, the [PAM authentication plugin](#) accepts a [service name](#):

```
CREATE USER foo2@test IDENTIFIED VIA pam USING 'mariadb';
```

The exact meaning of the additional argument would depend on the specific authentication plugin.

The `USING` or `AS` keyword can also be used to provide a plain-text password to a plugin if it's provided as an argument to the `PASSWORD()` function. This is only valid for [authentication plugins](#) that have implemented a hook for the `PASSWORD()` function. For example, the [ed25519](#) authentication plugin supports this:

```
CREATE USER safe@'%' IDENTIFIED VIA ed25519 USING PASSWORD('secret');
```

One can specify many authentication plugins, they all work as alternatives ways of authenticating a user:

```
CREATE USER safe@'%' IDENTIFIED VIA ed25519 USING PASSWORD('secret') OR unix_socket;
```

By default, when you create a user without specifying an authentication plugin, MariaDB uses the `mysql_native_password` plugin.

TLS Options

By default, prior to [MariaDB 11.4](#), MariaDB transmits data between the server and clients without encrypting it. This is generally acceptable when the server and client run on the same host or in networks where security is guaranteed through other means. However, in cases where the server and client exist on separate networks or they are in a high-risk network, the lack of encryption does introduce security concerns as a malicious actor could potentially eavesdrop on the traffic as it is sent over the network between them.

To mitigate this concern, MariaDB allows you to encrypt data in transit between the server and clients using the Transport Layer Security (TLS) protocol. TLS was formerly known as Secure Socket Layer (SSL), but strictly speaking the SSL protocol is a predecessor to TLS and, that version of the protocol is now considered insecure. The documentation still uses the term SSL often and for compatibility reasons TLS-related server system and status variables still use the prefix `ssl_`, but internally, MariaDB only supports its secure successors.

See [Secure Connections Overview](#) for more information about how to determine whether your MariaDB server has TLS support.

You can set certain TLS-related restrictions for specific user accounts. For instance, you might use this with user accounts that require access to sensitive data while sending it across networks that you do not control. These restrictions can be enabled for a user account with the [CREATE USER](#), [ALTER USER](#), or [GRANT](#) statements. The following options are available:

Option	Description
<code>REQUIRE NONE</code>	TLS is not required for this account, but can still be used.
<code>REQUIRE SSL</code>	The account must use TLS, but no valid X509 certificate is required. This option cannot be combined with other TLS options.
<code>REQUIRE X509</code>	The account must use TLS and must have a valid X509 certificate. This option implies <code>REQUIRE SSL</code> . This option cannot be combined with other TLS options.
<code>REQUIRE ISSUER 'issuer'</code>	The account must use TLS and must have a valid X509 certificate. Also, the Certificate Authority must be the one specified via the string <code>issuer</code> . This option implies <code>REQUIRE X509</code> . This option can be combined with the <code>SUBJECT</code> , and <code>CIPHER</code> options in any order.
<code>REQUIRE SUBJECT 'subject'</code>	The account must use TLS and must have a valid X509 certificate. Also, the certificate's Subject must be the one specified via the string <code>subject</code> . This option implies <code>REQUIRE X509</code> . This option can be combined with the <code>ISSUER</code> , and <code>CIPHER</code> options in any order.
<code>REQUIRE CIPHER 'cipher'</code>	The account must use TLS, but no valid X509 certificate is required. Also, the encryption used for the connection must use a specific cipher method specified in the string <code>cipher</code> . This option implies <code>REQUIRE SSL</code> . This option can be combined with the <code>ISSUER</code> , and <code>SUBJECT</code> options in any order.

The `REQUIRE` keyword must be used only once for all specified options, and the `AND` keyword can be used to separate individual options, but it is not required.

For example, you can create a user account that requires these TLS options with the following:

```
CREATE USER 'alice'@'%'
  REQUIRE SUBJECT '/CN=alice/O=My Dom, Inc./C=US/ST=Oregon/L=Portland'
  AND ISSUER '/C=FI/ST=Somewhere/L=City/ O=Some Company/CN=Peter Parker/[email protected]'
  AND CIPHER 'SHA-DES-CBC3-EDH-RSA';
```

If any of these options are set for a specific user account, then any client who tries to connect with that user account will have to be configured to connect with TLS.

See [Securing Connections for Client and Server](#) for information on how to enable TLS on the client and server.

Resource Limit Options

It is possible to set per-account limits for certain server resources. The following table shows the values that can be set per account:

Limit Type	Description
<code>MAX_QUERIES_PER_HOUR</code>	Number of statements that the account can issue per hour (including updates)
<code>MAX_UPDATES_PER_HOUR</code>	Number of updates (not queries) that the account can issue per hour
<code>MAX_CONNECTIONS_PER_HOUR</code>	Number of connections that the account can start per hour

MAX_USER_CONNECTIONS	Number of simultaneous connections that can be accepted from the same account; if it is 0, <code>max_connections</code> will be used instead; if <code>max_connections</code> is 0, there is no limit for this account's simultaneous connections.
MAX_STATEMENT_TIME	Timeout, in seconds, for statements executed by the user. See also Aborting Statements that Exceed a Certain Time to Execute .

If any of these limits are set to 0, then there is no limit for that resource for that user.

Here is an example showing how to create a user with resource limits:

```
CREATE USER 'someone'@'localhost' WITH
  MAX_USER_CONNECTIONS 10
  MAX_QUERIES_PER_HOUR 200;
```

The resources are tracked per account, which means `'user'@'server'`; not per user name or per connection.

The count can be reset for all users using [FLUSH USER_RESOURCES](#), [FLUSH PRIVILEGES](#) or `mariadb-admin reload`.

Per account resource limits are stored in the `user` table, in the `mysql` database. Columns used for resources limits are named `max_questions`, `max_updates`, `max_connections` (for `MAX_CONNECTIONS_PER_HOUR`), and `max_user_connections` (for `MAX_USER_CONNECTIONS`).

Account Names

Account names have both a user name component and a host name component, and are specified as

```
'user_name'@'host_name'.
```

The user name and host name may be unquoted, quoted as strings using double quotes (`"`) or single quotes (`'`), or quoted as identifiers using backticks (```). You must use quotes when using special characters (such as a hyphen) or wildcard characters. If you quote, you must quote the user name and host name separately (for example

```
'user_name'@'host_name').
```

Host Name Component

If the host name is not provided, it is assumed to be `'%'`.

Host names may contain the wildcard characters `%` and `_`. They are matched as if by the [LIKE](#) clause. If you need to use a wildcard character literally (for example, to match a domain name with an underscore), prefix the character with a backslash. See [LIKE](#) for more information on escaping wildcard characters.

Host name matches are case-insensitive. Host names can match either domain names or IP addresses. Use `'localhost'` as the host name to allow only local client connections. On Linux, the loopback interface (127.0.0.1) will not match `'localhost'` as it is not considered a local connection: this means that only connections via UNIX-domain sockets will match `'localhost'`.

You can use a netmask to match a range of IP addresses using `'base_ip/netmask'` as the host name. A user with an IP address `ip_addr` will be allowed to connect if the following condition is true:

```
ip_addr & netmask = base_ip
```

For example, given a user:

```
CREATE USER 'maria'@'247.150.130.0/255.255.255.0';
```

the IP addresses satisfying this condition range from 247.150.130.0 to 247.150.130.255.

Using `255.255.255.255` is equivalent to not using a netmask at all. Netmasks cannot be used for IPv6 addresses.

Note that the credentials added when creating a user with the `'%'` wildcard host will not grant access in all cases. For example, some systems come with an anonymous localhost user, and when connecting from localhost this will take precedence.

Before [MariaDB 10.6](#), the host name component could be up to 60 characters in length. Starting from [MariaDB 10.6](#), it can be up to 255 characters.

User Name Component

User names must match exactly, including case. A user name that is empty is known as an anonymous account and is allowed to match a login attempt with any user name component. These are described more in the next section.

For valid identifiers to use as user names, see [Identifier Names](#).

It is possible for more than one account to match when a user connects. MariaDB selects the first matching account after sorting according to the following criteria:

- Accounts with an exact host name are sorted before accounts using a wildcard in the host name. Host names using a netmask are considered to be exact for sorting.
- Accounts with a wildcard in the host name are sorted according to the position of the first wildcard character. Those with a wildcard character later in the host name sort before those with a wildcard character earlier in the host name.
- Accounts with a non-empty user name sort before accounts with an empty user name.
- Accounts with an empty user name are sorted last. As mentioned previously, these are known as anonymous accounts. These are described more in the next section.

The following table shows a list of example account as sorted by these criteria:

```
+-----+-----+
| User   | Host           |
+-----+-----+
| joffrey| 192.168.0.3   |
|        | 192.168.0.%   |
| joffrey| 192.168.%     |
|        | 192.168.%     |
+-----+-----+
```

Once connected, you only have the privileges granted to the account that matched, not all accounts that could have matched. For example, consider the following commands:

```
CREATE USER 'joffrey'@'192.168.0.3';
CREATE USER 'joffrey'@'%';
GRANT SELECT ON test.t1 TO 'joffrey'@'192.168.0.3';
GRANT SELECT ON test.t2 TO 'joffrey'@'%';
```

If you connect as joffrey from 192.168.0.3, you will have the `SELECT` privilege on the table `test.t1`, but not on the table `test.t2`. If you connect as joffrey from any other IP address, you will have the `SELECT` privilege on the table `test.t2`, but not on the table `test.t1`.

Usernames can be up to 80 characters long before 10.6 and starting from 10.6 it can be 128 characters long.

Anonymous Accounts

Anonymous accounts are accounts where the user name portion of the account name is empty. These accounts act as special catch-all accounts. If a user attempts to log into the system from a host, and an anonymous account exists with a host name portion that matches the user's host, then the user will log in as the anonymous account if there is no more specific account match for the user name that the user entered.

For example, here are some anonymous accounts:

```
CREATE USER ''@'localhost';
CREATE USER ''@'192.168.0.3';
```

Fixing a Legacy Default Anonymous Account

On some systems, the `mysql.db` table has some entries for the `''@'%'` anonymous account by default. Unfortunately, there is no matching entry in the `mysql.user/mysql.global_priv_table` table, which means that this anonymous account doesn't exactly exist, but it does have privileges--usually on the default `test` database created by `mariadb-install-db`. These account-less privileges are a legacy that is leftover from a time when MySQL's privilege system was less advanced.

This situation means that you will run into errors if you try to create a `''@'%'` account. For example:

```
CREATE USER ''@'%';
ERROR 1396 (HY000): Operation CREATE USER failed for ''@'%'
```

The fix is to `DELETE` the row in the `mysql.db` table and then execute `FLUSH PRIVILEGES`:

```
DELETE FROM mysql.db WHERE User='' AND Host='%';
FLUSH PRIVILEGES;
```

Note that `FLUSH PRIVILEGES` is only needed if one modifies the `mysql` tables directly. It is not needed when using `CREATE USER`, `DROP USER`, `GRANT` etc.

And then the account can be created:

```
CREATE USER ''@'%';
Query OK, 0 rows affected (0.01 sec)
```

See [MDEV-13486](#) for more information.

Password Expiry

Besides automatic password expiry, as determined by `default_password_lifetime`, password expiry times can be set on an individual user basis, overriding the global setting, for example:

```
CREATE USER 'monty'@'localhost' PASSWORD EXPIRE INTERVAL 120 DAY;
```

See [User Password Expiry](#) for more details.

Account Locking

Account locking permits privileged administrators to lock/unlock user accounts. No new client connections will be permitted if an account is locked (existing connections are not affected). For example: `<<sql>> CREATE USER 'marijn'@'localhost' ACCOUNT LOCK;`

See [Account Locking](#) for more details. `<</product>>`

From [MariaDB 10.4.7](#) and [MariaDB 10.5.8](#), the `lock_option` and `password_option` clauses can occur in either order.

1.1.1.1.2 ALTER USER

Syntax

```

ALTER USER [IF EXISTS]
  user_specification [,user_specification] ...
  [REQUIRE {NONE | tls_option [[AND] tls_option] ...}]
  [WITH resource_option [resource_option] ...]
  [lock_option] [password_option]

user_specification:
  username [authentication_option]

authentication_option:
  IDENTIFIED BY 'password'
  | IDENTIFIED BY PASSWORD 'password_hash'
  | IDENTIFIED {VIA|WITH} authentication_rule [OR authentication_rule] ...

authentication_rule:
  authentication_plugin
  | authentication_plugin {USING|AS} 'authentication_string'
  | authentication_plugin {USING|AS} PASSWORD('password')

tls_option
  SSL
  | X509
  | CIPHER 'cipher'
  | ISSUER 'issuer'
  | SUBJECT 'subject'

resource_option
  MAX_QUERIES_PER_HOUR count
  | MAX_UPDATES_PER_HOUR count
  | MAX_CONNECTIONS_PER_HOUR count
  | MAX_USER_CONNECTIONS count
  | MAX_STATEMENT_TIME time

password_option:
  PASSWORD EXPIRE
  | PASSWORD EXPIRE DEFAULT
  | PASSWORD EXPIRE NEVER
  | PASSWORD EXPIRE INTERVAL N DAY

lock_option:
  ACCOUNT LOCK
  | ACCOUNT UNLOCK
}

```

Contents

 3. [IDENTIFIED {VIA|WITH} authentication_plugin](#)
6. [TLS Options](#)
7. [Resource Limit Options](#)
8. [Password Expiry](#)
9. [Account Locking](#)

Description

The `ALTER USER` statement modifies existing MariaDB accounts. To use it, you must have the global [CREATE USER](#) privilege or the [UPDATE](#) privilege for the `mysql` database. The global [SUPER](#) privilege is also required if the `read_only` system variable is enabled.

If any of the specified user accounts do not yet exist, an error results. If an error occurs, `ALTER USER` will still modify the accounts that do not result in an error. Only one error is produced for all users which have not been modified.

For renaming an existing account (user name and/or host), see [RENAME USER](#).

IF EXISTS

When the `IF EXISTS` clause is used, MariaDB will return a warning instead of an error for each specified user that does not exist.

Account Names

For `ALTER USER` statements, account names are specified as the `username` argument in the same way as they are for `CREATE USER` statements. See [account names](#) from the `CREATE USER` page for details on how account names are specified.

`CURRENT_USER` or `CURRENT_USER()` can also be used to alter the account logged into the current session. For example, to change the current user's password to `mariadb`:

```
ALTER USER CURRENT_USER() IDENTIFIED BY 'mariadb';
```

Authentication Options

From [MariaDB 10.4](#), it is possible to use more than one authentication plugin for each user account. For example, this can be useful to slowly migrate users to the more secure `ed25519` authentication plugin over time, while allowing the old `mysql_native_password` authentication plugin as an alternative for the transitional period. See [Authentication from MariaDB 10.4](#) for more.

When running `ALTER USER`, not specifying an authentication option in the `IDENTIFIED VIA` clause will remove that authentication method. (However this was not the case before [MariaDB 10.4.13](#), see [MDEV-21928](#))

For example, a user is created with the ability to authenticate via both a password and `unix_socket`:

```
CREATE USER 'bob'@'localhost'
  IDENTIFIED VIA mysql_native_password USING PASSWORD('pwd')
  OR unix_socket;

SHOW CREATE USER 'bob'@'localhost'\G
***** 1. row *****
CREATE USER for bob@localhost: CREATE USER `bob`@`localhost`
  IDENTIFIED VIA mysql_native_password
  USING '*975B2CD4FF9AE554FE8AD33168FBFC326D2021DD'
  OR unix_socket
```

If the user's password is updated, but `unix_socket` authentication is not specified in the `IDENTIFIED VIA` clause, `unix_socket` authentication will no longer be permitted.

```
ALTER USER 'bob'@'localhost' IDENTIFIED VIA mysql_native_password
  USING PASSWORD('pwd2');

SHOW CREATE USER 'bob'@'localhost'\G
***** 1. row *****
CREATE USER for bob@localhost: CREATE USER `bob`@`localhost`
  IDENTIFIED BY PASSWORD '*38366FDA01695B6A5A9DD4E428D9FB8F7EB75512'
```

IDENTIFIED BY 'password'

The optional `IDENTIFIED BY` clause can be used to provide an account with a password. The password should be specified in plain text. It will be hashed by the `PASSWORD` function prior to being stored to the `mysql.user` table.

For example, if our password is `mariadb`, then we can set the account's password with:

```
ALTER USER foo2@test IDENTIFIED BY 'mariadb';
```

If you do not specify a password with the `IDENTIFIED BY` clause, the user will be able to connect without a password. A blank password is not a wildcard to match any password. The user must connect without providing a password if no password is set.

The only [authentication plugins](#) that this clause supports are `mysql_native_password` and `mysql_old_password`.

IDENTIFIED BY PASSWORD 'password_hash'

The optional `IDENTIFIED BY PASSWORD` clause can be used to provide an account with a password that has already been hashed. The password should be specified as a hash that was provided by the `PASSWORD#function`. It will be stored to the `mysql.user` table as-is.

For example, if our password is `mariadb`, then we can find the hash with:

```
SELECT PASSWORD('mariadb');
+-----+
| PASSWORD('mariadb') |
+-----+
| *54958E764CE10E50764C2EECB71D01F08549980 |
+-----+
```

And then we can set an account's password with the hash:

```
ALTER USER foo2@test
  IDENTIFIED BY PASSWORD '*54958E764CE10E50764C2EECB71D01F08549980';
```

If you do not specify a password with the `IDENTIFIED BY` clause, the user will be able to connect without a password. A blank password is not a wildcard to match any password. The user must connect without providing a password if no password is set.

The only [authentication plugins](#) that this clause supports are `mysql_native_password` and `mysql_old_password`.

IDENTIFIED {VIA|WITH} authentication_plugin

The optional `IDENTIFIED VIA authentication_plugin` allows you to specify that the account should be authenticated by a specific [authentication plugin](#). The plugin name must be an active authentication plugin as per [SHOW PLUGINS](#). If it doesn't show up in that output, then you will need to install it with [INSTALL PLUGIN](#) or [INSTALL SONAME](#).

For example, this could be used with the [PAM authentication plugin](#):

```
ALTER USER foo2@test IDENTIFIED VIA pam;
```

Some authentication plugins allow additional arguments to be specified after a `USING` or `AS` keyword. For example, the [PAM authentication plugin](#) accepts a [service name](#):

```
ALTER USER foo2@test IDENTIFIED VIA pam USING 'mariadb';
```

The exact meaning of the additional argument would depend on the specific authentication plugin.

From [MariaDB 10.4](#), the `USING` or `AS` keyword can also be used to provide a plain-text password to a plugin if it's provided as an argument to the `PASSWORD()` function. This is only valid for [authentication plugins](#) that have implemented a hook for the `PASSWORD()` function. For example, the [ed25519](#) authentication plugin supports this:

```
ALTER USER safe@%' IDENTIFIED VIA ed25519 USING PASSWORD('secret');
```

TLS Options

By default, MariaDB transmits data between the server and clients without encrypting it. This is generally acceptable when the server and client run on the same host or in networks where security is guaranteed through other means. However, in cases where the server and client exist on separate networks or they are in a high-risk network, the lack of encryption does introduce security concerns as a malicious actor could potentially eavesdrop on the traffic as it is sent over the network between them.

To mitigate this concern, MariaDB allows you to encrypt data in transit between the server and clients using the Transport Layer Security (TLS) protocol. TLS was formerly known as Secure Socket Layer (SSL), but strictly speaking the SSL protocol is a predecessor to TLS and, that version of the protocol is now considered insecure. The documentation still uses the term SSL often and for compatibility reasons TLS-related server system and status variables still use the prefix `ssl_`, but internally, MariaDB only supports its secure successors.

See [Secure Connections Overview](#) for more information about how to determine whether your MariaDB server has TLS support.

You can set certain TLS-related restrictions for specific user accounts. For instance, you might use this with user accounts

that require access to sensitive data while sending it across networks that you do not control. These restrictions can be enabled for a user account with the [CREATE USER](#), [ALTER USER](#), or [GRANT](#) statements. The following options are available:

Option	Description
REQUIRE NONE	TLS is not required for this account, but can still be used.
REQUIRE SSL	The account must use TLS, but no valid X509 certificate is required. This option cannot be combined with other TLS options.
REQUIRE X509	The account must use TLS and must have a valid X509 certificate. This option implies <code>REQUIRE SSL</code> . This option cannot be combined with other TLS options.
REQUIRE ISSUER 'issuer'	The account must use TLS and must have a valid X509 certificate. Also, the Certificate Authority must be the one specified via the string <code>issuer</code> . This option implies <code>REQUIRE X509</code> . This option can be combined with the <code>SUBJECT</code> , and <code>CIPHER</code> options in any order.
REQUIRE SUBJECT 'subject'	The account must use TLS and must have a valid X509 certificate. Also, the certificate's Subject must be the one specified via the string <code>subject</code> . This option implies <code>REQUIRE X509</code> . This option can be combined with the <code>ISSUER</code> , and <code>CIPHER</code> options in any order.
REQUIRE CIPHER 'cipher'	The account must use TLS, but no valid X509 certificate is required. Also, the encryption used for the connection must use a specific cipher method specified in the string <code>cipher</code> . This option implies <code>REQUIRE SSL</code> . This option can be combined with the <code>ISSUER</code> , and <code>SUBJECT</code> options in any order.

The `REQUIRE` keyword must be used only once for all specified options, and the `AND` keyword can be used to separate individual options, but it is not required.

For example, you can alter a user account to require these TLS options with the following:

```
ALTER USER 'alice'@'%'
  REQUIRE SUBJECT '/CN=alice/O=My Dom, Inc./C=US/ST=Oregon/L=Portland' AND
  ISSUER '/C=FI/ST=Somewhere/L=City/ O=Some Company/CN=Peter Parker/[email protected]'
  AND CIPHER 'SHA-DES-CBC3-EDH-RSA';
```

If any of these options are set for a specific user account, then any client who tries to connect with that user account will have to be configured to connect with TLS.

See [Securing Connections for Client and Server](#) for information on how to enable TLS on the client and server.

Resource Limit Options

It is possible to set per-account limits for certain server resources. The following table shows the values that can be set per account:

Limit Type	Description
MAX_QUERIES_PER_HOUR	Number of statements that the account can issue per hour (including updates)
MAX_UPDATES_PER_HOUR	Number of updates (not queries) that the account can issue per hour
MAX_CONNECTIONS_PER_HOUR	Number of connections that the account can start per hour
MAX_USER_CONNECTIONS	Number of simultaneous connections that can be accepted from the same account; if it is 0, <code>max_connections</code> will be used instead; if <code>max_connections</code> is 0, there is no limit for this account's simultaneous connections.
MAX_STATEMENT_TIME	Timeout, in seconds, for statements executed by the user. See also Aborting Statements that Exceed a Certain Time to Execute .

If any of these limits are set to 0, then there is no limit for that resource for that user.

Here is an example showing how to set an account's resource limits:

```
ALTER USER 'someone'@'localhost' WITH
  MAX_USER_CONNECTIONS 10
  MAX_QUERIES_PER_HOUR 200;
```

The resources are tracked per account, which means `'user'@'server'`; not per user name or per connection.

The count can be reset for all users using [FLUSH USER_RESOURCES](#), [FLUSH PRIVILEGES](#) or [mysqladmin reload](#).

Per account resource limits are stored in the `user` table, in the `mysql` database. Columns used for resources limits are named `max_questions`, `max_updates`, `max_connections` (for `MAX_CONNECTIONS_PER_HOUR`), and `max_user_connections` (for `MAX_USER_CONNECTIONS`).

Password Expiry

Besides automatic password expiry, as determined by `default_password_lifetime`, password expiry times can be set on an individual user basis, overriding the global setting, for example:

```
ALTER USER 'monty'@'localhost' PASSWORD EXPIRE INTERVAL 120 DAY;
ALTER USER 'monty'@'localhost' PASSWORD EXPIRE NEVER;
ALTER USER 'monty'@'localhost' PASSWORD EXPIRE DEFAULT;
```

See [User Password Expiry](#) for more details.

Account Locking

Account locking permits privileged administrators to lock/unlock user accounts. No new client connections will be permitted if an account is locked (existing connections are not affected). For example:

```
ALTER USER 'marijn'@'localhost' ACCOUNT LOCK;
```

See [Account Locking](#) for more details.

From [MariaDB 10.4.7](#) and [MariaDB 10.5.8](#), the `lock_option` and `password_option` clauses can occur in either order.

1.1.1.1.3 DROP USER

Syntax

```
DROP USER [IF EXISTS] user_name [, user_name] ...
```

Contents

- [Syntax](#)
- [Description](#)
 - [IF EXISTS](#)
- [Examples](#)

Description

The `DROP USER` statement removes one or more MariaDB accounts. It removes privilege rows for the account from all grant tables. To use this statement, you must have the global `CREATE USER` privilege or the `DELETE` privilege for the `mysql` database. Each account is named using the same format as for the `CREATE USER` statement; for example, `'jeffrey'@'localhost'`. If you specify only the user name part of the account name, a host name part of `'%'` is used. For additional information about specifying account names, see [CREATE USER](#).

Note that, if you specify an account that is currently connected, it will not be deleted until the connection is closed. The connection will not be automatically closed.

If any of the specified user accounts do not exist, `ERROR 1396 (HY000)` results. If an error occurs, `DROP USER` will still drop the accounts that do not result in an error. Only one error is produced for all users which have not been dropped:

```
ERROR 1396 (HY000): Operation DROP USER failed for 'u1'@'%','u2'@'%'
```

Failed `CREATE` or `DROP` operations, for both users and roles, produce the same error code.

IF EXISTS

If the `IF EXISTS` clause is used, MariaDB will return a note instead of an error if the user does not exist.

Examples

```
DROP USER bob;  
  
DROP USER foo2@localhost,foo2@'127.%';
```

IF EXISTS :

```
DROP USER bob;  
ERROR 1396 (HY000): Operation DROP USER failed for 'bob'@'%'  
  
DROP USER IF EXISTS bob;  
Query OK, 0 rows affected, 1 warning (0.00 sec)  
  
SHOW WARNINGS;  
+-----+-----+  
| Level | Code | Message |  
+-----+-----+  
| Note | 1974 | Can't drop user 'bob'@'%'; it doesn't exist |  
+-----+-----+
```

tls_option:
    SSL
    | X509
    | CIPHER 'cipher'
    | ISSUER 'issuer'
    | SUBJECT 'subject'

```

Description

The `GRANT` statement allows you to grant privileges or [roles](#) to accounts. To use `GRANT`, you must have the `GRANT OPTION` privilege, and you must have the privileges that you are granting.

Use the [REVOKE](#) statement to revoke privileges granted with the `GRANT` statement.

Use the [SHOW GRANTS](#) statement to determine what privileges an account has.

Account Names

For `GRANT` statements, account names are specified as the `username` argument in the same way as they are for [CREATE USER](#) statements. See [account names](#) from the `CREATE USER` page for details on how account names are specified.

Implicit Account Creation

The `GRANT` statement also allows you to implicitly create accounts in some cases.

If the account does not yet exist, then `GRANT` can implicitly create it. To implicitly create an account with `GRANT`, a user is required to have the same privileges that would be required to explicitly create the account with the `CREATE USER` statement.

If the `NO_AUTO_CREATE_USER SQL_MODE` is set, then accounts can only be created if authentication information is specified, or with a `CREATE USER` statement. If no authentication information is provided, `GRANT` will produce an error when the specified account does not exist, for example:

```
show variables like '%sql_mode%' ;
+-----+-----+
| Variable_name | Value |
+-----+-----+
| sql_mode      | NO_AUTO_CREATE_USER,NO_ENGINE_SUBSTITUTION |
+-----+-----+

GRANT USAGE ON *.* TO 'user123'@'%' IDENTIFIED BY '';
ERROR 1133 (28000): Can't find any matching row in the user table

GRANT USAGE ON *.* TO 'user123'@'%'
  IDENTIFIED VIA PAM using 'mariadb' require ssl ;
Query OK, 0 rows affected (0.00 sec)

select host, user from mysql.user where user='user123' ;

+-----+-----+
| host | user |
+-----+-----+
| %    | user123 |
+-----+-----+
```

Privilege Levels

Privileges can be set globally, for an entire database, for a table or routine, or for individual columns in a table. Certain privileges can only be set at certain levels.

Global privileges do not take effect immediately and are only applied to connections created after the `GRANT` statement was executed.

- [Global privileges *priv_type*](#) are granted using `*.*` for *priv_level*. Global privileges include privileges to administer the database and manage user accounts, as well as privileges for all tables, functions, and procedures. Global privileges are stored in the `mysql.user` table prior to [MariaDB 10.4](#), and in `mysql.global_priv` table afterwards.
- [Database privileges *priv_type*](#) are granted using `db_name.*` for *priv_level*, or using just `*` to use default database. Database privileges include privileges to create tables and functions, as well as privileges for all tables, functions, and procedures in the database. Database privileges are stored in the `mysql.db` table.
- [Table privileges *priv_type*](#) are granted using `db_name.tbl_name` for *priv_level*, or using just `tbl_name` to specify a table in the default database. The `TABLE` keyword is optional. Table privileges include the ability to select and change data in the table. Certain table privileges can be granted for individual columns.
- [Column privileges *priv_type*](#) are granted by specifying a table for *priv_level* and providing a column list after the privilege type. They allow you to control exactly which columns in a table users can select and change.
- [Function privileges *priv_type*](#) are granted using `FUNCTION db_name.routine_name` for *priv_level*, or using just `FUNCTION routine_name` to specify a function in the default database.
- [Procedure privileges *priv_type*](#) are granted using `PROCEDURE db_name.routine_name` for *priv_level*, or using just `PROCEDURE routine_name` to specify a procedure in the default database.

The `USAGE` Privilege

The `USAGE` privilege grants no real privileges. The `SHOW GRANTS` statement will show a global `USAGE` privilege for a newly-created user. You can use `USAGE` with the `GRANT` statement to change options like `GRANT OPTION` and `MAX_USER_CONNECTIONS` without changing any account privileges.

The `ALL PRIVILEGES` Privilege

The `ALL PRIVILEGES` privilege grants all available privileges. Granting all privileges only affects the given privilege level. For example, granting all privileges on a table does not grant any privileges on the database or globally.

Using `ALL PRIVILEGES` does not grant the special `GRANT OPTION` privilege.

You can use `ALL` instead of `ALL PRIVILEGES`.

The `GRANT OPTION` Privilege

Use the `WITH GRANT OPTION` clause to give users the ability to grant privileges to other users at the given privilege level. Users with the `GRANT OPTION` privilege can only grant privileges they have. They cannot grant privileges at a higher privilege level than they have the `GRANT OPTION` privilege.

The `GRANT OPTION` privilege cannot be set for individual columns. If you use `WITH GRANT OPTION` when specifying [column privileges](#), the `GRANT OPTION` privilege will be granted for the entire table.

Using the `WITH GRANT OPTION` clause is equivalent to listing `GRANT OPTION` as a privilege.

Global Privileges

The following table lists the privileges that can be granted globally. You can also grant all database, table, and function privileges globally. When granted globally, these privileges apply to all databases, tables, or functions, including those created later.

To set a global privilege, use `*.*` for *priv_level*.

BINLOG ADMIN

Enables administration of the [binary log](#), including the `PURGE BINARY LOGS` statement and setting the system variables:

- [binlog_annotate_row_events](#)
- [binlog_cache_size](#)
- [binlog_commit_wait_count](#)
- [binlog_commit_wait_usec](#)
- [binlog_direct_non_transactional_updates](#)
- [binlog_expire_logs_seconds](#)
- [binlog_file_cache_size](#)
- [binlog_format](#)
- [binlog_row_image](#)
- [binlog_row_metadata](#)
- [binlog_stmt_cache_size](#)
- [expire_logs_days](#)
- [log_bin_compress](#)
- [log_bin_compress_min_len](#)
- [log_bin_trust_function_creators](#)
- [max_binlog_cache_size](#)
- [max_binlog_size](#)
- [max_binlog_stmt_cache_size](#)
- [sql_log_bin](#) and
- [sync_binlog](#).

Added in [MariaDB 10.5.2](#).

BINLOG MONITOR

New name for [REPLICATION CLIENT](#) from [MariaDB 10.5.2](#), (`REPLICATION CLIENT` still supported as an alias for compatibility purposes). Permits running `SHOW` commands related to the [binary log](#), in particular the `SHOW BINLOG STATUS` and `SHOW BINARY LOGS` statements. Unlike [REPLICATION CLIENT](#) prior to [MariaDB 10.5](#), `SHOW REPLICATION STATUS` isn't included in this privilege, and [REPLICA MONITOR](#) is required.

BINLOG REPLAY

Enables replaying the binary log with the `BINLOG` statement (generated by [mariadb-binlog](#)), executing `SET timestamp`

when `secure_timestamp` is set to `replication`, and setting the session values of system variables usually included in BINLOG output, in particular:

- `gtid_domain_id`
- `gtid_seq_no`
- `pseudo_thread_id`
- `server_id`.

Added in [MariaDB 10.5.2](#)

CONNECTION ADMIN

Enables administering connection resource limit options. This includes ignoring the limits specified by: [max_user_connections](#) and [max_password_errors](#). And allowing one extra connection over [max_connections](#)

The statements specified in [init_connect](#) are not executed, [killing connections and queries](#) owned by other users is permitted. The following connection-related system variables can be changed:

- `connect_timeout`
- `disconnect_on_expired_password`
- `extra_max_connections`
- `init_connect`
- `max_connections`
- `max_connect_errors`
- `max_password_errors`
- `proxy_protocol_networks`
- `secure_auth`
- `slow_launch_time`
- `thread_pool_exact_stats`
- `thread_pool_dedicated_listener`
- `thread_pool_idle_timeout`
- `thread_pool_max_threads`
- `thread_pool_min_threads`
- `thread_pool_oversubscribe`
- `thread_pool_prio_kickup_timer`
- `thread_pool_priority`
- `thread_pool_size`, and
- `thread_pool_stall_limit`.

Added in [MariaDB 10.5.2](#).

CREATE USER

Create a user using the [CREATE USER](#) statement, or implicitly create a user with the `GRANT` statement.

FEDERATED ADMIN

Execute [CREATE SERVER](#), [ALTER SERVER](#), and [DROP SERVER](#) statements. Added in [MariaDB 10.5.2](#).

FILE

Read and write files on the server, using statements like [LOAD DATA INFILE](#) or functions like [LOAD_FILE\(\)](#). Also needed to create [CONNECT](#) outward tables. MariaDB server must have the permissions to access those files.

GRANT OPTION

Grant global privileges. You can only grant privileges that you have.

PROCESS

Show information about the active processes, for example via [SHOW PROCESSLIST](#) or [mariadb-admin processlist](#). If you have the `PROCESS` privilege, you can see all threads. Otherwise, you can see only your own threads (that is, threads associated with the MariaDB account that you are using).

READ_ONLY ADMIN

User ignores the `read_only` system variable, and can perform write operations even when the `read_only` option is active. Added in [MariaDB 10.5.2](#).

From [MariaDB 10.11.0](#), the `READ_ONLY ADMIN` privilege has been removed from [SUPER](#). The benefit of this is that one can remove the `READ_ONLY ADMIN` privilege from all users and ensure that no one can make any changes on any non-

temporary tables. This is useful on replicas when one wants to ensure that the replica is kept identical to the primary.

RELOAD

Execute [FLUSH](#) statements or equivalent [mariadb-admin](#) commands.

REPLICATION CLIENT

Execute [SHOW MASTER STATUS](#) and [SHOW BINARY LOGS](#) informative statements. Renamed to [BINLOG MONITOR](#) in [MariaDB 10.5.2](#) (but still supported as an alias for compatibility reasons). [SHOW SLAVE STATUS](#) was part of [REPLICATION CLIENT](#) prior to [MariaDB 10.5](#).

REPLICATION MASTER ADMIN

Permits administration of primary servers, including the [SHOW REPLICA HOSTS](#) statement, and setting the [gtid_binlog_state](#), [gtid_domain_id](#), [master_verify_checksum](#) and [server_id](#) system variables. Added in [MariaDB 10.5.2](#).

REPLICA MONITOR

Permit [SHOW REPLICA STATUS](#) and [SHOW RELAYLOG EVENTS](#). From [MariaDB 10.5.9](#).

When a user would upgrade from an older major release to a [MariaDB 10.5](#) minor release prior to [MariaDB 10.5.9](#), certain user accounts would lose capabilities. For example, a user account that had the [REPLICATION CLIENT](#) privilege in older major releases could run [SHOW REPLICA STATUS](#), but after upgrading to a [MariaDB 10.5](#) minor release prior to [MariaDB 10.5.9](#), they could no longer run [SHOW REPLICA STATUS](#), because that statement was changed to require the [REPLICATION REPLICA ADMIN](#) privilege.

This issue is fixed in [MariaDB 10.5.9](#) with this new privilege, which now grants the user the ability to execute [SHOW \[ALL\] \(SLAVE | REPLICA\) STATUS](#).

When a database is upgraded from an older major release to [MariaDB Server 10.5.9](#) or later, any user accounts with the [REPLICATION CLIENT](#) or [REPLICATION SLAVE](#) privileges will automatically be granted the new [REPLICA MONITOR](#) privilege. The privilege fix occurs when the server is started up, not when [mariadb-upgrade](#) is performed.

However, when a database is upgraded from an early 10.5 minor release to 10.5.9 and later, the user will have to fix any user account privileges manually.

REPLICATION REPLICA

Synonym for [REPLICATION SLAVE](#). From [MariaDB 10.5.1](#).

REPLICATION SLAVE

Accounts used by replica servers on the primary need this privilege. This is needed to get the updates made on the master. From [MariaDB 10.5.1](#), [REPLICATION REPLICA](#) is an alias for [REPLICATION SLAVE](#).

REPLICATION SLAVE ADMIN

Permits administering replica servers, including [START REPLICA/SLAVE](#), [STOP REPLICA/SLAVE](#), [CHANGE MASTER](#), [SHOW REPLICA/SLAVE STATUS](#), [SHOW RELAYLOG EVENTS](#) statements, replaying the binary log with the [BINLOG](#) statement (generated by [mariadb-binlog](#)), and setting the system variables:

- [gtid_cleanup_batch_size](#)
- [gtid_ignore_duplicates](#)
- [gtid_pos_auto_engines](#)
- [gtid_slave_pos](#)
- [gtid_strict_mode](#)
- [init_slave](#)
- [read_binlog_speed_limit](#)
- [relay_log_purge](#)
- [relay_log_recovery](#)
- [replicate_do_db](#)
- [replicate_do_table](#)
- [replicate_events_marked_for_skip](#)
- [replicate_ignore_db](#)
- [replicate_ignore_table](#)
- [replicate_wild_do_table](#)
- [replicate_wild_ignore_table](#)
- [slave_compressed_protocol](#)
- [slave_ddl_exec_mode](#)
- [slave_domain_parallel_threads](#)

- [slave_exec_mode](#)
- [slave_max_allowed_packet](#)
- [slave_net_timeout](#)
- [slave_parallel_max_queued](#)
- [slave_parallel_mode](#)
- [slave_parallel_threads](#)
- [slave_parallel_workers](#)
- [slave_run_triggers_for_rbr](#)
- [slave_sql_verify_checksum](#)
- [slave_transaction_retry_interval](#)
- [slave_type_conversions](#)
- [sync_master_info](#)
- [sync_relay_log](#), and
- [sync_relay_log_info](#).

Added in [MariaDB 10.5.2](#).

SET USER

Enables setting the `DEFINER` when creating [triggers](#), [views](#), [stored functions](#) and [stored procedures](#). Added in [MariaDB 10.5.2](#).

SHOW DATABASES

List all databases using the [SHOW DATABASES](#) statement. Without the `SHOW DATABASES` privilege, you can still issue the `SHOW DATABASES` statement, but it will only list databases containing tables on which you have privileges.

SHUTDOWN

Shut down the server using [SHUTDOWN](#) or the [mariadb-admin shutdown](#) command.

SUPER

Execute superuser statements: [CHANGE MASTER TO](#), [KILL](#) (users who do not have this privilege can only `KILL` their own threads), [PURGE LOGS](#), [SET global system variables](#), or the [mariadb-admin debug](#) command. Also, this permission allows the user to write data even if the `read_only` startup option is set, enable or disable logging, enable or disable replication on replica, specify a `DEFINER` for statements that support that clause, connect once reaching the `MAX_CONNECTIONS`. If a statement has been specified for the `init-connect mariabdb` option, that command will not be executed when a user with `SUPER` privileges connects to the server.

The `SUPER` privilege has been split into multiple smaller privileges from [MariaDB 10.5.2](#) to allow for more fine-grained privileges ([MDEV-21743](#)). The privileges are:

- [SET USER](#)
- [FEDERATED ADMIN](#)
- [CONNECTION ADMIN](#)
- [REPLICATION SLAVE ADMIN](#)
- [BINLOG ADMIN](#)
- [BINLOG REPLAY](#)
- [REPLICA MONITOR](#)
- [BINLOG MONITOR](#)
- [REPLICATION MASTER ADMIN](#)
- [READ_ONLY ADMIN](#)

However, the smaller privileges are still a part of the `SUPER` grant in [MariaDB 10.5.2](#). From [MariaDB 11.0.1](#) onwards, these grants are no longer a part of `SUPER` and need to be granted separately ([MDEV-29668](#)).

From [MariaDB 10.11.0](#), the `READ_ONLY ADMIN` privilege has been removed from `SUPER`. The benefit of this is that one can remove the `READ_ONLY ADMIN` privilege from all users and ensure that no one can make any changes on any non-temporary tables. This is useful on replicas when one wants to ensure that the replica is kept identical to the primary ([MDEV-29596](#)).

Database Privileges

The following table lists the privileges that can be granted at the database level. You can also grant all table and function privileges at the database level. Table and function privileges on a database apply to all tables or functions in that database, including those created later.

To set a privilege for a database, specify the database using `db_name.*` for *priv_level*, or just use `*` to specify the default database.

Privilege	Description
CREATE	Create a database using the CREATE DATABASE statement, when the privilege is granted for a database. You can grant the <code>CREATE</code> privilege on databases that do not yet exist. This also grants the <code>CREATE</code> privilege on all tables in the database.
CREATE ROUTINE	Create Stored Programs using the CREATE PROCEDURE and CREATE FUNCTION statements.
CREATE TEMPORARY TABLES	Create temporary tables with the CREATE TEMPORARY TABLE statement. This privilege enable writing and dropping those temporary tables
DROP	Drop a database using the DROP DATABASE statement, when the privilege is granted for a database. This also grants the <code>DROP</code> privilege on all tables in the database.
EVENT	Create, drop and alter <code>EVENT</code> s.
GRANT OPTION	Grant database privileges. You can only grant privileges that you have.
LOCK TABLES	Acquire explicit locks using the LOCK TABLES statement; you also need to have the <code>SELECT</code> privilege on a table, in order to lock it.
SHOW CREATE ROUTINE	Permit viewing the <code>SHOW CREATE</code> definition statement of a routine, for example SHOW CREATE FUNCTION , even if not the routine owner. From MariaDB 11.3.0 .

Table Privileges

Privilege	Description
ALTER	Change the structure of an existing table using the ALTER TABLE statement.
CREATE	Create a table using the CREATE TABLE statement. You can grant the <code>CREATE</code> privilege on tables that do not yet exist.
CREATE VIEW	Create a view using the CREATE_VIEW statement.
DELETE	Remove rows from a table using the DELETE statement.
DELETE HISTORY	Remove historical rows from a table using the DELETE HISTORY statement. Displays as <code>DELETE VERSIONING ROWS</code> when running SHOW GRANTS until MariaDB 10.3.15 and until MariaDB 10.4.5 (MDEV-17655), or when running <code>SHOW PRIVILEGES</code> until MariaDB 10.5.2 , MariaDB 10.4.13 and MariaDB 10.3.23 (MDEV-20382). From MariaDB 10.3.4 . From MariaDB 10.3.5 , if a user has the <code>SUPER</code> privilege but not this privilege, running <code>mariadb-upgrade</code> will grant this privilege as well.
DROP	Drop a table using the DROP TABLE statement or a view using the DROP VIEW statement. Also required to execute the TRUNCATE TABLE statement.
GRANT OPTION	Grant table privileges. You can only grant privileges that you have.
INDEX	Create an index on a table using the CREATE INDEX statement. Without the <code>INDEX</code> privilege, you can still create indexes when creating a table using the CREATE TABLE statement if the you have the <code>CREATE</code> privilege, and you can create indexes using the ALTER TABLE statement if you have the <code>ALTER</code> privilege.
INSERT	Add rows to a table using the INSERT statement. The <code>INSERT</code> privilege can also be set on individual columns; see Column Privileges below for details.
REFERENCES	Unused.
SELECT	Read data from a table using the SELECT statement. The <code>SELECT</code> privilege can also be set on individual columns; see Column Privileges below for details.
SHOW VIEW	Show the CREATE VIEW statement to create a view using the SHOW CREATE VIEW statement.

TRIGGER	Required to run the CREATE TRIGGER , DROP TRIGGER , and SHOW CREATE TRIGGER statements. When another user activates a trigger (running INSERT, UPDATE, or DELETE statements on the associated table), for the trigger to execute, the user that defined the trigger should have the TRIGGER privilege for the table. The user running the INSERT, UPDATE, or DELETE statements on the table is not required to have the TRIGGER privilege.
UPDATE	Update existing rows in a table using the UPDATE statement. UPDATE statements usually include a WHERE clause to update only certain rows. You must have SELECT privileges on the table or the appropriate columns for the WHERE clause. The UPDATE privilege can also be set on individual columns; see Column Privileges below for details.

Column Privileges

Some table privileges can be set for individual columns of a table. To use column privileges, specify the table explicitly and provide a list of column names after the privilege type. For example, the following statement would allow the user to read the names and positions of employees, but not other information from the same table, such as salaries.

```
GRANT SELECT (name, position) on Employee to 'jeffrey'@'localhost';
```

Privilege	Description
INSERT (column_list)	Add rows specifying values in columns using the INSERT statement. If you only have column-level INSERT privileges, you must specify the columns you are setting in the INSERT statement. All other columns will be set to their default values, or NULL.
REFERENCES (column_list)	Unused.
SELECT (column_list)	Read values in columns using the SELECT statement. You cannot access or query any columns for which you do not have SELECT privileges, including in WHERE, ON, GROUP BY, and ORDER BY clauses.
UPDATE (column_list)	Update values in columns of existing rows using the UPDATE statement. UPDATE statements usually include a WHERE clause to update only certain rows. You must have SELECT privileges on the table or the appropriate columns for the WHERE clause.

Function Privileges

Privilege	Description
ALTER ROUTINE	Change the characteristics of a stored function using the ALTER FUNCTION statement.
EXECUTE	Use a stored function. You need SELECT privileges for any tables or columns accessed by the function.
GRANT OPTION	Grant function privileges. You can only grant privileges that you have.

Procedure Privileges

Privilege	Description
ALTER ROUTINE	Change the characteristics of a stored procedure using the ALTER PROCEDURE statement.
EXECUTE	Execute a stored procedure using the CALL statement. The privilege to call a procedure may allow you to perform actions you wouldn't otherwise be able to do, such as insert rows into a table.
GRANT OPTION	Grant procedure privileges. You can only grant privileges that you have.

```
GRANT EXECUTE ON PROCEDURE mysql.create_db TO maintainer;
```

Proxy Privileges

Privilege	Description
-----------	-------------

PROXY	Permits one user to be a proxy for another.
-------	---

The `PROXY` privilege allows one user to proxy as another user, which means their privileges change to that of the proxy user, and the `CURRENT_USER()` function returns the user name of the proxy user.

The `PROXY` privilege only works with authentication plugins that support it. The default `mysql_native_password` authentication plugin does not support proxy users.

The `pam` authentication plugin is the only plugin included with MariaDB that currently supports proxy users. The `PROXY` privilege is commonly used with the `pam` authentication plugin to enable [user and group mapping with PAM](#).

For example, to grant the `PROXY` privilege to an [anonymous account](#) that authenticates with the `pam` authentication plugin, you could execute the following:

```
CREATE USER 'dba'@'%' IDENTIFIED BY 'strongpassword';
GRANT ALL PRIVILEGES ON *.* TO 'dba'@'%' ;

CREATE USER ''@'%' IDENTIFIED VIA pam USING 'mariadb';
GRANT PROXY ON 'dba'@'%' TO ''@'%' ;
```

A user account can only grant the `PROXY` privilege for a specific user account if the granter also has the `PROXY` privilege for that specific user account, and if that privilege is defined `WITH GRANT OPTION`. For example, the following example fails because the granter does not have the `PROXY` privilege for that specific user account at all:

```
SELECT USER(), CURRENT_USER();
+-----+-----+
| USER()          | CURRENT_USER() |
+-----+-----+
| alice@localhost | alice@localhost |
+-----+-----+

SHOW GRANTS;
+-----+
+-----+
| Grants for alice@localhost
|
+-----+
+-----+
| GRANT ALL PRIVILEGES ON *.* TO 'alice'@'localhost' IDENTIFIED BY PASSWORD
'*2470C0C06DEE42FD1618BB99005ADCA2EC9D1E19' |
+-----+
+-----+

GRANT PROXY ON 'dba'@'localhost' TO 'bob'@'localhost';
ERROR 1698 (28000): Access denied for user 'alice'@'localhost'
```

And the following example fails because the granter does have the `PROXY` privilege for that specific user account, but it is not defined `WITH GRANT OPTION`:

```

SELECT USER(), CURRENT_USER();
+-----+-----+
| USER()          | CURRENT_USER() |
+-----+-----+
| alice@localhost | alice@localhost |
+-----+-----+

SHOW GRANTS;
+-----+-----+
| Grants for alice@localhost
|
+-----+-----+
| GRANT ALL PRIVILEGES ON *.* TO 'alice'@'localhost' IDENTIFIED BY PASSWORD
'|*2470C0C06DEE42FD1618BB99005ADCA2EC9D1E19' |
| GRANT PROXY ON 'dba'@'localhost' TO 'alice'@'localhost'
|
+-----+-----+

GRANT PROXY ON 'dba'@'localhost' TO 'bob'@'localhost';
ERROR 1698 (28000): Access denied for user 'alice'@'localhost'

```

But the following example succeeds because the granter does have the `PROXY` privilege for that specific user account, and it is defined `WITH GRANT OPTION` :

```

SELECT USER(), CURRENT_USER();
+-----+-----+
| USER()          | CURRENT_USER() |
+-----+-----+
| alice@localhost | alice@localhost |
+-----+-----+

SHOW GRANTS;
+-----+-----+
| Grants for alice@localhost
|
+-----+-----+
| GRANT ALL PRIVILEGES ON *.* TO 'alice'@'localhost' IDENTIFIED BY PASSWORD
'|*2470C0C06DEE42FD1618BB99005ADCA2EC9D1E19' WITH GRANT OPTION |
| GRANT PROXY ON 'dba'@'localhost' TO 'alice'@'localhost' WITH GRANT OPTION
|
+-----+-----+

GRANT PROXY ON 'dba'@'localhost' TO 'bob'@'localhost';

```

A user account can grant the `PROXY` privilege for any other user account if the granter has the `PROXY` privilege for the `'@'%'` anonymous user account, like this:

```

GRANT PROXY ON '@'%' TO 'dba'@'localhost' WITH GRANT OPTION;

```

For example, the following example succeeds because the user can grant the `PROXY` privilege for any other user account:

```

SELECT USER(), CURRENT_USER();
+-----+-----+
| USER()          | CURRENT_USER() |
+-----+-----+
| alice@localhost | alice@localhost |
+-----+-----+

SHOW GRANTS;
+-----+
| Grants for alice@localhost
|
+-----+
| GRANT ALL PRIVILEGES ON *.* TO 'alice'@'localhost' IDENTIFIED BY PASSWORD
'|*2470C0C06DEE42FD1618BB99005ADCA2EC9D1E19' WITH GRANT OPTION |
| GRANT PROXY ON ''@%' TO 'alice'@'localhost' WITH GRANT OPTION
|
+-----+

GRANT PROXY ON 'app1_dba'@'localhost' TO 'bob'@'localhost';
Query OK, 0 rows affected (0.004 sec)

GRANT PROXY ON 'app2_dba'@'localhost' TO 'carol'@'localhost';
Query OK, 0 rows affected (0.004 sec)

```

The default `root` user accounts created by `mariadb-install-db` have this privilege. For example:

```

GRANT ALL PRIVILEGES ON *.* TO 'root'@'localhost' WITH GRANT OPTION;
GRANT PROXY ON ''@%' TO 'root'@'localhost' WITH GRANT OPTION;

```

This allows the default `root` user accounts to grant the `PROXY` privilege for any other user account, and it also allows the default `root` user accounts to grant others the privilege to do the same.

Authentication Options

The authentication options for the `GRANT` statement are the same as those for the `CREATE USER` statement.

IDENTIFIED BY 'password'

The optional `IDENTIFIED BY` clause can be used to provide an account with a password. The password should be specified in plain text. It will be hashed by the `PASSWORD` function prior to being stored.

For example, if our password is `mariadb`, then we can create the user with:

```

GRANT USAGE ON *.* TO foo2@test IDENTIFIED BY 'mariadb';

```

If you do not specify a password with the `IDENTIFIED BY` clause, the user will be able to connect without a password. A blank password is not a wildcard to match any password. The user must connect without providing a password if no password is set.

If the user account already exists and if you provide the `IDENTIFIED BY` clause, then the user's password will be changed. You must have the privileges needed for the `SET PASSWORD` statement to change a user's password with `GRANT`.

The only [authentication plugins](#) that this clause supports are `mysql_native_password` and `mysql_old_password`.

IDENTIFIED BY PASSWORD 'password_hash'

The optional `IDENTIFIED BY PASSWORD` clause can be used to provide an account with a password that has already been hashed. The password should be specified as a hash that was provided by the `PASSWORD` function. It will be stored as-is.

For example, if our password is `mariadb`, then we can find the hash with:

```

SELECT PASSWORD('mariadb');
+-----+
| PASSWORD('mariadb') |
+-----+
| *54958E764CE10E50764C2EECBB71D01F08549980 |
+-----+
1 row in set (0.00 sec)

```

And then we can create a user with the hash:

```

GRANT USAGE ON *.* TO foo2@test IDENTIFIED BY
PASSWORD '*54958E764CE10E50764C2EECBB71D01F08549980';

```

If you do not specify a password with the `IDENTIFIED BY` clause, the user will be able to connect without a password. A blank password is not a wildcard to match any password. The user must connect without providing a password if no password is set.

If the user account already exists and if you provide the `IDENTIFIED BY` clause, then the user's password will be changed. You must have the privileges needed for the `SET PASSWORD` statement to change a user's password with `GRANT`.

The only [authentication plugins](#) that this clause supports are `mysql_native_password` and `mysql_old_password`.

IDENTIFIED {VIA|WITH} authentication_plugin

The optional `IDENTIFIED VIA authentication_plugin` allows you to specify that the account should be authenticated by a specific [authentication plugin](#). The plugin name must be an active authentication plugin as per `SHOW PLUGINS`. If it doesn't show up in that output, then you will need to install it with `INSTALL PLUGIN` or `INSTALL SONAME`.

For example, this could be used with the [PAM authentication plugin](#):

```

GRANT USAGE ON *.* TO foo2@test IDENTIFIED VIA pam;

```

Some authentication plugins allow additional arguments to be specified after a `USING` or `AS` keyword. For example, the [PAM authentication plugin](#) accepts a [service name](#):

```

GRANT USAGE ON *.* TO foo2@test IDENTIFIED VIA pam USING 'mariadb';

```

The exact meaning of the additional argument would depend on the specific authentication plugin.

The `USING` or `AS` keyword can also be used to provide a plain-text password to a plugin if it's provided as an argument to the `PASSWORD()` function. This is only valid for [authentication plugins](#) that have implemented a hook for the `PASSWORD()` function. For example, the [ed25519](#) authentication plugin supports this:

```

CREATE USER safe@'%' IDENTIFIED VIA ed25519
USING PASSWORD('secret');

```

One can specify many authentication plugins, they all work as alternative ways of authenticating a user:

```

CREATE USER safe@'%' IDENTIFIED VIA ed25519
USING PASSWORD('secret') OR unix_socket;

```

By default, when you create a user without specifying an authentication plugin, MariaDB uses the `mysql_native_password` plugin.

Resource Limit Options

It is possible to set per-account limits for certain server resources. The following table shows the values that can be set per account:

Limit Type	Description
<code>MAX_QUERIES_PER_HOUR</code>	Number of statements that the account can issue per hour (including updates)
<code>MAX_UPDATES_PER_HOUR</code>	Number of updates (not queries) that the account can issue per hour
<code>MAX_CONNECTIONS_PER_HOUR</code>	Number of connections that the account can start per hour

MAX_USER_CONNECTIONS	Number of simultaneous connections that can be accepted from the same account; if it is 0, max_connections will be used instead; if max_connections is 0, there is no limit for this account's simultaneous connections.
MAX_STATEMENT_TIME	Timeout, in seconds, for statements executed by the user. See also Aborting Statements that Exceed a Certain Time to Execute .

If any of these limits are set to 0, then there is no limit for that resource for that user.

To set resource limits for an account, if you do not want to change that account's privileges, you can issue a GRANT statement with the USAGE privilege, which has no meaning. The statement can name some or all limit types, in any order.

Here is an example showing how to set resource limits:

```
GRANT USAGE ON *.* TO 'someone'@'localhost' WITH
MAX_USER_CONNECTIONS 0
MAX_QUERIES_PER_HOUR 200;
```

The resources are tracked per account, which means 'user'@'server'; not per user name or per connection.

The count can be reset for all users using FLUSH USER_RESOURCES, FLUSH PRIVILEGES or mariadb-admin reload.

Users with the CONNECTION ADMIN privilege (in MariaDB 10.5.2 and later) or the SUPER privilege are not restricted by max_user_connections or max_password_errors and they are allowed one additional connection when max_connections is reached.

Per account resource limits are stored in the user table, in the mysql database. Columns used for resources limits are named max_questions, max_updates, max_connections (for MAX_CONNECTIONS_PER_HOUR), and max_user_connections (for MAX_USER_CONNECTIONS).

TLS Options

By default, MariaDB transmits data between the server and clients without encrypting it. This is generally acceptable when the server and client run on the same host or in networks where security is guaranteed through other means. However, in cases where the server and client exist on separate networks or they are in a high-risk network, the lack of encryption does introduce security concerns as a malicious actor could potentially eavesdrop on the traffic as it is sent over the network between them.

To mitigate this concern, MariaDB allows you to encrypt data in transit between the server and clients using the Transport Layer Security (TLS) protocol. TLS was formerly known as Secure Socket Layer (SSL), but strictly speaking the SSL protocol is a predecessor to TLS and, that version of the protocol is now considered insecure. The documentation still uses the term SSL often and for compatibility reasons TLS-related server system and status variables still use the prefix ssl_, but internally, MariaDB only supports its secure successors.

See [Secure Connections Overview](#) for more information about how to determine whether your MariaDB server has TLS support.

You can set certain TLS-related restrictions for specific user accounts. For instance, you might use this with user accounts that require access to sensitive data while sending it across networks that you do not control. These restrictions can be enabled for a user account with the CREATE USER, ALTER USER, or GRANT statements. The following options are available:

Option	Description
REQUIRE NONE	TLS is not required for this account, but can still be used.
REQUIRE SSL	The account must use TLS, but no valid X509 certificate is required. This option cannot be combined with other TLS options.
REQUIRE X509	The account must use TLS and must have a valid X509 certificate. This option implies REQUIRE SSL. This option cannot be combined with other TLS options.
REQUIRE ISSUER 'issuer'	The account must use TLS and must have a valid X509 certificate. Also, the Certificate Authority must be the one specified via the string issuer. This option implies REQUIRE X509. This option can be combined with the SUBJECT, and CIPHER options in any order.
REQUIRE SUBJECT 'subject'	The account must use TLS and must have a valid X509 certificate. Also, the certificate's Subject must be the one specified via the string subject. This option implies REQUIRE X509. This option can be combined with the ISSUER, and CIPHER options in any order.

REQUIRE CIPHER 'cipher'	The account must use TLS, but no valid X509 certificate is required. Also, the encryption used for the connection must use a specific cipher method specified in the string <code>cipher</code> . This option implies <code>REQUIRE</code> <code>SSL</code> . This option can be combined with the <code>ISSUER</code> , and <code>SUBJECT</code> options in any order.
-------------------------------	---

The `REQUIRE` keyword must be used only once for all specified options, and the `AND` keyword can be used to separate individual options, but it is not required.

For example, you can create a user account that requires these TLS options with the following:

```
GRANT USAGE ON *.* TO 'alice'@'%'
  REQUIRE SUBJECT '/CN=alice/O=My Dom, Inc./C=US/ST=Oregon/L=Portland'
  AND ISSUER '/C=FI/ST=Somewhere/L=City/ O=Some Company/CN=Peter Parker/[email protected]'
  AND CIPHER 'SHA-DES-CBC3-EDH-RSA';
```

If any of these options are set for a specific user account, then any client who tries to connect with that user account will have to be configured to connect with TLS.

See [Securing Connections for Client and Server](#) for information on how to enable TLS on the client and server.

Roles

Syntax

```
GRANT role TO grantee [, grantee ... ]
[ WITH ADMIN OPTION ]

grantee:
  rolename
  username [authentication_option]
```

The `GRANT` statement is also used to grant the use of a [role](#) to one or more users or other roles. In order to be able to grant a role, the grantor doing so must have permission to do so (see `WITH ADMIN` in the [CREATE ROLE](#) article).

Specifying the `WITH ADMIN OPTION` permits the grantee to in turn grant the role to another.

For example, the following commands show how to grant the same role to a couple different users.

```
GRANT journalist TO hulda;

GRANT journalist TO berengar WITH ADMIN OPTION;
```

If a user has been granted a role, they do not automatically obtain all permissions associated with that role. These permissions are only in use when the user activates the role with the [SET ROLE](#) statement.

TO PUBLIC

MariaDB starting with [10.11.0](#) [blog post](#)

Syntax

```
GRANT <privilege> ON <database>.<object> TO PUBLIC;
REVOKE <privilege> ON <database>.<object> FROM PUBLIC;
```

`GRANT ... TO PUBLIC` grants privileges to all users with access to the server. The privileges also apply to users created after the privileges are granted. This can be useful when one only wants to state once that all users need to have a certain set of privileges.

When running [SHOW GRANTS](#), a user will also see all privileges inherited from `PUBLIC`. [SHOW GRANTS FOR PUBLIC](#) will only show `TO PUBLIC` grants.

Grant Examples

Granting Root-like Privileges

You can create a user that has privileges similar to the default `root` accounts by executing the following:

```
CREATE USER 'alexander'@'localhost';
GRANT ALL PRIVILEGES ON *.* TO 'alexander'@'localhost' WITH GRANT OPTION;
```

1.1.1.1.5 RENAME USER

Syntax

```
RENAME USER old_user TO new_user
[, old_user TO new_user] ...
```

Description

The `RENAME USER` statement renames existing MariaDB accounts. To use it, you must have the global `CREATE USER` privilege or the `UPDATE` privilege for the `mysql` database. Each account is named using the same format as for the `CREATE USER` statement; for example, `'jeffrey'@'localhost'`. If you specify only the user name part of the account name, a host name part of `'%'` is used.

If any of the old user accounts do not exist or any of the new user accounts already exist, `ERROR 1396 (HY000)` results. If an error occurs, `RENAME USER` will still rename the accounts that do not result in an error.

For modifying an existing account, see [ALTER USER](#).

Examples

```
CREATE USER 'donald', 'mickey';
RENAME USER 'donald' TO 'duck'@'localhost', 'mickey' TO 'mouse'@'localhost';
```

Renaming the host component of a user

```
RENAME USER 'foo'@'1.2.3.4' TO 'foo'@'10.20.30.40';
```

1.1.1.1.6 REVOKE

Contents

1. [Privileges](#)
 1. [Syntax](#)
 2. [Description](#)
 3. [Examples](#)
2. [Roles](#)
 1. [Syntax](#)
 2. [Description](#)
 3. [Example](#)

Privileges

Syntax

```
REVOKE
  priv_type [(column_list)]
  [, priv_type [(column_list)]] ...
ON [object_type] priv_level
FROM user [, user] ...

REVOKE ALL PRIVILEGES, GRANT OPTION
FROM user [, user] ...
```

Description

The `REVOKE` statement enables system administrators to revoke privileges (or roles - see [section below](#)) from MariaDB accounts. Each account is named using the same format as for the `GRANT` statement; for example, `'jeffrey'@'localhost'`. If you specify only the user name part of the account name, a host name part of `' % '` is used. For details on the levels at which privileges exist, the allowable `priv_type` and `priv_level` values, and the syntax for specifying users and passwords, see [GRANT](#).

To use the first `REVOKE` syntax, you must have the `GRANT OPTION` privilege, and you must have the privileges that you are revoking.

To revoke all privileges, use the second syntax, which drops all global, database, table, column, and routine privileges for the named user or users:

```
REVOKE ALL PRIVILEGES, GRANT OPTION FROM user [, user] ...
```

To use this `REVOKE` syntax, you must have the global `CREATE USER` privilege or the `UPDATE` privilege for the `mysql` database. See [GRANT](#).

Examples

```
REVOKE SUPER ON *.* FROM 'alexander'@'localhost';
```

Roles

Syntax

```
REVOKE role [, role ...]
      FROM grantee [, grantee2 ... ]

REVOKE ADMIN OPTION FOR role FROM grantee [, grantee2]
```

Description

`REVOKE` is also used to remove a [role](#) from a user or another role that it's previously been assigned to. If a role has previously been set as a [default role](#), `REVOKE` does not remove the record of the default role from the `mysql.user` table. If the role is subsequently granted again, it will again be the user's default. Use [SET DEFAULT ROLE NONE](#) to explicitly remove this.

Before [MariaDB 10.1.13](#), the `REVOKE role` statement was not permitted in [prepared statements](#).

Example

```
REVOKE journalist FROM hulda
```

1.1.1.1.7 SET PASSWORD

Syntax

```
SET PASSWORD [FOR user] =
{
    PASSWORD('some password')
  | OLD_PASSWORD('some password')
  | 'encrypted password'
}
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Authentication Plugin Support](#)
4. [Passwordless User Accounts](#)
5. [Example](#)

Description

The `SET PASSWORD` statement assigns a password to an existing MariaDB user account.

If the password is specified using the `PASSWORD()` or `OLD_PASSWORD()` function, the literal text of the password should be given. If the password is specified without using either function, the password should be the already-encrypted password value as returned by `PASSWORD()`.

`OLD_PASSWORD()` should only be used if your MariaDB/MySQL clients are very old (< 4.0.0).

With no `FOR` clause, this statement sets the password for the current user. Any client that has connected to the server using a non-anonymous account can change the password for that account.

With a `FOR` clause, this statement sets the password for a specific account on the current server host. Only clients that have the `UPDATE` privilege for the `mysql` database can do this. The user value should be given in `user_name@host_name` format, where `user_name` and `host_name` are exactly as they are listed in the User and Host columns of the `mysql.user` table (or view in MariaDB-10.4 onwards) entry.

The argument to `PASSWORD()` and the password given to MariaDB clients can be of arbitrary length.

Authentication Plugin Support

`SET PASSWORD` (with or without `PASSWORD()`) works for accounts authenticated via any [authentication plugin](#) that supports passwords stored in the `mysql.global_priv` table.

The `ed25519`, `mysql_native_password`, and `mysql_old_password` authentication plugins store passwords in the `mysql.global_priv` table.

If you run `SET PASSWORD` on an account that authenticates with one of these authentication plugins that stores passwords in the `mysql.global_priv` table, then the `PASSWORD()` function is evaluated by the specific authentication plugin used by the account. The authentication plugin hashes the password with a method that is compatible with that specific authentication plugin.

The `unix_socket`, `named_pipe`, `gssapi`, and `pam` authentication plugins do **not** store passwords in the `mysql.global_priv` table. These authentication plugins rely on other methods to authenticate the user.

If you attempt to run `SET PASSWORD` on an account that authenticates with one of these authentication plugins that doesn't store a password in the `mysql.global_priv` table, then MariaDB Server will issue an error like the following:

```
SET PASSWORD is ignored for users authenticating via unix_socket plugin
```

See [Authentication from MariaDB 10.4](#) for an overview of authentication changes in [MariaDB 10.4](#).

MariaDB until 10.3

In [MariaDB 10.3](#) and before, `SET PASSWORD` (with or without `PASSWORD()`) only works for accounts authenticated via `mysql_native_password` or `mysql_old_password` authentication plugins

Passwordless User Accounts

User accounts do not always require passwords to login.

The `unix_socket`, `named_pipe` and `gssapi` authentication plugins do not require a password to authenticate the user.

The `pam` authentication plugin may or may not require a password to authenticate the user, depending on the specific configuration.

The `mysql_native_password` and `mysql_old_password` authentication plugins require passwords for authentication, but the password can be blank. In that case, no password is required.

If you provide a password while attempting to log into the server as an account that doesn't require a password, then MariaDB server will simply ignore the password.

A user account can be defined to use multiple authentication plugins in a specific order of preference. This specific scenario may be more noticeable in these versions, since an account could be associated with some authentication plugins that require a password, and some that do not.

Example

For example, if you had an entry with User and Host column values of ' bob ' and ' % . loc . gov ', you would write the statement like this:

```
SET PASSWORD FOR 'bob'@'% . loc . gov' = PASSWORD('newpass');
```

If you want to delete a password for a user, you would do:

```
SET PASSWORD FOR 'bob'@localhost = PASSWORD("");
```

1.1.1.1.8 CREATE ROLE

Syntax

```
CREATE [OR REPLACE] ROLE [IF NOT EXISTS] role
[WITH ADMIN
 {CURRENT_USER | CURRENT_ROLE | user | role}]
```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [WITH ADMIN](#)
 2. [OR REPLACE](#)
 3. [IF NOT EXISTS](#)
3. [Examples](#)

Description

The `CREATE ROLE` statement creates one or more MariaDB [roles](#). To use it, you must have the global [CREATE USER](#) privilege or the [INSERT](#) privilege for the `mysql` database. For each account, `CREATE ROLE` creates a new row in the `mysql.user` table that has no privileges, and with the corresponding `is_role` field set to `Y`. It also creates a record in the `mysql.roles_mapping` table.

If any of the specified roles already exist, `ERROR 1396 (HY000)` results. If an error occurs, `CREATE ROLE` will still create the roles that do not result in an error. The maximum length for a role is 128 characters. Role names can be quoted, as explained in the [Identifier names](#) page. Only one error is produced for all roles which have not been created:

```
ERROR 1396 (HY000): Operation CREATE ROLE failed for 'a','b','c'
```

Failed `CREATE` or `DROP` operations, for both users and roles, produce the same error code.

`PUBLIC` and `NONE` are reserved, and cannot be used as role names. `NONE` is used to [unset a role](#) and `PUBLIC` has a special use in other systems, such as Oracle, so is reserved for compatibility purposes.

For valid identifiers to use as role names, see [Identifier Names](#).

WITH ADMIN

The optional `WITH ADMIN` clause determines whether the current user, the current role or another user or role has use of the newly created role. If the clause is omitted, `WITH ADMIN CURRENT_USER` is treated as the default, which means that the current user will be able to [GRANT](#) this role to users.

OR REPLACE

If the optional `OR REPLACE` clause is used, it acts as a shortcut for:

```
DROP ROLE IF EXISTS name;
CREATE ROLE name ...;
```

IF NOT EXISTS

When the `IF NOT EXISTS` clause is used, MariaDB will return a warning instead of an error if the specified role already exists. Cannot be used together with the `OR REPLACE` clause.

Examples

```
CREATE ROLE journalist;

CREATE ROLE developer WITH ADMIN lorinda@localhost;
```

Granting the role to another user. Only user `lorinda@localhost` has permission to grant the `developer` role:

```
SELECT USER();
+-----+
| USER() |
+-----+
| henning@localhost |
+-----+
...
GRANT developer TO ian@localhost;
Access denied for user 'henning'@'localhost'

SELECT USER();
+-----+
| USER() |
+-----+
| lorinda@localhost |
+-----+

GRANT m_role TO ian@localhost;
```

The `OR REPLACE` and `IF NOT EXISTS` clauses. The `journalist` role already exists:

```
CREATE ROLE journalist;
ERROR 1396 (HY000): Operation CREATE ROLE failed for 'journalist'

CREATE OR REPLACE ROLE journalist;
Query OK, 0 rows affected (0.00 sec)

CREATE ROLE IF NOT EXISTS journalist;
Query OK, 0 rows affected, 1 warning (0.00 sec)
```

```
SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Note | 1975 | Can't create role 'journalist'; it already exists |
+-----+-----+-----+
```

1.1.1.1.9 DROP ROLE

Syntax

```
DROP ROLE [IF EXISTS] role_name [,role_name ...]
```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [IF EXISTS](#)
3. [Examples](#)

Description

The `DROP ROLE` statement removes one or more MariaDB [roles](#). To use this statement, you must have the global [CREATE USER](#) privilege or the [DELETE](#) privilege for the `mysql` database.

`DROP ROLE` does not disable roles for connections which selected them with [SET ROLE](#). If a role has previously been set as a [default role](#), `DROP ROLE` does not remove the record of the default role from the `mysql.user` table. If the role is subsequently recreated and granted, it will again be the user's default. Use [SET DEFAULT ROLE NONE](#) to explicitly remove this.

If any of the specified user accounts do not exist, `ERROR 1396 (HY000)` results. If an error occurs, `DROP ROLE` will still drop the roles that do not result in an error. Only one error is produced for all roles which have not been dropped:

```
ERROR 1396 (HY000): Operation DROP ROLE failed for 'a','b','c'
```

Failed `CREATE` or `DROP` operations, for both users and roles, produce the same error code.

IF EXISTS

If the `IF EXISTS` clause is used, MariaDB will return a warning instead of an error if the role does not exist.

Examples

```
DROP ROLE journalist;
```

The same thing using the optional `IF EXISTS` clause:

```
DROP ROLE journalist;
ERROR 1396 (HY000): Operation DROP ROLE failed for 'journalist'

DROP ROLE IF EXISTS journalist;
Query OK, 0 rows affected, 1 warning (0.00 sec)

Note (Code 1975): Can't drop role 'journalist'; it doesn't exist
```

1.1.1.1.10 SET ROLE

Syntax

```
SET ROLE { role | NONE }
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Example](#)

Description

The `SET ROLE` statement enables a [role](#), along with all of its associated permissions, for the current session. To unset a role, use `NONE`.

If a role that doesn't exist, or to which the user has not been assigned, is specified, an `ERROR 1959 (OP000): Invalid role specification` error occurs.

An automatic `SET ROLE` is implicitly performed when a user connects if that user has been assigned a default role. See

Example

```

SELECT CURRENT_ROLE;
+-----+
| CURRENT_ROLE |
+-----+
| NULL        |
+-----+

SET ROLE staff;

SELECT CURRENT_ROLE;
+-----+
| CURRENT_ROLE |
+-----+
| staff        |
+-----+

SET ROLE NONE;

SELECT CURRENT_ROLE ();
+-----+
| CURRENT_ROLE () |
+-----+
| NULL           |
+-----+

```

1.1.1.1.11 SET DEFAULT ROLE

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

Syntax

```
SET DEFAULT ROLE { role | NONE } [ FOR user@host ]
```

Description

The `SET DEFAULT ROLE` statement sets a **default role** for a specified (or current) user. A default role is automatically enabled when a user connects (an implicit `SET ROLE` statement is executed immediately after a connection is established).

To be able to set a role as a default, the role must already have been granted to that user, and one needs the privileges to enable this role (if you cannot do `SET ROLE X`, you won't be able to do `SET DEFAULT ROLE X`). To set a default role for another user one needs to have write access to the `mysql` database.

To remove a user's default role, use `SET DEFAULT ROLE NONE [FOR user@host]`. The record of the default role is not removed if the role is **dropped** or **revoked**, so if the role is subsequently re-created or granted, it will again be the user's default role.

The default role is stored in the `default_role` column in the `mysql.user` table/view, as well as in the [Information Schema APPLICABLE_ROLES table](#), so these can be viewed to see which role has been assigned to a user as the default.

Examples

Setting a default role for the current user:

```
SET DEFAULT ROLE journalist;
```

Removing a default role from the current user:

```
SET DEFAULT ROLE NONE;
```

Setting a default role for another user. The role has to have been granted to the user before it can be set as default:

```
CREATE ROLE journalist;
CREATE USER taniel;

SET DEFAULT ROLE journalist FOR taniel;
ERROR 1959 (OP000): Invalid role specification `journalist`

GRANT journalist TO taniel;
SET DEFAULT ROLE journalist FOR taniel;
```

Viewing mysql.user:

```
select * from mysql.user where user='taniel'\G
***** 1. row *****
      Host: %
      User: taniel
...
      is_role: N
      default_role: journalist
...

```

Removing a default role for another user

```
SET DEFAULT ROLE NONE FOR taniel;
```

1.1.1.1.12 SHOW GRANTS

Contents

1. [Syntax](#)
2. [Description](#)
 1. [Users](#)
 2. [Roles](#)
 1. [Example](#)
 3. [FOR PUBLIC](#)

Syntax

```
SHOW GRANTS [FOR user|role]
```

Description

The `SHOW GRANTS` statement lists privileges granted to a particular user or role.

Users

The statement lists the `GRANT` statement or statements that must be issued to duplicate the privileges that are granted to a MariaDB user account. The account is named using the same format as for the `GRANT` statement; for example, `'jeffrey'@'localhost'`. If you specify only the user name part of the account name, a host name part of `'%'` is used. For additional information about specifying account names, see [GRANT](#).

```
SHOW GRANTS FOR 'root'@'localhost';
+-----+
| Grants for root@localhost |
+-----+
| GRANT ALL PRIVILEGES ON *.* TO 'root'@'localhost' WITH GRANT OPTION |
+-----+
```

To list the privileges granted to the account that you are using to connect to the server, you can use any of the following statements:

```
SHOW GRANTS;  
SHOW GRANTS FOR CURRENT_USER;  
SHOW GRANTS FOR CURRENT_USER ();
```

If `SHOW GRANTS FOR CURRENT_USER` (or any of the equivalent syntaxes) is used in `DEFINER` context (such as within a stored procedure that is defined with `SQL SECURITY DEFINER`), the grants displayed are those of the definer and not the invoker.

Note that the `DELETE HISTORY` privilege, introduced in [MariaDB 10.3.4](#), was displayed as `DELETE VERSIONING ROWS` when running `SHOW GRANTS` until [MariaDB 10.3.15](#) (MDEV-17655).

Roles

`SHOW GRANTS` can also be used to view the privileges granted to a [role](#).

Example

```
SHOW GRANTS FOR journalist;  
+-----+  
| Grants for journalist |  
+-----+  
| GRANT USAGE ON *.* TO 'journalist' |  
| GRANT DELETE ON `test`.* TO 'journalist' |  
+-----+
```

FOR PUBLIC

MariaDB starting with [10.11](#)

`GRANT ... TO PUBLIC` was introduced in [MariaDB 10.11](#) to grant privileges to all users. `SHOW GRANTS FOR PUBLIC` shows all these grants.

```
SHOW GRANTS FOR public;  
+-----+  
| Grants for PUBLIC |  
+-----+  
| GRANT ALL PRIVILEGES ON `dev_db`.* TO `PUBLIC` |  
+-----+
```

1.1.1.1.13 SHOW CREATE USER

Syntax

```
SHOW CREATE USER [user]
```

Description

Shows the `CREATE USER` statement that creates the given user. The statement requires the `SELECT` privilege for the `mysql` database, except for the current user. The `CREATE USER` statement for the current user is shown where no user is specified.

`SHOW CREATE USER` quotes identifiers according to the value of the `sql_quote_show_create` system variable.

Examples

```

CREATE USER foo4@test require cipher 'text'
    issuer 'foo_issuer' subject 'foo_subject';

SHOW CREATE USER foo4@test\G
***** 1. row *****
CREATE USER 'foo4'@'test'
    REQUIRE ISSUER 'foo_issuer'
    SUBJECT 'foo_subject'
    CIPHER 'text'

```

User Password Expiry:

```

CREATE USER 'monty'@'localhost' PASSWORD EXPIRE INTERVAL 120 DAY;

SHOW CREATE USER 'monty'@'localhost';
+-----+
| CREATE USER for monty@localhost |
+-----+
| CREATE USER 'monty'@'localhost' PASSWORD EXPIRE INTERVAL 120 DAY |
+-----+

```

1.1.1.2 Administrative SQL Statements

SQL statements for administering MariaDB.

Table Statements

[Documentation on creating, altering, analyzing and maintaining tables.](#)

ANALYZE and EXPLAIN Statements

[Articles on the ANALYZE and EXPLAIN statements](#)

BACKUP Commands

[Commands used by backup tools.](#)

FLUSH Commands

[Commands to flush or reset various caches in MariaDB.](#)

Replication Commands

[List of replication-related commands.](#)

Plugin SQL Statements

[List of SQL statements related to plugins.](#)

SET Commands

[The SET commands](#)

SHOW

[Articles on the various SHOW commands.](#)

System Tables

BINLOG

[Internal statement generated by mariadb-binlog.](#)

PURGE BINARY LOGS

[PURGE BINARY LOGS removes all binary logs from the server, prior to the provided date or log file.](#)

CACHE INDEX

[Caches MyISAM or Aria indexes](#)

DESCRIBE

[Information about columns in a table.](#)

EXECUTE Statement

Executes a previously PREPARED statement

HELP Command

The HELP command will retrieve syntax and help within the mariadb client.

KILL [CONNECTION | QUERY]

Kill connection by query or thread id.

LOAD INDEX

Loads one or more indexes from one or more MyISAM/Aria tables into a key buffer.

RESET

Overall description of the different RESET commands

SHUTDOWN

Shuts down the server.

USE [DATABASE]

Set the current default database.

There are [3 related questions](#)

1.1.1.2.1 Table Statements

Articles about creating, modifying, and maintaining tables in MariaDB.

ALTER

The various ALTER statements in MariaDB.

ANALYZE TABLE

Store key distributions for a table.

CHECK TABLE

Check table for errors.

CHECK VIEW

Check whether the view algorithm is correct.

CHECKSUM TABLE

Report a table checksum.

CREATE TABLE

Creates a new table.

DELETE

Delete rows from one or more tables.

DROP TABLE

Removes definition and data from one or more tables.

Installing System Tables (mariadb-install-db)

Using mariadb-install-db to create the system tables in the 'mysql' database directory.

OPTIMIZE TABLE

Reclaim unused space and defragment data.

RENAME TABLE

Change a table's name.

REPAIR TABLE

Repairs a table, if the storage engine supports this statement.

REPAIR VIEW

Fix view if the algorithms are swapped.

REPLACE

Equivalent to DELETE + INSERT, or just an INSERT if no rows are returned.

SHOW COLUMNS

Column information.

SHOW CREATE TABLE

Shows the CREATE TABLE statement that creates the table.

SHOW INDEX

Information about table indexes.

TRUNCATE TABLE

DROP and re-CREATE a table.

UPDATE

Modify rows in one or more tables.

Obsolete Table Commands

Table commands that have been removed from MariaDB [↗](#)

IGNORE

Suppress errors while trying to violate a UNIQUE constraint.

System-Versioned Tables

System-versioned tables record the history of all changes to table data.

There are [2 related questions](#) [↗](#).

1.1.1.2.1.1 ALTER

This category is for documentation on the various ALTER statements.

ALTER TABLE

Modify a table's definition.

ALTER DATABASE

Change the overall characteristics of a database.

ALTER EVENT

Change an existing event.

ALTER FUNCTION

Change the characteristics of a stored function.

ALTER LOGFILE GROUP

Only useful with MySQL Cluster, and has no effect in MariaDB.

ALTER PROCEDURE

Change stored procedure characteristics.

ALTER SEQUENCE

Change options for a SEQUENCE.

ALTER SERVER

Updates mysql.servers table.

ALTER TABLESPACE

ALTER TABLESPACE is not available in MariaDB.

ALTER USER

Modify an existing MariaDB account.

ALTER VIEW

Change a view definition.

There are [1 related questions](#).

1.1.1.2.1.1.1 ALTER TABLE

Syntax

```

ALTER [ONLINE] [IGNORE] TABLE [IF EXISTS] tbl_name
    [WAIT n | NOWAIT]
    alter_specification [, alter_specification] ...

alter_specification:
    table_option ...
| ADD [COLUMN] [IF NOT EXISTS] col_name column_definition
    [FIRST | AFTER col_name ]

Description

`ALTER TABLE` enables you to change the structure of an existing table. For example, you can add or delete columns, create or destroy indexes, change the type of existing columns, or rename columns or the table itself. You can also change the comment for the table and the storage engine of the table.

If another connection is using the table, a [metadata lock](#) is active, and this statement will wait until the lock is released. This is also true for non-transactional tables.

When adding a `UNIQUE` index on a column (or a set of columns) which have duplicated values, an error will be produced and the statement will be stopped. To suppress the error and force the creation of `UNIQUE` indexes, discarding duplicates, the `IGNORE` option can be specified. This can be useful if a column (or a set of columns) should be `UNIQUE` but it contains duplicate values; however, this technique provides no control on which rows are preserved and which are deleted. Also, note that `IGNORE` is accepted but ignored in `ALTER TABLE ... EXCHANGE PARTITION` statements.

This statement can also be used to rename a table. For details see [RENAME TABLE](#).

When an index is created, the storage engine may use a configurable buffer in the process. Incrementing the buffer speeds up the index creation. `Aria` and `MyISAM` allocate a buffer whose size is defined by `aria_sort_buffer_size` or

`mysam_sort_buffer_size`, also used for `REPAIR TABLE`. InnoDB allocates three buffers whose size is defined by `innodb_sort_buffer_size`.

Privileges

Executing the `ALTER TABLE` statement generally requires at least the `ALTER` privilege for the table or the database..

If you are renaming a table, then it also requires the `DROP`, `CREATE` and `INSERT` privileges for the table or the database as well.

Online DDL

Online DDL is supported with the `ALGORITHM` and `LOCK` clauses.

See [InnoDB Online DDL Overview](#) for more information on online DDL with [InnoDB](#).

ALTER ONLINE TABLE

`ALTER ONLINE TABLE` also works for partitioned tables.

Online `ALTER TABLE` is available by executing the following:

```
ALTER ONLINE TABLE ...;
```

This statement is equivalent to the following:

```
ALTER TABLE ... LOCK=NONE;
```

See the [LOCK](#) alter specification for more information.

WAIT/NOWAIT

Set the lock wait timeout. See [WAIT and NOWAIT](#).

IF EXISTS

The `IF EXISTS` and `IF NOT EXISTS` clauses are available for the following:

```
ADD COLUMN           [IF NOT EXISTS]
ADD INDEX            [IF NOT EXISTS]
ADD FOREIGN KEY     [IF NOT EXISTS]
ADD PARTITION       [IF NOT EXISTS]
CREATE INDEX         [IF NOT EXISTS]

DROP COLUMN          [IF EXISTS]
DROP INDEX           [IF EXISTS]
DROP FOREIGN KEY    [IF EXISTS]
DROP PARTITION      [IF EXISTS]
CHANGE COLUMN        [IF EXISTS]
MODIFY COLUMN        [IF EXISTS]
DROP INDEX           [IF EXISTS]
```

When `IF EXISTS` and `IF NOT EXISTS` are used in clauses, queries will not report errors when the condition is triggered for that clause. A warning with the same message text will be issued and the `ALTER` will move on to the next clause in the statement (or end if finished).

MariaDB starting with [10.5.2](#)

If this directive is used after `ALTER ... TABLE`, one will not get an error if the table doesn't exist.

Column Definitions

See [CREATE TABLE: Column Definitions](#) for information about column definitions.

Index Definitions

See [CREATE TABLE: Index Definitions](#) for information about index definitions.

The [CREATE INDEX](#) and [DROP INDEX](#) statements can also be used to add or remove an index.

Character Sets and Collations

```
CONVERT TO CHARACTER SET charset_name [COLLATE collation_name]
[DEFAULT] CHARACTER SET [=] charset_name
[DEFAULT] COLLATE [=] collation_name
```

See [Setting Character Sets and Collations](#) for details on setting the [character sets and collations](#).

Alter Specifications

Table Options

See [CREATE TABLE: Table Options](#) for information about table options.

ADD COLUMN

```
... ADD COLUMN [IF NOT EXISTS] (col_name column_definition,...)
```

Adds a column to the table. The syntax is the same as in [CREATE TABLE](#). If you are using `IF NOT EXISTS` the column will not be added if it was not there already. This is very useful when doing scripts to modify tables.

The `FIRST` and `AFTER` clauses affect the physical order of columns in the datafile. Use `FIRST` to add a column in the first (leftmost) position, or `AFTER` followed by a column name to add the new column in any other position. Note that, nowadays, the physical position of a column is usually irrelevant.

See also [Instant ADD COLUMN for InnoDB](#).

DROP COLUMN

```
... DROP COLUMN [IF EXISTS] col_name [CASCADE|RESTRICT]
```

Drops the column from the table. If you are using `IF EXISTS` you will not get an error if the column didn't exist. If the column is part of any index, the column will be dropped from them, except if you add a new column with identical name at the same time. The index will be dropped if all columns from the index were dropped. If the column was used in a view or trigger, you will get an error next time the view or trigger is accessed. Dropping a column that is part of a multi-column `UNIQUE` constraint is not permitted. For example:

```
CREATE TABLE a (
  a int,
  b int,
  primary key (a,b)
);

ALTER TABLE x DROP COLUMN a;
[42000][1072] Key column 'A' doesn't exist in table
```

The reason is that dropping column `a` would result in the new constraint that all values in column `b` be unique. In order to drop the column, an explicit `DROP PRIMARY KEY` and `ADD PRIMARY KEY` would be required. Up until [MariaDB 10.2.7](#), the column was dropped and the additional constraint applied, resulting in the following structure:

```
ALTER TABLE x DROP COLUMN a;
Query OK, 0 rows affected (0.46 sec)
```

```
DESC x;
+-----+-----+-----+-----+-----+
| Field | Type      | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+
| b     | int(11)   | NO   | PRI | NULL    |      |
+-----+-----+-----+-----+-----+
```

MariaDB supports instant DROP COLUMN. DROP COLUMN of an indexed column would imply [DROP INDEX](#) (and in the case of a non-UNIQUE multi-column index, possibly ADD INDEX). These will not be allowed with [ALGORITHM=INSTANT](#), but unlike prior to [MariaDB 10.4](#), they can be allowed with [ALGORITHM=NOCOPY](#)

[RESTRICT](#) and [CASCADE](#) are allowed to make porting from other database systems easier. In MariaDB, they do nothing.

MODIFY COLUMN

Allows you to modify the type of a column. The column will be at the same place as the original column and all indexes on the column will be kept. Note that when modifying column, you should specify all attributes for the new column.

```
CREATE TABLE t1 (a INT UNSIGNED AUTO_INCREMENT, PRIMARY KEY(a));
ALTER TABLE t1 MODIFY a BIGINT UNSIGNED AUTO_INCREMENT;
```

CHANGE COLUMN

Works like [MODIFY COLUMN](#) except that you can also change the name of the column. The column will be at the same place as the original column and all index on the column will be kept.

```
CREATE TABLE t1 (a INT UNSIGNED AUTO_INCREMENT, PRIMARY KEY(a));
ALTER TABLE t1 CHANGE a b BIGINT UNSIGNED AUTO_INCREMENT;
```

ALTER COLUMN

This lets you change column options.

```
CREATE TABLE t1 (a INT UNSIGNED AUTO_INCREMENT, b varchar(50), PRIMARY KEY(a));
ALTER TABLE t1 ALTER b SET DEFAULT 'hello';
```

RENAME INDEX/KEY

MariaDB starting with [10.5.2](#)

From [MariaDB 10.5.2](#), it is possible to rename an index using the `RENAME INDEX` (or `RENAME KEY`) syntax, for example:

```
ALTER TABLE t1 RENAME INDEX i_old TO i_new;
```

RENAME COLUMN

MariaDB starting with [10.5.2](#)

From [MariaDB 10.5.2](#), it is possible to rename a column using the `RENAME COLUMN` syntax, for example:

```
ALTER TABLE t1 RENAME COLUMN c_old TO c_new;
```

ADD PRIMARY KEY

Add a primary key.

For `PRIMARY KEY` indexes, you can specify a name for the index, but it is silently ignored, and the name of the index is always `PRIMARY`.

See [Getting Started with Indexes: Primary Key](#) for more information.

DROP PRIMARY KEY

Drop a primary key.

For `PRIMARY KEY` indexes, you can specify a name for the index, but it is silently ignored, and the name of the index is always `PRIMARY`.

See [Getting Started with Indexes: Primary Key](#) for more information.

ADD FOREIGN KEY

Add a foreign key.

For `FOREIGN KEY` indexes, a reference definition must be provided.

For `FOREIGN KEY` indexes, you can specify a name for the constraint, using the `CONSTRAINT` keyword. That name will be used in error messages.

First, you have to specify the name of the target (parent) table and a column or a column list which must be indexed and whose values must match to the foreign key's values. The `MATCH` clause is accepted to improve the compatibility with other DBMS's, but has no meaning in MariaDB. The `ON DELETE` and `ON UPDATE` clauses specify what must be done when a `DELETE` (or a `REPLACE`) statements attempts to delete a referenced row from the parent table, and when an `UPDATE` statement attempts to modify the referenced foreign key columns in a parent table row, respectively. The following options are allowed:

- `RESTRICT`: The delete/update operation is not performed. The statement terminates with a 1451 error (SQLSTATE '2300').
- `NO ACTION`: Synonym for `RESTRICT`.
- `CASCADE`: The delete/update operation is performed in both tables.
- `SET NULL`: The update or delete goes ahead in the parent table, and the corresponding foreign key fields in the child table are set to `NULL`. (They must not be defined as `NOT NULL` for this to succeed).
- `SET DEFAULT`: This option is implemented only for the legacy PBXT storage engine, which is disabled by default and no longer maintained. It sets the child table's foreign key fields to their `DEFAULT` values when the referenced parent table key entries are updated or deleted.

If either clause is omitted, the default behavior for the omitted clause is `RESTRICT`.

See [Foreign Keys](#) for more information.

DROP FOREIGN KEY

Drop a foreign key.

See [Foreign Keys](#) for more information.

ADD INDEX

Add a plain index.

Plain indexes are regular indexes that are not unique, and are not acting as a primary key or a foreign key. They are also not the "specialized" `FULLTEXT` or `SPATIAL` indexes. For limits on InnoDB indexes, see [InnoDB Limitations](#).

See [Getting Started with Indexes: Plain Indexes](#) for more information.

DROP INDEX

Drop a plain index.

Plain indexes are regular indexes that are not unique, and are not acting as a primary key or a foreign key. They are also not the "specialized" `FULLTEXT` or `SPATIAL` indexes.

See [Getting Started with Indexes: Plain Indexes](#) for more information.

ADD UNIQUE INDEX

Add a unique index.

The `UNIQUE` keyword means that the index will not accept duplicated values, except for NULLs. An error will raise if you try

to insert duplicate values in a UNIQUE index.

For `UNIQUE` indexes, you can specify a name for the constraint, using the `CONSTRAINT` keyword. That name will be used in error messages.

See [Getting Started with Indexes: Unique Index](#) for more information.

DROP UNIQUE INDEX

Drop a unique index.

The `UNIQUE` keyword means that the index will not accept duplicated values, except for NULLs. An error will raise if you try to insert duplicate values in a UNIQUE index.

For `UNIQUE` indexes, you can specify a name for the constraint, using the `CONSTRAINT` keyword. That name will be used in error messages.

See [Getting Started with Indexes: Unique Index](#) for more information.

ADD FULLTEXT INDEX

Add a `FULLTEXT` index.

See [Full-Text Indexes](#) for more information.

DROP FULLTEXT INDEX

Drop a `FULLTEXT` index.

See [Full-Text Indexes](#) for more information.

ADD SPATIAL INDEX

Add a `SPATIAL` index.

See [SPATIAL INDEX](#) for more information.

DROP SPATIAL INDEX

Drop a `SPATIAL` index.

See [SPATIAL INDEX](#) for more information.

ENABLE/ DISABLE KEYS

`DISABLE KEYS` will disable all non unique keys for the table for storage engines that support this (at least MyISAM and Aria). This can be used to [speed up inserts](#) into empty tables.

`ENABLE KEYS` will enable all disabled keys.

RENAME TO

Renames the table. See also [RENAME TABLE](#).

ADD CONSTRAINT

Modifies the table adding a [constraint](#) on a particular column or columns.

```
ALTER TABLE table_name
ADD CONSTRAINT [constraint_name] CHECK(expression);
```

Before a row is inserted or updated, all constraints are evaluated in the order they are defined. If any constraint fails, then the row will not be updated. One can use most deterministic functions in a constraint, including [UDF's](#).

```

CREATE TABLE account_ledger (
  id INT PRIMARY KEY AUTO_INCREMENT,
  transaction_name VARCHAR(100),
  credit_account VARCHAR(100),
  credit_amount INT,
  debit_account VARCHAR(100),
  debit_amount INT);

ALTER TABLE account_ledger
ADD CONSTRAINT is_balanced
CHECK((debit_amount + credit_amount) = 0);

```

The `constraint_name` is optional. If you don't provide one in the `ALTER TABLE` statement, MariaDB auto-generates a name for you. This is done so that you can remove it later using `DROP CONSTRAINT` clause.

You can disable all constraint expression checks by setting the variable `check_constraint_checks` to `OFF`. You may find this useful when loading a table that violates some constraints that you want to later find and fix in SQL.

To view constraints on a table, query `information_schema.TABLE_CONSTRAINTS`:

```

SELECT CONSTRAINT_NAME, TABLE_NAME, CONSTRAINT_TYPE
FROM information_schema.TABLE_CONSTRAINTS
WHERE TABLE_NAME = 'account_ledger';

```

CONSTRAINT_NAME	TABLE_NAME	CONSTRAINT_TYPE
is_balanced	account_ledger	CHECK

DROP CONSTRAINT

`DROP CONSTRAINT` for `UNIQUE` and `FOREIGN KEY` constraints was introduced in [MariaDB 10.2.22](#) and [MariaDB 10.3.13](#).

`DROP CONSTRAINT` for `CHECK` constraints was introduced in [MariaDB 10.2.1](#)

Modifies the table, removing the given constraint.

```

ALTER TABLE table_name
DROP CONSTRAINT constraint_name;

```

When you add a constraint to a table, whether through a `CREATE TABLE` or `ALTER TABLE...ADD CONSTRAINT` statement, you can either set a `constraint_name` yourself, or allow MariaDB to auto-generate one for you. To view constraints on a table, query `information_schema.TABLE_CONSTRAINTS`. For instance,

```

CREATE TABLE t (
  a INT,
  b INT,
  c INT,
  CONSTRAINT CHECK(a > b),
  CONSTRAINT check_equals CHECK(a = c));

SELECT CONSTRAINT_NAME, TABLE_NAME, CONSTRAINT_TYPE
FROM information_schema.TABLE_CONSTRAINTS
WHERE TABLE_NAME = 't';

```

CONSTRAINT_NAME	TABLE_NAME	CONSTRAINT_TYPE
check_equals	t	CHECK
CONSTRAINT_1	t	CHECK

To remove a constraint from the table, issue an `ALTER TABLE...DROP CONSTRAINT` statement. For example,

```

ALTER TABLE t DROP CONSTRAINT is_unique;

```

ADD SYSTEM VERSIONING

Add system versioning. See [System-versioned tables](#).

DROP SYSTEM VERSIONING

Drop system versioning. See [System-versioned tables](#).

ADD PERIOD FOR

See [System-versioned tables](#), [Application-time-period tables](#) or [Bitemporal Tables](#).

FORCE

`ALTER TABLE ... FORCE` can force MariaDB to re-build the table.

In [MariaDB 5.5](#) and before, this could only be done by setting the `ENGINE` table option to its old value. For example, for an InnoDB table, one could execute the following:

```
ALTER TABLE tab_name ENGINE = InnoDB;
```

The `FORCE` option can be used instead. For example, :

```
ALTER TABLE tab_name FORCE;
```

With InnoDB, the table rebuild will only reclaim unused space (i.e. the space previously used for deleted rows) if the `innodb_file_per_table` system variable is set to `ON` (the default). If the system variable is `OFF`, then the space will not be reclaimed, but it will be re-used for new data that's later added.

The rebuild may fail if conditions are violated due to a change in the `sql_mode`. For example:

```
CREATE OR REPLACE TABLE x (d DATE DEFAULT '0000-00-00');  
  
SET SQL_MODE='NO_ZERO_DATE';  
  
ALTER TABLE x FORCE;  
ERROR 1067 (42000): Invalid default value for 'd'
```

Partitions

ADD PARTITION

See [Partitioning Overview: Adding Partitions](#) for details.

ANALYZE PARTITION

See [Partitioning Overview: Analyzing Partitions](#) for details.

CHECK PARTITION

See [Partitioning Overview: Checking Partitions](#) for details.

COALESCE PARTITION

Reduces the number of HASH or KEY partitions in a table. See [Partitioning Overview: Coalescing Partitions](#).

CONVERT PARTITION / TABLE

`CONVERT PARTITION` and `CONVERT TABLE` were introduced in [MariaDB 10.7.1](#).

`CONVERT PARTITION` can be used to remove a partition from a table and make this an ordinary table. For example:

```
ALTER TABLE partitioned_table CONVERT PARTITION part1 TO TABLE normal_table;
```

`CONVERT TABLE` will take an existing table and move this to another table as its own partition with a specified [partition](#)

definition. For example the following moves `normal_table` to a partition of `partitioned_table` with a definition that its values, based on the `PARTITION BY` of the `partitioned_table`, are less than 12345.

```
ALTER TABLE partitioned_table CONVERT TABLE normal_table
TO PARTITION part1 VALUES LESS THAN (12345);
```

From [MariaDB 11.4](#), the optional `[[WITH | WITHOUT] VALIDATION]` is permitted.

See [Partitioning Overview: Converting Partitions to/from Tables](#) for more details.

See also [10.7 preview feature: CONVERT PARTITION](#) [\(mariadb.org blog post\)](#)

DROP PARTITION

Used to drop specific partitions (and discard all data within the specified partitions) for [RANGE](#) and [LIST](#) partitions. See [Partitioning Overview: Dropping Partitions](#).

EXCHANGE PARTITION

This is used to exchange the contents of a partition with another table. This is performed by swapping the tablespaces of the partition with the other table.

From [MariaDB 11.4](#), the optional `[[WITH | WITHOUT] VALIDATION]` is permitted.

See [Partitioning Overview: Exchanging Partitions](#) for more details.

See also [copying InnoDB's transportable tablespaces](#).

OPTIMIZE PARTITION

See [Partitioning Overview: Optimizing Partitions](#) for details.

REMOVE PARTITIONING

See [Partitioning Overview: Removing Partitioning](#).

REORGANIZE PARTITION

See [Partitioning Overview: Reorganizing Partitions](#).

TRUNCATE PARTITION

See [Partitioning Overview: Truncating Partitions](#).

DISCARD TABLESPACE

This is used to discard an InnoDB table's tablespace.

See [copying InnoDB's transportable tablespaces](#) for more information.

IMPORT TABLESPACE

This is used to import an InnoDB table's tablespace. The tablespace should have been copied from its original server after executing [FLUSH TABLES FOR EXPORT](#).

See [copying InnoDB's transportable tablespaces](#) for more information.

`ALTER TABLE ... IMPORT` only applies to InnoDB tables. Most other popular storage engines, such as Aria and MyISAM, will recognize their data files as soon as they've been placed in the proper directory under the `datadir`, and no special DDL is required to import them.

ALGORITHM

The `ALTER TABLE` statement supports the `ALGORITHM` clause. This clause is one of the clauses that is used to implement online DDL. `ALTER TABLE` supports several different algorithms. An algorithm can be explicitly chosen for an `ALTER TABLE` operation by setting the `ALGORITHM` clause. The supported values are:

- `ALGORITHM=DEFAULT` - This implies the default behavior for the specific statement, such as if no `ALGORITHM` clause is specified.

- `ALGORITHM=COPY`
- `ALGORITHM=INPLACE`
- `ALGORITHM=NOCOPY` - This was added in [MariaDB 10.3.7](#).
- `ALGORITHM=INSTANT` - This was added in [MariaDB 10.3.7](#).

See [InnoDB Online DDL Overview: ALGORITHM](#) for information on how the `ALGORITHM` clause affects InnoDB.

ALGORITHM=DEFAULT

The default behavior, which occurs if `ALGORITHM=DEFAULT` is specified, or if `ALGORITHM` is not specified at all, usually only makes a copy if the operation doesn't support being done in-place at all. In this case, the most efficient available algorithm will usually be used.

However, in [MariaDB 10.3.6](#) and before, if the value of the `old_alter_table` system variable is set to `ON`, then the default behavior is to perform `ALTER TABLE` operations by making a copy of the table using the old algorithm.

In [MariaDB 10.3.7](#) and later, the `old_alter_table` system variable is deprecated. Instead, the `alter_algorithm` system variable defines the default algorithm for `ALTER TABLE` operations. This was removed in [MariaDB 11.5](#) for the following reasons:

- `alter_algorithm` was introduced as a replacement for the `old_alter_table` that was used to force the usage of the original alter table algorithm (copy) in cases where the new alter algorithm did not work. The new option was added as a way to force the usage of a specific algorithm when it should instead have made it possible to disable algorithms that would not work for some reason.
- `alter_algorithm` introduced some cases where `ALTER TABLE` would not work without specifying the `ALGORITHM=XXX` option together with `ALTER TABLE`.
- Having different values of `alter_algorithm` on the primary and replica could cause replicas to stop unexpectedly.
- `ALTER TABLE FORCE`, as used by `mariadb-upgrade`, would not always work if `alter_algorithm` was set for the server.
- As part of [MDEV-33449](#) "improving repair of tables" it became clear that `alter-algorithm` made it harder to provide a better and more consistent `ALTER TABLE FORCE` and `REPAIR TABLE`, and it would be better to remove it.

ALGORITHM=COPY

`ALGORITHM=COPY` is the name for the original `ALTER TABLE` algorithm from early MariaDB versions.

When `ALGORITHM=COPY` is set, MariaDB essentially does the following operations:

```
-- Create a temporary table with the new definition
CREATE TEMPORARY TABLE tmp_tab (
...
);

-- Copy the data from the original table
INSERT INTO tmp_tab
  SELECT * FROM original_tab;

-- Drop the original table
DROP TABLE original_tab;

-- Rename the temporary table, so that it replaces the original one
RENAME TABLE tmp_tab TO original_tab;
```

This algorithm is very inefficient, but it is generic, so it works for all storage engines.

If `ALGORITHM=COPY` is specified, then the copy algorithm will be used even if it is not necessary. This can result in a lengthy table copy. If multiple `ALTER TABLE` operations are required that each require the table to be rebuilt, then it is best to specify all operations in a single `ALTER TABLE` statement, so that the table is only rebuilt once.

From [MariaDB 11.2](#), `ALTER TABLE` can now do most operations with `ALGORITHM=COPY`, `LOCK=NONE`. See [LOCK=NONE](#).

ALGORITHM=INPLACE

`ALGORITHM=COPY` can be incredibly slow, because the whole table has to be copied and rebuilt. `ALGORITHM=INPLACE` was introduced as a way to avoid this by performing operations in-place and avoiding the table copy and rebuild, when possible.

When `ALGORITHM=INPLACE` is set, the underlying storage engine uses optimizations to perform the operation while avoiding the table copy and rebuild. However, `INPLACE` is a bit of a misnomer, since some operations may still require the table to be rebuilt for some storage engines. Regardless, several operations can be performed without a full copy of the table for some storage engines.

A more accurate name would have been `ALGORITHM=ENGINE`, where `ENGINE` refers to an "engine-specific" algorithm.

If an `ALTER TABLE` operation supports `ALGORITHM=INPLACE`, then it can be performed using optimizations by the underlying storage engine, but it may rebuilt.

See [InnoDB Online DDL Operations with ALGORITHM=INPLACE](#) for more.

ALGORITHM=NOCOPY

`ALGORITHM=NOCOPY` was introduced in [MariaDB 10.3.7](#).

`ALGORITHM=INPLACE` can sometimes be surprisingly slow in instances where it has to rebuild the clustered index, because when the clustered index has to be rebuilt, the whole table has to be rebuilt. `ALGORITHM=NOCOPY` was introduced as a way to avoid this.

If an `ALTER TABLE` operation supports `ALGORITHM=NOCOPY`, then it can be performed without rebuilding the clustered index.

If `ALGORITHM=NOCOPY` is specified for an `ALTER TABLE` operation that does not support `ALGORITHM=NOCOPY`, then an error will be raised. In this case, raising an error is preferable, if the alternative is for the operation to rebuild the clustered index, and perform unexpectedly slowly.

See [InnoDB Online DDL Operations with ALGORITHM=NOCOPY](#) for more.

ALGORITHM=INSTANT

`ALGORITHM=INSTANT` was introduced in [MariaDB 10.3.7](#).

`ALGORITHM=INPLACE` can sometimes be surprisingly slow in instances where it has to modify data files.

`ALGORITHM=INSTANT` was introduced as a way to avoid this.

If an `ALTER TABLE` operation supports `ALGORITHM=INSTANT`, then it can be performed without modifying any data files.

If `ALGORITHM=INSTANT` is specified for an `ALTER TABLE` operation that does not support `ALGORITHM=INSTANT`, then an error will be raised. In this case, raising an error is preferable, if the alternative is for the operation to modify data files, and perform unexpectedly slowly.

See [InnoDB Online DDL Operations with ALGORITHM=INSTANT](#) for more.

LOCK

The `ALTER TABLE` statement supports the `LOCK` clause. This clause is one of the clauses that is used to implement online DDL. `ALTER TABLE` supports several different locking strategies. A locking strategy can be explicitly chosen for an `ALTER TABLE` operation by setting the `LOCK` clause. The supported values are:

DEFAULT

Acquire the least restrictive lock on the table that is supported for the specific operation. Permit the maximum amount of concurrency that is supported for the specific operation.

NONE

Acquire no lock on the table. Permit **all** concurrent DML. If this locking strategy is not permitted for an operation, then an error is raised. From [MariaDB 11.2](#), `ALTER TABLE` can do most operations with `ALGORITHM=COPY`, `LOCK=NONE`, that is, in most cases, unless the algorithm and lock level are explicitly specified, `ALTER TABLE` will be performed using the `COPY` algorithm while simultaneously allowing concurrent DML statements on the altered table. If this is not desired, one can explicitly specify a different lock level or set `old_mode` to [LOCK_ALTER_TABLE_COPY](#) that will make `ALGORITHM=COPY` use `LOCK=SHARED` by default (but still allowing `LOCK=NONE` to be specified explicitly).

SHARED

Acquire a read lock on the table. Permit **read-only** concurrent DML. If this locking strategy is not permitted for an operation, then an error is raised.

EXCLUSIVE

Acquire a write lock on the table. Do **not** permit concurrent DML.

Different storage engines support different locking strategies for different operations. If a specific locking strategy is chosen for an `ALTER TABLE` operation, and that table's storage engine does not support that locking strategy for that specific

operation, then an error will be raised.

If the `LOCK` clause is not explicitly set, then the operation uses `LOCK=DEFAULT`.

`ALTER ONLINE TABLE` is equivalent to `LOCK=NONE`. Therefore, the `ALTER ONLINE TABLE` statement can be used to ensure that your `ALTER TABLE` operation allows all concurrent DML.

See [InnoDB Online DDL Overview: LOCK](#) for information on how the `LOCK` clause affects InnoDB.

Index Options

See [CREATE TABLE](#) page for meaning of the index options.

Progress Reporting

MariaDB provides progress reporting for `ALTER TABLE` statement for clients that support the new progress reporting protocol. For example, if you were using the `mariadb` client, then the progress report might look like this::

```
ALTER TABLE test ENGINE=Aria;
Stage: 1 of 2 'copy to tmp table' 46% of stage
```

The progress report is also shown in the output of the `SHOW PROCESSLIST` statement and in the contents of the `information_schema.PROCESSLIST` table.

See [Progress Reporting](#) for more information.

Aborting ALTER TABLE Operations

If an `ALTER TABLE` operation is being performed and the connection is killed, the changes will be rolled back in a controlled manner. The rollback can be a slow operation as the time it takes is relative to how far the operation has progressed.

Aborting `ALTER TABLE ... ALGORITHM=COPY` was made faster in [MariaDB 10.2.13](#) by removing excessive undo logging ([MDEV-11415](#)). This significantly shortened the time it takes to abort a running `ALTER TABLE` operation, compared with earlier releases.

Atomic ALTER TABLE

MariaDB starting with [10.6.1](#)

From [MariaDB 10.6](#), `ALTER TABLE` is atomic for most engines, including InnoDB, MyRocks, MyISAM and Aria ([MDEV-25180](#)). This means that if there is a crash (server down or power outage) during an `ALTER TABLE` operation, after recovery, either the old table and associated triggers and status will be intact, or the new table will be active.

In older MariaDB versions one could get leftover `#sql-alter..`, `#sql-backup..` or `'table_name.frm'` files if the system crashed during the `ALTER TABLE` operation.

See [Atomic DDL](#) for more information.

Replication

MariaDB starting with [10.8.1](#)

Before [MariaDB 10.8.1](#), `ALTER TABLE` got fully executed on the primary first, and only then was it replicated and started executing on replicas. From [MariaDB 10.8.1](#), `ALTER TABLE` gains an option to replicate sooner and begin executing on replicas when it merely *starts* executing on the primary, not when it *finishes*. This way the replication lag caused by a heavy `ALTER TABLE` can be completely eliminated ([MDEV-11675](#)).

Examples

Adding a new column:

```
ALTER TABLE t1 ADD x INT;
```

Dropping a column:

```
ALTER TABLE t1 DROP x;
```

Modifying the type of a column:

```
ALTER TABLE t1 MODIFY x bigint unsigned;
```

Changing the name and type of a column:

```
ALTER TABLE t1 CHANGE a b bigint unsigned auto_increment;
```

Combining multiple clauses in a single ALTER TABLE statement, separated by commas:

```
ALTER TABLE t1 DROP x, ADD x2 INT, CHANGE y y2 INT;
```

Changing the storage engine and adding a comment:

```
ALTER TABLE t1
ENGINE = InnoDB
COMMENT = 'First of three tables containing usage info';
```

Rebuilding the table (the previous example will also rebuild the table if it was already InnoDB):

```
ALTER TABLE t1 FORCE;
```

Dropping an index:

```
ALTER TABLE rooms DROP INDEX u;
```

Adding a unique index:

```
ALTER TABLE rooms ADD UNIQUE INDEX u(room_number);
```

From [MariaDB 10.5.3](#), adding a primary key for an [application-time period table](#) with a [WITHOUT OVERLAPS](#) constraint:

```
ALTER TABLE rooms ADD PRIMARY KEY(room_number, p WITHOUT OVERLAPS);
```

From [MariaDB 10.8.1](#), ALTER query can be replicated faster with the setting of

```
SET @@SESSION.binlog_alter_two_phase = true;
```

prior the ALTER query. Binlog would contain two event groups

```
| master-bin.000001 | 495 | Gtid          | | 1 | 537 | GTID 0-1-2 START ALTER
| master-bin.000001 | 537 | Query         | | 1 | 655 | use `test`; alter table
| master-bin.000001 | 655 | Gtid          | | 1 | 700 | GTID 0-1-3 COMMIT ALTER
| master-bin.000001 | 700 | Query         | | 1 | 835 | use `test`; alter table
```

of which the first one gets delivered to replicas before ALTER is taken to actual execution on the primary.

1.1.1.2.1.1.2 ALTER DATABASE

Modifies a database, changing its overall characteristics.

Syntax

```
ALTER {DATABASE | SCHEMA} [db_name]
    alter_specification ...
ALTER {DATABASE | SCHEMA} db_name
    UPGRADE DATA DIRECTORY NAME

alter_specification:
    [DEFAULT] CHARACTER SET [=] charset_name
  | [DEFAULT] COLLATE [=] collation_name
  | COMMENT [=] 'comment'
```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [COMMENT](#)
3. [Examples](#)

Description

`ALTER DATABASE` enables you to change the overall characteristics of a database. These characteristics are stored in the `db.opt` file in the database directory. To use `ALTER DATABASE`, you need the `ALTER` privilege on the database. `ALTER SCHEMA` is a synonym for `ALTER DATABASE`.

The `CHARACTER SET` clause changes the default database character set. The `COLLATE` clause changes the default database collation. See [Character Sets and Collations](#) for more.

You can see what character sets and collations are available using, respectively, the [SHOW CHARACTER SET](#) and [SHOW COLLATION](#) statements.

Changing the default character set/collation of a database does not change the character set/collation of any [stored procedures](#) or [stored functions](#) that were previously created, and relied on the defaults. These need to be dropped and recreated in order to apply the character set/collation changes.

The database name can be omitted from the first syntax, in which case the statement applies to the default database.

The syntax that includes the `UPGRADE DATA DIRECTORY NAME` clause was added in MySQL 5.1.23. It updates the name of the directory associated with the database to use the encoding implemented in MySQL 5.1 for mapping database names to database directory names (see [Identifier to File Name Mapping](#)). This clause is for use under these conditions:

- It is intended when upgrading MySQL to 5.1 or later from older versions.
- It is intended to update a database directory name to the current encoding format if the name contains special characters that need encoding.
- The statement is used by `mariadb-check` (as invoked by `mariadb-upgrade`).

For example, if a database in MySQL 5.0 has a name of `a-b-c`, the name contains instance of the ``` character. In 5.0, the database directory is also named `a-b-c`, which is not necessarily safe for all file systems. In MySQL 5.1 and up, the same database name is encoded as `a@002db@002dc` to produce a file system-neutral directory name.

When a MySQL installation is upgraded to MySQL 5.1 or later from an older version, the server displays a name such as `a-b-c` (which is in the old format) as `#mysql50#a-b-c`, and you must refer to the name using the `#mysql50#` prefix. Use `UPGRADE DATA DIRECTORY NAME` in this case to explicitly tell the server to re-encode the database directory name to the current encoding format:

```
ALTER DATABASE `#mysql50#a-b-c` UPGRADE DATA DIRECTORY NAME;
```

After executing this statement, you can refer to the database as `a-b-c` without the special `#mysql50#` prefix.

COMMENT

MariaDB starting with 10.5.0

From [MariaDB 10.5.0](#), it is possible to add a comment of a maximum of 1024 bytes. If the comment length exceeds this length, a error/warning code 4144 is thrown. The database comment is also added to the `db.opt` file, as well as to the `information_schema.schemata` table.

Examples

```
ALTER DATABASE test CHARACTER SET='utf8' COLLATE='utf8_bin';
```

```
ALTER DATABASE p COMMENT='Presentations';
```

1.1.1.2.1.1.3 ALTER EVENT

Modifies one or more characteristics of an existing event.

Syntax

```
ALTER
  [DEFINER = { user | CURRENT_USER }]
  EVENT event_name
  [ON SCHEDULE schedule]
  [ON COMPLETION [NOT] PRESERVE]
  [RENAME TO new_event_name]
  [ENABLE | DISABLE | DISABLE ON SLAVE]
  [COMMENT 'comment']
  [DO sql_statement]
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

Description

The `ALTER EVENT` statement is used to change one or more of the characteristics of an existing [event](#) without the need to drop and recreate it. The syntax for each of the `DEFINER`, `ON SCHEDULE`, `ON COMPLETION`, `COMMENT`, `ENABLE` / `DISABLE`, and `DO` clauses is exactly the same as when used with [CREATE EVENT](#).

This statement requires the [EVENT](#) privilege. When a user executes a successful `ALTER EVENT` statement, that user becomes the definer for the affected event.

(In MySQL 5.1.11 and earlier, an event could be altered only by its definer, or by a user having the [SUPER](#) privilege.)

`ALTER EVENT` works only with an existing event:

```
ALTER EVENT no_such_event ON SCHEDULE EVERY '2:3' DAY_HOUR;
ERROR 1539 (HY000): Unknown event 'no_such_event'
```

Examples

```
ALTER EVENT myevent
  ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 2 HOUR
  DO
    UPDATE myschema.mytable SET mycol = mycol + 1;
```

1.1.1.2.1.1.4 ALTER FUNCTION

Syntax

```
ALTER FUNCTION func_name [characteristic ...]

characteristic:
  { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
  | SQL SECURITY { DEFINER | INVOKER }
  | COMMENT 'string'
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Example](#)

Description

This statement can be used to change the characteristics of a stored function. More than one change may be specified in an `ALTER FUNCTION` statement. However, you cannot change the parameters or body of a stored function using this statement; to make such changes, you must drop and re-create the function using [DROP FUNCTION](#) and [CREATE FUNCTION](#).

You must have the `ALTER ROUTINE` privilege for the function. (That privilege is granted automatically to the function creator.) If binary logging is enabled, the `ALTER FUNCTION` statement might also require the `SUPER` privilege, as described in [Binary Logging of Stored Routines](#).

Example

```
ALTER FUNCTION hello SQL SECURITY INVOKER;
```

1.1.1.2.1.1.5 ALTER LOGFILE GROUP

Syntax

```
ALTER LOGFILE GROUP logfile_group
  ADD UNDOFILE 'file_name'
  [INITIAL_SIZE [=] size]
  [WAIT]
  ENGINE [=] engine_name
```

The `ALTER LOGFILE GROUP` statement is not supported by MariaDB. It was originally inherited from MySQL NDB Cluster. See [MDEV-19295](#) for more information.

1.1.1.2.1.1.6 ALTER PROCEDURE

Syntax

```
ALTER PROCEDURE proc_name [characteristic ...]

characteristic:
  { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
  | SQL SECURITY { DEFINER | INVOKER }
  | COMMENT 'string'
```

Description

This statement can be used to change the characteristics of a [stored procedure](#). More than one change may be specified in an `ALTER PROCEDURE` statement. However, you cannot change the parameters or body of a stored procedure using this statement. To make such changes, you must drop and re-create the procedure using either [CREATE OR REPLACE PROCEDURE](#) (since [MariaDB 10.1.3](#)) or [DROP PROCEDURE](#) and [CREATE PROCEDURE](#) ([MariaDB 10.1.2](#) and before).

You must have the `ALTER ROUTINE` privilege for the procedure. By default, that privilege is granted automatically to the procedure creator. See [Stored Routine Privileges](#).

Example

```
ALTER PROCEDURE simpleproc SQL SECURITY INVOKER;
```

1.1.6.4 ALTER SEQUENCE

1.1.1.2.1.1.8 ALTER SERVER

Syntax

```
ALTER SERVER server_name  
  OPTIONS (option [, option] ...)
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

Description

Alters the server information for *server_name*, adjusting the specified options as per the [CREATE SERVER](#) command. The corresponding fields in the [mysql.servers table](#) are updated accordingly. This statement requires the [SUPER](#) privilege or, from [MariaDB 10.5.2](#), the [FEDERATED ADMIN](#) privilege.

ALTER SERVER is not written to the [binary log](#), irrespective of the [binary log format](#) being used. From [MariaDB 10.1.13](#), [Galera](#) replicates the [CREATE SERVER](#), [ALTER SERVER](#) and [DROP SERVER](#) statements.

Examples

```
ALTER SERVER s OPTIONS (USER 'sally');
```

1.1.1.2.1.1.9 ALTER TABLESPACE

The [ALTER TABLESPACE](#) statement is not supported by MariaDB. It was originally inherited from MySQL NDB Cluster. In MySQL 5.7 and later, the statement is also supported for InnoDB. However, MariaDB has chosen not to include that specific feature. See [MDEV-19294](#) for more information.

1.1.1.1.2 ALTER USER

1.1.1.2.1.1.11 ALTER VIEW

Syntax

```
ALTER  
  [ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]  
  [DEFINER = { user | CURRENT_USER }]  
  [SQL SECURITY { DEFINER | INVOKER }]  
  VIEW view_name [(column_list)]  
  AS select_statement  
  [WITH [CASCADED | LOCAL] CHECK OPTION]
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Example](#)

Description

This statement changes the definition of a [view](#), which must exist. The syntax is similar to that for [CREATE VIEW](#) and the effect is the same as for `CREATE OR REPLACE VIEW` if the view exists. This statement requires the `CREATE VIEW` and `DROP` [privileges](#) for the view, and some privilege for each column referred to in the `SELECT` statement. `ALTER VIEW` is allowed only to the definer or users with the [SUPER](#) privilege.

Example

```
ALTER VIEW v AS SELECT a, a*3 AS a2 FROM t;
```

1.1.1.2.1.2 ANALYZE TABLE

Syntax

```
ANALYZE [NO_WRITE_TO_BINLOG | LOCAL] TABLE tbl_name [,tbl_name ...]
[PERSISTENT FOR
 { ALL
 | COLUMNS ([col_name [,col_name ...]]) INDEXES ([index_name [,index_name ...]])
 }
]
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Performance Impact](#)
4. [Engine-Independent Statistics / PERSISTENT FOR](#)
5. [Useful Variables](#)
6. [Examples](#)

Description

`ANALYZE TABLE` analyzes and stores the key distribution for a table ([index statistics](#)). This statement works with [MyISAM](#), [Aria](#) and [InnoDB](#) tables. During the analysis, InnoDB will allow reads/writes, and MyISAM/Aria reads/inserts. For MyISAM tables, this statement is equivalent to using `myisamchk --analyze`.

`ANALYZE` uses histograms, which can provide a better selectivity than InnoDB statistics offer. InnoDB statistics work with a limited sample set and is therefore not as accurate as persistent statistics can be. For more information on how the analysis works within InnoDB, see [InnoDB Limitations](#).

MariaDB uses the stored key distribution to decide the order in which tables should be joined when you perform a join on something other than a constant. In addition, key distributions can be used when deciding which indexes to use for a specific table within a query.

This statement requires [SELECT and INSERT privileges](#) for the table.

By default, `ANALYZE TABLE` statements are written to the [binary log](#) and will be [replicated](#). The `NO_WRITE_TO_BINLOG` keyword (`LOCAL` is an alias) will ensure the statement is not written to the binary log.

From [MariaDB 10.3.19](#), `ANALYZE TABLE` statements are not logged to the binary log if `read_only` is set. See also [Read-Only Replicas](#).

From [MariaDB 10.6.16](#) `ANALYZE TABLE` is non-blocking and non-intrusive. A connection will start using new statistics for the query following the completion of the `ANALYZE TABLE`.

`ANALYZE TABLE` is also supported for partitioned tables. You can use `ALTER TABLE ... ANALYZE PARTITION` to analyze one or more partitions.

The [Aria](#) storage engine supports [progress reporting](#) for the `ANALYZE TABLE` statement.

Performance Impact

Note that analyzing tables with `ANALYZE` can have a performance impact and can use a lot of disk space for big tables. As column statistics usually do not change much over time, even when the table grows, there is no benefit to running `ANALYZE` very often.

Running `ANALYZE` is indicated:

- for newly populated tables,
- for tables that have additional columns added that are used in `WHERE` clauses,
- when a table has doubled in size,
- when you note that a query becomes slow because the table order has changed and you can see from [EXPLAIN](#) or [ANALYZE FORMAT=JSON](#) that the selectivity is wrong for a table.

`ANALYZE` isn't useful for table columns of type `UNIQUE`, `PRIMARY KEY`, `TIME`, or `CURRENT_TIME`. In `ANALYZE` queries, you should omit columns of those types.

Engine-Independent Statistics / PERSISTENT FOR

`ANALYZE TABLE` supports [engine-independent statistics](#). See [Engine-Independent Table Statistics: Collecting Statistics with the ANALYZE TABLE Statement](#) for more information.

Engine-independent statistics can be controlled (enabled and disabled) using the [use_stat_tables](#) variable and the [optimizer_use_condition_selectivity](#) variable. InnoDB-persistent statistics are controlled with the [innodb_stats_persistent](#) variable. Combining both kinds of statistics is possible.

The server relies on InnoDB statistics by default. That way, it can use some statistics even if `ANALYZE TABLE` is never run (or not often enough). This gives good enough results for the majority of queries. Some queries, however, need more statistical data so the optimizer can create a good plan. Slow queries indicate there aren't enough statistical data. Those queries can be accelerated by running `ANALYZE TABLE tbl PERSISTENT FOR ...`, where `tbl` indicates a table used by a slow query. You can also run `ANALYZE TABLE ... PERSISTENT FOR ALL`, but that has a significant performance impact.

Useful Variables

The following overview indicates when a particular variable was introduced. When multiple versions are given, it means variable options (like the default value) changed between the indicated versions.

Variable	Introduced in MariaDB version	Description
<code>analyze_sample_percentage</code>	10.4.3	Percentage of rows from the table <code>ANALYZE TABLE</code> will sample to collect table statistics. Set to 0 to let MariaDB decide what percentage of rows to sample.
<code>histogram_type</code>	10.4.3-11.0	Specifies the type of histograms created by <code>ANALYZE</code> . Options are <code>#SINGLE_PREC_HB</code> , <code>DOUBLE_PREC_HB</code> or <code>JSON_HB</code> .
<code>histogram_size</code>	10.7	Number of bytes or buckets (in case of <code>JSON_HB</code>) used for storing the histogram. If set to 0, no histograms are created by <code>ANALYZE</code> .]]
<code>log_slow_admin_statements</code>	11.0.1	Log slow <code>OPTIMIZE</code> , <code>ANALYZE</code> , <code>ALTER</code> and other administrative statements to the slow log if it is open. Deprecated. Use <code>log_slow_filter</code> instead.
<code>log_slow_filter</code>	(all versions)	Having <code>admin</code> in <code>log_slow_filter</code> will add slow <code>ANALYZE_TABLE</code> statements to the slow log.
<code>sort_buffer_size</code>	(all versions)	For calculating the number of duplicates, <code>ANALYZE TABLE</code> uses a buffer of <code>sort_buffer_size</code> bytes per column. You can slightly increase the speed of <code>ANALYZE TABLE</code> by increasing this variable.

Examples

```

-- update all engine-independent statistics for all columns and indexes
ANALYZE TABLE tbl PERSISTENT FOR ALL;

-- update specific columns and indexes:
ANALYZE TABLE tbl PERSISTENT FOR COLUMNS (col1,col2,...) INDEXES (idx1,idx2,...);

-- empty lists are allowed:
ANALYZE TABLE tbl PERSISTENT FOR COLUMNS (col1,col2,...) INDEXES ();
ANALYZE TABLE tbl PERSISTENT FOR COLUMNS () INDEXES (idx1,idx2,...);

-- the following will only update mysql.table_stats fields:
ANALYZE TABLE tbl PERSISTENT FOR COLUMNS () INDEXES ();

-- when use_stat_tables is set to 'COMPLEMENTARY' or 'PREFERABLY',
-- a simple ANALYZE TABLE collects engine-independent statistics for all columns and indexes.
SET SESSION use_stat_tables='COMPLEMENTARY';
ANALYZE TABLE tbl;

```

1.1.1.2.1.3 CHECK TABLE

Syntax

```

CHECK TABLE tbl_name [, tbl_name] ... [option] ...

option = {FOR UPGRADE | QUICK | FAST | MEDIUM | EXTENDED | CHANGED}

```

Description

`CHECK TABLE` checks a table or tables for errors. `CHECK TABLE` works for [Archive](#), [Aria](#), [CSV](#), [InnoDB](#) and [MyISAM](#) tables. For Aria and MyISAM tables, the key statistics are updated as well. For CSV, see also [Checking and Repairing CSV Tables](#).

As an alternative, [myisamchk](#) is a commandline tool for checking MyISAM tables when the tables are not being accessed. For Aria tables, there is a similar tool: [aria_chk](#).

For checking [dynamic columns](#) integrity, `COLUMN_CHECK()` can be used.

`CHECK TABLE` can also check views for problems, such as tables that are referenced in the view definition that no longer exist.

`CHECK TABLE` is also supported for partitioned tables. You can use `ALTER TABLE ... CHECK PARTITION` to check one or more partitions.

The meaning of the different options are as follows - note that this can vary a bit between storage engines:

FOR UPGRADE	Do a very quick check if the storage format for the table has changed so that one needs to do a REPAIR. This is only needed when one upgrades between major versions of MariaDB or MySQL. This is usually done by running mariadb-upgrade .
FAST	Only check tables that has not been closed properly or are marked as corrupt. Only supported by the MyISAM and Aria engines. For other engines the table is checked normally
CHANGED	Check only tables that has changed since last REPAIR / CHECK. Only supported by the MyISAM and Aria engines. For other engines the table is checked normally.
QUICK	Do a fast check. For MyISAM and Aria, this means skipping the check of the delete link chain, which may take some time.
MEDIUM	Scan also the data files. Checks integrity between data and index files with checksums. In most cases this should find all possible errors.
EXTENDED	Does a full check to verify every possible error. For InnoDB, Aria, and MyISAM, verify for each row that all its keys exists, and for those index keys, they point back to the primary clustered key. This may take a long time on large tables. This option was previously ignored by InnoDB before MariaDB 10.6.11 , MariaDB 10.7.7 , MariaDB 10.8.6 and MariaDB 10.9.4 . From MariaDB 11.8 , also checks for referential integrity.

For most cases running `CHECK TABLE` without options or `MEDIUM` should be good enough.

The [Aria](#) storage engine supports [progress reporting](#) for this statement.

If you want to know if two tables are identical, take a look at [CHECKSUM TABLE](#).

InnoDB

If `CHECK TABLE` finds an error in an InnoDB table, MariaDB might shutdown to prevent the error propagation. In this case, the problem will be reported in the error log. Otherwise the table or an index might be marked as corrupted, to prevent use. This does not happen with some minor problems, like a wrong number of entries in a secondary index. Those problems are reported in the output of `CHECK TABLE`.

Each tablespace contains a header with metadata. This header is not checked by this statement.

During the execution of `CHECK TABLE`, other threads may be blocked.

Examples

```
CHECK TABLE y EXTENDED;
+-----+-----+-----+
| Table | Op   | Msg_type | Msg_text |
+-----+-----+-----+
| test.y | check | status   | OK       |
+-----+-----+-----+
```

From [MariaDB 11.8](#):

```
CHECK TABLE t1 EXTENDED;
+-----+-----+-----+
| Table | Op   | Msg_type | Msg_text |
+-----+-----+-----+
| test.t1 | check | Warning  | No suitable key found for foreign key t2_ibfk_1 in table test.t1
+-----+-----+-----+

CHECK TABLE t2 EXTENDED;
+-----+-----+-----+
| Table | Op   | Msg_type | Msg_text |
+-----+-----+-----+
| test.t2 | check | status   | Cannot add or update a child row: a foreign key constraint fails
| test.t2 | check | status   | Cannot add or update a child row: a foreign key constraint fails
| test.t2 | check | status   | Cannot add or update a child row: a foreign key constraint fails
| test.t2 | check | error    | Corrupt
+-----+-----+-----+
```

1.1.1.2.1.4 CHECK VIEW

Syntax

```
CHECK VIEW view_name
```

Description

The `CHECK VIEW` statement was introduced in [MariaDB 10.0.18](#) to assist with fixing [MDEV-6916](#), an issue introduced in [MariaDB 5.2](#) where the view algorithms were swapped. It checks whether the view algorithm is correct. It is run as part of [mariadb-upgrade](#), and should not normally be required in regular use.

1.1.1.2.1.5 CHECKSUM TABLE

Syntax

```
CHECKSUM TABLE tbl_name [, tbl_name] ... [ QUICK | EXTENDED ]
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Identical Tables](#)
4. [Differences Between MariaDB and MySQL](#)

Description

`CHECKSUM TABLE` reports a table checksum. This is very useful if you want to know if two tables are the same (for example on a master and slave).

With `QUICK`, the live table checksum is reported if it is available, or `NULL` otherwise. This is very fast. A live checksum is enabled by specifying the `CHECKSUM=1` table option when you [create the table](#); currently, this is supported only for [Aria](#) and [MyISAM](#) tables.

With `EXTENDED`, the entire table is read row by row and the checksum is calculated. This can be very slow for large tables.

If neither `QUICK` nor `EXTENDED` is specified, MariaDB returns a live checksum if the table storage engine supports it and scans the table otherwise.

`CHECKSUM TABLE` requires the [SELECT privilege](#) for the table.

For a nonexistent table, `CHECKSUM TABLE` returns `NULL` and generates a warning.

The table row format affects the checksum value. If the row format changes, the checksum will change. This means that when a table created with a MariaDB/MySQL version is upgraded to another version, the checksum value will probably change.

Two identical tables should always match to the same checksum value; however, also for non-identical tables there is a very slight chance that they will return the same value as the hashing algorithm is not completely collision-free.

Identical Tables

Identical tables mean that the `CREATE` statement is identical and that the following variable, which affects the storage formats, was the same when the tables were created:

- [mysql56-temporal-format](#)

Differences Between MariaDB and MySQL

`CHECKSUM TABLE` may give a different result as MariaDB doesn't ignore `NULL`s in the columns as MySQL 5.1 does (Later MySQL versions should calculate checksums the same way as MariaDB). You can get the 'old style' checksum in MariaDB by starting `mariadb` with the `--old` option (deprecated from [MariaDB 10.9](#)) or setting `old_mode` to [COMPAT_5_1_CHECKSUM](#) (from [MariaDB 10.9](#)). Note however that that the `MyISAM` and `Aria` storage engines in MariaDB are using the new checksum internally, so if you are using this old mode, the `CHECKSUM` command will be slower as it needs to calculate the checksum row by row.

1.1.1.2.1.6 CREATE TABLE

Syntax

```
CREATE [OR REPLACE] [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name
    (create_definition,...) [table_options ]... [partition_options]
CREATE [OR REPLACE] [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name
    [(create_definition,...)] [table_options ]... [partition_options]
    select_statement
CREATE [OR REPLACE] [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name
    { LIKE old_table_name | (LIKE old_table_name) }

select_statement:
    [IGNORE | REPLACE] [AS] SELECT ... (Some legal select statement)
```

14. [Partitions](#)
15. [Sequences](#)
16. [Atomic DDL](#)
17. [Examples](#)

Description

Use the `CREATE TABLE` statement to create a table with the given name.

In its most basic form, the `CREATE TABLE` statement provides a table name followed by a list of columns, indexes, and constraints. By default, the table is created in the default database. Specify a database with `db_name.tbl_name`. If you quote the table name, you must quote the database name and table name separately as ``db_name`.`tbl_name``. This is particularly useful for `CREATE TABLE ... SELECT`, because it allows to create a table into a database, which contains data from other databases. See [Identifier Qualifiers](#).

If a table with the same name exists, error 1050 results. Use `IF NOT EXISTS` to suppress this error and issue a note instead. Use `SHOW WARNINGS` to see notes.

The `CREATE TABLE` statement automatically commits the current transaction, except when using the `TEMPORARY` keyword.

For valid identifiers to use as table names, see [Identifier Names](#).

Note: if the `default_storage_engine` is set to `ColumnStore` then it needs setting on all UMs. Otherwise when the tables using the default engine are replicated across UMs they will use the wrong engine. You should therefore not use this option as a session variable with `ColumnStore`.

[Microsecond precision](#) can be between 0-6. If no precision is specified it is assumed to be 0, for backward compatibility reasons.

Privileges

Executing the `CREATE TABLE` statement requires the `CREATE` privilege for the table or the database.

CREATE OR REPLACE

If the `OR REPLACE` clause is used and the table already exists, then instead of returning an error, the server will drop the existing table and replace it with the newly defined table.

This syntax was originally added to make [replication](#) more robust if it has to rollback and repeat statements such as `CREATE ... SELECT` on replicas.

```
CREATE OR REPLACE TABLE table_name (a int);
```

is basically the same as:

```
DROP TABLE IF EXISTS table_name;  
CREATE TABLE table_name (a int);
```

with the following exceptions:

- If `table_name` was locked with `LOCK TABLES` it will continue to be locked after the statement.
- Temporary tables are only dropped if the `TEMPORARY` keyword was used. (With `DROP TABLE`, temporary tables are preferred to be dropped before normal tables).

Things to be Aware of With CREATE OR REPLACE

- The table is dropped first (if it existed), after that the `CREATE` is done. Because of this, if the `CREATE` fails, then the

table will not exist anymore after the statement. If the table was used with `LOCK TABLES` it will be unlocked.

- One can't use `OR REPLACE` together with `IF EXISTS`.
- Replicas will by default use `CREATE OR REPLACE` when replicating `CREATE` statements that don't use `IF EXISTS`. This can be changed by setting the variable `slave-ddl-exec-mode` to `STRICT`.

CREATE TABLE IF NOT EXISTS

If the `IF NOT EXISTS` clause is used, then the table will only be created if a table with the same name does not already exist. If the table already exists, then a warning will be triggered by default.

CREATE TEMPORARY TABLE

Use the `TEMPORARY` keyword to create a temporary table that is only available to the current session. Temporary tables are dropped when the session ends. Temporary table names are specific to the session. They will not conflict with other temporary tables from other sessions even if they share the same name. They will shadow names of non-temporary tables or views, if they are identical. A temporary table can have the same name as a non-temporary table which is located in the same database. In that case, their name will reference the temporary table when used in SQL statements. You must have the `CREATE TEMPORARY TABLES` privilege on the database to create temporary tables. If no storage engine is specified, the `default_tmp_storage_engine` setting will determine the engine.

`ROCKSDB` temporary tables cannot be created by setting the `default_tmp_storage_engine` system variable, or using `CREATE TEMPORARY TABLE LIKE`. Before `MariaDB 10.7`, they could be specified, but would silently fail, and a `MyISAM` table would be created instead. From `MariaDB 10.7` an error is returned. Explicitly creating a temporary table with `ENGINE=ROCKSDB` has never been permitted.

CREATE TABLE ... LIKE

Use the `LIKE` clause instead of a full table definition to create an empty table with the same definition as another table, including columns, indexes, and table options. Foreign key definitions, as well as any `DATA DIRECTORY` or `INDEX DIRECTORY` table options specified on the original table, will not be created.

`LIKE` does not preserve the `TEMPORARY` status of the original table. To make the new table `TEMPORARY` as well, use `CREATE TEMPORARY TABLE ... LIKE`.

`LIKE` does not work with `views`, only base tables. Attempting to use it on a view will result in an error:

```
CREATE VIEW v (mycol) AS SELECT 'abc';

CREATE TABLE v2 LIKE v;
ERROR 1347 (HY000): 'test.v' is not of type 'BASE TABLE'
```

The same version of the table storage format as found in the original table is used for the new table.

`CREATE TABLE ... LIKE` performs the same checks as `CREATE TABLE`. So a statement may fail if a change in the `SQL_MODE` renders it invalid. For example:

```
CREATE OR REPLACE TABLE x (d DATE DEFAULT '0000-00-00');

SET SQL_MODE='NO_ZERO_DATE';

CREATE OR REPLACE TABLE y LIKE x;
ERROR 1067 (42000): Invalid default value for 'd'
```

CREATE TABLE ... SELECT

You can create a table containing data from other tables using the `CREATE ... SELECT` statement. Columns will be created in the table for each field returned by the `SELECT` query.

You can also define some columns normally and add other columns from a `SELECT`. You can also create columns in the normal way and assign them some values using the query, this is done to force a certain type or other field characteristics. The columns that are not named in the query will be placed before the others. For example:

```
CREATE TABLE test (a INT NOT NULL, b CHAR(10)) ENGINE=MyISAM
SELECT 5 AS b, c, d FROM another_table;
```

Remember that the query just returns data. If you want to use the same indexes, or the same columns attributes (`[NOT] NULL`, `DEFAULT`, `AUTO_INCREMENT`) in the new table, you need to specify them manually. Types and sizes are not automatically preserved if no data returned by the `SELECT` requires the full size, and `VARCHAR` could be converted into `CHAR`. The `CAST()` function can be used to force the new table to use certain types.

Aliases (`AS`) are taken into account, and they should always be used when you `SELECT` an expression (function, arithmetical operation, etc).

If an error occurs during the query, the table will not be created at all.

If the new table has a primary key or `UNIQUE` indexes, you can use the `IGNORE` or `REPLACE` keywords to handle duplicate key errors during the query. `IGNORE` means that the newer values must not be inserted an identical value exists in the index. `REPLACE` means that older values must be overwritten.

If the columns in the new table are more than the rows returned by the query, the columns populated by the query will be placed after other columns. Note that if the strict `SQL_MODE` is on, and the columns that are not names in the query do not have a `DEFAULT` value, an error will raise and no rows will be copied.

Concurrent inserts are not used during the execution of a `CREATE ... SELECT`.

If the table already exists, an error similar to the following will be returned:

```
ERROR 1050 (42S01): Table 't' already exists
```

If the `IF NOT EXISTS` clause is used and the table exists, a note will be produced instead of an error.

To insert rows from a query into an existing table, `INSERT ... SELECT` can be used.

Column Definitions

```
create_definition:
  { col_name column_definition | index_definition | period_definition | CHECK (expr) }

column_definition:
  data_type
  [NOT NULL | NULL] [DEFAULT default_value | (expression)]
  [ON UPDATE [NOW | CURRENT_TIMESTAMP] [(precision)]]
  [AUTO_INCREMENT] [ZEROFILL] [UNIQUE [KEY] | [PRIMARY] KEY]
  [INVISIBLE] [{WITH|WITHOUT} SYSTEM VERSIONING]
  [COMMENT 'string'] [REF_SYSTEM_ID = value]
  [reference_definition]
  | data_type [GENERATED ALWAYS]
  AS [ ROW {START|END} [NOT NULL ENABLE] [[PRIMARY] KEY]
    | (expression) [VIRTUAL | PERSISTENT | STORED] ]
    [INVISIBLE] [UNIQUE [KEY]] [COMMENT 'string']

constraint_definition:
  CONSTRAINT [constraint_name] CHECK (expression)
```

Note: Until [MariaDB 10.4](#), MariaDB accepts the shortcut format with a `REFERENCES` clause only in `ALTER TABLE` and `CREATE TABLE` statements, but that syntax does nothing. For example:

```
CREATE TABLE b(for_key INT REFERENCES a(not_key));
```

MariaDB simply parses it without returning any error or warning, for compatibility with other DBMS's. Before [MariaDB 10.2.1](#) this was also true for `CHECK` constraints. However, only the syntax described below creates foreign keys.

From [MariaDB 10.5](#), MariaDB will attempt to apply the constraint. See [Foreign Keys examples](#).

Each definition either creates a column in the table or specifies and index or constraint on one or more columns. See [Indexes](#) below for details on creating indexes.

Create a column by specifying a column name and a data type, optionally followed by column options. See [Data Types](#) for a full list of data types allowed in MariaDB.

NULL and NOT NULL

Use the `NULL` or `NOT NULL` options to specify that values in the column may or may not be `NULL`, respectively. By default, values may be `NULL`. See also [NULL Values in MariaDB](#).

DEFAULT Column Option

Specify a default value using the `DEFAULT` clause. If you don't specify `DEFAULT` then the following rules apply:

- If the column is not defined with `NOT NULL`, `AUTO_INCREMENT` or `TIMESTAMP`, an explicit `DEFAULT NULL` will be added. Note that in MySQL and in MariaDB before 10.1.6, you may get an explicit `DEFAULT` for primary key parts, if not specified with `NOT NULL`.

The default value will be used if you `INSERT` a row without specifying a value for that column, or if you specify `DEFAULT` for that column. Before [MariaDB 10.2.1](#) you couldn't usually provide an expression or function to evaluate at insertion time. You had to provide a constant default value instead. The one exception is that you may use `CURRENT_TIMESTAMP` as the default value for a `TIMESTAMP` column to use the current timestamp at insertion time.

`CURRENT_TIMESTAMP` may also be used as the default value for a `DATETIME`

You can use most functions in `DEFAULT`. Expressions should have parentheses around them. If you use a non deterministic function in `DEFAULT` then all inserts to the table will be [replicated](#) in [row mode](#). You can even refer to earlier columns in the `DEFAULT` expression (excluding `AUTO_INCREMENT` columns):

```
CREATE TABLE t1 (a int DEFAULT (1+1), b int DEFAULT (a+1));
CREATE TABLE t2 (a bigint primary key DEFAULT UUID_SHORT());
```

The `DEFAULT` clause cannot contain any [stored functions](#) or [subqueries](#), and a column used in the clause must already have been defined earlier in the statement.

It is possible to assign `BLOB` or `TEXT` columns a `DEFAULT` value. In versions prior to [MariaDB 10.2.1](#), assigning a default to these columns was not possible.

You can also use `DEFAULT (NEXT VALUE FOR sequence)`

AUTO_INCREMENT Column Option

Use `AUTO_INCREMENT` to create a column whose value can be set automatically from a simple counter. You can only use `AUTO_INCREMENT` on a column with an integer type. The column must be a key, and there can only be one `AUTO_INCREMENT` column in a table. If you insert a row without specifying a value for that column (or if you specify `0`, `NULL`, or `DEFAULT` as the value), the actual value will be taken from the counter, with each insertion incrementing the counter by one. You can still insert a value explicitly. If you insert a value that is greater than the current counter value, the counter is set based on the new value. An `AUTO_INCREMENT` column is implicitly `NOT NULL`. Use `LAST_INSERT_ID` to get the `AUTO_INCREMENT` value most recently used by an `INSERT` statement.

ZEROFILL Column Option

If the `ZEROFILL` column option is specified for a column using a [numeric](#) data type, then the column will be set to `UNSIGNED` and the spaces used by default to pad the field are replaced with zeros. `ZEROFILL` is ignored in expressions or as part of a `UNION`. `ZEROFILL` is a non-standard MySQL and MariaDB enhancement.

PRIMARY KEY Column Option

Use `PRIMARY KEY` to make a column a primary key. A primary key is a special type of a unique key. There can be at most one primary key per table, and it is implicitly `NOT NULL`.

Specifying a column as a unique key creates a unique index on that column. See the [Index Definitions](#) section below for more information.

UNIQUE KEY Column Option

Use `UNIQUE KEY` (or just `UNIQUE`) to specify that all values in the column must be distinct from each other. Unless the column is `NOT NULL`, there may be multiple rows with `NULL` in the column.

Specifying a column as a unique key creates a unique index on that column.

See the [Index Definitions](#) section below for more information.

COMMENT Column Option

You can provide a comment for each column using the `COMMENT` clause. The maximum length is 1024 characters. Use the [SHOW FULL COLUMNS](#) statement to see column comments.

REF_SYSTEM_ID

`REF_SYSTEM_ID` can be used to specify Spatial Reference System IDs for spatial data type columns. For example:

```
CREATE TABLE t1(g GEOMETRY(9,4) REF_SYSTEM_ID=101);
```

Generated Columns

A generated column is a column in a table that cannot explicitly be set to a specific value in a [DML query](#). Instead, its value is automatically generated based on an expression. This expression might generate the value based on the values of other columns in the table, or it might generate the value by calling [built-in functions](#) or [user-defined functions \(UDFs\)](#).

There are two types of generated columns:

- `PERSISTENT` or `STORED` : This type's value is actually stored in the table.
- `VIRTUAL` : This type's value is not stored at all. Instead, the value is generated dynamically when the table is queried. This type is the default.

Generated columns are also sometimes called computed columns or virtual columns.

For a complete description about generated columns and their limitations, see [Generated \(Virtual and Persistent/Stored\) Columns](#).

COMPRESSED

Certain columns may be compressed. See [Storage-Engine Independent Column Compression](#).

INVISIBLE

Columns may be made invisible, and hidden in certain contexts. See [Invisible Columns](#).

WITH SYSTEM VERSIONING Column Option

Columns may be explicitly marked as included from system versioning. See [System-versioned tables](#) for details.

WITHOUT SYSTEM VERSIONING Column Option

Columns may be explicitly marked as excluded from system versioning. See [System-versioned tables](#) for details.

Index Definitions

```

index_definition:
    {INDEX|KEY} [index_name] [index_type] (index_col_name,...) [index_option] ...
    {{{|}} {FULLTEXT|SPATIAL} [INDEX|KEY] [index_name] (index_col_name,...) [index_option] ...
    {{{|}} [CONSTRAINT [symbol]] PRIMARY KEY [index_type] (index_col_name,...) [index_option] ...
    {{{|}} [CONSTRAINT [symbol]] UNIQUE [INDEX|KEY] [index_name] [index_type]
(index_col_name,...) [index_option] ...
    {{{|}} [CONSTRAINT [symbol]] FOREIGN KEY [index_name] (index_col_name,...)

reference_definition

index_col_name:
    col_name [(length)] [ASC | DESC]

index_type:
    USING {BTREE | HASH | RTREE}

index_option:
    [ KEY_BLOCK_SIZE [=] value
    {{{|}} index_type
    {{{|}} WITH PARSER parser_name
    {{{|}} VISIBLE
    {{{|}} COMMENT 'string'
    {{{|}} CLUSTERING={YES| NO} ]
    [ IGNORED | NOT IGNORED ]

reference_definition:
    REFERENCES tbl_name (index_col_name,...)
    [MATCH FULL | MATCH PARTIAL | MATCH SIMPLE]
    [ON DELETE reference_option]
    [ON UPDATE reference_option]

reference_option:
    RESTRICT | CASCADE | SET NULL | NO ACTION

```

`INDEX` and `KEY` are synonyms.

Index names are optional, if not specified an automatic name will be assigned. Index name are needed to drop indexes and appear in error messages when a constraint is violated.

For limits on InnoDB indexes, see [InnoDB Limitations](#).

Index Categories

Plain Indexes

Plain indexes are regular indexes that are not unique, and are not acting as a primary key or a foreign key. They are also not the "specialized" `FULLTEXT` or `SPATIAL` indexes.

See [Getting Started with Indexes: Plain Indexes](#) for more information.

PRIMARY KEY

For `PRIMARY KEY` indexes, you can specify a name for the index, but it is ignored, and the name of the index is always `PRIMARY`. From [MariaDB 10.3.18](#) and [MariaDB 10.4.8](#), a warning is explicitly issued if a name is specified. Before then, the name was silently ignored.

See [Getting Started with Indexes: Primary Key](#) for more information.

UNIQUE

The `UNIQUE` keyword means that the index will not accept duplicated values, except for `NULLs`. An error will raise if you try to insert duplicate values in a `UNIQUE` index.

For `UNIQUE` indexes, you can specify a name for the constraint, using the `CONSTRAINT` keyword. That name will be used in error messages.

MariaDB starting with 10.5

Unique, if index type is not specified, is normally a `BTREE` index that can also be used by the optimizer to find rows. If the key is longer than the max key length for the used storage engine, a `HASH` key will be created. This enables MariaDB to enforce uniqueness for any type or number of columns.

See [Getting Started with Indexes: Unique Index](#) for more information.

FOREIGN KEY

For `FOREIGN KEY` indexes, a reference definition must be provided.

For `FOREIGN KEY` indexes, you can specify a name for the constraint, using the `CONSTRAINT` keyword. That name will be used in error messages.

First, you have to specify the name of the target (parent) table and a column or a column list which must be indexed and whose values must match to the foreign key's values. The `MATCH` clause is accepted to improve the compatibility with other DBMS's, but has no meaning in MariaDB. The `ON DELETE` and `ON UPDATE` clauses specify what must be done when a `DELETE` (or a `REPLACE`) statements attempts to delete a referenced row from the parent table, and when an `UPDATE` statement attempts to modify the referenced foreign key columns in a parent table row, respectively. The following options are allowed:

- `RESTRICT` : The delete/update operation is not performed. The statement terminates with a 1451 error (SQLSTATE '2300').
- `NO ACTION` : Synonym for `RESTRICT` .
- `CASCADE` : The delete/update operation is performed in both tables.
- `SET NULL` : The update or delete goes ahead in the parent table, and the corresponding foreign key fields in the child table are set to `NULL` . (They must not be defined as `NOT NULL` for this to succeed).
- `SET DEFAULT` : This option is currently implemented only for the PBXT storage engine, which is disabled by default and no longer maintained. It sets the child table's foreign key fields to their `DEFAULT` values when the referenced parent table key entries are updated or deleted.

If either clause is omitted, the default behavior for the omitted clause is `RESTRICT` .

See [Foreign Keys](#) for more information.

FULLTEXT

Use the `FULLTEXT` keyword to create full-text indexes.

See [Full-Text Indexes](#) for more information.

SPATIAL

Use the `SPATIAL` keyword to create geometric indexes.

See [SPATIAL INDEX](#) for more information.

Index Options

KEY_BLOCK_SIZE Index Option

The `KEY_BLOCK_SIZE` index option is similar to the `KEY_BLOCK_SIZE` table option.

With the [InnoDB](#) storage engine, if you specify a non-zero value for the `KEY_BLOCK_SIZE` table option for the whole table, then the table will implicitly be created with the `ROW_FORMAT` table option set to `COMPRESSED` . However, this does not happen if you just set the `KEY_BLOCK_SIZE` index option for one or more indexes in the table. The [InnoDB](#) storage engine ignores the `KEY_BLOCK_SIZE` index option. However, the `SHOW CREATE TABLE` statement may still report it for the index.

For information about the `KEY_BLOCK_SIZE` index option, see the `KEY_BLOCK_SIZE` table option below.

Index Types

Each storage engine supports some or all index types. See [Storage Engine Index Types](#) for details on permitted index types for each storage engine.

Different index types are optimized for different kind of operations:

- `BTREE` is the default type, and normally is the best choice. It is supported by all storage engines. It can be used to compare a column's value with a value using the `=`, `>`, `>=`, `<`, `<=`, `BETWEEN` , and `LIKE` operators. `BTREE` can also be used to find `NULL` values. Searches against an index prefix are possible.
- `HASH` is only supported by the `MEMORY` storage engine. `HASH` indexes can only be used for `=`, `<=`, and `>=` comparisons. It can not be used for the `ORDER BY` clause. Searches against an index prefix are not possible.
- `RTREE` is the default for [SPATIAL](#)  indexes, but if the storage engine does not support it `BTREE` can be used.

Index column names are listed between parenthesis. After each column, a prefix length can be specified. If no length is specified, the whole column will be indexed. `ASC` and `DESC` can be specified. Prior to [MariaDB 10.8](#), this was only for compatibility with other DBMSs, but had no meaning in MariaDB. From [MariaDB 10.8](#), individual columns in the index can now be explicitly sorted in ascending or descending order. This can be useful for optimizing certain ORDER BY cases ([MDEV-13756](#), [MDEV-26938](#), [MDEV-26939](#), [MDEV-26996](#)). From [MariaDB 11.4.0](#), not only ascending, but also descending, indexes can now be used to optimize `MIN()` and `MAX()` ([MDEV-27576](#)).

The maximum number of parts in an index is 32.

WITH PARSER Index Option

The `WITH PARSER` index option only applies to `FULLTEXT` indexes and contains the fulltext parser name. The fulltext parser must be an installed plugin.

VISIBLE Index Option

MariaDB starting with [10.5.3](#)

From [MariaDB 10.5.3](#), indexes can be declared visible. This is the default and it shows up in `SHOW CREATE TABLE`.

COMMENT Index Option

A comment of up to 1024 characters is permitted with the `COMMENT` index option.

The `COMMENT` index option allows you to specify a comment with user-readable text describing what the index is for. This information is not used by the server itself.

CLUSTERING Index Option

The `CLUSTERING` index option is only valid for tables using the [TokuDB](#) storage engine.

IGNORED / NOT IGNORED

MariaDB starting with [10.6.0](#)

From [MariaDB 10.6.0](#), indexes can be specified to be ignored by the optimizer. See [Ignored Indexes](#).

Periods

```
period_definition:
    PERIOD FOR [time_period_name | SYSTEM_TIME] (start_column_name, end_column_name)
```

MariaDB supports [System-versioned tables](#), [Application-time-period tables](#) or [Bitemporal Tables](#).

Constraint Expressions

Note: Before [MariaDB 10.2.1](#), constraint expressions were accepted in the syntax but ignored.

[MariaDB 10.2.1](#) introduced two ways to define a constraint:

- `CHECK (expression)` given as part of a column definition.
- `CONSTRAINT [constraint_name] CHECK (expression)`

Before a row is inserted or updated, all constraints are evaluated in the order they are defined. If any constraints fails, then the row will not be updated. One can use most deterministic functions in a constraint, including [UDFs](#).

```
create table t1 (a int check(a>0) ,b int check (b> 0), constraint abc check (a>b));
```

If you use the second format and you don't give a name to the constraint, then the constraint will get a auto generated name. This is done so that you can later delete the constraint with `ALTER TABLE DROP constraint_name`.

One can disable all constraint expression checks by setting the variable `check_constraint_checks` to `OFF`. This is useful for example when loading a table that violates some constraints that you want to later find and fix in SQL.

See [CONSTRAINT](#) for more information.

Table Options

For each individual table you create (or alter), you can set some table options. The general syntax for setting options is:

```
<OPTION_NAME> = <option_value>, [<OPTION_NAME> = <option_value> ...]
```

The equal sign is optional.

Some options are supported by the server and can be used for all tables, no matter what storage engine they use; other options can be specified for all storage engines, but have a meaning only for some engines. Also, engines can [extend](#)

`CREATE TABLE` [with new options](#).

If the `IGNORE_BAD_TABLE_OPTIONS SQL_MODE` is enabled, wrong table options generate a warning; otherwise, they generate an error.

```
table_option:
  [STORAGE] ENGINE [=] engine_name
| AUTO_INCREMENT [=] number
| AVG_ROW_LENGTH [=] number
| [DEFAULT] CHARACTER SET [=] charset_name
| CHECKSUM [=] {0 | 1}
| [DEFAULT] COLLATE [=] collation_name
| COMMENT [=] 'string'
| CONNECTION [=] 'connect_string'
| DATA DIRECTORY [=] 'absolute path to directory'
| DELAY_KEY_WRITE [=] {0 | 1}
| ENCRYPTED [=] {YES | NO}
| ENCRYPTION_KEY_ID [=] number
| IETF_QUOTES [=] {YES | NO}
| INDEX DIRECTORY [=] 'absolute path to directory'
| INSERT_METHOD [=] { NO | FIRST | LAST }
| KEY_BLOCK_SIZE [=] number
| MAX_ROWS [=] number
| MIN_ROWS [=] number
| PACK_KEYS [=] {0 | 1 | DEFAULT}
| PAGE_CHECKSUM [=] {0 | 1}
| PAGE_COMPRESSED [=] {0 | 1}
| PAGE_COMPRESSION_LEVEL [=] {0 .. 9}
| PASSWORD [=] 'string'
| ROW_FORMAT [=] {DEFAULT|DYNAMIC|FIXED|COMPRESSED|REDUNDANT|COMPACT|PAGE}
| SEQUENCE [=] {0|1}
| STATS_AUTO_RECALC [=] {DEFAULT|0|1}
| STATS_PERSISTENT [=] {DEFAULT|0|1}
| STATS_SAMPLE_PAGES [=] {DEFAULT|number}
| TABLESPACE tablespace_name
| TRANSACTIONAL [=] {0 | 1}
| UNION [=] (tbl_name[,tbl_name]...)
| WITH SYSTEM VERSIONING
```

[STORAGE] ENGINE

`[STORAGE] ENGINE` specifies a [storage engine](#) for the table. If this option is not used, the default storage engine is used instead. That is, the `default_storage_engine` session option value if it is set, or the value specified for the `--default-storage-engine` [mariadb startup option](#), or the default storage engine, [InnoDB](#). If the specified storage engine is not installed and active, the default value will be used, unless the `NO_ENGINE_SUBSTITUTION SQL MODE` is set (default). This is only true for `CREATE TABLE`, not for `ALTER TABLE`. For a list of storage engines that are present in your server, issue a [SHOW ENGINES](#).

AUTO_INCREMENT

`AUTO_INCREMENT` specifies the initial value for the [AUTO_INCREMENT](#) primary key. This works for MyISAM, Aria, InnoDB, MEMORY, and ARCHIVE tables. You can change this option with `ALTER TABLE`, but in that case the new value must be higher than the highest value which is present in the `AUTO_INCREMENT` column. If the storage engine does not support this option, you can insert (and then delete) a row having the wanted value - 1 in the `AUTO_INCREMENT` column.

AVG_ROW_LENGTH

`AVG_ROW_LENGTH` is the average rows size. It only applies to tables using [MyISAM](#) and [Aria](#) storage engines that have the `ROW_FORMAT` table option set to `FIXED` format.

[MyISAM](#) uses `MAX_ROWS` and `AVG_ROW_LENGTH` to decide the maximum size of a table (default: 256TB, or the maximum file size allowed by the system).

[DEFAULT] CHARACTER SET/CHARSET

`[DEFAULT] CHARACTER SET` (or `[DEFAULT] CHARSET`) is used to set a default character set for the table. This is the character set used for all columns where an explicit character set is not specified. If this option is omitted or `DEFAULT` is specified, the database's default character set will be used (except for the [JSON data type](#), which is `utf8mb4` by default). See [Setting Character Sets and Collations](#) for details on setting the [character sets](#).

CHECKSUM/TABLE_CHECKSUM

`CHECKSUM` (or `TABLE_CHECKSUM`) can be set to 1 to maintain a live checksum for all table's rows. This makes write operations slower, but [CHECKSUM TABLE](#) will be very fast. This option is only supported for [MyISAM](#) and [Aria tables](#).

[DEFAULT] COLLATE

`[DEFAULT] COLLATE` is used to set a default collation for the table. This is the collation used for all columns where an explicit character set is not specified. If this option is omitted or `DEFAULT` is specified, the database's default option will be used (except for the [JSON data type](#), which uses `utf8mb4_bin` by default). See [Setting Character Sets and Collations](#) for details on setting the [collations](#)

COMMENT

`COMMENT` is a comment for the table. The maximum length is 2048 characters. Also used to define table parameters when creating a [Spider](#) table.

CONNECTION

`CONNECTION` is used to specify a server name or a connection string for a [Spider](#), [CONNECT](#), [Federated](#) or [FederatedX table](#).

DATA DIRECTORY/INDEX DIRECTORY

`DATA DIRECTORY` and `INDEX DIRECTORY` are supported for [MyISAM](#) and [Aria](#), and `DATA DIRECTORY` is also supported by [InnoDB](#) if the `innodb_file_per_table` server system variable is enabled, but only in `CREATE TABLE`, not in `ALTER TABLE`. So, carefully choose a path for [InnoDB](#) tables at creation time, because it cannot be changed without dropping and re-creating the table. These options specify the paths for data files and index files, respectively. If these options are omitted, the database's directory will be used to store data files and index files. Note that these table options do not work for [partitioned](#) tables (use the partition options instead), or if the server has been invoked with the `--skip-symbolic-links startup option`. To avoid the overwriting of old files with the same name that could be present in the directories, you can use the `the --keep_files_on_create option` (an error will be issued if files already exist). These options are ignored if the `NO_DIR_IN_CREATE SQL_MODE` is enabled (useful for replicas). Also note that symbolic links cannot be used for [InnoDB](#) tables.

`DATA DIRECTORY` works by creating symlinks from where the table would normally have been (inside the `datadir`) to where the option specifies. For security reasons, to avoid bypassing the privilege system, the server does not permit symlinks inside the `datadir`. Therefore, `DATA DIRECTORY` cannot be used to specify a location inside the `datadir`. An attempt to do so will result in an error `1210 (HY000) Incorrect arguments to DATA DIRECTORY`.

DELAY_KEY_WRITE

`DELAY_KEY_WRITE` is supported by [MyISAM](#) and [Aria](#), and can be set to 1 to speed up write operations. In that case, when data are modified, the indexes are not updated until the table is closed. Writing the changes to the index file altogether can be much faster. However, note that this option is applied only if the `delay_key_write` server variable is set to 'ON'. If it is 'OFF' the delayed index writes are always disabled, and if it is 'ALL' the delayed index writes are always used, disregarding the value of `DELAY_KEY_WRITE`.

ENCRYPTED

The `ENCRYPTED` table option can be used to manually set the encryption status of an [InnoDB](#) table. See [InnoDB Encryption](#) for more information.

Aria does not support the `ENCRYPTED` table option. See [MDEV-18049](#).

See [Data-at-Rest Encryption](#) for more information.

ENCRYPTION_KEY_ID

The `ENCRYPTION_KEY_ID` table option can be used to manually set the encryption key of an [InnoDB](#) table. See [InnoDB Encryption](#) for more information.

Aria does not support the `ENCRYPTION_KEY_ID` table option. See [MDEV-18049](#).

See [Data-at-Rest Encryption](#) for more information.

IETF_QUOTES

For the [CSV](#) storage engine, the `IETF_QUOTES` option, when set to `YES`, enables IETF-compatible parsing of embedded quote and comma characters. Enabling this option for a table improves compatibility with other tools that use CSV, but is not compatible with MySQL CSV tables, or MariaDB CSV tables created without this option. Disabled by default.

INSERT_METHOD

`INSERT_METHOD` is only used with [MERGE](#) tables. This option determines in which underlying table the new rows should be inserted. If you set it to 'NO' (which is the default) no new rows can be added to the table (but you will still be able to perform `INSERT` s directly against the underlying tables). `FIRST` means that the rows are inserted into the first table, and `LAST` means that they are inserted into the last table.

KEY_BLOCK_SIZE

`KEY_BLOCK_SIZE` is used to determine the size of key blocks, in bytes or kilobytes. However, this value is just a hint, and the storage engine could modify or ignore it. If `KEY_BLOCK_SIZE` is set to 0, the storage engine's default value will be used.

With the [InnoDB](#) storage engine, if you specify a non-zero value for the `KEY_BLOCK_SIZE` table option for the whole table, then the table will implicitly be created with the [ROW_FORMAT](#) table option set to `COMPRESSED`.

MIN_ROWS/MAX_ROWS

`MIN_ROWS` and `MAX_ROWS` let the storage engine know how many rows you are planning to store as a minimum and as a maximum. These values will not be used as real limits, but they help the storage engine to optimize the table. `MIN_ROWS` is only used by [MEMORY](#) storage engine to decide the minimum memory that is always allocated. `MAX_ROWS` is used to decide the minimum size for indexes.

PACK_KEYS

`PACK_KEYS` can be used to determine whether the indexes will be compressed. Set it to 1 to compress all keys. With a value of 0, compression will not be used. With the `DEFAULT` value, only long strings will be compressed. Uncompressed keys are faster.

PAGE_CHECKSUM

`PAGE_CHECKSUM` is only applicable to [Aria](#) tables, and determines whether indexes and data should use page checksums for extra safety.

PAGE_COMPRESSED

`PAGE_COMPRESSED` is used to enable [InnoDB page compression](#) for [InnoDB](#) tables.

PAGE_COMPRESSION_LEVEL

`PAGE_COMPRESSION_LEVEL` is used to set the compression level for [InnoDB page compression](#) for [InnoDB](#) tables. The

table must also have the `PAGE_COMPRESSED` table option set to `1` .

Valid values for `PAGE_COMPRESSION_LEVEL` are 1 (the best speed) through 9 (the best compression), .

PASSWORD

`PASSWORD` is unused.

RAID_TYPE

`RAID_TYPE` is an obsolete option, as the raid support has been disabled since MySQL 5.0.

ROW_FORMAT

The `ROW_FORMAT` table option specifies the row format for the data file. Possible values are engine-dependent.

Supported MyISAM Row Formats

For [MyISAM](#), the supported row formats are:

- `FIXED`
- `DYNAMIC`
- `COMPRESSED`

The `COMPRESSED` row format can only be set by the [myisampack](#) command line tool.

See [MyISAM Storage Formats](#) for more information.

Supported Aria Row Formats

For [Aria](#), the supported row formats are:

- `PAGE`
- `FIXED`
- `DYNAMIC` .

See [Aria Storage Formats](#) for more information.

Supported InnoDB Row Formats

For [InnoDB](#), the supported row formats are:

- `COMPACT`
- `REDUNDANT`
- `COMPRESSED`
- `DYNAMIC` .

If the `ROW_FORMAT` table option is set to `FIXED` for an InnoDB table, then the server will either return an error or a warning depending on the value of the `innodb_strict_mode` system variable. If the `innodb_strict_mode` system variable is set to `OFF` , then a warning is issued, and MariaDB will create the table using the default row format for the specific MariaDB server version. If the `innodb_strict_mode` system variable is set to `ON` , then an error will be raised.

See [InnoDB Storage Formats](#) for more information.

Other Storage Engines and ROW_FORMAT

Other storage engines do not support the `ROW_FORMAT` table option.

SEQUENCE

If the table is a [sequence](#), then it will have the `SEQUENCE` set to `1` .

STATS_AUTO_RECALC

`STATS_AUTO_RECALC` indicates whether to automatically recalculate persistent statistics (see `STATS_PERSISTENT` , below) for an InnoDB table. If set to `1` , statistics will be recalculated when more than 10% of the data has changed. When set to `0` , stats will be recalculated only when an [ANALYZE TABLE](#) is run. If set to `DEFAULT` , or left out, the value set by the

`innodb_stats_auto_recalc` system variable applies. See [InnoDB Persistent Statistics](#).

STATS_PERSISTENT

`STATS_PERSISTENT` indicates whether the InnoDB statistics created by `ANALYZE TABLE` will remain on disk or not. It can be set to `1` (on disk), `0` (not on disk, the pre-MariaDB 10 behavior), or `DEFAULT` (the same as leaving out the option), in which case the value set by the `innodb_stats_persistent` system variable will apply. Persistent statistics stored on disk allow the statistics to survive server restarts, and provide better query plan stability. See [InnoDB Persistent Statistics](#).

STATS_SAMPLE_PAGES

`STATS_SAMPLE_PAGES` indicates how many pages are used to sample index statistics. If `0` or `DEFAULT`, the default value, the `innodb_stats_sample_pages` value is used. See [InnoDB Persistent Statistics](#).

TRANSACTIONAL

`TRANSACTIONAL` is only applicable for Aria tables. In future Aria tables created with this option will be fully transactional, but currently this provides a form of crash protection. See [Aria Storage Engine](#) for more details.

UNION

`UNION` must be specified when you create a MERGE table. This option contains a comma-separated list of MyISAM tables which are accessed by the new table. The list is enclosed between parenthesis. Example: `UNION = (t1,t2)`

WITH SYSTEM VERSIONING

`WITH SYSTEM VERSIONING` is used for creating [System-versioned tables](#).

Partitions

```

partition_options:
    PARTITION BY
        { [LINEAR] HASH(expr)
        | [LINEAR] KEY(column_list)
        | RANGE(expr)
        | LIST(expr)
        | SYSTEM_TIME [INTERVAL time_quantity time_unit] [LIMIT num] }
    [PARTITIONS num]
    [SUBPARTITION BY
        { [LINEAR] HASH(expr)
        | [LINEAR] KEY(column_list) }
    [SUBPARTITIONS num]
    ]
    [(partition_definition [, partition_definition] ...)]

partition_definition:
    [PARTITION] partition_name
    [VALUES {LESS THAN {(expr) | MAXVALUE} | IN (value_list)}]
    [[STORAGE] ENGINE [=] engine_name]
    [COMMENT [=] 'comment_text' ]
    [DATA DIRECTORY [=] 'data_dir']
    [INDEX DIRECTORY [=] 'index_dir']
    [MAX_ROWS [=] max_number_of_rows]
    [MIN_ROWS [=] min_number_of_rows]
    [TABLESPACE [=] tablespace_name]
    [NODEGROUP [=] node_group_id]
    [(subpartition_definition [, subpartition_definition] ...)]

subpartition_definition:
    SUBPARTITION logical_name
    [[STORAGE] ENGINE [=] engine_name]
    [COMMENT [=] 'comment_text' ]
    [DATA DIRECTORY [=] 'data_dir']
    [INDEX DIRECTORY [=] 'index_dir']
    [MAX_ROWS [=] max_number_of_rows]
    [MIN_ROWS [=] min_number_of_rows]
    [TABLESPACE [=] tablespace_name]
    [NODEGROUP [=] node_group_id]

```

If the `PARTITION BY` clause is used, the table will be [partitioned](#). A partition method must be explicitly indicated for partitions and subpartitions. Partition methods are:

- `[LINEAR] HASH` creates a hash key which will be used to read and write rows. The partition function can be any valid SQL expression which returns an `INTEGER` number. Thus, it is possible to use the `HASH` method on an integer column, or on functions which accept integer columns as an argument. However, `VALUES LESS THAN` and `VALUES IN` clauses can not be used with `HASH`. An example:

```

CREATE TABLE t1 (a INT, b CHAR(5), c DATETIME)
PARTITION BY HASH ( YEAR(c) );

```

`[LINEAR] HASH` can be used for subpartitions, too.

- `[LINEAR] KEY` is similar to `HASH`, but the index has an even distribution of data. Also, the expression can only be a column or a list of columns. `VALUES LESS THAN` and `VALUES IN` clauses can not be used with `KEY`.
- `RANGE` partitions the rows using on a range of values, using the `VALUES LESS THAN` operator. `VALUES IN` is not allowed with `RANGE`. The partition function can be any valid SQL expression which returns a single value.
- `LIST` assigns partitions based on a table's column with a restricted set of possible values. It is similar to `RANGE`, but `VALUES IN` must be used for at least 1 columns, and `VALUES LESS THAN` is disallowed.
- `SYSTEM_TIME` partitioning is used for [System-versioned tables](#) to store historical data separately from current data.

Only `HASH` and `KEY` can be used for subpartitions, and they can be `[LINEAR]`.

It is possible to define up to 8092 partitions and subpartitions.

The number of defined partitions can be optionally specified as `PARTITION count`. This can be done to avoid specifying all partitions individually. But you can also declare each individual partition and, additionally, specify a `PARTITIONS count` clause; in the case, the number of `PARTITION`s must equal count.

Also see [Partitioning Types Overview](#).

MariaDB starting with [10.7.1](#) 

From [MariaDB 10.7](#), the `PARTITION` keyword is now optional as part of the partition definition, for example, instead of:

```
create or replace table t1 (x int)
partition by range(x) (
  partition p1 values less than (10),
  partition p2 values less than (20),
  partition p3 values less than (30),
  partition p4 values less than (40),
  partition p5 values less than (50),
  partition pn values less than maxvalue);
```

the following can also be used:

```
create or replace table t1 (x int)
partition by range(x) (
  p1 values less than (10),
  p2 values less than (20),
  p3 values less than (30),
  p4 values less than (40),
  p5 values less than (50),
  pn values less than maxvalue);
```

Sequences

`CREATE TABLE` can also be used to create a [SEQUENCE](#). See [CREATE SEQUENCE](#) and [Sequence Overview](#).

Atomic DDL

MariaDB starting with [10.6.1](#)

[MariaDB 10.6.1](#) supports [Atomic DDL](#). `CREATE TABLE` is atomic, except for `CREATE OR REPLACE`, which is only crash safe.

Examples

```
create table if not exists test (
  a bigint auto_increment primary key,
  name varchar(128) charset utf8,
  key name (name(32))
) engine=InnoDB default charset latin1;
```

This example shows a couple of things:

- Usage of `IF NOT EXISTS`; if the table already existed, it will not be created. There will not be any error for the client, just a warning.
- How to create a `PRIMARY KEY` that is [automatically generated](#).
- How to specify a table-specific [character set](#) and another for a column.
- How to create an index (`name`) that is only partly indexed (to save space).

The following clauses will work from [MariaDB 10.2.1](#)  only.

```
CREATE TABLE t1 (
  a int DEFAULT (1+1),
  b int DEFAULT (a+1),
  expires DATETIME DEFAULT (NOW() + INTERVAL 1 YEAR),
  x BLOB DEFAULT USER()
);
```

1.1.1.2.1.7 DELETE

Contents

1. [Syntax](#)
2. [Description](#)
 1. [AS](#)
 2. [PARTITION](#)
 3. [FOR PORTION OF](#)
 4. [RETURNING](#)
 5. [Same Source and Target Table](#)
 6. [DELETE HISTORY](#)
3. [Examples](#)
 1. [Deleting from the Same Source and Target](#)

Syntax

Single-table syntax:

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
FROM tbl_name [PARTITION (partition_list)]
[FOR PORTION OF period FROM expr1 TO expr2]
[AS alias] -- from MariaDB 11.6
[WHERE where_condition]
[ORDER BY ...]
[LIMIT row_count]
[RETURNING select_expr
[, select_expr ...]]
```

Multiple-table syntax:

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
tbl_name[.*] [, tbl_name[.*]] ...
FROM table_references
[WHERE where_condition]
```

Or:

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
FROM tbl_name[.*] [, tbl_name[.*]] ...
USING table_references
[WHERE where_condition]
```

Trimming history:

```
DELETE HISTORY
FROM tbl_name [PARTITION (partition_list)]
[BEFORE SYSTEM_TIME [TIMESTAMP|TRANSACTION] expression]
```

Description

Option	Description
LOW_PRIORITY	Wait until all SELECT's are done before starting the statement. Used with storage engines that uses table locking (MyISAM, Aria etc). See HIGH_PRIORITY and LOW_PRIORITY clauses for details.
QUICK	Signal the storage engine that it should expect that a lot of rows are deleted. The storage engine can do things to speed up the DELETE like ignoring merging of data blocks until all rows are deleted from the block (instead of when a block is half full). This speeds up things at the expense of lost space in data blocks. At least MyISAM and Aria support this feature.
IGNORE	Don't stop the query even if a not-critical error occurs (like data overflow). See How IGNORE works for a full description.

For the single-table syntax, the `DELETE` statement deletes rows from `tbl_name` and returns a count of the number of deleted rows. This count can be obtained by calling the `ROW_COUNT()` function. The `WHERE` clause, if given, specifies the conditions that identify which rows to delete. With no `WHERE` clause, all rows are deleted. If the `ORDER BY` clause is specified, the rows are deleted in the order that is specified. The `LIMIT` clause places a limit on the number of rows that can be deleted.

For the multiple-table syntax, `DELETE` deletes from each `tbl_name` the rows that satisfy the conditions. In this case, [ORDER BY](#) and [LIMIT](#) cannot be used. A `DELETE` can also reference tables which are located in different databases; see [Identifier Qualifiers](#) for the syntax.

`where_condition` is an expression that evaluates to true for each row to be deleted. It is specified as described in [SELECT](#).

Currently, you cannot delete from a table and select from the same table in a subquery.

You need the `DELETE` privilege on a table to delete rows from it. You need only the `SELECT` privilege for any columns that are only read, such as those named in the `WHERE` clause. See [GRANT](#).

As stated, a `DELETE` statement with no `WHERE` clause deletes all rows. A faster way to do this, when you do not need to know the number of deleted rows, is to use `TRUNCATE TABLE`. However, within a transaction or if you have a lock on the table, `TRUNCATE TABLE` cannot be used whereas `DELETE` can. See [TRUNCATE TABLE](#), and [LOCK](#).

AS

MariaDB starting with [11.6](#)

From [MariaDB 11.6](#), single table `DELETE`s support aliases. For example:

```
CREATE TABLE t1 (c1 INT);
INSERT INTO t1 VALUES (1), (2);

DELETE FROM t1 AS a1 WHERE a1.c1 = 2;
```

PARTITION

See [Partition Pruning and Selection](#) for details.

FOR PORTION OF

See [Application Time Periods - Deletion by Portion](#).

RETURNING

It is possible to return a resultset of the deleted rows for a single table to the client by using the syntax `DELETE ... RETURNING select_expr [, select_expr2 ...]`

Any of SQL expression that can be calculated from a single row fields is allowed. Subqueries are allowed. The `AS` keyword is allowed, so it is possible to use aliases.

The use of aggregate functions is not allowed. `RETURNING` cannot be used in multi-table `DELETE`s.

Same Source and Target Table

It is possible to delete from a table with the same source and target. For example:

```
DELETE FROM t1 WHERE c1 IN (SELECT b.c1 FROM t1 b WHERE b.c2=0);
```

DELETE HISTORY

One can use `DELETE HISTORY` to delete historical information from [System-versioned tables](#).

Examples

How to use the [ORDER BY](#) and [LIMIT](#) clauses:

```
DELETE FROM page_hit ORDER BY timestamp LIMIT 1000000;
```

How to use the `RETURNING` clause:

```
DELETE FROM t RETURNING f1;
+-----+
| f1   |
+-----+
|    5 |
|   50 |
|  500 |
+-----+
```

The following statement joins two tables: one is only used to satisfy a WHERE condition, but no row is deleted from it; rows from the other table are deleted, instead.

```
DELETE post FROM blog INNER JOIN post WHERE blog.id = post.blog_id;
```

Deleting from the Same Source and Target

```
CREATE TABLE t1 (c1 INT, c2 INT);
DELETE FROM t1 WHERE c1 IN (SELECT b.c1 FROM t1 b WHERE b.c2=0);
```

Until [MariaDB 10.3.1](#), this returned:

```
ERROR 1093 (HY000): Table 't1' is specified twice, both as a target for 'DELETE'
and as a separate source for
```

From [MariaDB 10.3.1](#):

```
Query OK, 0 rows affected (0.00 sec)
```

1.1.1.2.1.8 DROP TABLE

Syntax

```
DROP [TEMPORARY] TABLE [IF EXISTS] [/*COMMENT TO SAVE*/]
tbl_name [, tbl_name] ...
[WAIT n|NOWAIT]
[RESTRICT | CASCADE]
```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [WAIT/NOWAIT](#)
3. [DROP TABLE in replication](#)
4. [Dropping an Internal #sql-... Table](#)
5. [Dropping All Tables in a Database](#)
6. [Atomic DROP TABLE](#)
7. [Examples](#)
8. [Notes](#)

Description

`DROP TABLE` removes one or more tables. You must have the `DROP` privilege for each table. All table data and the table definition are removed, as well as [triggers](#) associated to the table, so be careful with this statement! If any of the tables named in the argument list do not exist, MariaDB returns an error indicating by name which non-existing tables it was unable to drop, but it also drops all of the tables in the list that do exist.

Important: When a table is dropped, user privileges on the table are not automatically dropped. See [GRANT](#).

If another thread is using the table in an explicit transaction or an autocommit transaction, then the thread acquires a [metadata lock \(MDL\)](#) on the table. The `DROP TABLE` statement will wait in the "Waiting for table metadata lock" [thread state](#) until the MDL is released. MDLs are released in the following cases:

- If an MDL is acquired in an explicit transaction, then the MDL will be released when the transaction ends.

- If an MDL is acquired in an autocommit transaction, then the MDL will be released when the statement ends.
- Transactional and non-transactional tables are handled the same.

Note that for a partitioned table, `DROP TABLE` permanently removes the table definition, all of its partitions, and all of the data which was stored in those partitions. It also removes the partitioning definition (`.par`) file associated with the dropped table.

For each referenced table, `DROP TABLE` drops a temporary table with that name, if it exists. If it does not exist, and the `TEMPORARY` keyword is not used, it drops a non-temporary table with the same name, if it exists. The `TEMPORARY` keyword ensures that a non-temporary table will not accidentally be dropped.

Use `IF EXISTS` to prevent an error from occurring for tables that do not exist. A `NOTE` is generated for each non-existent table when using `IF EXISTS`. See [SHOW WARNINGS](#).

If a [foreign key](#) references this table, the table cannot be dropped. In this case, it is necessary to drop the foreign key first.

`RESTRICT` and `CASCADE` are allowed to make porting from other database systems easier. In MariaDB, they do nothing.

The comment before the table names (`/*COMMENT TO SAVE*/`) is stored in the [binary log](#). That feature can be used by replication tools to send their internal messages.

It is possible to specify table names as `db_name.tab_name`. This is useful to delete tables from multiple databases with one statement. See [Identifier Qualifiers](#) for details.

The [DROP privilege](#) is required to use `DROP TABLE` on non-temporary tables. For temporary tables, no privilege is required, because such tables are only visible for the current session.

Note: `DROP TABLE` automatically commits the current active transaction, unless you use the `TEMPORARY` keyword.

MariaDB starting with [10.5.4](#)

From [MariaDB 10.5.4](#), `DROP TABLE` reliably deletes table remnants inside a storage engine even if the `.frm` file is missing. Before then, a missing `.frm` file would result in the statement failing.

WAIT/NOWAIT

Set the lock wait timeout. See [WAIT and NOWAIT](#).

DROP TABLE in replication

`DROP TABLE` has the following characteristics in [replication](#):

- `DROP TABLE IF EXISTS` are always logged.
- `DROP TABLE` without `IF EXISTS` for tables that don't exist are not written to the [binary log](#).
- Dropping of `TEMPORARY` tables are prefixed in the log with `TEMPORARY`. These drops are only logged when running [statement](#) or [mixed mode](#) replication.
- One `DROP TABLE` statement can be logged with up to 3 different `DROP` statements:
 - `DROP TEMPORARY TABLE list_of_non_transactional_temporary_tables`
 - `DROP TEMPORARY TABLE list_of_transactional_temporary_tables`
 - `DROP TABLE list_of_normal_tables`

`DROP TABLE` on the primary is treated on the replica as `DROP TABLE IF EXISTS`. You can change that by setting [slave-ddl-exec-mode](#) to `STRICT`.

Dropping an Internal #sql-... Table

From [MariaDB 10.6](#), `DROP TABLE` is atomic and the following does not apply. Until [MariaDB 10.5](#), if the `mariadb` process is killed during an `ALTER TABLE` you may find a table named `#sql-...` in your data directory. These temporary tables will always be deleted automatically.

If you want to delete one of these tables explicitly you can do so by using the following syntax:

```
DROP TABLE `#mysql150##sql-...`;
```

When running an `ALTER TABLE...ALGORITHM=INPLACE` that rebuilds the table, InnoDB will create an internal `#sql-ib` table.

The same name as the `.frm` file is used for the intermediate copy of the table. The `#sql-ib` names are used by `TRUNCATE` and delayed `DROP`.

The #sql-ib tables will be deleted automatically.

Dropping All Tables in a Database

The best way to drop all tables in a database is by executing `DROP DATABASE`, which will drop the database itself, and all tables in it.

However, if you want to drop all tables in the database, but you also want to keep the database itself and any other non-table objects in it, then you would need to execute `DROP TABLE` to drop each individual table. You can construct these `DROP TABLE` commands by querying the `TABLES` table in the `information_schema` database. For example:

```
SELECT CONCAT('DROP TABLE IF EXISTS `', TABLE_SCHEMA,`.`', TABLE_NAME, `;`)
FROM information_schema.TABLES
WHERE TABLE_SCHEMA = 'mydb';
```

Atomic DROP TABLE

MariaDB starting with [10.6.1](#)

From [MariaDB 10.6](#), `DROP TABLE` for a single table is atomic ([MDEV-25180](#)) for most engines, including InnoDB, MyRocks, MyISAM and Aria.

This means that if there is a crash (server down or power outage) during `DROP TABLE`, all tables that have been processed so far will be completely dropped, including related trigger files and status entries, and the [binary log](#) will include a `DROP TABLE` statement for the dropped tables. Tables for which the drop had not started will be left intact.

In older MariaDB versions, there was a small chance that, during a server crash happening in the middle of `DROP TABLE`, some storage engines that were using multiple storage files, like [MyISAM](#), could have only a part of its internal files dropped.

In [MariaDB 10.5](#), `DROP TABLE` was extended to be able to delete a table that was only partly dropped ([MDEV-11412](#)) as explained above. Atomic `DROP TABLE` is the final piece to make `DROP TABLE` fully reliable.

Dropping multiple tables is crash-safe.

See [Atomic DDL](#) for more information.

Examples

```
DROP TABLE Employees, Customers;
```

Notes

Beware that `DROP TABLE` can drop both tables and [sequences](#). This is mainly done to allow old tools like [mariadb-dump](#) (previously `mysqldump`) to work with sequences.

1.1.1.2.1.9 Installing System Tables (mariadb-install-db)

`mariadb-install-db` initializes the MariaDB data directory and creates the [system tables](#) in the `mysql` database, if they do not exist. MariaDB uses these tables to manage [privileges](#), [roles](#), and [plugins](#). It also uses them to provide the data for the `help` command in the `mariadb` client.

`mariadb-install-db` works by starting MariaDB Server's `mysqld` process in `--bootstrap` mode and sending commands to create the [system tables](#) and their content.

There is a version specifically for Windows, [mysql_install_db.exe](#).

To invoke `mariadb-install-db`, use the following syntax:

```
mariadb-install-db --user=mysql
```

For the options supported by `mariadb-install-db`, see [mariadb-install-db: Options](#).

For the option groups read by `mariadb-install-db`, see [mariadb-install-db: Option Groups](#).

See [mariadb-install-db: Installing System Tables](#) for information on the installation process.

See [mariadb-install-db: Troubleshooting Issues](#) for information on how to troubleshoot the installation process.

1.1.1.2.1.10 mysqlcheck

`mysqlcheck` is a tool for checking, repairing, analyzing and optimizing tables.

From [MariaDB 10.5](#), the client is called `mariadb-check`. It can still be accessed under its original `mysqlcheck` name via a symlink in Linux, or an alternate binary in Windows.

See [mariadb-check](#) for details.

1.1.1.2.1.11 OPTIMIZE TABLE

Syntax

```
OPTIMIZE [NO_WRITE_TO_BINLOG | LOCAL] TABLE
tbl_name [, tbl_name] ...
[WAIT n | NOWAIT]
```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [WAIT/NOWAIT](#)
 2. [Defragmenting](#)
 3. [Updating an InnoDB fulltext index](#)
 4. [Defragmenting InnoDB tablespaces](#)

Description

`OPTIMIZE TABLE` has two main functions. It can either be used to defragment tables, or to update the InnoDB fulltext index.

WAIT/NOWAIT

Set the lock wait timeout. See [WAIT and NOWAIT](#).

Defragmenting

`OPTIMIZE TABLE` works for [InnoDB](#) (before [MariaDB 10.1.1](#), only if the `innodb_file_per_table` server system variable is set), [Aria](#), [MyISAM](#) and [ARCHIVE](#) tables, and should be used if you have deleted a large part of a table or if you have made many changes to a table with variable-length rows (tables that have [VARCHAR](#), [VARBINARY](#), [BLOB](#), or [TEXT](#) columns). Deleted rows are maintained in a linked list and subsequent `INSERT` operations reuse old row positions.

This statement requires [SELECT and INSERT privileges](#) for the table.

By default, `OPTIMIZE TABLE` statements are written to the [binary log](#) and will be [replicated](#). The `NO_WRITE_TO_BINLOG` keyword (`LOCAL` is an alias) will ensure the statement is not written to the binary log.

`OPTIMIZE TABLE` statements are not logged to the binary log if `read_only` is set. See also [Read-Only Replicas](#).

`OPTIMIZE TABLE` is also supported for partitioned tables. You can use `ALTER TABLE ... OPTIMIZE PARTITION` to optimize one or more partitions.

You can use `OPTIMIZE TABLE` to reclaim the unused space and to defragment the data file. With other storage engines, `OPTIMIZE TABLE` does nothing by default, and returns this message: "The storage engine for the table doesn't support optimize". However, if the server has been started with the `--skip-new` option, `OPTIMIZE TABLE` is linked to [ALTER TABLE](#), and recreates the table. This operation frees the unused space and updates index statistics.

The [Aria](#) storage engine supports [progress reporting](#) for this statement.

If a [MyISAM](#) table is fragmented, [concurrent inserts](#) will not be performed until an `OPTIMIZE TABLE` statement is executed on that table, unless the `concurrent_insert` server system variable is set to `ALWAYS`.

Updating an InnoDB fulltext index

When rows are added or deleted to an InnoDB [fulltext index](#), the index is not immediately re-organized, as this can be an expensive operation. Change statistics are stored in a separate location . The fulltext index is only fully re-organized when an `OPTIMIZE TABLE` statement is run.

By default, an `OPTIMIZE TABLE` will defragment a table. In order to use it to update fulltext index statistics, the [innodb_optimize_fulltext_only](#) system variable must be set to `1` . This is intended to be a temporary setting, and should be reset to `0` once the fulltext index has been re-organized.

Since fulltext re-organization can take a long time, the [innodb_ft_num_word_optimize](#) variable limits the re-organization to a number of words (2000 by default). You can run multiple `OPTIMIZE` statements to fully re-organize the index.

Defragmenting InnoDB tablespaces

MariaDB 10.1.1 [merged](#) the Facebook/Kakao defragmentation patch, allowing one to use `OPTIMIZE TABLE` to defragment InnoDB tablespaces. For this functionality to be enabled, the [innodb_defragment](#) system variable must be enabled. No new tables are created and there is no need to copy data from old tables to new tables. Instead, this feature loads `n` pages (determined by [innodb-defragment-n-pages](#)) and tries to move records so that pages would be full of records and then frees pages that are fully empty after the operation. Note that tablespace files (including `ibdata1`) will not shrink as the result of defragmentation, but one will get better memory utilization in the InnoDB buffer pool as there are fewer data pages in use.

See [Defragmenting InnoDB Tablespaces](#) for more details.

1.1.1.2.1.12 RENAME TABLE

Syntax

```
RENAME TABLE[S] [IF EXISTS] tbl_name
[WAIT n | NOWAIT]
TO new_tbl_name
[, tbl_name2 TO new_tbl_name2] ...
```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [IF EXISTS](#)
 2. [WAIT/NOWAIT](#)
 3. [Privileges](#)
 4. [Atomic RENAME TABLE](#)

Description

This statement renames one or more tables or [views](#), but not the privileges associated with them. For InnoDB tables, it also triggers a reload of [InnoDB statistics](#).

IF EXISTS

If this directive is used, one will not get an error if the table to be renamed doesn't exist.

The rename operation is done atomically, which means that no other session can access any of the tables while the rename is running. For example, if you have an existing table `old_table`, you can create another table `new_table` that has the same structure but is empty, and then replace the existing table with the empty one as follows (assuming that `backup_table` does not already exist):

```
CREATE TABLE new_table (...);
RENAME TABLE old_table TO backup_table, new_table TO old_table;
```

`tbl_name` can optionally be specified as `db_name.tbl_name`. See [Identifier Qualifiers](#). This allows to use `RENAME` to move a table from a database to another (as long as they are on the same filesystem):

```
RENAME TABLE db1.t TO db2.t;
```

Note that moving a table to another database is not possible if it has some [triggers](#). Trying to do so produces the following error:

```
ERROR 1435 (HY000): Trigger in wrong schema
```

Also, views cannot be moved to another database:

```
ERROR 1450 (HY000): Changing schema from 'old_db' to 'new_db' is not allowed.
```

Multiple tables can be renamed in a single statement. The presence or absence of the optional `S` (`RENAME TABLE` or `RENAME TABLES`) has no impact, whether a single or multiple tables are being renamed.

If a `RENAME TABLE` renames more than one table and one renaming fails, all renames executed by the same statement are rolled back.

Renames are always executed in the specified order. Knowing this, it is also possible to swap two tables' names:

```
RENAME TABLE t1 TO tmp_table,  
             t2 TO t1,  
             tmp_table TO t2;
```

WAIT/NOWAIT

Set the lock wait timeout. See [WAIT and NOWAIT](#).

Privileges

Executing the `RENAME TABLE` statement requires the [DROP](#), [CREATE](#) and [INSERT](#) privileges for the table or the database.

Atomic RENAME TABLE

MariaDB starting with [10.6.1](#)

From [MariaDB 10.6](#), `RENAME TABLE` is atomic for most engines, including InnoDB, MyRocks, MyISAM and Aria ([MDEV-23842](#)). This means that if there is a crash (server down or power outage) during `RENAME TABLE`, all tables will revert to their original names and any changes to trigger files will be reverted.

In older MariaDB version there was a small chance that, during a server crash happening in the middle of `RENAME TABLE`, some tables could have been renamed (in the worst case partly) while others would not be renamed.

See [Atomic DDL](#) for more information.

1.1.1.2.1.13 REPAIR TABLE

Syntax

<= [MariaDB 11.4](#)

```
REPAIR [NO_WRITE_TO_BINLOG | LOCAL] TABLE  
      tbl_name [, tbl_name] ...  
      [QUICK] [EXTENDED] [USE_FRM]
```

>= [MariaDB 11.5](#)

```
REPAIR [NO_WRITE_TO_BINLOG | LOCAL] TABLE  
      tbl_name [, tbl_name] ...  
      [QUICK] [EXTENDED] [USE_FRM] [FORCE]
```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [QUICK](#)
 2. [EXTENDED](#)
 3. [USE_FRM](#)
 4. [FORCE](#)
 5. [Partitioned Tables](#)
 6. [Progress Reporting](#)

Description

`REPAIR TABLE` repairs a possibly corrupted table. By default, it has the same effect as

```
myisamchk --recover tbl_name
```

or

```
aria_chk --recover tbl_name
```

See [aria_chk](#) and [myisamchk](#) for more.

`REPAIR TABLE` works for [Archive](#), [Aria](#), [CSV](#) and [MyISAM](#) tables. For [InnoDB](#), see [recovery modes](#). For [CSV](#), see also [Checking and Repairing CSV Tables](#). For [Archive](#), this statement also improves compression. If the storage engine does not support this statement, a warning is issued.

This statement requires [SELECT](#) and [INSERT](#) privileges for the table.

By default, `REPAIR TABLE` statements are written to the [binary log](#) and will be [replicated](#). The `NO_WRITE_TO_BINLOG` keyword (`LOCAL` is an alias) will ensure the statement is not written to the binary log.

From [MariaDB 10.3.19](#), `REPAIR TABLE` statements are not logged to the binary log if `read_only` is set. See also [Read-Only Replicas](#).

When an index is recreated, the storage engine may use a configurable buffer in the process. Incrementing the buffer speeds up the index creation. [Aria](#) and [MyISAM](#) allocate a buffer whose size is defined by `aria_sort_buffer_size` or `myisam_sort_buffer_size`, also used for [ALTER TABLE](#).

QUICK

When specified, `REPAIR TABLE` will not modify the data file, only attempting to repair the index file. The same behavior can be achieved with `myisamchk --recover --quick`.

EXTENDED

Creates the index row by row rather than sorting and creating a single index. Similar to `myisamchk --safe-recover`.

USE_FRM

For use only when the index file is missing or its header corrupted. MariaDB then attempts to recreate it using the `.frm` file. There is no equivalent `myisamchk` option.

MariaDB starting with [11.5](#)

FORCE

The `FORCE` argument was added in [MariaDB 11.5](#) to allow one to first run internal repair to fix damaged blocks and then follow it with `ALTER TABLE` ([MDEV-33449](#)).

Partitioned Tables

`REPAIR TABLE` is also supported for [partitioned tables](#) with the `ALTER TABLE ... REPAIR PARTITION` statement. However, the `USE_FRM` option cannot be used with this statement on a partitioned table. See [Repairing Partitions](#) for details.

Progress Reporting

The [Aria](#) storage engine supports [progress reporting](#) for this statement.

1.1.1.2.1.14 REPAIR VIEW

Syntax

```
REPAIR [NO_WRITE_TO_BINLOG | LOCAL] VIEW view_name[, view_name] ... [FROM MYSQL]
```

Contents

1. [Syntax](#)
2. [Description](#)

Description

The `REPAIR VIEW` statement was introduced to assist with fixing [MDEV-6916](#), an issue introduced in [MariaDB 5.2](#) where the view algorithms were swapped compared to their MySQL on disk representation. It checks whether the view algorithm is correct. It is run as part of [mariadb-upgrade](#), and should not normally be required in regular use.

By default it corrects the checksum and if necessary adds the `mariadb-version` field. If the optional `FROM MYSQL` clause is used, and no `mariadb-version` field is present, the `MERGE` and `TEMPTABLE` algorithms are toggled.

By default, `REPAIR VIEW` statements are written to the [binary log](#) and will be [replicated](#). The `NO_WRITE_TO_BINLOG` keyword (`LOCAL` is an alias) will ensure the statement is not written to the binary log.

1.1.1.2.1.15 REPLACE

Syntax

```
REPLACE [LOW_PRIORITY | DELAYED]
[INTO] tbl_name [PARTITION (partition_list)] [(col,...)]
{VALUES | VALUE} ({expr | DEFAULT},...), (...),...
[RETURNING select_expr
[, select_expr ...]]
```

Or:

```
REPLACE [LOW_PRIORITY | DELAYED]
[INTO] tbl_name [PARTITION (partition_list)]
SET col=(expr | DEFAULT), ...
[RETURNING select_expr
[, select_expr ...]]
```

Or:

```
REPLACE [LOW_PRIORITY | DELAYED]
[INTO] tbl_name [PARTITION (partition_list)] [(col,...)]
SELECT ...
[RETURNING select_expr
[, select_expr ...]]
```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [PARTITION](#)
 2. [REPLACE RETURNING](#)
 1. [Examples](#)
3. [Examples](#)

Description

`REPLACE` works exactly like `INSERT`, except that if an old row in the table has the same value as a new row for a `PRIMARY KEY` or a `UNIQUE` index, the old row is deleted before the new row is inserted. If the table has more than one `UNIQUE` keys, it is possible that the new row conflicts with more than one row. In this case, all conflicting rows will be deleted.

The table name can be specified in the form `db_name.tbl_name` or, if a default database is selected, in the form `tbl_name` (see [Identifier Qualifiers](#)). This allows to use `REPLACE ... SELECT` to copy rows between different databases.

MariaDB starting with [10.5.0](#)

The `RETURNING` clause was introduced in [MariaDB 10.5.0](#)

Basically it works like this:

```
BEGIN;
SELECT 1 FROM t1 WHERE key=# FOR UPDATE;
IF found-row
    DELETE FROM t1 WHERE key=# ;
ENDIF
INSERT INTO t1 VALUES (...);
END;
```

The above can be replaced with:

```
REPLACE INTO t1 VALUES (...)
```

`REPLACE` is a MariaDB/MySQL extension to the SQL standard. It either inserts, or deletes and inserts. For other MariaDB/MySQL extensions to standard SQL --- that also handle duplicate values --- see [IGNORE](#) and [INSERT ON DUPLICATE KEY UPDATE](#).

Note that unless the table has a `PRIMARY KEY` or `UNIQUE` index, using a `REPLACE` statement makes no sense. It becomes equivalent to `INSERT`, because there is no index to be used to determine whether a new row duplicates another.

Values for all columns are taken from the values specified in the `REPLACE` statement. Any missing columns are set to their default values, just as happens for `INSERT`. You cannot refer to values from the current row and use them in the new row. If you use an assignment such as `'SET col = col + 1'`, the reference to the column name on the right hand side is treated as `DEFAULT(col)`, so the assignment is equivalent to `'SET col = DEFAULT(col) + 1'`.

To use `REPLACE`, you must have both the `INSERT` and `DELETE` [privileges](#) for the table.

There are some gotchas you should be aware of, before using `REPLACE`:

- If there is an `AUTO_INCREMENT` field, a new value will be generated.
- If there are foreign keys, `ON DELETE` action will be activated by `REPLACE`.
- [Triggers](#) on `DELETE` and `INSERT` will be activated by `REPLACE`.

To avoid some of these behaviors, you can use `INSERT ... ON DUPLICATE KEY UPDATE`.

This statement activates `INSERT` and `DELETE` triggers. See [Trigger Overview](#) for details.

PARTITION

See [Partition Pruning and Selection](#) for details.

REPLACE RETURNING

`REPLACE ... RETURNING` returns a resultset of the replaced rows.

This returns the listed columns for all the rows that are replaced, or alternatively, the specified `SELECT` expression. Any SQL expressions which can be calculated can be used in the select expression for the `RETURNING` clause, including virtual columns and aliases, expressions which use various operators such as bitwise, logical and arithmetic operators, string functions, date-time functions, numeric functions, control flow functions, secondary functions and stored functions. Along with this, statements which have subqueries and prepared statements can also be used.

Examples

Simple REPLACE statement

```
REPLACE INTO t2 VALUES (1,'Leopard'),(2,'Dog') RETURNING id2, id2+id2
as Total ,id2|id2, id2&&id2;
+-----+
| id2 | Total | id2|id2 | id2&&id2 |
+-----+
| 1 | 2 | 1 | 1 |
| 2 | 4 | 2 | 1 |
+-----+
```

Using stored functions in RETURNING

```
DELIMITER |
CREATE FUNCTION f(arg INT) RETURNS INT
BEGIN
RETURN (SELECT arg+arg);
END|

DELIMITER ;
PREPARE stmt FROM "REPLACE INTO t2 SET id2=3, animal2='Fox' RETURNING f2(id2),
UPPER(animal2)";

EXECUTE stmt;
+-----+
| f2(id2) | UPPER(animal2) |
+-----+
| 6 | FOX |
+-----+
```

Subqueries in the statement

```
REPLACE INTO t1 SELECT * FROM t2 RETURNING (SELECT id2 FROM t2 WHERE
id2 IN (SELECT id2 FROM t2 WHERE id2=1)) AS new_id;
+-----+
| new_id |
+-----+
| 1 |
| 1 |
| 1 |
| 1 |
+-----+
```

Subqueries in the RETURNING clause that return more than one row or column cannot be used..

Aggregate functions cannot be used in the RETURNING clause. Since aggregate functions work on a set of values and if the purpose is to get the row count, ROW_COUNT() with SELECT can be used, or it can be used in REPLACE...SEL== Description

REPLACE ... RETURNING returns a resultset of the replaced rows.

This returns the listed columns for all the rows that are replaced, or alternatively, the specified SELECT expression. Any SQL expressions which can be calculated can be used in the select expression for the RETURNING clause, including virtual columns and aliases, expressions which use various operators such as bitwise, logical and arithmetic operators, string functions, date-time functions, numeric functions, control flow functions, secondary functions and stored functions. Along with this, statements which have subqueries and prepared statements can also be used.

Examples

Simple REPLACE statement

```
REPLACE INTO t2 VALUES (1,'Leopard'),(2,'Dog') RETURNING id2, id2+id2
as Total ,id2|id2, id2&&id2;
+-----+
| id2 | Total | id2|id2 | id2&&id2 |
+-----+
| 1 | 2 | 1 | 1 |
| 2 | 4 | 2 | 1 |
+-----+
```

```

DELIMITER |
CREATE FUNCTION f(arg INT) RETURNS INT
  BEGIN
    RETURN (SELECT arg+arg);
  END|

DELIMITER ;
PREPARE stmt FROM "REPLACE INTO t2 SET id2=3, animal2='Fox' RETURNING f2(id2),
UPPER(animal2)";

EXECUTE stmt;
+-----+
| f2(id2) | UPPER(animal2) |
+-----+
|      6 | FOX             |
+-----+

```

Subqueries in the statement

```

REPLACE INTO t1 SELECT * FROM t2 RETURNING (SELECT id2 FROM t2 WHERE
id2 IN (SELECT id2 FROM t2 WHERE id2=1)) AS new_id;
+-----+
| new_id |
+-----+
|      1 |
|      1 |
|      1 |
|      1 |
+-----+

```

Subqueries in the RETURNING clause that return more than one row or column cannot be used..

Aggregate functions cannot be used in the RETURNING clause. Since aggregate functions work on a set of values and if the purpose is to get the row count, ROW_COUNT() with SELECT can be used, or it can be used in REPLACE...SELECT...RETURNING if the table in the RETURNING clause is not the same as the REPLACE table. ECT...RETURNING if the table in the RETURNING clause is not the same as the REPLACE table.

1.1.1.2.1.16 SHOW COLUMNS

Syntax

```

SHOW [FULL] {COLUMNS | FIELDS} FROM tbl_name [FROM db_name]
[LIKE 'pattern' | WHERE expr]

```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

Description

SHOW COLUMNS displays information about the columns in a given table. It also works for views. The LIKE clause, if present on its own, indicates which column names to match. The WHERE and LIKE clauses can be given to select rows using more general conditions, as discussed in [Extended SHOW](#).

If the data types differ from what you expect them to be based on a CREATE TABLE statement, note that MariaDB sometimes changes data types when you create or alter a table. The conditions under which this occurs are described in the [Silent Column Changes](#) article.

The FULL keyword causes the output to include the column collation and comments, as well as the privileges you have for each column.

You can use db_name.tbl_name as an alternative to the tbl_name FROM db_name syntax. In other words, these two statements are equivalent:

```
SHOW COLUMNS FROM mytable FROM mydb;
SHOW COLUMNS FROM mydb.mytable;
```

`SHOW COLUMNS` displays the following values for each table column:

Field indicates the column name.

Type indicates the column data type.

Collation indicates the collation for non-binary string columns, or NULL for other columns. This value is displayed only if you use the `FULL` keyword.

The **Null** field contains YES if NULL values can be stored in the column, NO if not.

The **Key** field indicates whether the column is indexed:

- If **Key** is empty, the column either is not indexed or is indexed only as a secondary column in a multiple-column, non-unique index.
- If **Key** is **PRI**, the column is a `PRIMARY KEY` or is one of the columns in a multiple-column `PRIMARY KEY`.
- If **Key** is **UNI**, the column is the first column of a unique-valued index that cannot contain `NULL` values.
- If **Key** is **MUL**, multiple occurrences of a given value are allowed within the column. The column is the first column of a non-unique index or a unique-valued index that can contain `NULL` values.

If more than one of the **Key** values applies to a given column of a table, **Key** displays the one with the highest priority, in the order PRI, UNI, MUL.

A `UNIQUE` index may be displayed as **PRI** if it cannot contain `NULL` values and there is no `PRIMARY KEY` in the table. A `UNIQUE` index may display as **MUL** if several columns form a composite `UNIQUE` index; although the combination of the columns is unique, each column can still hold multiple occurrences of a given value.

The **Default** field indicates the default value that is assigned to the column.

The **Extra** field contains any additional information that is available about a given column.

Value	Description
<code>AUTO_INCREMENT</code>	The column was created with the <code>AUTO_INCREMENT</code> keyword.
<code>PERSISTENT</code>	The column was created with the <code>PERSISTENT</code> keyword. (New in 5.3)
<code>VIRTUAL</code>	The column was created with the <code>VIRTUAL</code> keyword. (New in 5.3)
<code>on update CURRENT_TIMESTAMP</code>	The column is a <code>TIMESTAMP</code> column that is automatically updated on <code>INSERT</code> and <code>UPDATE</code> .

Privileges indicates the privileges you have for the column. This value is displayed only if you use the `FULL` keyword.

Comment indicates any comment the column has. This value is displayed only if you use the `FULL` keyword.

`SHOW FIELDS` is a synonym for `SHOW COLUMNS`. Also `DESCRIBE` and `EXPLAIN` can be used as shortcuts.

You can also list a table's columns with:

```
mariadb-show db_name tbl_name
```

See the [mariadb-show](#) command for more details.

The `DESCRIBE` statement provides information similar to `SHOW COLUMNS`. The `information_schema.COLUMNS` table provides similar, but more complete, information.

The `SHOW CREATE TABLE`, `SHOW TABLE STATUS`, and `SHOW INDEX` statements also provide information about tables.

Examples

```
SHOW COLUMNS FROM city;
```

Field	Type	Null	Key	Default	Extra
Id	int(11)	NO	PRI	NULL	auto_increment
Name	char(35)	NO			
Country	char(3)	NO	UNI		
District	char(20)	YES	MUL		
Population	int(11)	NO		0	

```
SHOW COLUMNS FROM employees WHERE Type LIKE 'Varchar%';
```

Field	Type	Null	Key	Default	Extra
first_name	varchar(30)	NO	MUL	NULL	
last_name	varchar(40)	NO		NULL	
position	varchar(25)	NO		NULL	
home_address	varchar(50)	NO		NULL	
home_phone	varchar(12)	NO		NULL	
employee_code	varchar(25)	NO	UNI	NULL	

1.1.1.2.1.17 SHOW CREATE TABLE

Syntax

```
SHOW CREATE TABLE tbl_name
```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [Index Order](#)
3. [Examples](#)

Description

Shows the [CREATE TABLE](#) statement that creates the given table. The statement requires the [SELECT privilege](#) for the table. This statement also works with [views](#) and [SEQUENCE](#).

`SHOW CREATE TABLE` quotes table and column names according to the value of the [sql_quote_show_create](#) server system variable.

Certain [SQL_MODE](#) values can result in parts of the original [CREATE](#) statement not being included in the output. MariaDB-specific table options, column options, and index options are not included in the output of this statement if the [NO_TABLE_OPTIONS](#), [NO_FIELD_OPTIONS](#) and [NO_KEY_OPTIONS SQL_MODE](#) flags are used. All MariaDB-specific table attributes are also not shown when a non-MariaDB/MySQL emulation mode is used, which includes [ANSI](#), [DB2](#), [POSTGRESQL](#), [MSSQL](#), [MAXDB](#) or [ORACLE](#).

Invalid table options, column options and index options are normally commented out (note, that it is possible to create a table with invalid options, by altering a table of a different engine, where these options were valid). To have them uncommented, enable the [IGNORE_BAD_TABLE_OPTIONS SQL_MODE](#). Remember that replaying a [CREATE TABLE](#) statement with uncommented invalid options will fail with an error, unless the [IGNORE_BAD_TABLE_OPTIONS SQL_MODE](#) is in effect.

Note that `SHOW CREATE TABLE` is not meant to provide metadata about a table. It provides information about how the table was declared, but the real table structure could differ a bit. For example, if an index has been declared as `HASH`, the `CREATE TABLE` statement returned by `SHOW CREATE TABLE` will declare that index as `HASH`; however, it is possible that the index is in fact a `BTREE`, because the storage engine does not support `HASH`.

MariaDB permits [TEXT](#) and [BLOB](#) data types to be assigned a [DEFAULT](#) value. As a result, `SHOW CREATE TABLE` will append a `DEFAULT NULL` to nullable [TEXT](#) or [BLOB](#) fields if no specific default is provided.

Numbers are no longer quoted in the `DEFAULT` clause in `SHOW CREATE` statement. Prior to [MariaDB 10.2.2](#), MariaDB quoted numbers.

Index Order

Indexes are sorted and displayed in the following order, which may differ from the order of the `CREATE TABLE` statement.

- PRIMARY KEY
- UNIQUE keys where all column are NOT NULL
- UNIQUE keys that don't contain partial segments
- Other UNIQUE keys
- LONG UNIQUE keys
- Normal keys
- Fulltext keys

See `sql/sql_table.cc` for details.

Examples

```
SHOW CREATE TABLE t\G
***** 1. row *****
      Table: t
Create Table: CREATE TABLE `t` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `s` char(60) DEFAULT NULL,
  PRIMARY KEY (`id`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

With `sql_quote_show_create` off:

```
SHOW CREATE TABLE t\G
***** 1. row *****
      Table: t
Create Table: CREATE TABLE t (
  id int(11) NOT NULL AUTO_INCREMENT,
  s char(60) DEFAULT NULL,
  PRIMARY KEY (id)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

Unquoted numeric DEFAULTs, from [MariaDB 10.2.2](#):

```
CREATE TABLE td (link TINYINT DEFAULT 1);

SHOW CREATE TABLE td\G
***** 1. row *****
      Table: td
Create Table: CREATE TABLE `td` (
  `link` tinyint(4) DEFAULT 1
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

Quoted numeric DEFAULTs, until [MariaDB 10.2.1](#):

```
CREATE TABLE td (link TINYINT DEFAULT 1);

SHOW CREATE TABLE td\G
***** 1. row *****
      Table: td
Create Table: CREATE TABLE `td` (
  `link` tinyint(4) DEFAULT '1'
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

`SQL_MODE` impacting the output:

```

SELECT @@sql_mode;
+-----+
| @@sql_mode |
+-----+
| STRICT_TRANS_TABLES,ERROR_FOR_DIVISION_BY_ZERO,NO_AUTO_CREATE_USER,NO_ENGINE_SUBSTITUTION |
+-----+

CREATE TABLE `t1` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `msg` varchar(100) DEFAULT NULL,
  PRIMARY KEY (`id`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
;

SHOW CREATE TABLE t1\G
***** 1. row *****
      Table: t1
Create Table: CREATE TABLE `t1` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `msg` varchar(100) DEFAULT NULL,
  PRIMARY KEY (`id`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1

SET SQL_MODE=ORACLE;

SHOW CREATE TABLE t1\G
***** 1. row *****
      Table: t1
Create Table: CREATE TABLE "t1" (
  "id" int(11) NOT NULL,
  "msg" varchar(100) DEFAULT NULL,
  PRIMARY KEY ("id")

```

1.1.1.2.1.18 SHOW INDEX

Syntax

```

SHOW {INDEX | INDEXES | KEYS}
FROM tbl_name [FROM db_name]
[WHERE expr]

```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

Description

`SHOW INDEX` returns table index information. The format resembles that of the `SQLStatistics` call in ODBC.

You can use `db_name.tbl_name` as an alternative to the `tbl_name FROM db_name` syntax. These two statements are equivalent:

```

SHOW INDEX FROM mytable FROM mydb;
SHOW INDEX FROM mydb.mytable;

```

`SHOW KEYS` and `SHOW INDEXES` are synonyms for `SHOW INDEX`.

You can also list a table's indexes with the `mariadb-show` command:

```

mariadb-show -k db_name tbl_name

```

The `information_schema.STATISTICS` table stores similar information.

The following fields are returned by `SHOW INDEX`.

Field	Description
Table	Table name
Non_unique	1 if the index permits duplicate values, 0 if values must be unique.
Key_name	Index name. The primary key is always named <code>PRIMARY</code> .
Seq_in_index	The column's sequence in the index, beginning with 1.
Column_name	Column name.
Collation	Either <code>A</code> , if the column is sorted in ascending order in the index, or <code>NULL</code> if it's not sorted.
Cardinality	Estimated number of unique values in the index. The cardinality statistics are calculated at various times, and can help the optimizer make improved decisions.
Sub_part	<code>NULL</code> if the entire column is included in the index, or the number of included characters if not.
Packed	<code>NULL</code> if the index is not packed, otherwise how the index is packed.
Null	<code>NULL</code> if <code>NULL</code> values are permitted in the column, an empty string if <code>NULL</code> s are not permitted.
Index_type	The index type, which can be <code>BTREE</code> , <code>FULLTEXT</code> , <code>HASH</code> or <code>RTREE</code> . See Storage Engine Index Types .
Comment	Other information, such as whether the index is disabled.
Index_comment	Contents of the <code>COMMENT</code> attribute when the index was created.
Ignored	Whether or not an index will be ignored by the optimizer. See Ignored Indexes . From MariaDB 10.6.0 .

The `WHERE` and `LIKE` clauses can be given to select rows using more general conditions, as discussed in [Extended SHOW](#).

Examples

```
CREATE TABLE IF NOT EXISTS `employees_example` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `first_name` varchar(30) NOT NULL,
  `last_name` varchar(40) NOT NULL,
  `position` varchar(25) NOT NULL,
  `home_address` varchar(50) NOT NULL,
  `home_phone` varchar(12) NOT NULL,
  `employee_code` varchar(25) NOT NULL,
  PRIMARY KEY (`id`),
  UNIQUE KEY `employee_code` (`employee_code`),
  KEY `first_name` (`first_name`,`last_name`)
) ENGINE=Aria;

INSERT INTO `employees_example` (`first_name`, `last_name`, `position`, `home_address`,
`home_phone`, `employee_code`)
VALUES
('Mustapha', 'Mond', 'Chief Executive Officer', '692 Promiscuous Plaza', '326-555-3492',
'MM1'),
('Henry', 'Foster', 'Store Manager', '314 Savage Circle', '326-555-3847', 'HF1'),
('Bernard', 'Marx', 'Cashier', '1240 Ambient Avenue', '326-555-8456', 'BM1'),
('Lenina', 'Crowne', 'Cashier', '281 Bumblepuppy Boulevard', '328-555-2349', 'LC1'),
('Fanny', 'Crowne', 'Restocker', '1023 Bokanovsky Lane', '326-555-6329', 'FC1'),
('Helmholtz', 'Watson', 'Janitor', '944 Soma Court', '329-555-2478', 'HW1');
```

```

SHOW INDEXES FROM employees_example\G
***** 1. row *****
      Table: employees_example
      Non_unique: 0
      Key_name: PRIMARY
      Seq_in_index: 1
      Column_name: id
      Collation: A
      Cardinality: 6
      Sub_part: NULL

```

1.1.1.2.1.19 TRUNCATE TABLE

Syntax

```

TRUNCATE [TABLE] tbl_name
[WAIT n | NOWAIT]

```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [WAIT/NOWAIT](#)
 2. [Oracle-mode](#)
 3. [Performance](#)

Description

`TRUNCATE TABLE` empties a table completely. It requires the `DROP` privilege. See [GRANT](#).

`tbl_name` can also be specified in the form `db_name.tbl_name` (see [Identifier Qualifiers](#)).

Logically, `TRUNCATE TABLE` is equivalent to a `DELETE` statement that deletes all rows, but there are practical differences under some circumstances.

`TRUNCATE TABLE` will fail for an [InnoDB table](#) if any `FOREIGN KEY` constraints from other tables reference the table, returning the error:

```
ERROR 1701 (42000): Cannot truncate a table referenced in a foreign key constraint
```

Foreign Key constraints between columns in the same table are permitted.

For an [InnoDB table](#), if there are no `FOREIGN KEY` constraints, [InnoDB](#) performs fast truncation by dropping the original table and creating an empty one with the same definition, which is much faster than deleting rows one by one. The [AUTO_INCREMENT](#) counter is reset by `TRUNCATE TABLE`, regardless of whether there is a `FOREIGN KEY` constraint.

The count of rows affected by `TRUNCATE TABLE` is accurate only when it is mapped to a `DELETE` statement.

For other storage engines, `TRUNCATE TABLE` differs from `DELETE` in the following ways:

- Truncate operations drop and re-create the table, which is much faster than deleting rows one by one, particularly for large tables.
- Truncate operations cause an implicit commit.
- Truncation operations cannot be performed if the session holds an active table lock.
- Truncation operations do not return a meaningful value for the number of deleted rows. The usual result is "0 rows affected," which should be interpreted as "no information."
- As long as the table format file `tbl_name.frm` is valid, the table can be re-created as an empty table with `TRUNCATE TABLE`, even if the data or index files have become corrupted.
- The table handler does not remember the last used [AUTO_INCREMENT](#) value, but starts counting from the beginning. This is true even for [MyISAM](#) and [InnoDB](#), which normally do not reuse sequence values.
- When used with partitioned tables, `TRUNCATE TABLE` preserves the partitioning; that is, the data and index files are dropped and re-created, while the partition definitions (`.par`) file is unaffected.
- Since truncation of a table does not make any use of `DELETE`, the `TRUNCATE` statement does not invoke `ON DELETE` triggers.
- `TRUNCATE TABLE` will only reset the values in the [Performance Schema summary tables](#) to zero or null, and will not remove the rows.

For the purposes of binary logging and [replication](#), `TRUNCATE TABLE` is treated as `DROP TABLE` followed by `CREATE TABLE` (DDL rather than DML).

`TRUNCATE TABLE` does not work on [views](#). Currently, `TRUNCATE TABLE` drops all historical records from a [system-versioned table](#).

WAIT/NOWAIT

Set the lock wait timeout. See [WAIT and NOWAIT](#).

Oracle-mode

[Oracle-mode](#) from [MariaDB 10.3](#) permits the optional keywords `REUSE STORAGE` or `DROP STORAGE` to be used.

```
TRUNCATE [TABLE] tbl_name [{DROP | REUSE} STORAGE] [WAIT n | NOWAIT]
```

These have no effect on the operation.

Performance

`TRUNCATE TABLE` is faster than `DELETE`, because it drops and re-creates a table.

With `InnoDB`, `TRUNCATE TABLE` is slower if `innodb_file_per_table=ON` is set (the default). This is because `TRUNCATE TABLE` unlinks the underlying tablespace file, which can be an expensive operation. See [MDEV-8069](#) for more details.

The performance issues with `innodb_file_per_table=ON` can be exacerbated in cases where the `InnoDB` buffer pool is very large and `innodb_adaptive_hash_index=ON` is set. In that case, using `DROP TABLE` followed by `CREATE TABLE` instead of `TRUNCATE TABLE` may perform better. Setting `innodb_adaptive_hash_index=OFF` (it defaults to `ON` before `MariaDB 10.5`) can also help. In `MariaDB 10.2` only, from `MariaDB 10.2.19`, this performance can also be improved by setting `innodb_safe_truncate=OFF`. See [MDEV-9459](#) for more details.

Setting `innodb_adaptive_hash_index=OFF` can also improve `TRUNCATE TABLE` performance in general. See [MDEV-16796](#) for more details.

1.1.1.2.1.20 UPDATE

Syntax

Single-table syntax:

```
UPDATE [LOW_PRIORITY] [IGNORE] table_reference
  [PARTITION (partition_list)]
  [FOR PORTION OF period FROM expr1 TO expr2]
  SET col1={expr1|DEFAULT} [, col2={expr2|DEFAULT}] ...
  [WHERE where_condition]
  [ORDER BY ...]
  [LIMIT row_count]
```

Multiple-table syntax:

```
UPDATE [LOW_PRIORITY] [IGNORE] table_references
  SET col1={expr1|DEFAULT} [, col2={expr2|DEFAULT}] ...
  [WHERE where_condition]
```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [PARTITION](#)
 2. [FOR PORTION OF](#)
 3. [UPDATE Statements With the Same Source and Target](#)
3. [Example](#)

Description

For the single-table syntax, the `UPDATE` statement updates columns of existing rows in the named table with new values. The `SET` clause indicates which columns to modify and the values they should be given. Each value can be given as an expression, or the keyword `DEFAULT` to set a column explicitly to its default value. The `WHERE` clause, if given, specifies the conditions that identify which rows to update. With no `WHERE` clause, all rows are updated. If the `ORDER BY` clause is specified, the rows are updated in the order that is specified. The `LIMIT` clause places a limit on the number of rows that can be updated.

Both clauses can be used with multiple-table updates. Prior to `MariaDB 10.3`, for the multiple-table syntax, `UPDATE` updates rows in each table named in `table_references` that satisfy the conditions. In this case, `ORDER BY` and `LIMIT` could not be used.

An `UPDATE` can also reference tables which are located in different databases; see [Identifier Qualifiers](#) for the syntax.

`where_condition` is an expression that evaluates to true for each row to be updated.

`table_references` and `where_condition` are as specified as described in [SELECT](#).

For single-table updates, assignments are evaluated in left-to-right order, while for multi-table updates, there is no guarantee of a particular order. If the `SIMULTANEOUS_ASSIGNMENT` `sql_mode` is set, `UPDATE` statements evaluate all assignments simultaneously.

You need the `UPDATE` privilege only for columns referenced in an `UPDATE` that are actually updated. You need only the `SELECT` privilege for any columns that are read but not modified. See [GRANT](#).

The `UPDATE` statement supports the following modifiers:

- If you use the `LOW_PRIORITY` keyword, execution of the `UPDATE` is delayed until no other clients are reading from the table. This affects only storage engines that use only table-level locking (MyISAM, MEMORY, MERGE). See [HIGH_PRIORITY and LOW_PRIORITY clauses](#) for details.
- If you use the `IGNORE` keyword, the update statement does not abort even if errors occur during the update. Rows for which duplicate-key conflicts occur are not updated. Rows for which columns are updated to values that would cause data conversion errors are updated to the closest valid values instead.

PARTITION

See [Partition Pruning and Selection](#) for details.

FOR PORTION OF

See [Application Time Periods - Updating by Portion](#).

UPDATE Statements With the Same Source and Target

`UPDATE` statements may have the same source and target. For example, given the following table:

```
DROP TABLE t1;
CREATE TABLE t1 (c1 INT, c2 INT);
INSERT INTO t1 VALUES (10,10), (20,20);

UPDATE t1 SET c1=c1+1 WHERE c2=(SELECT MAX(c2) FROM t1);

SELECT * FROM t1;
+-----+-----+
| c1   | c2   |
+-----+-----+
| 10  | 10  |
| 21  | 20  |
+-----+-----+
```

Example

Single-table syntax:

```
UPDATE table_name SET column1 = value1, column2 = value2 WHERE id=100;
```

Multiple-table syntax:

```
UPDATE tab1, tab2 SET tab1.column1 = value1, tab1.column2 = value2 WHERE tab1.id = tab2.id;
```

1.1.1.2.1.21 IGNORE

The `IGNORE` option tells the server to ignore some common errors.

`IGNORE` can be used with the following statements:

- [DELETE](#)
- [INSERT](#) (see also [INSERT IGNORE](#))
- [LOAD DATA INFILE](#)
- [UPDATE](#)
- [ALTER TABLE](#)
- [CREATE TABLE ... SELECT](#)
- [INSERT ... SELECT](#)

The logic used:

- Variables out of ranges are replaced with the maximum/minimum value.
- `SQL_MODEs` `STRICT_TRANS_TABLES`, `STRICT_ALL_TABLES`, `NO_ZERO_IN_DATE`, `NO_ZERO_DATE` are ignored.
- Inserting `NULL` in a `NOT NULL` field will insert 0 (in a numerical field), 0000-00-00 (in a date field) or an empty string (in a character field).

- Rows that cause a duplicate key error or break a foreign key constraint are not inserted, updated, or deleted.

The following errors are ignored:

Error number	Symbolic error name	Description
1022	ER_DUP_KEY	Can't write; duplicate key in table '%s'
1048	ER_BAD_NULL_ERROR	Column '%s' cannot be null
1062	ER_DUP_ENTRY	Duplicate entry '%s' for key %d
1242	ER_SUBQUERY_NO_1_ROW	Subquery returns more than 1 row
1264	ER_WARN_DATA_OUT_OF_RANGE	Out of range value for column '%s' at row %ld
1265	WARN_DATA_TRUNCATED	Data truncated for column '%s' at row %ld
1292	ER_TRUNCATED_WRONG_VALUE	Truncated incorrect %s value: '%s'
1366	ER_TRUNCATED_WRONG_VALUE_FOR_FIELD	Incorrect integer value
1369	ER_VIEW_CHECK_FAILED	CHECK OPTION failed '%s.%s'
1451	ER_ROW_IS_REFERENCED_2	Cannot delete or update a parent row
1452	ER_NO_REFERENCED_ROW_2	Cannot add or update a child row: a foreign key constraint fails (%s)
1526	ER_NO_PARTITION_FOR_GIVEN_VALUE	Table has no partition for value %s
1586	ER_DUP_ENTRY_WITH_KEY_NAME	Duplicate entry '%s' for key '%s'
1591	ER_NO_PARTITION_FOR_GIVEN_VALUE_SILENT	Table has no partition for some existing values
1748	ER_ROW_DOES_NOT_MATCH_GIVEN_PARTITION_SET	Found a row not matching the given partition set

Ignored errors normally generate a warning.

A property of the `IGNORE` clause consists in causing transactional engines and non-transactional engines (like InnoDB and Aria) to behave the same way. For example, normally a multi-row insert which tries to violate a `UNIQUE` constraint is completely rolled back on InnoDB, but might be partially executed on Aria. With the `IGNORE` clause, the statement will be partially executed in both engines.

Duplicate key errors also generate warnings. The `OLD_MODE` server variable can be used to prevent this.

1.1.7.1 System-Versioned Tables

1.1.1.2.2 ANALYZE and EXPLAIN Statements

ANALYZE FORMAT=JSON

Mix of the `EXPLAIN FORMAT=JSON` and `ANALYZE` statement features.

ANALYZE FORMAT=JSON Examples

Examples with `ANALYZE FORMAT=JSON`.

ANALYZE Statement

Invokes the optimizer, executes the statement, and then produces `EXPLAIN` output.

ANALYZE: Interpreting rows and filtered members

This article describes how to interpret `r_rows` and `r_filtered members` in `AN...` [↗](#)

EXPLAIN

`EXPLAIN` returns information about index usage, as well as being a synonym for `DESCRIBE`.

EXPLAIN ANALYZE

Old implementation, now `ANALYZE` statement

EXPLAIN FORMAT=JSON

Variant of `EXPLAIN` that produces output in JSON form

SHOW EXPLAIN

Shows an execution plan for a running query.

Using Buffer UPDATE Algorithm

Explanation of UPDATE's "Using Buffer" algorithm.

1.1.1.2.2.1 ANALYZE FORMAT=JSON

Contents

1. [Basic Execution Data](#)
2. [Advanced Execution Data](#)
 1. [InnoDB engine statistics](#)
3. [SHOW ANALYZE FORMAT=JSON](#)
4. [Data About Individual Query Plan Nodes](#)
5. [Use Cases](#)

`ANALYZE FORMAT=JSON` is a mix of the `EXPLAIN FORMAT=JSON` and `ANALYZE` statement features. The `ANALYZE FORMAT=JSON $statement` will execute `$statement`, and then print the output of `EXPLAIN FORMAT=JSON`, amended with data from the query execution.

Basic Execution Data

You can get the following also from tabular `ANALYZE` statement form:

- `r_rows` is provided for any node that reads rows. It shows how many rows were read, on average
- `r_filtered` is provided whenever there is a condition that is checked. It shows the percentage of rows left after checking the condition.

Advanced Execution Data

The most important data not available in the regular tabular `ANALYZE` statement are:

- `r_loops` field. This shows how many times the node was executed. Most query plan elements have this field.
- `r_total_time_ms` field. It shows how much time in total, in milliseconds, was spent executing this node. If the node has subnodes, their execution time is included.
 - For UPDATE and DELETE statements, top-level `query_block.r_total_time_ms` does include the time to make row deletions/updates but does NOT include the time to commit the changes.
- `r_buffer_size` field. Query plan nodes that make use of buffers report the size of buffer that was used.

InnoDB engine statistics

Starting from [MariaDB 10.6.15](#), [MariaDB 10.8.8](#), [MariaDB 10.9.8](#), [MariaDB 10.10.6](#), [MariaDB 10.11.5](#), [MariaDB 11.0.3](#), [MariaDB 11.1.2](#) and [MariaDB 11.2.1 \(MDEV-31577\)](#), the following statistics are reported for InnoDB tables:

```

"r_engine_stats": {
  "pages_accessed": integer,
  "pages_updated": integer,
  "pages_read_count": integer,
  "pages_prefetch_read_count": integer,
  "pages_read_time_ms": double,
  "old_rows_read": integer
}

```

Only non-zero members are printed.

- `pages_accessed` is the total number of buffer pool pages accessed when reading this table.
- `pages_updated` is the total number of buffer pool pages that were modified during the execution of the statement.
- `pages_read_count` is the number of pages that InnoDB had to read from disk for this table. If the query touches "hot" data in the InnoDB buffer pool, this value will be 0 and not present.
- `pages_prefetch_read_count` Number of pages for which read-ahead was initiated. Not all such pages will necessarily be accessed.
- `pages_read_time_ms` is the total time spent reading the table.
- `old_rows_read` is the number of old row versions that InnoDB had to read. Old row version is the version of the row that is not visible to this transaction.

SHOW ANALYZE FORMAT=JSON

MariaDB starting with [10.9](#)

`SHOW ANALYZE FORMAT=JSON` for `<connection_id>` extends `ANALYZE [FORMAT=JSON] <select>` to allow one to analyze a query currently running in another connection.

Data About Individual Query Plan Nodes

- `filesort` node reports whether sorting was done with `LIMIT n` parameter, and how many rows were in the sort result.
- `block-nl-join` node has `r_loops` field, which allows to tell whether `Using join buffer` was efficient
- `range-checked-for-each-record` reports counters that show the result of the check.
- `expression-cache` is used for subqueries, and it reports how many times the cache was used, and what cache hit ratio was.
- `union_result` node has `r_rows` so one can see how many rows were produced after UNION operation
- and so forth

Use Cases

See [Examples of ANALYZE FORMAT=JSON](#).

1.1.1.2.2.2 ANALYZE FORMAT=JSON Examples

Example #1

Customers who have ordered more than 1M goods.

```
ANALYZE FORMAT=JSON
SELECT COUNT(*)
FROM customer
WHERE
  (SELECT SUM(o_totalprice) FROM orders WHERE o_custkey=c_custkey) > 1000*1000;
```

The query takes 40 seconds over cold cache

```

EXPLAIN: {
  "query_block": {
    "select_id": 1,
    "r_loops": 1,
    "r_total_time_ms": 39872,
    "table": {
      "table_name": "customer",
      "access_type": "index",
      "key": "i_c_nationkey",
      "key_length": "5",
      "used_key_parts": ["c_nationkey"],
      "r_loops": 1,
      "rows": 150303,
      "r_rows": 150000,
      "r_total_time_ms": 270.3,
      "filtered": 100,
      "r_filtered": 60.691,
      "attached_condition": "((subquery#2) > <cache>((1000 * 1000))",
      "using_index": true
    },
  },
  "subqueries": [
    {
      "query_block": {
        "select_id": 2,
        "r_loops": 150000,
        "r_total_time_ms": 39531,
        "table": {
          "table_name": "orders",
          "access_type": "ref",
          "possible_keys": ["i_o_custkey"],
          "key": "i_o_custkey",
          "key_length": "5",
          "used_key_parts": ["o_custkey"],
          "ref": ["dbt3sf1.customer.c_custkey"],
          "r_loops": 150000,
          "rows": 7,
          "r_rows": 10,
          "r_total_time_ms": 39208,
          "filtered": 100,
          "r_filtered": 100
        }
      }
    }
  ]
}

```

`ANALYZE` shows that 39.2 seconds were spent in the subquery, which was executed 150K times (for every row of outer table).

1.1.1.2.2.3 ANALYZE Statement

Contents

1. [Description](#)
2. [Command Output](#)
3. [Interpreting the Output](#)
 1. [Joins](#)
 2. [Meaning of NULL in r_rows and r_filtered](#)
4. [ANALYZE FORMAT=JSON](#)
5. [Notes](#)

Description

The `ANALYZE` statement is similar to the `EXPLAIN` statement. `ANALYZE` statement will invoke the optimizer, execute

the statement, and then produce `EXPLAIN` output instead of the result set. The `EXPLAIN` output will be annotated with statistics from statement execution.

This lets one check how close the optimizer's estimates about the query plan are to the reality. `ANALYZE` produces an overview, while the `ANALYZE FORMAT=JSON` command provides a more detailed view of the query plan and the query execution.

The syntax is

```
ANALYZE explainable_statement;
```

where the statement is any statement for which one can run `EXPLAIN`.

Command Output

Consider an example:

```
ANALYZE SELECT * FROM tbl1
WHERE key1
      BETWEEN 10 AND 200 AND
      col1 LIKE 'foo%'\G
```

```
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: tbl1
         type: range
possible_keys: key1
          key: key1
         key_len: 5
          ref: NULL
         rows: 181
        r_rows: 181
       filtered: 100.00
      r_filtered: 10.50
         Extra: Using index condition; Using where
```

Compared to `EXPLAIN`, `ANALYZE` produces two extra columns:

- `r_rows` is an observation-based counterpart of the `rows` column. It shows how many rows were actually read from the table.
- `r_filtered` is an observation-based counterpart of the `filtered` column. It shows which fraction of rows was left after applying the `WHERE` condition.

Interpreting the Output

Joins

Let's consider a more complicated example.

```
ANALYZE SELECT *
FROM orders, customer
WHERE
  customer.c_custkey=orders.o_custkey AND
  customer.c_acctbal < 0 AND
  orders.o_totalprice > 200*1000
```

```

+----+-----+-----+-----+-----+-----+-----+-----+
| id | select_type | table | type | possible_keys | key | key_len | ref |
| rows | r_rows | filtered | r_filtered | Extra | | | |
+----+-----+-----+-----+-----+-----+-----+-----+
| 1 | SIMPLE | customer | ALL | PRIMARY,... | NULL | NULL | NULL |
| 149095 | 150000 | 18.08 | 9.13 | Using where | | | |
| 1 | SIMPLE | orders | ref | i_o_custkey | i_o_custkey | 5 | |
customer.c_custkey | 7 | 10 | 100.00 | 30.03 | Using where | | |
+----+-----+-----+-----+-----+-----+-----+

```

Here, one can see that

- For table customer, **customer.rows=149095, customer.r_rows=150000**. The estimate for number of rows we will read was fairly precise
- **customer.filtered=18.08, customer.r_filtered=9.13**. The optimizer somewhat overestimated the number of records that will match selectivity of condition attached to `customer` table (in general, when you have a full scan and `r_filtered` is less than 15%, it's time to consider adding an appropriate index).
- For table orders, **orders.rows=7, orders.r_rows=10**. This means that on average, there are 7 orders for a given `c_custkey`, but in our case there were 10, which is close to the expectation (when this number is consistently far from the expectation, it may be time to run `ANALYZE TABLE`, or even edit the table statistics manually to get better query plans).
- **orders.filtered=100, orders.r_filtered=30.03**. The optimizer didn't have any way to estimate which fraction of records will be left after it checks the condition that is attached to table orders (it's `orders.o_totalprice > 200*1000`). So, it used 100%. In reality, it is 30%. 30% is typically not selective enough to warrant adding new indexes. For joins with many tables, it might be worth to collect and use [column statistics](#) for columns in question, this may help the optimizer to pick a better query plan.

Meaning of NULL in r_rows and r_filtered

Let's modify the previous example slightly

```

ANALYZE SELECT *
FROM orders, customer
WHERE
  customer.c_custkey=orders.o_custkey AND
  customer.c_acctbal < -0 AND
  customer.c_comment LIKE '%foo%' AND
  orders.o_totalprice > 200*1000;

```

```

+----+-----+-----+-----+-----+-----+-----+-----+
| id | select_type | table | type | possible_keys | key | key_len | ref |
| rows | r_rows | filtered | r_filtered | Extra | | | |
+----+-----+-----+-----+-----+-----+-----+
| 1 | SIMPLE | customer | ALL | PRIMARY,... | NULL | NULL | NULL |
| 149095 | 150000 | 18.08 | 0.00 | Using where | | | |
| 1 | SIMPLE | orders | ref | i_o_custkey | i_o_custkey | 5 | |
customer.c_custkey | 7 | NULL | 100.00 | NULL | Using where | | |
+----+-----+-----+-----+-----+-----+-----+

```

Here, one can see that **orders.r_rows=NULL** and **orders.r_filtered=NULL**. This means that table orders was not scanned even once. Indeed, we can also see `customer.r_filtered=0.00`. This shows that a part of WHERE attached to table `customer` was never satisfied (or, satisfied in less than 0.01% of cases).

ANALYZE FORMAT=JSON

[ANALYZE FORMAT=JSON](#) produces JSON output. It produces much more information than tabular `ANALYZE`.

Notes

- `ANALYZE UPDATE` or `ANALYZE DELETE` will actually make updates/deletes (`ANALYZE SELECT` will perform the

- select operation and then discard the resultset).
- PostgreSQL has a similar command, `EXPLAIN ANALYZE`.
- The [EXPLAIN in the slow query log](#) feature allows MariaDB to have `ANALYZE` output of slow queries printed into the [slow query log](#) (see [MDEV-6388](#)).

1.1.1.2.2.4 EXPLAIN

Syntax

```
EXPLAIN tbl_name [col_name | wild]
```

Or

```
EXPLAIN [EXTENDED | PARTITIONS | FORMAT=JSON]
{SELECT select_options | UPDATE update_options | DELETE delete_options}
```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [Columns in EXPLAIN ... SELECT](#)
 1. ["Select_type" Column](#)
 2. ["Type" Column](#)
 3. ["Extra" Column](#)
 2. [EXPLAIN EXTENDED](#)
3. [Examples](#)
 1. [Example of ref_or_null Optimization](#)

Description

The `EXPLAIN` statement can be used either as a synonym for `DESCRIBE` or as a way to obtain information about how MariaDB executes a `SELECT`, `UPDATE` or `DELETE` statement:

- `'EXPLAIN tbl_name'` is synonymous with `'DESCRIBE tbl_name'` or `'SHOW COLUMNS FROM tbl_name'`.
- When you precede a `SELECT`, `UPDATE` or a `DELETE` statement with the keyword `EXPLAIN`, MariaDB displays information from the optimizer about the query execution plan. That is, MariaDB explains how it would process the `SELECT`, `UPDATE` or `DELETE`, including information about how tables are joined and in which order. `EXPLAIN EXTENDED` can be used to provide additional information.
- `EXPLAIN PARTITIONS` is useful only when examining queries involving partitioned tables. For details, see [Partition pruning and selection](#).
- [ANALYZE statement](#) performs the query as well as producing EXPLAIN output, and provides actual as well as estimated statistics.
- `EXPLAIN` output can be printed in the [slow query log](#). See [EXPLAIN in the Slow Query Log](#) for details.

`SHOW EXPLAIN` shows the output of a running statement. In some cases, its output can be closer to reality than `EXPLAIN`.

The [ANALYZE statement](#) runs a statement and returns information about its execution plan. It also shows additional columns, to check how much the optimizer's estimation about filtering and found rows are close to reality.

There is an online [EXPLAIN Analyzer](#) that you can use to share `EXPLAIN` and `EXPLAIN EXTENDED` output with others.

`EXPLAIN` can acquire metadata locks in the same way that `SELECT` does, as it needs to know table metadata and, sometimes, data as well.

Columns in EXPLAIN ... SELECT

Column name	Description
<code>id</code>	Sequence number that shows in which order tables are joined.
<code>select_type</code>	What kind of <code>SELECT</code> the table comes from.
<code>table</code>	Alias name of table. Materialized temporary tables for sub queries are named <code><subquery#></code>

type	How rows are found from the table (join type).
possible_keys	keys in table that could be used to find rows in the table
key	The name of the key that is used to retrieve rows. NULL is no key was used.
key_len	How many bytes of the key that was used (shows if we are using only parts of the multi-column key).
ref	The reference that is used as the key value.
rows	An estimate of how many rows we will find in the table for each key lookup.
Extra	Extra information about this join.

Here are descriptions of the values for some of the more complex columns in `EXPLAIN ... SELECT` :

"Select_type" Column

The `select_type` column can have the following values:

Value	Description	Comment
DEPENDENT SUBQUERY	The SUBQUERY is DEPENDENT .	
DEPENDENT UNION	The UNION is DEPENDENT .	
DERIVED	The SELECT is DERIVED from the PRIMARY .	
MATERIALIZED	The SUBQUERY is MATERIALIZED .	Materialized tables will be populated at first access and will be accessed by the primary key (= one key lookup). Number of rows in EXPLAIN shows the cost of populating the table
PRIMARY	The SELECT is in the outermost query, but there is also a SUBQUERY within it.	
SIMPLE	It is a simple SELECT query without any SUBQUERY or UNION .	
SUBQUERY	The SELECT is a SUBQUERY of the PRIMARY .	
UNCACHEABLE SUBQUERY	The SUBQUERY is UNCACHEABLE .	
UNCACHEABLE UNION	The UNION is UNCACHEABLE .	
UNION	The SELECT is a UNION of the PRIMARY .	
UNION RESULT	The result of the UNION .	
LATERAL DERIVED	The SELECT uses a Lateral Derived optimization	

"Type" Column

This column contains information on how the table is accessed.

Value	Description
ALL	A full table scan is done for the table (all rows are read). This is bad if the table is large and the table is joined against a previous table! This happens when the optimizer could not find any usable index to access rows.
const	There is only one possibly matching row in the table. The row is read before the optimization phase and all columns in the table are treated as constants.
eq_ref	A unique index is used to find the rows. This is the best possible plan to find the row.

filter	A second index is being used with the Rowid Filtering Optimization .
fulltext	A fulltext index is used to access the rows.
index_merge	A 'range' access is done for for several index and the found rows are merged. The key column shows which keys are used.
index_subquery	This is similar as ref, but used for sub queries that are transformed to key lookups.
index	A full scan over the used index. Better than ALL but still bad if index is large and the table is joined against a previous table.
range	The table will be accessed with a key over one or more value ranges.
ref_or_null	Like 'ref' but in addition another search for the 'null' value is done if the first value was not found. This happens usually with sub queries.
ref	A non unique index or prefix of an unique index is used to find the rows. Good if the prefix doesn't match many rows.
system	The table has 0 or 1 rows.
unique_subquery	This is similar as eq_ref, but used for sub queries that are transformed to key lookups

"Extra" Column

This column consists of one or more of the following values, separated by ','

Note that some of these values are detected after the optimization phase.

The optimization phase can do the following changes to the `WHERE` clause:

- Add the expressions from the `ON` and `USING` clauses to the `WHERE` clause.
- Constant propagation: If there is `column=constant`, replace all column instances with this constant.
- Replace all columns from 'const' tables with their values.
- Remove the used key columns from the `WHERE` (as this will be tested as part of the key lookup).
- Remove impossible constant sub expressions. For example `WHERE '(a=1 and a=2) OR b=1'` becomes `'b=1'`.
- Replace columns with other columns that has identical values: Example: `WHERE a=b and a=c` may be treated as `'WHERE a=b and a=c and b=c'`.
- Add extra conditions to detect impossible row conditions earlier. This happens mainly with `OUTER JOIN` where we in some cases add detection of `NULL` values in the `WHERE` (Part of 'Not exists' optimization). This can cause an unexpected 'Using where' in the Extra column.
- For each table level we remove expressions that have already been tested when we read the previous row. Example: When joining tables `t1` with `t2` using the following `WHERE 't1.a=1 and t1.a=t2.b'`, we don't have to test `'t1.a=1'` when checking rows in `t2` as we already know that this expression is true.

Value	Description
const row not found	The table was a system table (a table with should exactly one row), but no row was found.
Distinct	If distinct optimization (remove duplicates) was used. This is marked only for the last table in the <code>SELECT</code> .
Full scan on NULL key	The table is a part of the sub query and if the value that is used to match the sub query will be <code>NULL</code> , we will do a full table scan.
Impossible HAVING	The used <code>HAVING</code> clause is always false so the <code>SELECT</code> will return no rows.
Impossible WHERE noticed after reading const tables.	The used <code>WHERE</code> clause is always false so the <code>SELECT</code> will return no rows. This case was detected after we had read all 'const' tables and used the column values as constant in the <code>WHERE</code> clause. For example: <code>WHERE const_column=5 and const_column</code> had a value of 4.
Impossible WHERE	The used <code>WHERE</code> clause is always false so the <code>SELECT</code> will return no rows. For example: <code>WHERE 1=2</code>
No matching min/max row	During early optimization of <code>MIN()</code> / <code>MAX()</code> values it was detected that no row could match the <code>WHERE</code> clause. The <code>MIN()</code> / <code>MAX()</code> function will return <code>NULL</code> .
no matching row in const table	The table was a const table (a table with only one possible matching row), but no row was found.

No tables used	The <code>SELECT</code> was a sub query that did not use any tables. For example a there was no <code>FROM</code> clause or a <code>FROM DUAL</code> clause.
Not exists	Stop searching after more row if we find one single matching row. This optimization is used with <code>LEFT JOIN</code> where one is explicitly searching for rows that doesn't exists in the <code>LEFT JOIN</code> TABLE . Example: <code>SELECT * FROM t1 LEFT JOIN t2 on (...) WHERE t2.not_null_column IS NULL</code> . As <code>t2.not_null_column</code> can only be <code>NULL</code> if there was no matching row for on condition, we can stop searching if we find a single matching row.
Open_frm_only	For <code>information_schema</code> tables. Only the <code>frm</code> (table definition file was opened) was opened for each matching row.
Open_full_table	For <code>information_schema</code> tables. A full table open for each matching row is done to retrieve the requested information. (Slow)
Open_trigger_only	For <code>information_schema</code> tables. Only the trigger file definition was opened for each matching row.
Range checked for each record (index map: ...)	This only happens when there was no good default index to use but there may some index that could be used when we can treat all columns from previous table as constants. For each row combination the optimizer will decide which index to use (if any) to fetch a row from this table. This is not fast, but faster than a full table scan that is the only other choice. The index map is a bitmask that shows which index are considered for each row condition.
Scanned 0/1/all databases	For <code>information_schema</code> tables. Shows how many times we had to do a directory scan.
Select tables optimized away	All tables in the join was optimized away. This happens when we are only using <code>COUNT(*)</code> , <code>MIN()</code> and <code>MAX()</code> functions in the <code>SELECT</code> and we where able to replace all of these with constants.
Skip_open_table	For <code>information_schema</code> tables. The queried table didn't need to be opened.
unique row not found	The table was detected to be a const table (a table with only one possible matching row) during the early optimization phase, but no row was found.
Using filesort	Filesort is needed to resolve the query. This means an extra phase where we first collect all columns to sort, sort them with a disk based merge sort and then use the sorted set to retrieve the rows in sorted order. If the column set is small, we store all the columns in the sort file to not have to go to the database to retrieve them again.
Using index	Only the index is used to retrieve the needed information from the table. There is no need to perform an extra seek to retrieve the actual record.
Using index condition	Like 'Using where ' but the where condition is pushed down to the table engine for internal optimization at the index level.
Using index condition (BKA)	Like 'Using index condition ' but in addition we use batch key access to retrieve rows.
Using index for group-by	The index is being used to resolve a <code>GROUP BY</code> or <code>DISTINCT</code> query. The rows are not read. This is very efficient if the table has a lot of identical index entries as duplicates are quickly jumped over.
Using intersect(...)	For <code>index_merge</code> joins. Shows which index are part of the intersect.
Using join buffer	We store previous row combinations in a row buffer to be able to match each row against all of the rows combinations in the join buffer at one go.
Using sort_union(...)	For <code>index_merge</code> joins. Shows which index are part of the union.
Using temporary	A temporary table is created to hold the result. This typically happens if you are using <code>GROUP BY</code> , <code>DISTINCT</code> or <code>ORDER BY</code> .
Using where	A <code>WHERE</code> expression (in additional to the possible key lookup) is used to check if the row should be accepted. If you don't have 'Using where' together with a join type of <code>ALL</code> , you are probably doing something wrong!
Using where with pushed condition	Like 'Using where ' but the where condition is pushed down to the table engine for internal optimization at the row level.

EXPLAIN EXTENDED

The `EXTENDED` keyword adds another column, *filtered*, to the output. This is a percentage estimate of the table rows that will be filtered by the condition.

An `EXPLAIN EXTENDED` will always throw a warning, as it adds extra *Message* information to a subsequent `SHOW WARNINGS` statement. This includes what the `SELECT` query would look like after optimizing and rewriting rules are applied and how the optimizer qualifies columns and tables.

Examples

As synonym for `DESCRIBE` or `SHOW COLUMNS FROM`:

```
DESCRIBE city;
+-----+-----+-----+-----+-----+-----+
| Field      | Type      | Null | Key | Default | Extra      |
+-----+-----+-----+-----+-----+-----+
| Id         | int(11)   | NO   | PRI | NULL    | auto_increment |
| Name       | char(35)  | YES  |     | NULL    |              |
| Country    | char(3)   | NO   | UNI |         |              |
| District   | char(20)  | YES  | MUL |         |              |
| Population | int(11)   | YES  |     | NULL    |              |
+-----+-----+-----+-----+-----+-----+
```

A simple set of examples to see how `EXPLAIN` can identify poor index usage:

```

CREATE TABLE IF NOT EXISTS `employees_example` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `first_name` varchar(30) NOT NULL,
  `last_name` varchar(40) NOT NULL,
  `position` varchar(25) NOT NULL,
  `home_address` varchar(50) NOT NULL,
  `home_phone` varchar(12) NOT NULL,
  `employee_code` varchar(25) NOT NULL,
  PRIMARY KEY (`id`),
  UNIQUE KEY `employee_code` (`employee_code`),
  KEY `first_name` (`first_name`,`last_name`)
) ENGINE=Aria;

INSERT INTO `employees_example` (`first_name`, `last_name`, `position`, `home_address`,
`home_phone`, `employee_code`)
VALUES
('Mustapha', 'Mond', 'Chief Executive Officer', '692 Promiscuous Plaza', '326-555-3492',
'MM1'),
('Henry', 'Foster', 'Store Manager', '314 Savage Circle', '326-555-3847', 'HF1'),
('Bernard', 'Marx', 'Cashier', '1240 Ambient Avenue', '326-555-8456', 'BM1'),
('Lenina', 'Crowne', 'Cashier', '281 Bumblepuppy Boulevard', '328-555-2349', 'LC1'),
('Fanny', 'Crowne', 'Restocker', '1023 Bokanovsky Lane', '326-555-6329', 'FC1'),
('Helmholtz', 'Watson', 'Janitor', '944 Soma Court', '329-555-2478', 'HW1');

```

```
SHOW INDEXES FROM employees_example;
```

```

+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+-----+
| Table          | Non_unique | Key_name      | Seq_in_index | Column_name   | Collation |
+-----+-----+-----+-----+-----+-----+-----+-----+
| employees_example |          0 | PRIMARY      |             1 | id            | A         |
+-----+-----+-----+-----+-----+-----+-----+-----+
| employees_example |          0 | employee_code |             1 | employee_code | A         |
+-----+-----+-----+-----+-----+-----+-----+-----+
| employees_example |          1 | first_name    |             1 | first_name    | A         |
+-----+-----+-----+-----+-----+-----+-----+-----+
| employees_example |          1 | first_name    |             2 | last_name     | A         |
+-----+-----+-----+-----+-----+-----+-----+-----+

```

SELECT on a primary key:

```

EXPLAIN SELECT * FROM employees_example WHERE id=1;
+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+
| id  | select_type | table          | type | possible_keys | key      | key_len | ref  |
+-----+-----+-----+-----+-----+-----+-----+-----+
| 1  | SIMPLE      | employees_example | const | PRIMARY      | PRIMARY | 4       | const |
+-----+-----+-----+-----+-----+-----+-----+-----+

```

The type is *const*, which means that only one possible result could be returned. Now, returning the same record but searching by their phone number:

```

EXPLAIN SELECT * FROM employees_example WHERE home_phone='326-555-3492';
+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+
| id  | select_type | table          | type | possible_keys | key      | key_len | ref  | rows |
+-----+-----+-----+-----+-----+-----+-----+-----+
| 1  | SIMPLE      | employees_example | ALL  | NULL          | NULL    | NULL    | NULL | 6    |
+-----+-----+-----+-----+-----+-----+-----+-----+

```

Here, the type is *All*, which means no index could be used. Looking at the rows count, a full table scan (all six rows) had to be performed in order to retrieve the record. If it's a requirement to search by phone number, an index will have to be created.

SHOW EXPLAIN example:

```
SHOW EXPLAIN FOR 1;
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| id   | select_type | table | type | possible_keys | key | key_len | ref | rows | Extra |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| 1    | SIMPLE     | tbl  | index | NULL          | a   | 5       | NULL | 1000107 | Using index |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
1 row in set, 1 warning (0.00 sec)
```

Example of `ref_or_null` Optimization

```
SELECT * FROM table_name
WHERE key_column=expr OR key_column IS NULL;
```

`ref_or_null` is something that often happens when you use subqueries with `NOT IN` as then one has to do an extra check for `NULL` values if the first value didn't have a matching row.

1.1.1.2.2.5 EXPLAIN ANALYZE

The syntax for the `EXPLAIN ANALYZE` feature was changed to `ANALYZE statement`, available since [MariaDB 10.1.0](#). See [ANALYZE statement](#).

1.1.1.2.2.6 EXPLAIN FORMAT=JSON

Contents

- [Synopsis](#)
- [Output is different from MySQL](#)
- [Output Format](#)

Synopsis

`EXPLAIN FORMAT=JSON` is a variant of `EXPLAIN` command that produces output in JSON form. The output always has one row which has only one column titled "JSON". The contents are a JSON representation of the query plan, formatted for readability:

```
EXPLAIN FORMAT=JSON SELECT * FROM t1 WHERE coll=1\G
```

```
***** 1. row *****
EXPLAIN: {
  "query_block": {
    "select_id": 1,
    "table": {
      "table_name": "t1",
      "access_type": "ALL",
      "rows": 1000,
      "filtered": 100,
      "attached_condition": "(t1.coll = 1)"
    }
  }
}
```

Output is different from MySQL

The output of MariaDB's `EXPLAIN FORMAT=JSON` is different from `EXPLAIN FORMAT=JSON` in MySQL. The reasons for that are:

- MySQL's output has deficiencies. Some are listed here: [EXPLAIN FORMAT=JSON in MySQL](#)

- The output of MySQL's `EXPLAIN FORMAT=JSON` is not defined. Even MySQL Workbench has trouble parsing it (see this [blog post](#)).
- MariaDB has query optimizations that MySQL does not have. Ergo, MariaDB generates query plans that MySQL does not generate.

A (as yet incomplete) list of how MariaDB's output is different from MySQL can be found here: [EXPLAIN FORMAT=JSON differences from MySQL](#).

Output Format

TODO: MariaDB's output format description.

1.1.1.2.2.7 SHOW EXPLAIN

Contents

1. [Syntax](#)
2. [Description](#)
 1. [EXPLAIN FOR CONNECTION](#)
 2. [FORMAT=JSON](#)
 3. [Possible Errors](#)
 4. [Differences Between SHOW EXPLAIN and EXPLAIN Outputs](#)
 1. [Background](#)
 2. [List of Recorded Differences](#)
 3. [Required Permissions](#)

Syntax

```
SHOW EXPLAIN [FORMAT=JSON] FOR <connection_id>;
EXPLAIN [FORMAT=JSON] FOR CONNECTION <connection_id>;
```

Description

The `SHOW EXPLAIN` command allows one to get an [EXPLAIN](#) (that is, a description of a query plan) of a query running in a certain connection.

```
SHOW EXPLAIN FOR <connection_id>;
```

will produce an `EXPLAIN` output for the query that connection number `connection_id` is running. The connection id can be obtained with [SHOW PROCESSLIST](#).

```
SHOW EXPLAIN FOR 1;
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| id   | select_type | table | type | possible_keys | key | key_len | ref | rows | Extra |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| 1   | SIMPLE     | tbl  | index | NULL         | a   | 5       | NULL | 1000107 | Using index |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
1 row in set, 1 warning (0.00 sec)
```

The output is always accompanied with a warning which shows the query the target connection is running (this shows what the `EXPLAIN` is for):

```
SHOW WARNINGS;
+-----+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+-----+
| Note  | 1003 | select sum(a) from tbl |
+-----+-----+-----+-----+
1 row in set (0.00 sec)
```

EXPLAIN FOR CONNECTION

MariaDB starting with [10.9](#)

The `EXPLAIN FOR CONNECTION` syntax was added for MySQL compatibility.

FORMAT=JSON

MariaDB starting with [10.9](#)

`SHOW EXPLAIN [FORMAT=JSON] FOR <connection_id>` extends `SHOW EXPLAIN` to return more detailed JSON output.

Possible Errors

The output can be only produced if the target connection is *currently* running a query, which has a ready query plan. If this is not the case, the output will be:

```
SHOW EXPLAIN FOR 2;  
ERROR 1932 (HY000): Target is not running an EXPLAINable command
```

You will get this error when:

- the target connection is not running a command for which one can run `EXPLAIN`
- the target connection is running a command for which one can run `EXPLAIN`, but
 - there is no query plan yet (for example, tables are open and locks are acquired before the query plan is produced)

Differences Between SHOW EXPLAIN and EXPLAIN Outputs

Background

In MySQL, `EXPLAIN` execution takes a slightly different route from the way the real query (typically the `SELECT`) is optimized. This is unfortunate, and has caused a number of bugs in `EXPLAIN`. (For example, see [MDEV-326](#), [MDEV-410](#), and [lp:1013343](#). [lp:992942](#) is not directly about `EXPLAIN`, but it also would not have existed if MySQL didn't try to delete parts of a query plan in the middle of the query)

`SHOW EXPLAIN` examines a running `SELECT`, and hence its output may be slightly different from what `EXPLAIN SELECT` would produce. We did our best to make sure that either the difference is negligible, or `SHOW EXPLAIN`'s output is closer to reality than `EXPLAIN`'s output.

List of Recorded Differences

- `SHOW EXPLAIN` may have `Extra='no matching row in const table'`, where `EXPLAIN` would produce `Extra='Impossible WHERE ...'`
- For queries with subqueries, `SHOW EXPLAIN` may print `select_type==PRIMARY` where regular `EXPLAIN` used to print `select_type==SIMPLE`, or vice versa.

Required Permissions

Running `SHOW EXPLAIN` requires the same permissions as running `SHOW PROCESSLIST` would.

1.1.1.2.2.8 Using Buffer UPDATE Algorithm

This article explains the `UPDATE` statement's *Using Buffer* algorithm.

Take the following table and query:

Name	Salary
Babatunde	1000
Jolana	1050
Pankaja	1300

```
UPDATE employees SET salary = salary+100 WHERE salary < 2000;
```

Suppose the *employees* table has an index on the *salary* column, and the optimizer decides to use a range scan on that index.

The optimizer starts a range scan on the *salary* index. We find the first record *Babatunde, 1000*. If we do an on-the-fly update, we immediately instruct the storage engine to change this record to be *Babatunde, 1000+100=1100*.

Then we proceed to search for the next record, and find *Jolana, 1050*. We instruct the storage engine to update it to be *Jolana, 1050+100=1150*.

Then we proceed to search for the next record ... and what happens next depends on the storage engine. In some storage engines, data changes are visible immediately, so we will find the *Babatunde, 1100* record that we wrote at the first step, modifying it again, giving Babatunde an undeserved raise. Then we will see Babatunde again and again, looping continually.

In order to prevent such situations, the optimizer checks whether the UPDATE statement is going to change key values for the keys it is using. In that case, it will use a different algorithm:

1. Scan everyone with "salary<2000", remembering the rowids of the rows in a buffer.
2. Read the buffer and apply the updates.

This way, each row will be updated only once.

The `Using buffer` `EXPLAIN` output indicates that the buffer as described above will be used.

1.1.1.2.3 BACKUP Commands

Commands used by backup tools

BACKUP STAGE

Commands to be used by a MariaDB backup tool.

BACKUP LOCK

Blocks a table from DDL statements.

Mariabackup and BACKUP STAGE Commands

How Mariabackup could use BACKUP STAGE commands.

Storage Snapshots and BACKUP STAGE Commands

How storage snapshots could use BACKUP STAGE commands.

1.1.1.2.3.1 BACKUP STAGE

MariaDB starting with [10.4.1](#)

The `BACKUP STAGE` commands were introduced in [MariaDB 10.4.1](#).

Contents

1. [Syntax](#)
2. [Goals with BACKUP STAGE Commands](#)
3. [BACKUP STAGE Commands](#)
 1. [BACKUP STAGE START](#)
 2. [BACKUP STAGE FLUSH](#)
 3. [BACKUP STAGE BLOCK_DDL](#)
 4. [BACKUP STAGE BLOCK_COMMIT](#)
 5. [BACKUP STAGE END](#)
4. [Using BACKUP STAGE Commands with Backup Tools](#)
 1. [Using BACKUP STAGE Commands with Mariabackup](#)
 2. [Using BACKUP STAGE Commands with Storage Snapshots](#)
5. [Privileges](#)
6. [Notes](#)

The `BACKUP STAGE` commands are a set of commands to make it possible to make an efficient external backup tool.

Syntax

```
BACKUP STAGE [START | FLUSH | BLOCK_DDL | BLOCK_COMMIT | END ]
```

In the following text, a transactional table means InnoDB or "InnoDB-like engine with redo log that can lock redo purges and can be copied without locks by an outside process".

Goals with BACKUP STAGE Commands

- To be able to do a majority of the backup with the minimum possible server locks. Especially for transactional tables (InnoDB, MyRocks etc) there is only need for a very short block of new commits while copying statistics and log tables.
- DDL are only needed to be blocked for a very short duration of the backup while `mysqlbackup` is copying the tables affected by DDL during the initial part of the backup.
- Most non transactional tables (those that are not in use) will be copied during `BACKUP STAGE START`. The exceptions are system statistic and log tables that are not blocked during the backup until `BLOCK_COMMIT`.
- Should work efficiently with backup tools that use disk snapshots.
- Should work as efficiently as possible for all table types that store data on the local disks.
- As little copying as possible under higher level stages/locks. For example, `.frm` (dictionary) and `.trn` (trigger) files should be copying while copying the table data.

BACKUP STAGE Commands

BACKUP STAGE START

The `START` stage is designed for the following tasks:

- Blocks purge of redo files for storage engines that needs this (Aria)
- Start logging of DDL commands into 'datadir/ddl.log'. This may take a short time as the command has to wait until there are no active DDL commands.

BACKUP STAGE FLUSH

The `FLUSH` stage is designed for the following tasks:

- FLUSH all changes for inactive non-transactional tables, except for statistics and log tables.
- Close all tables that are not in use, to ensure they are marked as closed for the backup.
- BLOCK all new write locks for all non transactional tables (except statistics and log tables). The command will not wait for tables that are in use by read-only transactions.

DDLs don't have to be blocked at this stage as they can't cause the table to be in an inconsistent state. This is true also for non-transactional tables.

BACKUP STAGE BLOCK_DDL

The `BLOCK_DDL` stage is designed for the following tasks:

- Wait for all statements using write locked non-transactional tables to end.
- Blocks `CREATE TABLE`, `DROP TABLE`, `TRUNCATE TABLE`, and `RENAME TABLE`.
- Blocks also start off a **new ALTER TABLE** and the **final rename phase** of `ALTER TABLE`. Running `ALTER TABLES` are not blocked.

BACKUP STAGE BLOCK_COMMIT

The `BLOCK_COMMIT` stage is designed for the following tasks:

- Lock the binary log and commit/rollback to ensure that no changes are committed to any tables. If there are active commits or data to be copied to the binary log this will be allowed to finish. Active transactions will not affect `BLOCK_COMMIT`.
- This doesn't lock temporary tables that are not used by replication. However these will be blocked when it's time to write to the binary log.
- Lock system log tables and statistics tables, flush them and mark them closed.

When the `BLOCK_COMMIT`'s stages return, this is the 'backup time'. Everything committed will be in the backup and everything not committed will roll back.

Transactional engines will continue to do changes to the redo log during the `BLOCK_COMMIT` stage, but this is not important as all of these will roll back later as the changes will not be committed.

BACKUP STAGE END

The `END` stage is designed for the following tasks:

- End DDL logging
- Free resources

Using `BACKUP STAGE` Commands with Backup Tools

Using `BACKUP STAGE` Commands with Mariabackup

The `BACKUP STAGE` commands are a set of commands to make it possible to make an efficient external backup tool. How `Mariabackup` uses these commands depends on which version you are using. Prior to [MariaDB 10.11.8](#), [MariaDB 11.0.6](#), [MariaDB 11.1.5](#) and [MariaDB 11.2.4](#), this depended on whether you are using the version that is bundled with MariaDB Community Server or the version that is bundled with [MariaDB Enterprise Server](#). See [Mariabackup and BACKUP STAGE Commands](#) for some examples on how `Mariabackup` uses these commands. From [MariaDB 10.11.8](#), [MariaDB 11.0.6](#), [MariaDB 11.1.5](#) and [MariaDB 11.2.4](#), these features were ported from MariaDB Enterprise Server ([MDEV-32932](#)).

Using `BACKUP STAGE` Commands with Storage Snapshots

The `BACKUP STAGE` commands are a set of commands to make it possible to make an efficient external backup tool. These commands could even be used by tools that perform backups by taking a snapshot of a file system, SAN, or some other kind of storage device. See [Storage Snapshots and BACKUP STAGE Commands](#) for some examples on how to use each `BACKUP STAGE` command in an efficient way.

Privileges

`BACKUP STAGE` requires the [RELOAD](#) privilege.

Notes

- Only one connection can run `BACKUP STAGE START`. If a second connection tries, it will wait until the first one has executed `BACKUP STAGE END`.
- If the user skips a `BACKUP STAGE`, then all intermediate backup stages will automatically be run. This will allow us to add new stages within the `BACKUP STAGE` hierarchy in the future with even more precise locks without causing problems for tools using an earlier version of the `BACKUP STAGE` implementation.
- One can use the `max_statement_time` or `lock_wait_timeout` system variables to ensure that a `BACKUP STAGE` command doesn't block the server too long.
- DDL logging is only available from [MariaDB 10.11.8](#), [MariaDB 11.0.6](#), [MariaDB 11.1.5](#) and [MariaDB 11.2.4](#), or in [MariaDB Enterprise Server](#).
- A disconnect will automatically release backup stages.
- There is no easy way to see which is the current stage.

1.1.1.2.3.2 BACKUP LOCK

MariaDB starting with [10.4.2](#)

The `BACKUP LOCK` command was introduced in [MariaDB 10.4.2](#).

Contents

1. [Syntax](#)
2. [Usage in a Backup Tool](#)
3. [Privileges](#)
4. [Notes](#)
5. [Implementation](#)

`BACKUP LOCK` blocks a table from DDL statements. This is mainly intended to be used by tools like `mariabackup` that need to ensure there are no DDLs on a table while the table files are opened. For example, for an Aria table that stores data in 3 files with extensions `.frm`, `.MAI` and `.MAD`. Normal read/write operations can continue as normal.

Syntax

To lock a table:

```
BACKUP LOCK table_name
```

To unlock a table:

```
BACKUP UNLOCK
```

Usage in a Backup Tool

```
BACKUP LOCK [database.]table_name;  
- Open all files related to a table (for example, t.frm, t.MAI and t.MYD)  
BACKUP UNLOCK;  
- Copy data  
- Close files
```

This ensures that all files are from the same generation, that is created at the same time by the MariaDB server. This works, because the open files will point to the original table files which will not be affected if there is any ALTER TABLE while copying the files.

Privileges

Prior to [MariaDB 10.4.33](#), [MariaDB 10.5.24](#), [MariaDB 10.6.17](#), [MariaDB 10.11.7](#), [MariaDB 11.0.5](#), [MariaDB 11.1.4](#), [MariaDB 11.2.3](#), [MariaDB 11.3.2](#) and [MariaDB 11.4.1](#), BACKUP LOCK requires the [RELOAD](#) privilege.

From [MariaDB 10.4.33](#), [MariaDB 10.5.24](#), [MariaDB 10.6.17](#), [MariaDB 10.11.7](#), [MariaDB 11.0.5](#), [MariaDB 11.1.4](#), [MariaDB 11.2.3](#), [MariaDB 11.3.2](#) and [MariaDB 11.4.1](#), BACKUP LOCK is also accessible to those with [database LOCK TABLES](#) privileges.

Notes

- The idea is that the `BACKUP LOCK` should be held for as short a time as possible by the backup tool. The time to take an uncontested lock is very short! One can easily do 50,000 locks/unlocks per second on low end hardware.
- One should use different connections for `BACKUP STAGE` commands and `BACKUP LOCK`.

Implementation

- Internally, BACKUP LOCK is implemented by taking an `MDLSHARED_HIGH_PRIO` MDL lock on the table object, which protects the table from any DDL operations.

2.3.4.12 Mariabackup and BACKUP STAGE Commands

1.1.1.2.3.4 Storage Snapshots and BACKUP STAGE Commands

MariaDB starting with [10.4.1](#)
The `BACKUP STAGE` commands were introduced in [MariaDB 10.4.1](#).

Contents

1. [Generic Backup Process with Storage Snapshots](#)

The `BACKUP STAGE` commands are a set of commands to make it possible to make an efficient external backup tool. These commands could even be used by tools that perform backups by taking a snapshot of a file system, SAN, or some other kind of storage device.

Generic Backup Process with Storage Snapshots

A tool that backs up MariaDB by taking a snapshot of a file system, SAN, or some other kind of storage device could use each `BACKUP STAGE` command in the following way:

- First, execute the following:

```
BACKUP STAGE START
BACKUP STAGE BLOCK_COMMIT
```

- Then, take the snapshot.
- Then, execute the following:

```
BACKUP STAGE END
```

The above ensures that all non-transactional tables are properly flushed to disk before the snapshot is done. Using `BACKUP STAGE` commands is also more efficient than using the `FLUSH TABLES WITH READ LOCK` command as the above set of commands will not block or be blocked by write operations to transactional tables.

Note that when the backup is completed, one should delete all files with the "#sql" prefix, as these are files used by concurrent running `ALTER TABLE`. Note that InnoDB will on server restart automatically delete any tables with the "#sql" prefix.

1.1.1.2.4 FLUSH Commands

Commands to reset (flush) various caches in MariaDB.

FLUSH

Clear or reload various internal caches.

FLUSH QUERY CACHE

Defragmenting the query cache

FLUSH TABLES FOR EXPORT

Flushes changes to disk for specific tables.

There are [2 related questions](#)

1.1.1.2.4.1 FLUSH

Syntax

```
FLUSH [NO_WRITE_TO_BINLOG | LOCAL]
      flush_option [, flush_option] ...
```

or when flushing tables:

```
FLUSH [NO_WRITE_TO_BINLOG | LOCAL] TABLES [table_list] [table_flush_option]
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [FLUSH RELAY LOGS](#)
 1. [Compatibility with MySQL](#)
4. [FLUSH STATUS](#)
 1. [Global Status Variables that Support FLUSH STATUS](#)
5. [FLUSH TABLES](#)
 1. [Purpose of FLUSH TABLES](#)
 2. [Purpose of FLUSH TABLES WITH READ LOCK](#)
 3. [Purpose of FLUSH TABLES table_list](#)
 4. [Purpose of FLUSH TABLES table_list WITH READ LOCK](#)
 5. [Implementation of FLUSH TABLES](#)
 6. [Implementation of FLUSH TABLES WITH READ LOCK](#)
 7. [Implementation of FLUSH TABLES table_list](#)
 8. [Implementation of FLUSH TABLES table_list FOR EXPORT](#)
6. [FLUSH SSL](#)
7. [Reducing Memory Usage](#)

where `table_list` is a list of tables separated by `,` (comma).

Description

The `FLUSH` statement clears or reloads various internal caches used by MariaDB. To execute `FLUSH`, you must have the `RELOAD` privilege. See [GRANT](#).

The `RESET` statement is similar to `FLUSH`. See [RESET](#).

You cannot issue a `FLUSH` statement from within a [stored function](#) or a [trigger](#). Doing so within a stored procedure is permitted, as long as it is not called by a stored function or trigger. See [Stored Routine Limitations](#), [Stored Function Limitations](#) and [Trigger Limitations](#).

If a listed table is a view, an error like the following will be produced:

```
ERROR 1347 (HY000): 'test.v' is not BASE TABLE
```

By default, `FLUSH` statements are written to the [binary log](#) and will be [replicated](#). The `NO_WRITE_TO_BINLOG` keyword (`LOCAL` is an alias) will ensure the statement is not written to the binary log.

The different flush options are:

Option	Description
<code>CHANGED_PAGE_BITMAPS</code>	XtraDB only. Internal command used for backup purposes. See the Information Schema CHANGED_PAGE_BITMAPS Table .
<code>CLIENT_STATISTICS</code>	Reset client statistics (see SHOW CLIENT_STATISTICS).
<code>DES_KEY_FILE</code>	Reloads the DES key file (Specified with the <code>--des-key-file</code> startup option).
<code>HOSTS</code>	Flush the hostname cache (used for converting ip to host names and for unblocking blocked hosts. See max_connect_errors and performance_schema.host_cache
<code>INDEX_STATISTICS</code>	Reset index statistics (see SHOW INDEX_STATISTICS).

[ERROR ENGINE GENERAL SLOW RELAY] LOGS	Close and reopen the specified log type, or all log types if none are specified. <code>FLUSH RELAY LOGS [connection-name]</code> can be used to flush the relay logs for a specific connection. Only one connection can be specified per <code>FLUSH</code> command. See Multi-source replication . <code>FLUSH ENGINE LOGS</code> will delete all unneeded Aria redo logs. <code>FLUSH BINARY LOGS DELETE_DOMAIN_ID=(list-of-domains)</code> can be used to discard obsolete GTID domains from the server's binary log state. In order for this to be successful, no event group from the listed GTID domains can be present in existing binary log files. If some still exist, then they must be purged prior to executing this command. If the command completes successfully, then it also rotates the binary log .
BINARY LOGS	<code>FLUSH BINARY LOGS</code> rotates the current binary log .
BINARY LOGS DELETE_DOMAIN_ID=(list-of-domains)	<code>FLUSH BINARY LOGS DELETE_DOMAIN_ID</code> can be used to discard obsolete GTID domains from the server's binary log state. In order for this to be successful, no event group from the listed GTID domains can be present in existing binary log files. If some still exist, then they must be purged prior to executing this command. If the command completes successfully, then it also rotates the binary log .
MASTER	Deprecated option, use RESET MASTER instead.
PRIVILEGES	Reload all privileges from the privilege tables in the <code>mysql</code> database. If the server is started with <code>--skip-grant-table</code> option, this will activate the privilege tables again.
QUERY CACHE	Defragment the query cache to better utilize its memory. If you want to reset the query cache, you can do it with RESET QUERY CACHE .
QUERY_RESPONSE_TIME	See the QUERY_RESPONSE_TIME plugin.
QUERY_RESPONSE_TIME_READ	See the QUERY_RESPONSE_TIME plugin. From MariaDB 11.5 .
QUERY_RESPONSE_TIME_READ_WRITE	See the QUERY_RESPONSE_TIME plugin. From MariaDB 11.5 .
QUERY_RESPONSE_TIME_WRITE	See the QUERY_RESPONSE_TIME plugin. From MariaDB 11.5 .
SLAVE	Deprecated option, use RESET REPLICA or RESET SLAVE instead.
SSL	Used to dynamically reinitialize the server's TLS context by reloading the files defined by several TLS system variables . See FLUSH SSL for more information.
[GLOBAL SESSION] STATUS	Resets all server status variables that can be reset to 0. Not all global status variables support this, so not all global values are reset. From MariaDB 11.5 , <code>GLOBAL</code> or <code>SESSION</code> can be specified. See FLUSH STATUS for more information.
TABLE[S]	Close tables given as options or all open tables if no table list was used. From MariaDB 10.4.1 ↗ , using without any table list will only close tables not in use, and tables not locked by the <code>FLUSH TABLES</code> connection. If there are no locked tables, <code>FLUSH TABLES</code> will be instant and will not cause any waits, as it no longer waits for tables in use. When a table list is provided, from MariaDB 10.4.1 ↗ , the server will wait for the end of any transactions that are using the tables. Previously, <code>FLUSH TABLES</code> only waited for the statements to complete.
TABLE[S] ... FOR EXPORT	For InnoDB tables, flushes table changes to disk to permit binary table copies while the server is running. See FLUSH TABLES ... FOR EXPORT for more.
TABLE[S] WITH READ LOCK	Closes all open tables. New tables are only allowed to be opened with read locks until an UNLOCK TABLES is given.
TABLE[S] WITH READ LOCK AND DISABLE CHECKPOINT	As <code>TABLES WITH READ LOCK</code> but also disable all checkpoint writes by transactional table engines. This is useful when doing a disk snapshot of all tables.
TABLE_STATISTICS	Reset table statistics (see SHOW TABLE_STATISTICS).
USER_RESOURCES	Resets all per hour user resources . This enables clients that have exhausted their resources to connect again.
USER_STATISTICS	Reset user statistics (see SHOW USER_STATISTICS).
USER_VARIABLES	Reset user variables (see User-defined variables).

You can also use the [mariadb-admin](#) client to flush things. Use `mariadb-admin --help` to examine what flush commands

it supports.

FLUSH RELAY LOGS

```
FLUSH RELAY LOGS 'connection_name';
```

Compatibility with MySQL

MariaDB starting with [10.7.0](#) 

The `FOR CHANNEL` keyword was added for MySQL compatibility. This is identical to using the `channel_name` directly after the `FLUSH` command.

For example, one can now use:

```
FLUSH RELAY LOGS FOR CHANNEL 'connection_name';
```

FLUSH STATUS

Server status variables can be reset by executing the following:

```
FLUSH STATUS;
```

This requires the `RELOAD` privilege

Until [MariaDB 11.5](#), the variables flushed are mainly session, but also some global. Not all session (or global) variables are flushed - the decision was made per variable.

MariaDB starting with [11.5](#)

From [MariaDB 11.5](#) it is possible to specify `FLUSH GLOBAL` or `FLUSH SESSION`. Flushing of global status variables has been moved to `FLUSH GLOBAL STATUS` (in [MariaDB 11.5](#), this flushes only the global variables previously flushed by `FLUSH STATUS`. In a future release, it is intended for this to reset all global summary variables.) `FLUSH SESSION STATUS` is a synonym for `FLUSH STATUS`.

One can use `old-mode=OLD_FLUSH_STATUS` to restore the old behavior of the `FLUSH STATUS`.

Global Status Variables that Support `FLUSH STATUS`

Not all global status variables support being reset by `FLUSH STATUS`. Currently, the following is an incomplete list of status variables are reset by `FLUSH GLOBAL STATUS` in 11.5 or `FLUSH STATUS` in earlier versions:

FLUSH TABLES

MariaDB starting with [10.11.12](#)

Prior to [MariaDB 10.11.12](#), [MariaDB 11.4.6](#) and [MariaDB 11.8.2](#), FLUSH TABLES caused [InnoDB statistics](#) to be reloaded or recalculated. From [MariaDB 10.11.12](#), [MariaDB 11.4.6](#) and [MariaDB 11.8.2](#), this is no longer the case. [RENAME TABLE](#) is unaffected, and will continue to trigger a reload of the statistics.

Purpose of FLUSH TABLES

The purpose of `FLUSH TABLES` is to clean up the open table cache and table definition cache of tables that are not in use. This frees up memory and file descriptors. Normally this is not needed as the caches work on a first-in, first-out basis, but can be useful if the server seems to use too much memory for some reason.

Purpose of FLUSH TABLES WITH READ LOCK

`FLUSH TABLES WITH READ LOCK` is useful if you want to take a backup of some tables. When `FLUSH TABLES WITH READ LOCK` returns, all write access to tables is blocked and all tables are marked as 'properly closed' on disk. The tables can still be used for read operations.

Purpose of FLUSH TABLES table_list

`FLUSH TABLES table_list` is useful if you want to copy a table object or files to or from the server. This command puts a lock that stops new users of the table and will wait until everyone has stopped using the table. The table is then removed from the table definition and table cache.

Note that it's up to the user to ensure that no one is accessing the table between `FLUSH TABLES` and the table is copied to or from the server. This can be secured by using [LOCK TABLES](#).

If there are any tables locked by the connection that is using `FLUSH TABLES` all the locked tables will be closed as part of the flush and reopened and relocked before `FLUSH TABLES` returns. This allows one to copy the table after `FLUSH TABLES` returns without having any writes on the table. For now this works with most tables, except InnoDB as InnoDB may do background purges on the table even while it's write locked.

Purpose of FLUSH TABLES table_list WITH READ LOCK

`FLUSH TABLES table_list WITH READ LOCK` should work as `FLUSH TABLES WITH READ LOCK`, but only those tables that are listed will be properly closed. However in practice this works exactly like `FLUSH TABLES WITH READ LOCK` as the `FLUSH` command has anyway to wait for all WRITE operations to end because we are depending on a global read lock for this code. In the future we should consider fixing this to instead use meta data locks.

Implementation of FLUSH TABLES

- Free memory and file descriptors not in use

Implementation of FLUSH TABLES WITH READ LOCK

- Lock all tables read only for simple old style backup.
- All background writes are suspended and tables are marked as closed.
- No statement requiring table changes are allowed for any user until `UNLOCK TABLES`.

Instead of using `FLUSH TABLE WITH READ LOCK` one should in most cases instead use [BACKUP STAGE BLOCK_COMMIT](#).

Implementation of FLUSH TABLES table_list

- Free memory and file descriptors for tables not in use from table list.
- Lock given tables as read only.
- Wait until all translations has ended that uses any of the given tables.
- Wait until all background writes are suspended and tables are marked as closed.

Implementation of FLUSH TABLES table_list FOR EXPORT

- Free memory and file descriptors for tables not in use from table list
- Lock given tables as read.
- Wait until all background writes are suspended and tables are marked as closed.
- Check that all tables supports `FOR EXPORT`
- No changes to these tables allowed until `UNLOCK TABLES`

This is basically the same behavior as in old MariaDB version if one first lock the tables, then do `FLUSH TABLES`. The tables will be copyable until `UNLOCK TABLES`.

FLUSH SSL

In [MariaDB 10.4](#) and later, the `FLUSH SSL` command can be used to dynamically reinitialize the server's [TLS](#) context. This is most useful if you need to replace a certificate that is about to expire without restarting the server.

This operation is performed by reloading the files defined by the following [TLS system variables](#):

- [ssl_cert](#)
- [ssl_key](#)
- [ssl_ca](#)
- [ssl_capath](#)
- [ssl_crl](#)
- [ssl_crlpath](#)

These [TLS system variables](#) are not dynamic, so their values can **not** be changed without restarting the server.

If you want to dynamically reinitialize the server's [TLS](#) context, then you need to change the certificate and key files at the relevant paths defined by these [TLS system variables](#), without actually changing the values of the variables. See [MDEV-19341](#) [🔗](#) for more information.

Reducing Memory Usage

To flush some of the global caches that take up memory, you could execute the following command:

```
FLUSH LOCAL HOSTS,
      QUERY CACHE,
      TABLE_STATISTICS,
      INDEX_STATISTICS,
      USER_STATISTICS;
```

1.1.1.2.4.2 FLUSH QUERY CACHE

Description

You can defragment [the query cache](#) to better utilize its memory with the `FLUSH QUERY CACHE` statement. The statement does not remove any queries from the cache.

The [RESET QUERY CACHE](#) statement removes all query results from the query cache. The [FLUSH TABLES](#) statement also does this.

1.1.1.2.4.3 FLUSH TABLES FOR EXPORT

Syntax

```
FLUSH TABLE[S] table_name [, table_name] FOR EXPORT
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Example](#)

Description

`FLUSH TABLES ... FOR EXPORT` flushes changes to the specified tables to disk so that binary copies can be made while the server is still running. This works for [Archive](#), [Aria](#), [CSV](#), [InnoDB](#), [MyISAM](#) and [MERGE](#) tables.

The table is read locked until one has issued [UNLOCK TABLES](#).

If a storage engine does not support `FLUSH TABLES FOR EXPORT`, a 1031 error (`SQLSTATE 'HY000'`) is produced.

If `FLUSH TABLES ... FOR EXPORT` is in effect in the session, the following statements will produce an error if attempted:

- `FLUSH TABLES WITH READ LOCK`
- `FLUSH TABLES ... WITH READ LOCK`
- `FLUSH TABLES ... FOR EXPORT`
- Any statement trying to update any table

If any of the following statements is in effect in the session, attempting `FLUSH TABLES ... FOR EXPORT` will produce an error.

- `FLUSH TABLES ... WITH READ LOCK`

- FLUSH TABLES ... FOR EXPORT
- LOCK TABLES ... READ
- LOCK TABLES ... WRITE

FLUSH FOR EXPORT is not written to the [binary log](#).

This statement requires the [RELOAD](#) and the [LOCK TABLES](#) privileges.

If one of the specified tables cannot be locked, none of the tables will be locked.

If a table does not exist, an error like the following will be produced:

```
ERROR 1146 (42S02): Table 'test.xxx' doesn't exist
```

If a table is a view, an error like the following will be produced:

```
ERROR 1347 (HY000): 'test.v' is not BASE TABLE
```

Example

```
FLUSH TABLES test.t1 FOR EXPORT;
# Copy files related to the table (see below)
UNLOCK TABLES;
```

For a full description, please see [copying MariaDB tables](#).

1.1.1.2.5 Replication Commands

The terms *master* and *slave* have historically been used in replication, and MariaDB has begun the process of adding *primary* and *replica* synonyms. The old terms will continue to be used to maintain backward compatibility - see [MDEV-18777](#) to follow progress on this effort.

A list of replication-related commands. See [replication](#) for more replication-related information.

CHANGE MASTER TO

Set or change replica parameters for connecting to the primary.

START SLAVE

Start replica threads.

STOP SLAVE

Stop replica threads.

RESET REPLICA

Forget replica connection information and start a new relay log file.

SET GLOBAL SQL_SLAVE_SKIP_COUNTER

Skips a number of events from the primary.

SHOW RELAYLOG EVENTS

Show events in the relay log.

SHOW REPLICA STATUS

Show status for one or all primaries.

SHOW MASTER STATUS

Status information about the binary log.

SHOW REPLICA HOSTS

Display replicas currently registered with the primary.

RESET MASTER

Delete binary log files.

1.1.1.2.5.1 CHANGE MASTER TO

The terms *master* and *slave* have historically been used in replication, and MariaDB has begun the process of adding *primary* and *replica* synonyms. The old terms will continue to be used to maintain backward compatibility - see [MDEV-18777](#) to follow progress on this effort.

Syntax

```
CHANGE MASTER ['connection_name'] TO master_def [, master_def] ...  
[FOR CHANNEL 'channel_name']
```

master_def:

```
    MASTER_BIND = 'interface_name'  
| MASTER_HOST = 'host_name'  
| MASTER_USER = 'user_name'  
| MASTER_PASSWORD = 'password'  
| MASTER_PORT = port_num  
| MASTER_CONNECT_RETRY = interval  
| MASTER_HEARTBEAT_PERIOD = interval  
| MASTER_LOG_FILE = 'master_log_name'  
| MASTER_LOG_POS = master_log_pos  
| RELAY_LOG_FILE = 'relay_log_name'  
| RELAY_LOG_POS = relay_log_pos  
| MASTER_DELAY = interval  
| MASTER_SSL = {0|1}  
| MASTER_SSL_CA = 'ca_file_name'  
| MASTER_SSL_CAPATH = 'ca_directory_name'  
| MASTER_SSL_CERT = 'cert_file_name'  
| MASTER_SSL_CRL = 'crl_file_name'  
| MASTER_SSL_CRLPATH = 'crl_directory_name'  
| MASTER_SSL_KEY = 'key_file_name'  
| MASTER_SSL_CIPHER = 'cipher_list'  
| MASTER_SSL_VERIFY_SERVER_CERT = {0|1}  
| MASTER_USE_GTID = {current_pos|slave_pos|no}  
| MASTER_DEMOTE_TO_SLAVE = bool  
| IGNORE_SERVER_IDS = (server_id_list)  
| DO_DOMAIN_IDS = ([N,..])  
| IGNORE_DOMAIN_IDS = ([N,..])
```

9. Example

Description

`CHANGE MASTER` is used on a replica to setup or change [replication](#) settings for connecting to the primary.

MariaDB starting with [10.7.0](#) 

The `FOR CHANNEL` keyword was added for MySQL compatibility. This is identical to using the `channel_name` directly after `CHANGE MASTER`.

Multi-Source Replication

If you are using [multi-source replication](#), then you need to specify a connection name when you execute `CHANGE MASTER`.

There are two ways to do this:

- Setting the `default_master_connection` system variable prior to executing `CHANGE MASTER`.
- Setting the `connection_name` parameter when executing `CHANGE MASTER`.

`default_master_connection`

```
SET default_master_connection = 'gandalf';
STOP SLAVE;
CHANGE MASTER TO
  MASTER_PASSWORD='new3cret';
START SLAVE;
```

connection_name

```
STOP SLAVE 'gandalf';
CHANGE MASTER 'gandalf' TO
  MASTER_PASSWORD='new3cret';
START SLAVE 'gandalf';
```

Options

Connection Options

MASTER_USER

The `MASTER_USER` option for `CHANGE MASTER` defines the user account that the [replica](#) will use to connect to the [primary](#).

This user account will need the [REPLICATION SLAVE](#) privilege (or, from [MariaDB 10.5.1](#), the [REPLICATION REPLICATION](#) on the primary).

For example:

```
STOP SLAVE;
CHANGE MASTER TO
  MASTER_USER='repl',
  MASTER_PASSWORD='new3cret';
START SLAVE;
```

The maximum length of the `MASTER_USER` string is 96 characters until [MariaDB 10.5](#), and 128 characters from [MariaDB 10.6](#).

MASTER_PASSWORD

The `MASTER_PASSWORD` option for `CHANGE MASTER` defines the password that the [replica](#) will use to connect to the [primary](#) as the user account defined by the `MASTER_USER` option.

For example:

```
STOP SLAVE;
CHANGE MASTER TO
  MASTER_PASSWORD='new3cret';
START SLAVE;
```

The maximum length of the `MASTER_PASSWORD` string is 32 characters. The effective maximum length of the string depends on how many bytes are used per character and can be up to 96 characters.

Due to [MDEV-29994](#), the password can be silently truncated to 41 characters when MariaDB is restarted. For this reason it is recommended to use a password that is shorter than this.

MASTER_HOST

The `MASTER_HOST` option for `CHANGE MASTER` defines the hostname or IP address of the [primary](#).

If you set the value of the `MASTER_HOST` option to the empty string, then that is not the same as not setting the option's value at all. If you set the value of the `MASTER_HOST` option to the empty string, then the `CHANGE MASTER` command will fail with an error. In [MariaDB 5.3](#) and before, if you set the value of the `MASTER_HOST` option to the empty string, then the `CHANGE MASTER` command would succeed, but the subsequent `START SLAVE` command would fail.

For example:

```
STOP SLAVE;
CHANGE MASTER TO
  MASTER_HOST='dbserver1.example.com',
  MASTER_USER='repl',
  MASTER_PASSWORD='new3cret',
  MASTER_USE_GTID=slave_pos;
START SLAVE;
```

If you set the value of the `MASTER_HOST` option in a `CHANGE MASTER` command, then the replica assumes that the primary is different from before, even if you set the value of this option to the same value it had previously. In this scenario, the replica will consider the old values for the primary's [binary log](#) file name and position to be invalid for the new primary. As a side effect, if you do not explicitly set the values of the [MASTER_LOG_FILE](#) and [MASTER_LOG_POS](#) options in the statement, then the statement will be implicitly appended with `MASTER_LOG_FILE=''` and `MASTER_LOG_POS=4`. However, if you enable [GTID](#) mode for replication by setting the [MASTER_USE_GTID](#) option to some value other than `no` in the statement, then these values will effectively be ignored anyway.

Replicas cannot connect to primaries using Unix socket files or Windows named pipes. The replica must connect to the primary using TCP/IP.

The maximum length of the `MASTER_HOST` string is 60 characters until [MariaDB 10.5](#), and 255 characters from [MariaDB 10.6](#).

MASTER_PORT

The `MASTER_PORT` option for `CHANGE MASTER` defines the TCP/IP port of the [primary](#).

For example:

```
STOP SLAVE;
CHANGE MASTER TO
  MASTER_HOST='dbserver1.example.com',
  MASTER_PORT=3307,
  MASTER_USER='repl',
  MASTER_PASSWORD='new3cret',
  MASTER_USE_GTID=slave_pos;
START SLAVE;
```

If you set the value of the `MASTER_PORT` option in a `CHANGE MASTER` command, then the replica assumes that the primary is different from before, even if you set the value of this option to the same value it had previously. In this scenario, the replica will consider the old values for the primary's [binary log](#) file name and position to be invalid for the new primary. As a side effect, if you do not explicitly set the values of the [MASTER_LOG_FILE](#) and [MASTER_LOG_POS](#) options in the statement, then the statement will be implicitly appended with `MASTER_LOG_FILE=''` and `MASTER_LOG_POS=4`. However, if you enable [GTID](#) mode for replication by setting the [MASTER_USE_GTID](#) option to some value other than `no` in the statement, then these values will effectively be ignored anyway.

Replicas cannot connect to primaries using Unix socket files or Windows named pipes. The replica must connect to the primary using TCP/IP.

MASTER_CONNECT_RETRY

The `MASTER_CONNECT_RETRY` option for `CHANGE MASTER` defines how many seconds that the replica will wait between connection retries. The default is `60`.

```
STOP SLAVE;
CHANGE MASTER TO
  MASTER_CONNECT_RETRY=20;
START SLAVE;
```

The number of connection attempts is limited by the `master_retry_count` option. It can be set either on the command-line or in a server [option group](#) in an [option file](#) prior to starting up the server. For example:

```
[mariadb]
...
master_retry_count=4294967295
```

MASTER_BIND

The `MASTER_BIND` option for `CHANGE MASTER` is only supported by MySQL 5.6.2 and later and by MySQL NDB Cluster 7.3.1 and later. This option is not supported by MariaDB. See [MDEV-19248](#) for more information.

MASTER_HEARTBEAT_PERIOD

The `MASTER_HEARTBEAT_PERIOD` option for `CHANGE MASTER` can be used to set the interval in seconds between replication heartbeats. Whenever the primary's [binary log](#) is updated with an event, the waiting period for the next heartbeat is reset.

This option's *interval* argument has the following characteristics:

- It is a decimal value with a range of 0 to 4294967 seconds.
- It has a resolution of hundredths of a second.
- Its smallest valid non-zero value is 0.001.
- Its default value is the value of the `slave_net_timeout` system variable divided by 2.
- If it's set to 0, then heartbeats are disabled.

Heartbeats are sent by the primary only if there are no unsent events in the binary log file for a period longer than the interval.

If the `RESET SLAVE` statement is executed, then the heartbeat interval is reset to the default.

If the `slave_net_timeout` system variable is set to a value that is lower than the current heartbeat interval, then a warning will be issued.

TLS Options

The TLS options are used for providing information about [TLS](#). The options can be set even on replicas that are compiled without TLS support. The TLS options are saved to either the default `master.info` file or the file that is configured by the `master_info_file` option, but these TLS options are ignored unless the replica supports TLS.

See [Replication with Secure Connections](#) for more information.

MASTER_SSL

The `MASTER_SSL` option for `CHANGE MASTER` tells the replica whether to force [TLS](#) for the connection. The valid values are 0 or 1. Required to be set to 1 for the other `MASTER_SSL*` options to have any effect.

For example:

```
STOP SLAVE;
CHANGE MASTER TO
  MASTER_SSL=1;
START SLAVE;
```

MASTER_SSL_CA

The `MASTER_SSL_CA` option for `CHANGE MASTER` defines a path to a PEM file that should contain one or more X509 certificates for trusted Certificate Authorities (CAs) to use for [TLS](#). This option requires that you use the absolute path, not a relative path.

For example:

```

STOP SLAVE;
CHANGE MASTER TO
  MASTER_SSL_CERT='/etc/my.cnf.d/certificates/server-cert.pem',
  MASTER_SSL_KEY='/etc/my.cnf.d/certificates/server-key.pem',
  MASTER_SSL_CA='/etc/my.cnf.d/certificates/ca.pem',
  MASTER_SSL_VERIFY_SERVER_CERT=1;
START SLAVE;

```

See [Secure Connections Overview: Certificate Authorities \(CAs\)](#) for more information.

The maximum length of `MASTER_SSL_CA` string is 511 characters.

MASTER_SSL_CAPATH

The `MASTER_SSL_CAPATH` option for `CHANGE MASTER` defines a path to a directory that contains one or more PEM files that should each contain one X509 certificate for a trusted Certificate Authority (CA) to use for [TLS](#). This option requires that you use the absolute path, not a relative path. The directory specified by this option needs to be run through the [openssl rehash](#) command.

For example:

```

STOP SLAVE;
CHANGE MASTER TO
  MASTER_SSL_CERT='/etc/my.cnf.d/certificates/server-cert.pem',
  MASTER_SSL_KEY='/etc/my.cnf.d/certificates/server-key.pem',
  MASTER_SSL_CAPATH='/etc/my.cnf.d/certificates/ca/',
  MASTER_SSL_VERIFY_SERVER_CERT=1;
START SLAVE;

```

See [Secure Connections Overview: Certificate Authorities \(CAs\)](#) for more information.

The maximum length of `MASTER_SSL_CA_PATH` string is 511 characters.

MASTER_SSL_CERT

The `MASTER_SSL_CERT` option for `CHANGE MASTER` defines a path to the X509 certificate file to use for [TLS](#). This option requires that you use the absolute path, not a relative path.

For example:

```

STOP SLAVE;
CHANGE MASTER TO
  MASTER_SSL_CERT='/etc/my.cnf.d/certificates/server-cert.pem',
  MASTER_SSL_KEY='/etc/my.cnf.d/certificates/server-key.pem',
  MASTER_SSL_CA='/etc/my.cnf.d/certificates/ca.pem',
  MASTER_SSL_VERIFY_SERVER_CERT=1;
START SLAVE;

```

The maximum length of `MASTER_SSL_CERT` string is 511 characters.

MASTER_SSL_CRL

The `MASTER_SSL_CRL` option for `CHANGE MASTER` defines a path to a PEM file that should contain one or more revoked X509 certificates to use for [TLS](#). This option requires that you use the absolute path, not a relative path.

This option is only supported if the server was built with OpenSSL. If the server was built with yaSSL, then this option is not supported. See [TLS and Cryptography Libraries Used by MariaDB](#) for more information about which libraries are used on which platforms.

For example:

```

STOP SLAVE;
CHANGE MASTER TO
  MASTER_SSL_CERT='/etc/my.cnf.d/certificates/server-cert.pem',
  MASTER_SSL_KEY='/etc/my.cnf.d/certificates/server-key.pem',
  MASTER_SSL_CA='/etc/my.cnf.d/certificates/ca.pem',
  MASTER_SSL_VERIFY_SERVER_CERT=1,
  MASTER_SSL_CRL='/etc/my.cnf.d/certificates/crl.pem';
START SLAVE;

```

See [Secure Connections Overview: Certificate Revocation Lists \(CRLs\)](#) for more information.

The maximum length of `MASTER_SSL_CRL` string is 511 characters.

MASTER_SSL_CRLPATH

The `MASTER_SSL_CRLPATH` option for `CHANGE MASTER` defines a path to a directory that contains one or more PEM files that should each contain one revoked X509 certificate to use for [TLS](#). This option requires that you use the absolute path, not a relative path. The directory specified by this variable needs to be run through the [openssl rehash](#)  command.

This option is only supported if the server was built with OpenSSL. If the server was built with yaSSL, then this option is not supported. See [TLS and Cryptography Libraries Used by MariaDB](#) for more information about which libraries are used on which platforms.

For example:

```
STOP SLAVE;
CHANGE MASTER TO
  MASTER_SSL_CERT='/etc/my.cnf.d/certificates/server-cert.pem',
  MASTER_SSL_KEY='/etc/my.cnf.d/certificates/server-key.pem',
  MASTER_SSL_CA='/etc/my.cnf.d/certificates/ca.pem',
  MASTER_SSL_VERIFY_SERVER_CERT=1,
  MASTER_SSL_CRLPATH='/etc/my.cnf.d/certificates/crl/';
START SLAVE;
```

See [Secure Connections Overview: Certificate Revocation Lists \(CRLs\)](#) for more information.

The maximum length of `MASTER_SSL_CRL_PATH` string is 511 characters.

MASTER_SSL_KEY

The `MASTER_SSL_KEY` option for `CHANGE MASTER` defines a path to a private key file to use for [TLS](#). This option requires that you use the absolute path, not a relative path.

For example:

```
STOP SLAVE;
CHANGE MASTER TO
  MASTER_SSL_CERT='/etc/my.cnf.d/certificates/server-cert.pem',
  MASTER_SSL_KEY='/etc/my.cnf.d/certificates/server-key.pem',
  MASTER_SSL_CA='/etc/my.cnf.d/certificates/ca.pem',
  MASTER_SSL_VERIFY_SERVER_CERT=1;
START SLAVE;
```

The maximum length of `MASTER_SSL_KEY` string is 511 characters.

MASTER_SSL_CIPHER

The `MASTER_SSL_CIPHER` option for `CHANGE MASTER` defines the list of permitted ciphers or cipher suites to use for [TLS](#). Besides cipher names, if MariaDB was compiled with OpenSSL, this option could be set to "SSLv3" or "TLSv1.2" to allow all SSLv3 or all TLSv1.2 ciphers. Note that the TLSv1.3 ciphers cannot be excluded when using OpenSSL, even by using this option. See [Using TLSv1.3](#) for details.

For example:

```
STOP SLAVE;
CHANGE MASTER TO
  MASTER_SSL_CERT='/etc/my.cnf.d/certificates/server-cert.pem',
  MASTER_SSL_KEY='/etc/my.cnf.d/certificates/server-key.pem',
  MASTER_SSL_CA='/etc/my.cnf.d/certificates/ca.pem',
  MASTER_SSL_VERIFY_SERVER_CERT=1,
  MASTER_SSL_CIPHER='TLSv1.2';
START SLAVE;
```

The maximum length of `MASTER_SSL_CIPHER` string is 511 characters.

MASTER_SSL_VERIFY_SERVER_CERT

The `MASTER_SSL_VERIFY_SERVER_CERT` option for `CHANGE MASTER` enables [server certificate verification](#). This option is disabled by default prior to [MariaDB 11.4](#), and enabled by default from [MariaDB 11.4](#).

For example:

```
STOP SLAVE;
CHANGE MASTER TO
  MASTER_SSL_CERT='/etc/my.cnf.d/certificates/server-cert.pem',
  MASTER_SSL_KEY='/etc/my.cnf.d/certificates/server-key.pem',
  MASTER_SSL_CA='/etc/my.cnf.d/certificates/ca.pem',
  MASTER_SSL_VERIFY_SERVER_CERT=1;
START SLAVE;
```

See [Secure Connections Overview: Server Certificate Verification](#) for more information.

Binary Log Options

These options are related to the [binary log](#) position on the primary.

MASTER_LOG_FILE

The `MASTER_LOG_FILE` option for `CHANGE MASTER` can be used along with `MASTER_LOG_POS` to specify the coordinates at which the [replica's I/O thread](#) should begin reading from the primary's [binary logs](#) the next time the thread starts.

For example:

```
STOP SLAVE;
CHANGE MASTER TO
  MASTER_LOG_FILE='master2-bin.001',
  MASTER_LOG_POS=4;
START SLAVE;
```

The `MASTER_LOG_FILE` and `MASTER_LOG_POS` options cannot be specified if the `RELAY_LOG_FILE` and `RELAY_LOG_POS` options were also specified.

The `MASTER_LOG_FILE` and `MASTER_LOG_POS` options are effectively ignored if you enable [GTID](#) mode for replication by setting the `MASTER_USE_GTID` option to some value other than `no` in the statement.

MASTER_LOG_POS

The `MASTER_LOG_POS` option for `CHANGE MASTER` can be used along with `MASTER_LOG_FILE` to specify the coordinates at which the [replica's I/O thread](#) should begin reading from the primary's [binary logs](#) the next time the thread starts.

For example:

```
STOP SLAVE;
CHANGE MASTER TO
  MASTER_LOG_FILE='master2-bin.001',
  MASTER_LOG_POS=4;
START SLAVE;
```

The `MASTER_LOG_FILE` and `MASTER_LOG_POS` options cannot be specified if the `RELAY_LOG_FILE` and `RELAY_LOG_POS` options were also specified.

The `MASTER_LOG_FILE` and `MASTER_LOG_POS` options are effectively ignored if you enable [GTID](#) mode for replication by setting the `MASTER_USE_GTID` option to some value other than `no` in the statement.

Relay Log Options

These options are related to the [relay log](#) position on the replica.

RELAY_LOG_FILE

The `RELAY_LOG_FILE` option for `CHANGE MASTER` can be used along with the `RELAY_LOG_POS` option to specify the coordinates at which the replica's SQL thread should begin reading from the relay log the next time the thread starts.

The `CHANGE MASTER` statement usually deletes all relay log files. However, if the `RELAY_LOG_FILE` and/or `RELAY_LOG_POS` options are specified, then existing relay log files are kept.

When you want to change the relay log position, you only need to stop the replica's SQL thread. The replica's I/O thread can continue running. The `STOP SLAVE` and `START SLAVE` statements support the `SQL_THREAD` option for this scenario. For example:

```
STOP SLAVE SQL_THREAD;
CHANGE MASTER TO
  RELAY_LOG_FILE='slave-relay-bin.006',
  RELAY_LOG_POS=4025;
START SLAVE SQL_THREAD;
```

When the value of this option is changed, the metadata about the replica's SQL thread's position in the relay logs will also be changed in the `relay-log.info` file or the file that is configured by the `relay_log_info_file` system variable.

The `RELAY_LOG_FILE` and `RELAY_LOG_POS` options cannot be specified if the `MASTER_LOG_FILE` and `MASTER_LOG_POS` options were also specified.

RELAY_LOG_POS

The `RELAY_LOG_POS` option for `CHANGE MASTER` can be used along with the `RELAY_LOG_FILE` option to specify the coordinates at which the replica's SQL thread should begin reading from the relay log the next time the thread starts.

The `CHANGE MASTER` statement usually deletes all relay log files. However, if the `RELAY_LOG_FILE` and/or `RELAY_LOG_POS` options are specified, then existing relay log files are kept.

When you want to change the relay log position, you only need to stop the replica's SQL thread. The replica's I/O thread can continue running. The `STOP SLAVE` and `START SLAVE` statements support the `SQL_THREAD` option for this scenario. For example:

```
STOP SLAVE SQL_THREAD;
CHANGE MASTER TO
  RELAY_LOG_FILE='slave-relay-bin.006',
  RELAY_LOG_POS=4025;
START SLAVE SQL_THREAD;
```

When the value of this option is changed, the metadata about the replica's SQL thread's position in the relay logs will also be changed in the `relay-log.info` file or the file that is configured by the `relay_log_info_file` system variable.

The `RELAY_LOG_FILE` and `RELAY_LOG_POS` options cannot be specified if the `MASTER_LOG_FILE` and `MASTER_LOG_POS` options were also specified.

GTID Options

MASTER_USE_GTID

The `MASTER_USE_GTID` option for `CHANGE MASTER` can be used to configure the replica to use the global transaction ID (GTID) when connecting to a primary. The possible values are:

- `current_pos` - Replicate in GTID mode and use `gtid_current_pos` as the position to start downloading transactions from the primary. Using to transition to primary can break the replication state if the replica executes local transactions due to actively updating `gtid_current_pos` with `gtid_binlog_pos` and `gtid_slave_pos`. Use the new, safe, `MASTER_DEMOTE_TO_SLAVE=<bool>` option instead.
- `slave_pos` - Replicate in GTID mode and use `gtid_slave_pos` as the position to start downloading transactions from the primary. From MariaDB 10.5.1, `replica_pos` is an alias for `slave_pos`.
- `no` - Don't replicate in GTID mode.

For example:

```
STOP SLAVE;
CHANGE MASTER TO
  MASTER_USE_GTID = current_pos;
START SLAVE;
```

Or:

```
STOP SLAVE;
SET GLOBAL gtid_slave_pos='0-1-153';
CHANGE MASTER TO
  MASTER_USE_GTID = slave_pos;
START SLAVE;
```

MASTER_DEMOTE_TO_SLAVE

MariaDB starting with [10.10](#)

Used to transition a primary to become a replica. Replaces the old `MASTER_USE_GTID=current_pos` with a safe alternative by forcing users to set `Using_Gtid=Slave_Pos` and merging `gtid_binlog_pos` into `gtid_slave_pos` once at `CHANGE MASTER TO` time. If `gtid_slave_pos` is more recent than `gtid_binlog_pos` (as in the case of chain replication), the replication state should be preserved.

For example:

```
STOP SLAVE;
CHANGE MASTER TO
  MASTER_DEMOTE_TO_SLAVE = 1;
START SLAVE;
```

Replication Filter Options

Also see [Replication filters](#).

IGNORE_SERVER_IDS

The `IGNORE_SERVER_IDS` option for `CHANGE MASTER` can be used to configure a [replica](#) to ignore [binary log](#) events that originated from certain servers. Filtered [binary log](#) events will not get logged to the replica's [relay log](#), and they will not be applied by the replica.

The option's value can be specified by providing a comma-separated list of [server_id](#) values. For example:

```
STOP SLAVE;
CHANGE MASTER TO
  IGNORE_SERVER_IDS = (3,5);
START SLAVE;
```

If you would like to clear a previously set list, then you can set the value to an empty list. For example:

```
STOP SLAVE;
CHANGE MASTER TO
  IGNORE_SERVER_IDS = ();
START SLAVE;
```

DO_DOMAIN_IDS

The `DO_DOMAIN_IDS` option for `CHANGE MASTER` can be used to configure a [replica](#) to only apply [binary log](#) events if the transaction's `GTID` is in a specific `gtid_domain_id` value. Filtered [binary log](#) events will not get logged to the replica's [relay log](#), and they will not be applied by the replica.

The option's value can be specified by providing a comma-separated list of `gtid_domain_id` values. Duplicate values are automatically ignored. For example:

```
STOP SLAVE;
CHANGE MASTER TO
  DO_DOMAIN_IDS = (1,2);
START SLAVE;
```

If you would like to clear a previously set list, then you can set the value to an empty list. For example:

```
STOP SLAVE;
CHANGE MASTER TO
  DO_DOMAIN_IDS = ();
START SLAVE;
```

The `DO_DOMAIN_IDS` option and the `IGNORE_DOMAIN_IDS` option cannot both be set to non-empty values at the same time. If you want to set the `DO_DOMAIN_IDS` option, and the `IGNORE_DOMAIN_IDS` option was previously set, then you need to clear the value of the `IGNORE_DOMAIN_IDS` option. For example:

```
STOP SLAVE;
CHANGE MASTER TO
  IGNORE_DOMAIN_IDS = (),
  DO_DOMAIN_IDS = (1,2);
START SLAVE;
```

The `DO_DOMAIN_IDS` option can only be specified if the replica is replicating in `GTID` mode. Therefore, the `MASTER_USE_GTID` option must also be set to some value other than `no` in order to use this option.

IGNORE_DOMAIN_IDS

The `IGNORE_DOMAIN_IDS` option for `CHANGE MASTER` can be used to configure a replica to ignore binary log events if the transaction's `GTID` is in a specific `gtid_domain_id` value. Filtered binary log events will not get logged to the replica's relay log, and they will not be applied by the replica.

The option's value can be specified by providing a comma-separated list of `gtid_domain_id` values. Duplicate values are automatically ignored. For example:

```
STOP SLAVE;
CHANGE MASTER TO
  IGNORE_DOMAIN_IDS = (1,2);
START SLAVE;
```

If you would like to clear a previously set list, then you can set the value to an empty list. For example:

```
STOP SLAVE;
CHANGE MASTER TO
  IGNORE_DOMAIN_IDS = ();
START SLAVE;
```

The `DO_DOMAIN_IDS` option and the `IGNORE_DOMAIN_IDS` option cannot both be set to non-empty values at the same time. If you want to set the `IGNORE_DOMAIN_IDS` option, and the `DO_DOMAIN_IDS` option was previously set, then you need to clear the value of the `DO_DOMAIN_IDS` option. For example:

```
STOP SLAVE;
CHANGE MASTER TO
  DO_DOMAIN_IDS = (),
  IGNORE_DOMAIN_IDS = (1,2);
START SLAVE;
```

The `IGNORE_DOMAIN_IDS` option can only be specified if the replica is replicating in `GTID` mode. Therefore, the `MASTER_USE_GTID` option must also be set to some value other than `no` in order to use this option.

Delayed Replication Options

MASTER_DELAY

The `MASTER_DELAY` option for `CHANGE MASTER` can be used to enable [delayed replication](#). This option specifies the time in seconds (at least) that a replica should lag behind the primary up to a maximum value of 2147483647, or about 68 years. Before executing an event, the replica will first wait, if necessary, until the given time has passed since the event was created on the primary. The result is that the replica will reflect the state of the primary some time back in the past. The default is zero, no delay.

```
STOP SLAVE;
CHANGE MASTER TO
  MASTER_DELAY=3600;
START SLAVE;
```

Changing Option Values

If you don't specify a given option when executing the `CHANGE MASTER` statement, then the option keeps its old value in most cases. Most of the time, there is no need to specify the options that do not need to change. For example, if the password for the user account that the replica uses to connect to its primary has changed, but no other options need to change, then you can just change the `MASTER_PASSWORD` option by executing the following commands:

```
STOP SLAVE;
CHANGE MASTER TO
  MASTER_PASSWORD='new3cret';
START SLAVE;
```

There are some cases where options are implicitly reset, such as when the `MASTER_HOST` and `MASTER_PORT` options are changed.

Option Persistence

The values of the `MASTER_LOG_FILE` and `MASTER_LOG_POS` options (i.e. the [binary log](#) position on the primary) and most other options are written to either the default `master.info` file or the file that is configured by the `master_info_file` option. The [replica's I/O thread](#) keeps this [binary log](#) position updated as it downloads events only when `MASTER_USE_GTID` option is set to `NO`. Otherwise the file is not updated on a per event basis.

The `master_info_file` option can be set either on the command-line or in a server [option group](#) in an [option file](#) prior to starting up the server. For example:

```
[mariadb]
...
master_info_file=/mariadb/myserver1-master.info
```

The values of the `RELAY_LOG_FILE` and `RELAY_LOG_POS` options (i.e. the [relay log](#) position) are written to either the default `relay-log.info` file or the file that is configured by the `relay_log_info_file` system variable. The [replica's SQL thread](#) keeps this [relay log](#) position updated as it applies events.

The `relay_log_info_file` system variable can be set either on the command-line or in a server [option group](#) in an [option file](#) prior to starting up the server. For example:

```
[mariadb]
...
relay_log_info_file=/mariadb/myserver1-relay-log.info
```

GTID Persistence

If the replica is replicating [binary log](#) events that contain [GTIDs](#), then the [replica's SQL thread](#) will write every GTID that it applies to the `mysql.gtid_slave_pos` table. This GTID can be inspected and modified through the `gtid_slave_pos` system variable.

If the replica has the `log_slave_updates` system variable enabled and if the replica has the [binary log](#) enabled, then every write by the [replica's SQL thread](#) will also go into the replica's [binary log](#). This means that [GTIDs](#) of replicated transactions would be reflected in the value of the `gtid_binlog_pos` system variable.

Creating a Replica from a Backup

The `CHANGE MASTER` statement is useful for setting up a replica when you have a backup of the primary and you also have

the [binary log](#) position or [GTID](#) position corresponding to the backup.

After restoring the backup on the replica, you could execute something like this to use the [binary log](#) position:

```
CHANGE MASTER TO
  MASTER_LOG_FILE='master2-bin.001',
  MASTER_LOG_POS=4;
START SLAVE;
```

Or you could execute something like this to use the [GTID](#) position:

```
SET GLOBAL gtid_slave_pos='0-1-153';
CHANGE MASTER TO
  MASTER_USE_GTID=slave_pos;
START SLAVE;
```

See [Setting up a Replication Slave with Mariabackup](#) for more information on how to do this with [Mariabackup](#).

Example

The following example changes the primary and primary's binary log coordinates. This is used when you want to set up the replica to replicate the primary:

```
CHANGE MASTER TO
  MASTER_HOST='master2.mycompany.com',
  MASTER_USER='replication',
  MASTER_PASSWORD='big3cret',
  MASTER_PORT=3306,
  MASTER_LOG_FILE='master2-bin.001',
  MASTER_LOG_POS=4,
  MASTER_CONNECT_RETRY=10;
START SLAVE;
```

1.1.1.2.5.2 START SLAVE

The terms *master* and *slave* have historically been used in replication, and MariaDB has begun the process of adding *primary* and *replica* synonyms. The old terms will continue to be used to maintain backward compatibility - see [MDEV-18777](#) to follow progress on this effort.

Syntax

```
START SLAVE ["connection_name"] [thread_type [, thread_type] ... ] [FOR CHANNEL
"connection_name"]
START SLAVE ["connection_name"] [SQL_THREAD] UNTIL
  MASTER_LOG_FILE = 'log_name', MASTER_LOG_POS = log_pos [FOR CHANNEL "connection_name"]
START SLAVE ["connection_name"] [SQL_THREAD] UNTIL
  RELAY_LOG_FILE = 'log_name', RELAY_LOG_POS = log_pos [FOR CHANNEL "connection_name"]
START SLAVE ["connection_name"] [SQL_THREAD] UNTIL
  MASTER_GTID_POS = <GTID position> [FOR CHANNEL "connection_name"]
START ALL SLAVES [thread_type [, thread_type]]

START REPLICA ["connection_name"] [thread_type [, thread_type] ... ] -- from 10.5.1
START REPLICA ["connection_name"] [SQL_THREAD] UNTIL
  MASTER_LOG_FILE = 'log_name', MASTER_LOG_POS = log_pos -- from 10.5.1
START REPLICA ["connection_name"] [SQL_THREAD] UNTIL
  RELAY_LOG_FILE = 'log_name', RELAY_LOG_POS = log_pos -- from 10.5.1
START REPLICA ["connection_name"] [SQL_THREAD] UNTIL
  MASTER_GTID_POS = <GTID position> -- from 10.5.1
START ALL REPLICAS [thread_type [, thread_type]] -- from 10.5.1

thread_type: IO_THREAD | SQL_THREAD
```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [START SLAVE UNTIL](#)
 1. [SQL_BEFORE_GTIDS|SQL_AFTER_GTIDS](#)
 2. [connection_name](#)
 3. [START ALL SLAVES](#)
 4. [START REPLICA](#)

Description

`START SLAVE` (`START REPLICA` from [MariaDB 10.5.1](#)) with no `thread_type` options starts both of the replica threads (see [replication](#)) needed to connect with a master setup with `CHANGE MASTER TO`. The I/O thread reads events from the primary server and stores them in the [relay log](#). The SQL thread reads events from the relay log and executes them. `START SLAVE` requires the `SUPER` privilege, or, from [MariaDB 10.5.2](#), the `REPLICATION SLAVE ADMIN` privilege.

If `START SLAVE` succeeds in starting the replica threads, it returns without any error. However, even in that case, it might be that the replica threads start and then later stop (for example, because they do not manage to connect to the primary or read its [binary log](#), or some other problem). `START SLAVE` does not warn you about this. You must check the replica's [error log](#) for error messages generated by the replica threads, or check that they are running satisfactorily with `SHOW SLAVE STATUS` (`SHOW REPLICA STATUS` from [MariaDB 10.5.1](#)).

START SLAVE UNTIL

`START SLAVE UNTIL` refers to the `SQL_THREAD` replica position at which the `SQL_THREAD` replication will halt. If `SQL_THREAD` isn't specified both threads are started.

`START SLAVE UNTIL master_gtid_pos=xxx` is also supported. See [Global Transaction ID/START SLAVE UNTIL master_gtid_pos=xxx](#) for more details.

MariaDB starting with [11.3.0](#)

`SQL_BEFORE_GTIDS|SQL_AFTER_GTIDS`

[MariaDB 11.3](#) extended the `START SLAVE UNTIL` command with the options `SQL_BEFORE_GTIDS` and `SQL_AFTER_GTIDS` to allow control of whether the replica stops before or after a provided GTID state. Its syntax is:

```
START SLAVE UNTIL (SQL_BEFORE_GTIDS|SQL_AFTER_GTIDS)="<gtid\_list>"
```

See [Global Transaction ID#SQL_BEFORE_GTIDS/SQL_AFTER_GTIDS](#) for details.

connection_name

If there is only one nameless primary, or the default primary (as specified by the `default_master_connection` system variable) is intended, `connection_name` can be omitted. If provided, the `START SLAVE` statement will apply to the specified primary. `connection_name` is case-insensitive.

MariaDB starting with [10.7.0](#)

The `FOR CHANNEL` keyword was added for MySQL compatibility. This is identical as using the `channel_name` directly after `START SLAVE`.

START ALL SLAVES

`START ALL SLAVES` starts all configured replicas (replicas with `master_host` not empty) that were not started before. It will give a `note` for all started connections. You can check the notes with `SHOW WARNINGS`.

START REPLICA

MariaDB starting with [10.5.1](#)

`START REPLICA` is an alias for `START SLAVE` from [MariaDB 10.5.1](#).

1.1.1.2.5.3 STOP SLAVE

The terms *master* and *slave* have historically been used in replication, and MariaDB has begun the process of adding *primary* and *replica* synonyms. The old terms will continue to be used to maintain backward compatibility - see [MDEV-18777](#) to follow progress on this effort.

Syntax

```
STOP SLAVE ["connection_name"] [thread_type [, thread_type] ... ] [FOR CHANNEL "connection_name"]

STOP ALL SLAVES [thread_type [, thread_type]]

STOP REPLICAS ["connection_name"] [thread_type [, thread_type] ... ] -- from 10.5.1

STOP ALL REPLICAS [thread_type [, thread_type]] -- from 10.5.1

thread_type: IO_THREAD | SQL_THREAD
```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [STOP ALL SLAVES](#)
 2. [connection_name](#)
 3. [STOP REPLICAS](#)

Description

Stops the replica threads. `STOP SLAVE` requires the [SUPER](#) privilege, or, from [MariaDB 10.5.2](#), the [REPLICATION SLAVE ADMIN](#) privilege.

Like [START SLAVE](#), this statement may be used with the `IO_THREAD` and `SQL_THREAD` options to name the thread or threads to be stopped. In almost all cases, one never need to use the `thread_type` options.

`STOP SLAVE` waits until any current replication event group affecting one or more non-transactional tables has finished executing (if there is any such replication group), or until the user issues a [KILL QUERY](#) or [KILL CONNECTION](#) statement.

Note that `STOP SLAVE` doesn't delete the connection permanently. Next time you execute [START SLAVE](#) or the MariaDB server restarts, the replica connection is restored with its [original arguments](#). If you want to delete a connection, you should execute [RESET SLAVE](#).

STOP ALL SLAVES

`STOP ALL SLAVES` stops all your running replicas. It will give you a `note` for every stopped connection. You can check the notes with [SHOW WARNINGS](#).

connection_name

The `connection_name` option is used for [multi-source replication](#).

If there is only one nameless master, or the default master (as specified by the [default_master_connection](#) system variable) is intended, `connection_name` can be omitted. If provided, the `STOP SLAVE` statement will apply to the specified master. `connection_name` is case-insensitive.

MariaDB starting with [10.7.0](#)

The `FOR CHANNEL` keyword was added for MySQL compatibility. This is identical as using the `channel_name` directly after `STOP SLAVE`.

STOP REPLICAS

MariaDB starting with [10.5.1](#)

`STOP REPLICAS` is an alias for `STOP SLAVE` from [MariaDB 10.5.1](#).

1.1.1.2.5.4 RESET REPLICA

The terms *master* and *slave* have historically been used in replication, and MariaDB has begun the process of adding *primary* and *replica* synonyms. The old terms will continue to be used to maintain backward compatibility - see [MDEV-18777](#) to follow progress on this effort.

Syntax

```
RESET REPLICA ["connection_name"] [ALL] [FOR CHANNEL "connection_name"] -- from MariaDB 10.5.1
RESET SLAVE ["connection_name"] [ALL] [FOR CHANNEL "connection_name"]
```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [connection_name](#)

Description

RESET REPLICA (RESET SLAVE) makes the replica forget its [replication](#) position in the master's [binary log](#). This statement is meant to be used for a clean start. It deletes the master.info and relay-log.info files, all the [relay log](#) files, and starts a new relay log file. To use RESET REPLICA, the replica threads must be stopped (use [STOP REPLICA](#) if necessary).

Note: All relay log files are deleted, even if they have not been completely executed by the slave SQL thread. (This is a condition likely to exist on a replication slave if you have issued a STOP REPLICA statement or if the slave is highly loaded.)

Note: RESET REPLICA does not reset the global `gtid_slave_pos` variable. This means that a replica server configured with `CHANGE MASTER TO MASTER_USE_GTID=slave_pos` will not receive events with GTIDs occurring before the state saved in `gtid_slave_pos`. If the intent is to reprocess these events, `gtid_slave_pos` must be manually reset, e.g. by executing `set global gtid_slave_pos=""`.

Connection information stored in the master.info file is immediately reset using any values specified in the corresponding startup options. This information includes values such as master host, master port, master user, and master password. If the replica SQL thread was in the middle of replicating temporary tables when it was stopped, and RESET REPLICA is issued, these replicated temporary tables are deleted on the slave.

The `ALL` also resets the `PORT`, `HOST`, `USER` and `PASSWORD` parameters for the slave. If you are using a connection name, it will permanently delete it and it will not show up anymore in [SHOW ALL REPLICAS STATUS](#).

connection_name

The `connection_name` option is used for [multi-source replication](#).

If there is only one nameless primary, or the default primary (as specified by the [default_master_connection](#) system variable) is intended, `connection_name` can be omitted. If provided, the `RESET REPLICA` statement will apply to the specified primary. `connection_name` is case-insensitive.

MariaDB starting with [10.7.0](#)

The `FOR CHANNEL` keyword was added for MySQL compatibility. This is identical as using the `channel_name` directly after `RESET REPLICA`.

MariaDB starting with [11.6.0](#)

From [MariaDB 11.6](#), `RESET REPLICA` resets the Master/Slave_last_event_time values (see [SHOW REPLICA STATUS](#)).

1.1.1.2.5.5 SET GLOBAL SQL_SLAVE_SKIP_COUNTER

Syntax

```
SET GLOBAL sql_slave_skip_counter = N
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Example](#)
4. [Multiple Replication Domains](#)

Description

This statement skips the next *N* events from the primary. This is useful for recovering from [replication](#) stops caused by a statement.

If multi-source replication is used, this statement applies to the default connection. It could be necessary to change the value of the [default_master_connection](#) system variable.

Note that, if the event is a [transaction](#), the whole transaction will be skipped. With non-transactional engines, an event is always a single statement.

This statement is valid only when the replica threads are not running. Otherwise, it produces an error.

The statement does not automatically restart the replica threads.

Example

```
SHOW SLAVE STATUS \G
...
SET GLOBAL sql_slave_skip_counter = 1;
START SLAVE;
```

Multi-source replication:

```
SET @@default_master_connection = 'master_01';
SET GLOBAL SQL_SLAVE_SKIP_COUNTER = 1;
START SLAVE;
```

Multiple Replication Domains

`sql_slave_skip_counter` can't be used to skip transactions on a replica if [GTID replication](#) is in use and if `gtid_slave_pos` contains multiple `gtid_domain_id` values. In that case, you'll get an error like the following:

```
ERROR 1966 (HY000): When using parallel replication and GTID with multiple
replication domains, @@sql_slave_skip_counter can not be used. Instead,
setting @@gtid_slave_pos explicitly can be used to skip to after a given GTID
position.
```

In order to skip transactions in cases like this, you will have to manually change `gtid_slave_pos`.

1.1.1.2.5.6 SHOW RELAYLOG EVENTS

The terms *master* and *slave* have historically been used in replication, and MariaDB has begun the process of adding *primary* and *replica* synonyms. The old terms will continue to be used to maintain backward compatibility - see [MDEV-18777](#) to follow progress on this effort.

Syntax

```
SHOW RELAYLOG ['connection_name'] EVENTS
  [IN 'log_name'] [FROM pos] [LIMIT [offset,] row_count]
  [ FOR CHANNEL 'channel_name']
```

Description

On [replicas](#), this command shows the events in the [relay log](#). If 'log_name' is not specified, the first relay log is shown.

Syntax for the `LIMIT` clause is the same as for [SELECT ... LIMIT](#).

Using the `LIMIT` clause is highly recommended because the `SHOW RELAYLOG EVENTS` command returns the complete contents of the relay log, which can be quite large.

This command does not return events related to setting user and system variables. If you need those, use [mariadb-binlog](#).

On the primary, this command does nothing.

Requires the [REPLICA MONITOR](#) privilege (\geq [MariaDB 10.5.9](#)), the [REPLICATION SLAVE ADMIN](#) privilege (\geq [MariaDB 10.5.2](#)) or the [REPLICATION SLAVE](#) privilege (\leq [MariaDB 10.5.1](#)).

connection_name

If there is only one nameless primary, or the default primary (as specified by the [default_master_connection](#) system variable) is intended, `connection_name` can be omitted. If provided, the `SHOW RELAYLOG` statement will apply to the specified primary. `connection_name` is case-insensitive.

MariaDB starting with [10.7.0](#) [↗](#)

The `FOR CHANNEL` keyword was added for MySQL compatibility. This is identical as using the `channel_name` directly after `SHOW RELAYLOG`.

1.1.1.2.5.7 SHOW REPLICA STATUS

Syntax

```
SHOW SLAVE ["connection_name"] STATUS [FOR CHANNEL "connection_name"]
SHOW REPLICA ["connection_name"] STATUS [FOR CHANNEL "connection_name"] -- From MariaDB 10.5.1
```

or

```
SHOW ALL SLAVES STATUS
SHOW ALL REPLICAS STATUS -- From MariaDB 10.5.1
```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [Multi-Source](#)
 2. [Column Descriptions](#)
3. [Examples](#)

Description

This statement is to be run on a replica and provides status information on essential parameters of the [replica](#) threads.

This statement requires the [SUPER](#) privilege, the [REPLICATION_CLIENT](#) privilege, or, from [MariaDB 10.5.2](#), the [REPLICATION SLAVE ADMIN](#) privilege, or, from [MariaDB 10.5.9](#), the [REPLICA MONITOR](#) privilege.

Multi-Source

The `ALL` and `"connection_name"` options allow you to connect to [many primaries at the same time](#).

`ALL SLAVES` (or `ALL REPLICAS` from [MariaDB 10.5.1](#)) gives you a list of all connections to the primary nodes.

The rows will be sorted according to `Connection_name`.

If you specify a `connection_name`, you only get the information about that connection. If `connection_name` is not used, then the name set by `default_master_connection` is used. If the connection name doesn't exist you will get an error:
`There is no master connection for 'xxx'.`

MariaDB starting with [10.7.0](#)
The `FOR CHANNEL` keyword was added for MySQL compatibility. This is identical to using the `channel_name` directly after `SHOW SLAVE`.

Column Descriptions

The order in which the columns appear depends on the MariaDB version. This means that extracting a column value is best done by comparing the field name instead of using a fixed offset into the row.

MariaDB starting with [11.6.0](#)
These columns can also be viewed/extracted from the `INFORMATION_SCHEMA.SLAVE_STATUS` table

Name	Description
<code>Connection_name</code>	Name of the primary connection. Returned with <code>SHOW ALL SLAVES STATUS</code> (or <code>SHOW ALL REPLICAS STATUS</code> from MariaDB 10.5.1) only.
<code>Slave_SQL_State</code>	State of SQL thread. Returned with <code>SHOW ALL SLAVES STATUS</code> (or <code>SHOW ALL REPLICAS STATUS</code> from MariaDB 10.5.1) only. See Slave SQL Thread States .
<code>Slave_IO_State</code>	State of I/O thread. See Slave I/O Thread States .
<code>Master_host</code>	Master host that the replica is connected to.
<code>Master_user</code>	Account user name being used to connect to the primary.
<code>Master_port</code>	The port being used to connect to the primary.
<code>Connect_Retry</code>	Time in seconds between retries to connect. The default is 60. The CHANGE MASTER TO statement can set this. The <code>master-retry-count</code> option determines the maximum number of reconnection attempts.
<code>Master_Log_File</code>	Name of the primary binary log file that the I/O thread is currently reading from.
<code>Read_Master_Log_Pos</code>	Position up to which the I/O thread has read in the current primary binary log file.
<code>Relay_Log_File</code>	Name of the relay log file that the SQL thread is currently processing.
<code>Relay_Log_Pos</code>	Position up to which the SQL thread has finished processing in the current relay log file.
<code>Relay_Master_Log_File</code>	Name of the primary binary log file that contains the most recent event executed by the SQL thread.
<code>Slave_IO_Running</code>	Whether the replica I/O thread is running and connected (<code>Yes</code>), running but not connected to a primary (<code>Connecting</code>) or not running (<code>No</code>).
<code>Slave_SQL_Running</code>	Whether or not the SQL thread is running.
<code>Replicate_Rewrite_DB</code>	Databases specified for replicating and rewriting with the <code>replicate_rewrite_db</code> option. Added in MariaDB 10.11
<code>Replicate_Do_DB</code>	Databases specified for replicating with the <code>replicate_do_db</code> option.
<code>Replicate_Ignore_DB</code>	Databases specified for ignoring with the <code>replicate_ignore_db</code> option.
<code>Replicate_Do_Table</code>	Tables specified for replicating with the <code>replicate_do_table</code> option.
<code>Replicate_Ignore_Table</code>	Tables specified for ignoring with the <code>replicate_ignore_table</code> option.
<code>Replicate_Wild_Do_Table</code>	Tables specified for replicating with the <code>replicate_wild_do_table</code> option.
<code>Replicate_Wild_Ignore_Table</code>	Tables specified for ignoring with the <code>replicate_wild_ignore_table</code> option.

Last_Errno	Alias for <code>Last_SQL_Errno</code> (see below)
Last_Error	Alias for <code>Last_SQL_Error</code> (see below)
Skip_Counter	Number of events that a replica skips from the master, as recorded in the <code>sql_slave_skip_counter</code> system variable.
Exec_Master_Log_Pos	Position up to which the SQL thread has processed in the current master <code>binary log</code> file. Can be used to start a new replica from a current replica with the <code>CHANGE MASTER TO ... MASTER_LOG_POS</code> option.
Relay_Log_Space	Total size of all relay log files combined.
Until_Condition	One of four possible values: <code>None</code> , <code>Master</code> , <code>Relay</code> , or <code>Gtid</code> , depending on the respective <code>START SLAVE UNTIL</code> condition.
Until_Log_File	The <code>MASTER_LOG_FILE</code> value of the <code>START SLAVE UNTIL</code> condition.
Until_Log_Pos	The <code>MASTER_LOG_POS</code> value of the <code>START SLAVE UNTIL</code> condition.
Master_SSL_Allowed	Whether an SSL connection is permitted (<code>Yes</code>), not permitted (<code>No</code>) or permitted but without the replica having SSL support enabled (<code>Ignored</code>)
Master_SSL_CA_File	The <code>MASTER_SSL_CA</code> option of the <code>CHANGE MASTER TO</code> statement.
Master_SSL_CA_Path	The <code>MASTER_SSL_CAPATH</code> option of the <code>CHANGE MASTER TO</code> statement.
Master_SSL_Cert	The <code>MASTER_SSL_CERT</code> option of the <code>CHANGE MASTER TO</code> statement.
Master_SSL_Cipher	The <code>MASTER_SSL_CIPHER</code> option of the <code>CHANGE MASTER TO</code> statement.
Master_SSL_Key	The <code>MASTER_SSL_KEY</code> option of the <code>CHANGE MASTER TO</code> statement.
Seconds_Behind_Master	Difference between the timestamp logged on the master for the event that the replica is currently processing, and the current timestamp on the replica. Zero if the replica is not currently processing an event. With serial replication, <code>seconds_behind_master</code> is updated when the SQL thread begins executing a transaction. With <code>parallel replication</code> , <code>seconds_behind_master</code> is updated only after transactions commit. Starting in MariaDB 10.3.38 , 10.4.28 , 10.5.19 , 10.6.12 , 10.8.7 , 10.9.5 , 10.10.3 , and 10.11.2 , an exception is drawn on the parallel replica to additionally update <code>seconds_behind_master</code> when the first transaction received after idling is queued to a worker for execution, to provide a reliable initial value for the duration until a transaction commits. Additional behaviors to be aware of are as follows: 1) <code>Seconds_Behind_Master</code> will update for ignored events, e.g. those skipped due to <code>sql_slave_skip_counter</code> . 2) On the serial replica, transactions with prior timestamps can update <code>Seconds_Behind_Master</code> such that it can go backwards, though this is not true for the parallel replica. 3) When configured with <code>MASTER_DELAY</code> , as a replicated transaction begins executing (i.e. on a serial or post-idle parallel replica), <code>Seconds_Behind_Master</code> will update before delaying, and while delaying occurs will grow to encompass the configured value. 4) There is a known issue, tracked by MDEV-17516 , such that <code>Seconds_Behind_Master</code> will initially present as <code>0</code> on replica restart until a replicated transaction begins executing, even if the last replica session was lagging behind when stopped.
Master_SSL_Verify_Server_Cert	The <code>MASTER_SSL_VERIFY_SERVER_CERT</code> option of the <code>CHANGE MASTER TO</code> statement.
Last_IO_Errno	<code>Error code</code> of the most recent error that caused the I/O thread to stop (also recorded in the replica's error log). <code>0</code> means no error. <code>RESET SLAVE</code> or <code>RESET MASTER</code> will reset this value.
Last_IO_Error	<code>Error message</code> of the most recent error that caused the I/O thread to stop (also recorded in the replica's error log). An empty string means no error. <code>RESET SLAVE</code> or <code>RESET MASTER</code> will reset this value.
Last_SQL_Errno	<code>Error code</code> of the most recent error that caused the SQL thread to stop (also recorded in the replica's error log). <code>0</code> means no error. <code>RESET SLAVE</code> or <code>RESET MASTER</code> will reset this value.
Last_SQL_Error	<code>Error message</code> of the most recent error that caused the SQL thread to stop (also recorded in the replica's error log). An empty string means no error. <code>RESET SLAVE</code> or <code>RESET MASTER</code> will reset this value.

Replicate_Ignore_Server_Ids	List of server_ids that are currently being ignored for replication purposes, or an empty string for none, as specified in the <code>IGNORE_SERVER_IDS</code> option of the <code>CHANGE MASTER TO</code> statement.
Master_Server_Id	The master's server_id value.
Master_SSL_Crl	The <code>MASTER_SSL_CRL</code> option of the <code>CHANGE MASTER TO</code> statement.
Master_SSL_Crlpath	The <code>MASTER_SSL_CRLPATH</code> option of the <code>CHANGE MASTER TO</code> statement.
Using_Gtid	Whether or not global transaction ID's are being used for replication (can be <code>No</code> , <code>Slave_Pos</code> , or <code>Current_Pos</code>).
Gtid_IO_Pos	Current global transaction ID value.
Retried_transactions	Number of retried transactions for this connection. Returned with <code>SHOW ALL SLAVES STATUS</code> only.
Max_relay_log_size	Max relay log size for this connection. Returned with <code>SHOW ALL SLAVES STATUS</code> only.
Executed_log_entries	How many log entries the replica has executed. Returned with <code>SHOW ALL SLAVES STATUS</code> only.
Slave_received_heartbeats	How many heartbeats we have got from the master. Returned with <code>SHOW ALL SLAVES STATUS</code> only.
Slave_heartbeat_period	How often to request a heartbeat packet from the master (in seconds). Returned with <code>SHOW ALL SLAVES STATUS</code> only.
Gtid_Slave_Pos	GTID of the last event group replicated on a replica server, for each replication domain, as stored in the <code>gtid_slave_pos</code> system variable. Returned with <code>SHOW ALL SLAVES STATUS</code> only.
SQL_Delay	Value specified by <code>MASTER_DELAY</code> in <code>CHANGE MASTER</code> (or 0 if none).
SQL_Remaining_Delay	When the replica is delaying the execution of an event due to <code>MASTER_DELAY</code> , this is the number of seconds of delay remaining before the event will be applied. Otherwise, the value is <code>NULL</code> .
Slave_SQL_Running_State	The state of the SQL driver threads, same as in <code>SHOW PROCESSLIST</code> . When the replica is delaying the execution of an event due to <code>MASTER_DELAY</code> , this field displays: " <code>Waiting until MASTER_DELAY seconds after master executed event</code> " .
Slave_DDL_Groups	This status variable counts the occurrence of DDL statements. This is a replica-side counter for optimistic parallel replication.
Slave_Non_Transactional_Groups	This status variable counts the occurrence of non-transactional event groups. This is a replica-side counter for optimistic parallel replication.
Slave_Transactional_Groups	This status variable counts the occurrence of transactional event groups. This is a replica-side counter for optimistic parallel replication.
Replicate_Rewrite_DB	Value of configured <code>replicate_rewrite_db</code> system variable/option.
Retried_transactions	The number of times that replicating transactions have been retried due to temporary errors (e.g. deadlocks in parallel replication).
Max_relay_log_size	Maximum size of the relay log (configured by variable <code>max_relay_log_size</code>).
Executed_log_entries	Number of binary log events that have been executed, irrespective of error outcome (i.e. if the event execution results in an error, this number will still increase).
Slave_received_heartbeats	Number of Heartbeat Log Events  that the slave has received. Note this counter does not reset when the slave is restarted; only when a new <code>CHANGE MASTER</code> command has executed.
Slave_heartbeat_period	Configured (by <code>CHANGE MASTER TO MASTER_HEARTBEAT_PERIOD</code>) interval in seconds between replication heartbeats.
Gtid_Slave_Pos	The value of the global variable <code>gtid_slave_pos</code> , i.e. the GTID of the last transaction applied to the database by the server's replica threads for each replication domain.

Master_last_event_time	Timestamp of the last event read from the primary by the IO thread. NULL until the replica has started and the replica has read one query event from the primary that changes data. From MariaDB 11.6 .
Slave_last_event_time	Primary timestamp of the last event committed on the replica. NULL until the replica has started and the replica has read one query event from the primary that changes data. From MariaDB 11.6 .
Master_Slave_time_diff	The difference of the above two timestamps. NULL until the replica has started and the replica has read one query event from the primary that changes data. From MariaDB 11.6 .

Examples

If you issue this statement using the [mariadb](#) client, you can use a `\G` statement terminator rather than a semicolon to obtain a more readable vertical layout.

```

SHOW SLAVE STATUS\G
***** 1. row *****
      Slave_IO_State: Waiting for master to send event

```

1.1.1.2.5.8 SHOW MASTER STATUS

Syntax

```
SHOW MASTER STATUS
SHOW BINLOG STATUS -- From MariaDB 10.5.2
```

Description

Provides status information about the [binary log](#) files of the primary.

This statement requires the [SUPER](#) privilege, the [REPLICATION_CLIENT](#) privilege, or, from [MariaDB 10.5.2](#), the [BINLOG MONITOR](#) privilege.

To see information about the current [GTIDs](#) in the binary log, use the [gtid_binlog_pos](#) variable.

`SHOW MASTER STATUS` was renamed to `SHOW BINLOG STATUS` in [MariaDB 10.5.2](#), but the old name remains an alias for compatibility purposes.

Example

```
SHOW MASTER STATUS;
+-----+-----+-----+-----+
| File           | Position | Binlog_Do_DB | Binlog_Ignore_DB |
+-----+-----+-----+-----+
| mariadb-bin.000016 | 475 | | |
+-----+-----+-----+-----+
SELECT @@global.gtid_binlog_pos;
+-----+
| @@global.gtid_binlog_pos |
+-----+
| 0-1-2 |
+-----+
```

1.1.1.2.5.9 SHOW REPLICA HOSTS

Contents

- [Syntax](#)
- [Description](#)
 - [SHOW REPLICA HOSTS](#)

Syntax

```
SHOW SLAVE HOSTS
SHOW REPLICA HOSTS -- from MariaDB 10.5.1
```

Description

This command is run on the primary and displays a list of replicas that are currently registered with it. The output looks like this:

```
SHOW SLAVE HOSTS;
+-----+-----+-----+-----+
| Server_id | Host      | Port | Master_id |
+-----+-----+-----+-----+
| 192168010 | iconnect2 | 3306 | 192168011 |
| 1921680101 | athena    | 3306 | 192168011 |
+-----+-----+-----+-----+
```

- **Server_id**: The unique server ID of the replica server, as configured in the server's option file, or on the command line with `--server-id=value`.
- **Host**: The host name of the replica server, as configured in the server's option file, or on the command line with `--report-host=host_name` (note that this can differ from the machine name as configured in the operating system). Starting in [MariaDB 10.5.1](#), if a replica doesn't configure `--report-host` explicitly, the value for the `Host` column is automatically extracted using the network connection's host name or IP address. Prior to 10.5, the `Host` value is left blank if a replica's `--report-host` parameter is not configured.
- **Port**: The port the replica server is listening on.
- **Master_id**: The unique server ID of the primary server that the replica server is replicating from.

Some MariaDB and MySQL versions report another variable, `rpl_recovery_rank`. This variable was never used, and was eventually removed in [MariaDB 10.1.2](#).

Requires the [REPLICATION MASTER ADMIN](#) privilege (\geq [MariaDB 10.5.2](#)) or the [REPLICATION SLAVE](#) privilege (\leq [MariaDB 10.5.1](#)).

SHOW REPLICA HOSTS

MariaDB starting with [10.5.1](#)

`SHOW REPLICA HOSTS` is an alias for `SHOW SLAVE HOSTS` from [MariaDB 10.5.1](#).

1.1.1.2.5.10 RESET MASTER

```
RESET MASTER [TO #]
```

Deletes all [binary log](#) files listed in the index file, resets the binary log index file to be empty, and creates a new binary log file with a suffix of `.000001`.

If `TO #` is given, then the first new binary log file will start from number `#`.

This statement is for use only when the master is started for the first time, and should never be used if any slaves are actively [replicating](#) from the binary log.

1.1.1.2.6 Plugin SQL Statements

Plugin commands.

SHOW PLUGINS

Display information about installed plugins.

SHOW PLUGINS SONAME

Information about all available plugins, installed or not.

INSTALL PLUGIN

Install a plugin.

UNINSTALL PLUGIN

Remove a single installed plugin.

INSTALL SONAME

Installs all plugins from a given library.

UNINSTALL SONAME

Remove all plugins belonging to a specified library.

mysql_plugin

Old name for mariadb-plugin.

1.1.1.2.6.1 SHOW PLUGINS

Syntax

```
SHOW PLUGINS;
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

Description

`SHOW PLUGINS` displays information about installed [plugins](#). The `Library` column indicates the plugin library - if it is `NULL`, the plugin is built-in and cannot be uninstalled.

The `PLUGINS` table in the `information_schema` database contains more detailed information.

For specific information about storage engines (a particular type of plugin), see the `information_schema.ENGINES` table and the `SHOW ENGINES` statement.

Examples

```
SHOW PLUGINS;
```

Name	Status	Type	Library	License
binlog	ACTIVE	STORAGE ENGINE	NULL	GPL
mysql_native_password	ACTIVE	AUTHENTICATION	NULL	GPL
mysql_old_password	ACTIVE	AUTHENTICATION	NULL	GPL

BLACKHOLE	ACTIVE	STORAGE ENGINE	NULL	GPL
FEEDBACK	DISABLED	INFORMATION SCHEMA	NULL	GPL
partition	ACTIVE	STORAGE ENGINE	NULL	GPL
pam	ACTIVE	AUTHENTICATION	auth_pam.so	GPL

1.1.1.2.6.2 SHOW PLUGINS SONAME

Syntax

```
SHOW PLUGINS SONAME { library | LIKE 'pattern' | WHERE expr };
```

Description

`SHOW PLUGINS SONAME` displays information about compiled-in and all server plugins in the `plugin_dir` directory, including plugins that haven't been installed.

Examples

```
SHOW PLUGINS SONAME 'ha_example.so';
+-----+-----+-----+-----+-----+
| Name      | Status      | Type           | Library      | License |
+-----+-----+-----+-----+-----+
| EXAMPLE   | NOT INSTALLED | STORAGE ENGINE | ha_example.so | GPL     |
| UNUSABLE  | NOT INSTALLED | DAEMON         | ha_example.so | GPL     |
+-----+-----+-----+-----+-----+
```

There is also a corresponding `information_schema` table, called `ALL_PLUGINS`, which contains more complete information.

1.1.1.2.6.3 INSTALL PLUGIN

Syntax

```
INSTALL PLUGIN [IF NOT EXISTS] plugin_name SONAME 'plugin_library'
```

Contents

- [Syntax](#)
- [Description](#)
 - [IF NOT EXISTS](#)
- [Examples](#)

Description

This statement installs an individual [plugin](#) from the specified library. To install the whole library (which could be required), use `INSTALL SONAME`. See also [Installing a Plugin](#).

`plugin_name` is the name of the plugin as defined in the plugin declaration structure contained in the library file. Plugin names are not case sensitive. For maximal compatibility, plugin names should be limited to ASCII letters, digits, and underscore, because they are used in C source files, shell command lines, M4 and Bourne shell scripts, and SQL environments.

`plugin_library` is the name of the shared library that contains the plugin code. The file name extension can be omitted (which makes the statement look the same on all architectures).

The shared library must be located in the plugin directory (that is, the directory named by the `plugin_dir` system variable). The library must be in the plugin directory itself, not in a subdirectory. By default, `plugin_dir` is plugin directory under the directory named by the `pkglibdir` configuration variable, but it can be changed by setting the value of `plugin_dir` at server startup. For example, set its value in a `my.cnf` file:

```
[mariadb]
plugin_dir=/path/to/plugin/directory
```

If the value of `plugin_dir` is a relative path name, it is taken to be relative to the base directory (the value of the `basedir` system variable).

`INSTALL PLUGIN` adds a line to the `mysql.plugin` table that describes the plugin. This table contains the plugin name and library file name.

`INSTALL PLUGIN` causes the server to read option (`my.cnf`) files just as during server startup. This enables the plugin to pick up any relevant options from those files. It is possible to add plugin options to an option file even before loading a plugin (if the loose prefix is used). It is also possible to uninstall a plugin, edit `my.cnf` , and install the plugin again. Restarting the plugin this way enables it to the new option values without a server restart.

`INSTALL PLUGIN` also loads and initializes the plugin code to make the plugin available for use. A plugin is initialized by executing its initialization function, which handles any setup that the plugin must perform before it can be used.

To use `INSTALL PLUGIN` , you must have the [INSERT privilege](#) for the `mysql.plugin` table.

At server startup, the server loads and initializes any plugin that is listed in the `mysql.plugin` table. This means that a plugin is installed with `INSTALL PLUGIN` only once, not every time the server starts. Plugin loading at startup does not occur if the server is started with the `--skip-grant-tables` option.

When the server shuts down, it executes the de-initialization function for each plugin that is loaded so that the plugin has a chance to perform any final cleanup.

If you need to load plugins for a single server startup when the `--skip-grant-tables` option is given (which tells the server not to read system tables), use the `--plugin-load` [mariadb option](#).

IF NOT EXISTS

When the `IF NOT EXISTS` clause is used, MariaDB will return a note instead of an error if the specified plugin already exists. See [SHOW WARNINGS](#).

Examples

```
INSTALL PLUGIN sphinx SONAME 'ha_sphinx.so';
```

The extension can also be omitted:

```
INSTALL PLUGIN innodb SONAME 'ha_xtradb';
```

```
INSTALL PLUGIN IF NOT EXISTS example SONAME 'ha_example';  
Query OK, 0 rows affected (0.104 sec)
```

```
INSTALL PLUGIN IF NOT EXISTS example SONAME 'ha_example';  
Query OK, 0 rows affected, 1 warning (0.000 sec)
```

```
SHOW WARNINGS;
```

```
+-----+-----+-----+  
| Level | Code | Message |  
+-----+-----+-----+  
| Note  | 1968 | Plugin 'example' already installed |  
+-----+-----+-----+
```

1.1.1.2.6.4 UNINSTALL PLUGIN

Syntax

```
UNINSTALL PLUGIN [IF EXISTS] plugin_name
```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [IF EXISTS](#)
3. [Examples](#)

Description

This statement removes a single installed [plugin](#). To uninstall the whole library which contains the plugin, use [UNINSTALL SONAME](#). You cannot uninstall a plugin if any table that uses it is open.

`plugin_name` must be the name of some plugin that is listed in the `mysql.plugin` table. The server executes the plugin's deinitialization function and removes the row for the plugin from the `mysql.plugin` table, so that subsequent server restarts will not load and initialize the plugin. `UNINSTALL PLUGIN` does not remove the plugin's shared library file.

To use `UNINSTALL PLUGIN`, you must have the [DELETE](#) privilege for the `mysql.plugin` table.

MariaDB starting with [10.4.0](#)

IF EXISTS

If the `IF EXISTS` clause is used, MariaDB will return a note instead of an error if the plugin does not exist. See [SHOW WARNINGS](#).

Examples

```
UNINSTALL PLUGIN example;
```

From [MariaDB 10.4.0](#):

```
UNINSTALL PLUGIN IF EXISTS example;
Query OK, 0 rows affected (0.099 sec)

UNINSTALL PLUGIN IF EXISTS example;
Query OK, 0 rows affected, 1 warning (0.000 sec)

SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message                               |
+-----+-----+-----+
| Note  | 1305 | PLUGIN example does not exist        |
+-----+-----+-----+
```

1.1.1.2.6.5 INSTALL SONAME

Syntax

```
INSTALL SONAME 'plugin_library'
```

Contents

- [1. Syntax](#)
- [2. Description](#)
- [3. Examples](#)

Description

This statement is a variant of [INSTALL PLUGIN](#). It installs **all** [plugins](#) from a given `plugin_library`. See [INSTALL PLUGIN](#) for details.

`plugin_library` is the name of the shared library that contains the plugin code. The file name extension (for example, `libmyplugin.so` or `libmyplugin.dll`) can be omitted (which makes the statement look the same on all architectures).

The shared library must be located in the plugin directory (that is, the directory named by the `plugin_dir` system variable). The library must be in the plugin directory itself, not in a subdirectory. By default, `plugin_dir` is plugin directory under the directory named by the `pkglibdir` configuration variable, but it can be changed by setting the value of `plugin_dir` at server startup. For example, set its value in a `my.cnf` file:

```
[mariadb]
plugin_dir=/path/to/plugin/directory
```

If the value of `plugin_dir` is a relative path name, it is taken to be relative to the MySQL base directory (the value of the

`basedir` system variable).

`INSTALL SONAME` adds one or more lines to the `mysql.plugin` table that describes the plugin. This table contains the plugin name and library file name.

`INSTALL SONAME` causes the server to read option (`my.cnf`) files just as during server startup. This enables the plugin to pick up any relevant options from those files. It is possible to add plugin options to an option file even before loading a plugin (if the loose prefix is used). It is also possible to uninstall a plugin, edit `my.cnf` , and install the plugin again. Restarting the plugin this way enables it to the new option values without a server restart.

`INSTALL SONAME` also loads and initializes the plugin code to make the plugin available for use. A plugin is initialized by executing its initialization function, which handles any setup that the plugin must perform before it can be used.

To use `INSTALL SONAME` , you must have the [INSERT privilege](#) for the `mysql.plugin` table.

At server startup, the server loads and initializes any plugin that is listed in the `mysql.plugin` table. This means that a plugin is installed with `INSTALL SONAME` only once, not every time the server starts. Plugin loading at startup does not occur if the server is started with the `--skip-grant-tables` option.

When the server shuts down, it executes the de-initialization function for each plugin that is loaded so that the plugin has a chance to perform any final cleanup.

If you need to load plugins for a single server startup when the `--skip-grant-tables` option is given (which tells the server not to read system tables), use the `--plugin-load` [mariadb option](#).

If you need to install only one plugin from a library, use the [INSTALL PLUGIN](#) statement.

Examples

To load the [LOCALES plugin](#) and all of its `information_schema` tables with one statement, use

```
INSTALL SONAME 'locales';
```

This statement can be used instead of `INSTALL PLUGIN` even when the library contains only one plugin:

```
INSTALL SONAME 'ha_sequence';
```

1.1.1.2.6.6 UNINSTALL SONAME

Syntax

```
UNINSTALL SONAME [IF EXISTS] 'plugin_library'
```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [IF EXISTS](#)
3. [Examples](#)

Description

This statement is a variant of [UNINSTALL PLUGIN](#) statement, that removes all [plugins](#) belonging to a specified `plugin_library` . See [UNINSTALL PLUGIN](#) for details.

`plugin_library` is the name of the shared library that contains the plugin code. The file name extension (for example, `libmyplugin.so` or `libmyplugin.dll`) can be omitted (which makes the statement look the same on all architectures).

To use `UNINSTALL SONAME` , you must have the [DELETE privilege](#) for the `mysql.plugin` table.

MariaDB starting with [10.4.0](#) [↗](#)
`IF EXISTS`

If the `IF EXISTS` clause is used, MariaDB will return a note instead of an error if the plugin library does not exist. See [SHOW WARNINGS](#).

Examples

To uninstall the XtraDB plugin and all of its `information_schema` tables with one statement, use

```
UNINSTALL SONAME 'ha_xtradb';
```

From [MariaDB 10.4.0](#) [↗](#):

```
UNINSTALL SONAME IF EXISTS 'ha_example';
Query OK, 0 rows affected (0.099 sec)

UNINSTALL SONAME IF EXISTS 'ha_example';
Query OK, 0 rows affected, 1 warning (0.000 sec)

SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Note   | 1305 | SONAME ha_example.so does not exist |
+-----+-----+-----+
```

1.3.43.12 mysql_plugin

1.1.1.2.7 SET Commands

SET

Set a variable value.

SET CHARACTER SET

Maps all strings sent between the current client and the server with the given mapping.

SET GLOBAL SQL_SLAVE_SKIP_COUNTER

Skips a number of events from the primary.

SET NAMES

The character set used to send statements to the server, and results back to the client.

SET PASSWORD

Assign password to an existing MariaDB user.

SET ROLE

Enable a role.

SET SQL_LOG_BIN

Set binary logging for the current connection.

SET STATEMENT

Set variable values on a per-query basis.

SET TRANSACTION

Sets the transaction isolation level.

SET Variable

Used to insert a value into a variable with a code block.

There are [1 related questions](#) [↗](#).

1.1.1.2.7.1 SET

Syntax

```
SET variable_assignment [, variable_assignment] ...

variable_assignment:
    user_var_name = expr
  | [GLOBAL | SESSION] system_var_name = expr
  | [@@global. | @@session. | @@]system_var_name = expr
```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [GLOBAL / SESSION](#)
 2. [DEFAULT](#)
3. [Examples](#)

One can also set a user variable in any expression with this syntax:

```
user_var_name:= expr
```

Description

The `SET` statement assigns values to different types of variables that affect the operation of the server or your client. Older versions of MySQL employed `SET OPTION`, but this syntax was deprecated in favor of `SET` without `OPTION`, and was removed in [MariaDB 10.0](#).

Changing a system variable by using the `SET` statement does not make the change permanently. To do so, the change must be made in a [configuration file](#).

For setting variables on a per-query basis, see [SET STATEMENT](#).

See [SHOW VARIABLES](#) for documentation on viewing server system variables.

See [Server System Variables](#) for a list of all the system variables.

GLOBAL / SESSION

When setting a system variable, the scope can be specified as either `GLOBAL` or `SESSION`.

A global variable change affects all new sessions. It does not affect any currently open sessions, including the one that made the change.

A session variable change affects the current session only.

If the variable has a session value, not specifying either `GLOBAL` or `SESSION` will be the same as specifying `SESSION`. If the variable only has a global value, not specifying `GLOBAL` or `SESSION` will apply to the change to the global value.

DEFAULT

Setting a global variable to `DEFAULT` will restore it to the server default, and setting a session variable to `DEFAULT` will restore it to the current global value.

Examples

- [innodb_sync_spin_loops](#) is a global variable.
- [skip_parallel_replication](#) is a session variable.
- [max_error_count](#) is both global and session.

```

SELECT VARIABLE_NAME, SESSION_VALUE, GLOBAL_VALUE FROM
INFORMATION_SCHEMA.SYSTEM_VARIABLES WHERE
  VARIABLE_NAME IN ('max_error_count', 'skip_parallel_replication', 'innodb_sync_spin_loops');
+-----+-----+-----+
| VARIABLE_NAME          | SESSION_VALUE | GLOBAL_VALUE |
+-----+-----+-----+
| MAX_ERROR_COUNT        | 64            | 64           |
| SKIP_PARALLEL_REPLICATION | OFF         | NULL       |
| INNODB_SYNC_SPIN_LOOPS  | NULL       | 30           |
+-----+-----+-----+

```

Setting the session values:

```

SET max_error_count=128;Query OK, 0 rows affected (0.000 sec)

SET skip_parallel_replication=ON;Query OK, 0 rows affected (0.000 sec)

SET innodb_sync_spin_loops=60;
ERROR 1229 (HY000): Variable 'innodb_sync_spin_loops' is a GLOBAL variable
and should be set with SET GLOBAL

SELECT VARIABLE_NAME, SESSION_VALUE, GLOBAL_VALUE FROM
INFORMATION_SCHEMA.SYSTEM_VARIABLES WHERE
  VARIABLE_NAME IN ('max_error_count', 'skip_parallel_replication', 'innodb_sync_spin_loops');
+-----+-----+-----+
| VARIABLE_NAME          | SESSION_VALUE | GLOBAL_VALUE |
+-----+-----+-----+
| MAX_ERROR_COUNT        | 128           | 64           |
| SKIP_PARALLEL_REPLICATION | ON          | NULL       |
| INNODB_SYNC_SPIN_LOOPS  | NULL       | 30           |
+-----+-----+-----+

```

Setting the global values:

```

SET GLOBAL max_error_count=256;

SET GLOBAL skip_parallel_replication=ON;
ERROR 1228 (HY000): Variable 'skip_parallel_replication' is a SESSION variable
and can't be used with SET GLOBAL

SET GLOBAL innodb_sync_spin_loops=120;

SELECT VARIABLE_NAME, SESSION_VALUE, GLOBAL_VALUE FROM
INFORMATION_SCHEMA.SYSTEM_VARIABLES WHERE
  VARIABLE_NAME IN ('max_error_count', 'skip_parallel_replication', 'innodb_sync_spin_loops');
+-----+-----+-----+
| VARIABLE_NAME          | SESSION_VALUE | GLOBAL_VALUE |
+-----+-----+-----+
| MAX_ERROR_COUNT        | 128           | 256          |
| SKIP_PARALLEL_REPLICATION | ON          | NULL       |
| INNODB_SYNC_SPIN_LOOPS  | NULL       | 120          |
+-----+-----+-----+

```

SHOW VARIABLES will by default return the session value unless the variable is global only.

```

SHOW VARIABLES LIKE 'max_error_count';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| max_error_count | 128 |
+-----+-----+

SHOW VARIABLES LIKE 'skip_parallel_replication';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| skip_parallel_replication | ON |
+-----+-----+

SHOW VARIABLES LIKE 'innodb_sync_spin_loops';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| innodb_sync_spin_loops | 120 |
+-----+-----+

```

Using the inplace syntax:

```

SELECT (@a:=1);
+-----+
| (@a:=1) |
+-----+
| 1 |
+-----+

SELECT @a;
+-----+
| @a |
+-----+
| 1 |
+-----+

```

1.1.1.2.7.2 SET CHARACTER SET

Syntax

```

SET {CHARACTER SET | CHARSET}
   {charset_name | DEFAULT}

```

Description

Sets the [character_set_client](#) and [character_set_results](#) session system variables to the specified character set and [collation_connection](#) to the value of [collation_database](#), which implicitly sets [character_set_connection](#) to the value of [character_set_database](#).

This maps all strings sent between the current client and the server with the given mapping.

Example

```
SHOW VARIABLES LIKE 'character_set\_%';
```

```
+-----+-----+
| Variable_name          | Value      |
+-----+-----+
| character_set_client   | utf8       |
| character_set_connection | utf8       |
| character_set_database | latin1     |
| character_set_filesystem | binary     |
| character_set_results  | utf8       |
| character_set_server   | latin1     |
| character_set_system   | utf8       |
+-----+-----+
```

```
SHOW VARIABLES LIKE 'collation%';
```

```
+-----+-----+
| Variable_name          | Value      |
+-----+-----+
| collation_connection   | utf8_general_ci |
| collation_database     | latin1_swedish_ci |
| collation_server       | latin1_swedish_ci |
+-----+-----+
```

```
SET CHARACTER SET utf8mb4;
```

```
SHOW VARIABLES LIKE 'character_set\_%';
```

```
+-----+-----+
| Variable_name          | Value      |
+-----+-----+
| character_set_client   | utf8mb4    |
| character_set_connection | latin1     |
| character_set_database | latin1     |
| character_set_filesystem | binary     |
| character_set_results  | utf8mb4    |
| character_set_server   | latin1     |
| character_set_system   | utf8       |
+-----+-----+
```

```
SHOW VARIABLES LIKE 'collation%';
```

```
+-----+-----+
| Variable_name          | Value      |
+-----+-----+
| collation_connection   | latin1_swedish_ci |
| collation_database     | latin1_swedish_ci |
| collation_server       | latin1_swedish_ci |
+-----+-----+
```

1.1.1.2.5.5 SET GLOBAL SQL_SLAVE_SKIP_COUNTER

1.1.1.2.7.4 SET NAMES

Syntax

```
SET NAMES {'charset_name'
          [COLLATE 'collation_name'] | DEFAULT}
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

Description

Sets the [character_set_client](#), [character_set_connection](#), [character_set_results](#) and, implicitly, the [collation_connection](#) session system variables to the specified character set and collation.

This determines which [character set](#) the client will use to send statements to the server, and the server will use for sending

results back to the client.

`ucs2`, `utf16`, `utf16le` and `utf32` are not valid character sets for `SET NAMES`, as they cannot be used as client character sets.

The collation clause is optional. If not defined (or if `DEFAULT` is specified), the [default collation for the character set](#) will be used.

Quotes are optional for the character set or collation clauses.

Examples

Prior to [MariaDB 10.6](#), the `utf8` [character set](#) (and related collation) was the default for the given variables:

```

SELECT VARIABLE_NAME, SESSION_VALUE
FROM INFORMATION_SCHEMA.SYSTEM_VARIABLES WHERE
VARIABLE_NAME LIKE 'character_set_c%' OR
VARIABLE_NAME LIKE 'character_set_re%' OR
VARIABLE_NAME LIKE 'collation_c%';
+-----+-----+
| VARIABLE_NAME          | SESSION_VALUE |
+-----+-----+
| CHARACTER_SET_RESULTS  | utf8          |
| CHARACTER_SET_CONNECTION | utf8          |
| CHARACTER_SET_CLIENT   | utf8          |
| COLLATION_CONNECTION   | utf8_general_ci |
+-----+-----+

SET NAMES big5;

SELECT VARIABLE_NAME, SESSION_VALUE
FROM INFORMATION_SCHEMA.SYSTEM_VARIABLES WHERE
VARIABLE_NAME LIKE 'character_set_c%' OR
VARIABLE_NAME LIKE 'character_set_re%' OR
VARIABLE_NAME LIKE 'collation_c%';
+-----+-----+
| VARIABLE_NAME          | SESSION_VALUE |
+-----+-----+
| CHARACTER_SET_RESULTS  | big5          |
| CHARACTER_SET_CONNECTION | big5          |
| CHARACTER_SET_CLIENT   | big5          |
| COLLATION_CONNECTION   | big5_chinese_ci |
+-----+-----+

SET NAMES 'latin1' COLLATE 'latin1_bin';

SELECT VARIABLE_NAME, SESSION_VALUE
FROM INFORMATION_SCHEMA.SYSTEM_VARIABLES WHERE
VARIABLE_NAME LIKE 'character_set_c%' OR
VARIABLE_NAME LIKE 'character_set_re%' OR
VARIABLE_NAME LIKE 'collation_c%';
+-----+-----+
| VARIABLE_NAME          | SESSION_VALUE |
+-----+-----+
| CHARACTER_SET_RESULTS  | latin1        |
| CHARACTER_SET_CONNECTION | latin1        |
| CHARACTER_SET_CLIENT   | latin1        |
| COLLATION_CONNECTION   | latin1_bin    |
+-----+-----+

SET NAMES DEFAULT;

SELECT VARIABLE_NAME, SESSION_VALUE
FROM INFORMATION_SCHEMA.SYSTEM_VARIABLES WHERE
VARIABLE_NAME LIKE 'character_set_c%' OR
VARIABLE_NAME LIKE 'character_set_re%' OR
VARIABLE_NAME LIKE 'collation_c%';
+-----+-----+
| VARIABLE_NAME          | SESSION_VALUE |
+-----+-----+
| CHARACTER_SET_RESULTS  | latin1        |
| CHARACTER_SET_CONNECTION | latin1        |
| CHARACTER_SET_CLIENT   | latin1        |
| COLLATION_CONNECTION   | latin1_swedish_ci |
+-----+-----+

```

From [MariaDB 10.6](#) to [MariaDB 11.7](#), the utf8 character set (and related collations) became an alias for utf8mb3 rather than the other way around. [MariaDB 11.4](#) added the `character_set_collations` variable, so the SELECT query is more specific in this example:

```

SELECT VARIABLE_NAME, SESSION_VALUE
  FROM INFORMATION_SCHEMA.SYSTEM_VARIABLES WHERE
VARIABLE_NAME LIKE 'character_set_con%' OR
VARIABLE_NAME LIKE 'character_set_cl%' OR
VARIABLE_NAME LIKE 'character_set_re%' OR
VARIABLE_NAME LIKE 'collation_c%';

```

```

+-----+-----+
| VARIABLE_NAME          | SESSION_VALUE          |
+-----+-----+
| CHARACTER_SET_RESULTS  | utf8mb3                |
| CHARACTER_SET_CONNECTION | utf8mb3                |
| CHARACTER_SET_CLIENT   | utf8mb3                |
| COLLATION_CONNECTION   | utf8mb3_general_ci    |
+-----+-----+

```

```
SET NAMES utf8mb4;
```

```

SELECT VARIABLE_NAME, SESSION_VALUE
  FROM INFORMATION_SCHEMA.SYSTEM_VARIABLES WHERE
VARIABLE_NAME LIKE 'character_set_con%' OR
VARIABLE_NAME LIKE 'character_set_cl%' OR
VARIABLE_NAME LIKE 'character_set_re%' OR
VARIABLE_NAME LIKE 'collation_c%';

```

```

+-----+-----+
| VARIABLE_NAME          | SESSION_VALUE          |
+-----+-----+
| CHARACTER_SET_RESULTS  | utf8mb4                |
| CHARACTER_SET_CONNECTION | utf8mb4                |
| CHARACTER_SET_CLIENT   | utf8mb4                |
| COLLATION_CONNECTION   | utf8mb4_general_ci    |
+-----+-----+

```

From [MariaDB 11.8](#), `utf8mb4` became the default for the affected variables:

```
SET NAMES DEFAULT;
```

```

SELECT VARIABLE_NAME, SESSION_VALUE
  FROM INFORMATION_SCHEMA.SYSTEM_VARIABLES WHERE
VARIABLE_NAME LIKE 'character_set_con%' OR
VARIABLE_NAME LIKE 'character_set_cl%' OR
VARIABLE_NAME LIKE 'character_set_re%' OR
VARIABLE_NAME LIKE 'collation_c%';

```

```

+-----+-----+
| VARIABLE_NAME          | SESSION_VALUE          |
+-----+-----+
| CHARACTER_SET_RESULTS  | utf8mb4                |
| CHARACTER_SET_CONNECTION | utf8mb4                |
| CHARACTER_SET_CLIENT   | utf8mb4                |
| COLLATION_CONNECTION   | utf8mb4_uca1400_ai_ci |
+-----+-----+

```

1.1.1.1.7 SET PASSWORD

1.1.1.1.10 SET ROLE

1.1.1.2.7.7 SET SQL_LOG_BIN

Syntax

```
SET [SESSION] sql_log_bin = {0|1}
```

Description

Sets the `sql_log_bin` system variable, which disables or enables [binary logging](#) for the current connection, if the client has

the `SUPER` privilege. The statement is refused with an error if the client does not have that privilege.

Note that setting `sql_log_bin=1` has no effect if `log_bin` variable, which enables global binary logging, is not set.

Before [MariaDB 5.5](#) and before MySQL 5.6 one could also set `sql_log_bin` as a global variable. This was disabled as this was too dangerous as it could damage replication.

1.1.1.2.7.8 SET STATEMENT

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [Limitations](#)
5. [Source](#)

`SET STATEMENT` can be used to set the value of a system variable for the duration of the statement. It is also possible to set multiple variables.

Syntax

```
SET STATEMENT var1=value1 [, var2=value2, ...]
FOR <statement>
```

where `varN` is a system variable (list of allowed variables is provided below), and `valueN` is a constant literal.

Description

```
SET STATEMENT var1=value1 FOR stmt
```

is roughly equivalent to

```
SET @save_value=@var1;
SET SESSION var1=value1;
stmt;
SET SESSION var1=@save_value;
```

The server parses the whole statement before executing it, so any variables set in this fashion that affect the parser may not have the expected effect. Examples include the charset variables, `sql_mode=ansi_quotes`, etc.

Examples

One can limit statement execution time `max_statement_time`:

```
SET STATEMENT max_statement_time=1000 FOR SELECT ... ;
```

One can switch on/off individual optimizations:

```
SET STATEMENT optimizer_switch='materialization=off' FOR SELECT ....;
```

It is possible to enable MRR/BKA for a query:

```
SET STATEMENT join_cache_level=6, optimizer_switch='mrr=on' FOR SELECT ...
```

Note that it makes no sense to try to set a session variable inside a `SET STATEMENT`:

```
#USELESS STATEMENT
SET STATEMENT sort_buffer_size = 100000 for SET SESSION sort_buffer_size = 200000;
```

For the above, after setting `sort_buffer_size` to 200000 it will be reset to its original state (the state before the `SET STATEMENT` started) after the statement execution.

Limitations

There are a number of variables that cannot be set on per-query basis. These include:

- `autocommit`
- `character_set_client`
- `character_set_connection`
- `character_set_filesystem`
- `collation_connection`
- `default_master_connection`
- `debug_sync`
- `interactive_timeout`
- `gtid_domain_id`
- `last_insert_id`
- `log_slow_filter`
- `log_slow_rate_limit`
- `log_slow_verbosity`
- `long_query_time`
- `min_examined_row_limit`
- `profiling`
- `profiling_history_size`
- `query_cache_type`
- `rand_seed1`
- `rand_seed2`
- `skip_replication`
- `slow_query_log`
- `sql_log_off`
- `tx_isolation`
- `wait_timeout`

Source

- The feature was originally implemented as a Google Summer of Code 2009 project by Joseph Lukas.
- Percona Server 5.6 included it as [Per-query variable statement](#)
- MariaDB ported the patch and fixed *many* bugs. The task in MariaDB Jira is [MDEV-5231](#)

1.1.1.9.4 SET TRANSACTION

1.1.1.2.7.10 SET Variable

Syntax

```
SET var_name = expr [, var_name = expr] ...
```

Contents

1. [Syntax](#)
2. [Description](#)

Description

The `SET` statement in [stored programs](#) is an extended version of the general `SET` statement. Referenced variables may be ones declared inside a stored program, global system variables, or user-defined variables.

The `SET` statement in stored programs is implemented as part of the pre-existing `SET` syntax. This allows an extended syntax of `SET a=x,`

`b=y, ...` where different variable types (locally declared variables, global and session server variables, user-defined variables) can be mixed. This also allows combinations of local variables and some options that make sense only for system variables; in that case, the options are recognized but ignored.

`SET` can be used with both [local variables](#) and [user-defined variables](#).

When setting several variables using the columns returned by a query, `SELECT INTO` should be preferred.

To set many variables to the same value, the `LAST_VALUE()` function can be used.

Below is an example of how a user-defined variable may be set:

```
SET @x = 1;
```

1.1.1.2.8 SHOW

Articles on the various SHOW commands.

About SHOW

General information about the SHOW statement.

Extended Show

Extended SHOW with WHERE and LIKE.

SHOW ANALYZE

Retrieve ANALYZE-like output from a currently running statement.

SHOW AUTHORS

Information about the people who work on MariaDB.

SHOW BINARY LOGS

SHOW BINARY LOGS lists all binary logs on the server.

SHOW BINLOG EVENTS

Show events in the binary log.

SHOW CHARACTER SET

Available character sets.

SHOW CLIENT_STATISTICS

Statistics about client connections.

SHOW COLLATION

Supported collations.

SHOW COLUMNS

Column information.

SHOW CONTRIBUTORS

Companies and people who financially contribute to MariaDB.

SHOW CREATE DATABASE

Shows the CREATE DATABASE statement that creates the database.

SHOW CREATE EVENT

Displays the CREATE EVENT statement that creates a given event.

SHOW CREATE FUNCTION

Shows the CREATE statement that creates the function.

SHOW CREATE PACKAGE

Show the CREATE statement that creates the given package specification.

SHOW CREATE PACKAGE BODY

Show the CREATE statement that creates the given package body (i.e. implementation).

SHOW CREATE PROCEDURE

Shows the CREATE statement that creates the specific stored procedure.

SHOW CREATE SEQUENCE

Shows the `CREATE SEQUENCE` statement that creates the sequence.

SHOW CREATE SERVER

Shows the `CREATE SERVER` statement that created the given server definition.

SHOW CREATE TABLE

Shows the `CREATE TABLE` statement that creates the table.

SHOW CREATE TRIGGER

Shows the `CREATE TRIGGER` statement that creates the trigger.

SHOW CREATE USER

Show the `CREATE USER` statement that creates a specified user.

SHOW CREATE VIEW

Shows the `CREATE VIEW` statement that creates a view.

SHOW DATABASES

Lists the databases on the server.

SHOW ENGINE

Show storage engine information.

SHOW ENGINE INNODB STATUS

Display extensive InnoDB information.

SHOW ENGINES

Server storage engine info

SHOW ERRORS

Displays errors.

SHOW EVENTS

Shows information about events

SHOW EXPLAIN

Shows an execution plan for a running query.

SHOW FUNCTION CODE

Representation of the internal implementation of the stored function

SHOW FUNCTION STATUS

Stored function characteristics

SHOW GRANTS

View `GRANT` statements.

SHOW INDEX

Information about table indexes.

SHOW INDEX_STATISTICS

Index usage statistics.

SHOW INNODB STATUS (removed)

Removed synonym for `SHOW ENGINE INNODB STATUS` [↗](#)

SHOW LOCALES

View locales information.

SHOW MASTER STATUS

Status information about the binary log.

SHOW OPEN TABLES

List non-temporary open tables.

SHOW PACKAGE BODY STATUS

Returns characteristics of stored package bodies (implementations).

SHOW PACKAGE STATUS

Returns characteristics of stored package specifications.

SHOW PLUGINS

Display information about installed plugins.

SHOW PLUGINS SONAME

Information about all available plugins, installed or not.

SHOW PRIVILEGES

Shows the list of supported system privileges.

SHOW PROCEDURE CODE

Display internal implementation of a stored procedure.

SHOW PROCEDURE STATUS

Stored procedure characteristics.

SHOW PROCESSLIST

Running threads and information about them.

SHOW PROFILE

Display statement resource usage

SHOW PROFILES

Show statement resource usage

SHOW QUERY_RESPONSE_TIME

Retrieving information from the QUERY_RESPONSE_TIME plugin.

SHOW RELAYLOG EVENTS

Show events in the relay log.

SHOW REPLICA HOSTS

Display replicas currently registered with the primary.

SHOW REPLICA STATUS

Show status for one or all primaries.

SHOW STATUS

Server status information.

SHOW TABLE STATUS

SHOW TABLES with information about non-temporary tables.

SHOW TABLES

List of non-temporary tables, views or sequences.

SHOW TABLE_STATISTICS

Table usage statistics.

SHOW TRIGGERS

Shows currently-defined triggers

SHOW USER_STATISTICS

User activity statistics.

SHOW USER_VARIABLES

Shows user variables

SHOW VARIABLES

Displays the values of system variables.

SHOW WARNINGS

Displays errors, warnings and notes.

SHOW WSREP_MEMBERSHIP

Galera node cluster membership information.

SHOW WSREP_STATUS

Galera node cluster status information.

There are [1 related questions](#).

1.1.1.2.8.1 About SHOW

`SHOW` has many forms that provide information about databases, tables, columns, or status information about the server.

These include:

- `SHOW AUTHORS`
- `SHOW BINLOG STATUS`
- `SHOW CHARACTER SET [like_or_where]`
- `SHOW COLLATION [like_or_where]`
- `SHOW [FULL] COLUMNS FROM tbl_name [FROM db_name] [like_or_where]`
- `SHOW CONTRIBUTORS`
- `SHOW CREATE DATABASE db_name`
- `SHOW CREATE EVENT event_name`
- `SHOW CREATE FUNCTION`
- `SHOW CREATE PACKAGE package_name`
- `SHOW CREATE PACKAGE BODY package_name`
- `SHOW CREATE PROCEDURE proc_name`
- `SHOW CREATE SEQUENCE sequence_name`
- `SHOW CREATE TABLE tbl_name`
- `SHOW CREATE TRIGGER trigger_name`
- `SHOW CREATE USER user`
- `SHOW CREATE VIEW view_name`
- `SHOW DATABASES [like_or_where]`
- `SHOW ENGINE engine_name {STATUS | MUTEX}`
- `SHOW [STORAGE] ENGINES`
- `SHOW ERRORS [LIMIT [offset,] row_count]`
- `SHOW [FULL] EVENTS`
- `SHOW FUNCTION CODE func_name`
- `SHOW FUNCTION STATUS [like_or_where]`
- `SHOW GRANTS FOR user`
- `SHOW INDEX FROM tbl_name [FROM db_name]`
- `SHOW INDEX_STATISTICS`
- `SHOW LOCALES`
- `SHOW MASTER STATUS`
- `SHOW OPEN TABLES [FROM db_name] [like_or_where]`
- `SHOW PACKAGE BODY STATUS`
- `SHOW PACKAGE STATUS`
- `SHOW PLUGINS`
- `SHOW PROCEDURE CODE proc_name`
- `SHOW PROCEDURE STATUS [like_or_where]`
- `SHOW PRIVILEGES`
- `SHOW [FULL] PROCESSLIST`
- `SHOW PROFILE [types] [FOR QUERY n] [OFFSET n] [LIMIT n]`
- `SHOW PROFILES`
- `SHOW QUERY_RESPONSE_TIME`
- `SHOW RELAYLOG EVENTS`
- `SHOW REPLICA HOSTS`

- [SHOW REPLICA STATUS](#)
- [SHOW \[GLOBAL | SESSION\] STATUS \[like_or_where\]](#)
- [SHOW TABLE STATUS \[FROM db_name\] \[like_or_where\]](#)
- [SHOW TABLE_STATISTICS](#)
- [SHOW TABLES \[FROM db_name\] \[like_or_where\]](#)
- [SHOW TRIGGERS \[FROM db_name\] \[like_or_where\]](#)
- [SHOW USER_STATISTICS](#)
- [SHOW USER_VARIABLES](#)
- [SHOW \[GLOBAL | SESSION\] VARIABLES \[like_or_where\]](#)
- [SHOW WARNINGS \[LIMIT \[offset,\] row_count\]](#)
- [SHOW WSREP_MEMBERSHIP](#)
- [SHOW WSREP_STATUS](#)

```
like_or_where:
    LIKE 'pattern'
| WHERE expr
```

If the syntax for a given `SHOW` statement includes a `LIKE 'pattern'` part, `'pattern'` is a string that can contain the SQL `" % "` and `" _ "` wildcard characters. The pattern is useful for restricting statement output to matching values.

Several `SHOW` statements also accept a `WHERE` clause that provides more flexibility in specifying which rows to display. See [Extended Show](#).

1.1.1.2.8.2 Extended Show

Contents

1. [Examples](#)

The following `SHOW` statements can be extended by using a `WHERE` clause and a `LIKE` clause to refine the results:

- [SHOW CHARACTER SET](#)
- [SHOW COLLATION](#)
- [SHOW COLUMNS](#)
- [SHOW DATABASES](#)
- [SHOW FUNCTION STATUS](#)
- [SHOW INDEX](#)
- [SHOW OPEN TABLES](#)
- [SHOW PACKAGE STATUS](#)
- [SHOW PACKAGE BODY STATUS](#)
- [SHOW INDEX](#)
- [SHOW PROCEDURE STATUS](#)
- [SHOW STATUS](#)
- [SHOW TABLE STATUS](#)
- [SHOW TABLES](#)
- [SHOW TRIGGERS](#)
- [SHOW VARIABLES](#)

As with a regular `SELECT`, the `WHERE` clause can be used for the specific columns returned, and the `LIKE` clause with the regular wildcards.

Examples

```
SHOW TABLES;
+-----+
| Tables_in_test |
+-----+
| animal_count  |
| animals       |
| are_the_moose |
| aria_test2    |
| t1            |
| view1         |
+-----+
```

Showing the tables beginning with `a` only.

```
SHOW TABLES WHERE Tables_in_test LIKE 'a%';
```

```
+-----+
| Tables_in_test |
+-----+
| animal_count  |
| animals       |
| are_the_moose |
| aria_test2    |
+-----+
```

Variables whose name starts with *aria* and with a value of greater than 8192:

```
SHOW VARIABLES WHERE Variable_name LIKE 'aria%' AND Value >8192;
```

```
+-----+-----+
| Variable_name          | Value          |
+-----+-----+
| aria_checkpoint_log_activity | 1048576       |
| aria_log_file_size      | 1073741824    |
| aria_max_sort_file_size | 9223372036853727232 |
| aria_pagecache_buffer_size | 134217728     |
| aria_sort_buffer_size   | 134217728     |
+-----+-----+
```

Shortcut, just returning variables whose name begins with *aria*.

```
SHOW VARIABLES LIKE 'aria%';
```

```
+-----+-----+
| Variable_name          | Value          |
+-----+-----+
| aria_block_size       | 8192           |
| aria_checkpoint_interval | 30             |
| aria_checkpoint_log_activity | 1048576       |
| aria_force_start_after_recovery_failures | 0             |
| aria_group_commit     | none           |
| aria_group_commit_interval | 0             |
| aria_log_file_size    | 1073741824    |
| aria_log_purge_type   | immediate     |
| aria_max_sort_file_size | 9223372036853727232 |
| aria_page_checksum    | ON            |
| aria_pagecache_age_threshold | 300           |
| aria_pagecache_buffer_size | 134217728     |
| aria_pagecache_division_limit | 100           |
| aria_recover          | NORMAL        |
| aria_repair_threads   | 1             |
| aria_sort_buffer_size | 134217728     |
| aria_stats_method     | nulls_unequal |
| aria_sync_log_dir     | NEWFILE       |
| aria_used_for_temp_tables | ON            |
+-----+-----+
```

1.1.1.2.8.3 SHOW ANALYZE

MariaDB starting with [10.9](#)

SHOW ANALYZE was added in [MariaDB 10.9](#).

Contents

1. [Syntax](#)
2. [Description](#)
3. [Intended Usage](#)
4. [Examples](#)
 1. [Example 1: Row Counts](#)
 2. [Example 2: Timing Information](#)

Syntax

```
SHOW ANALYZE [FORMAT=JSON] FOR <connection_id>;
```

Description

SHOW ANALYZE allows one to retrieve ANALYZE-like output from a currently running statement. The command

```
SHOW ANALYZE [FORMAT=JSON] FOR <connection_id>;
```

connects to the query running in connection `connection_id`, gets information about the query plan it is executing, *also gets information about the runtime statistics of the execution so far* and returns it in a format similar to ANALYZE [FORMAT=JSON] output.

This is similar to the SHOW EXPLAIN command, the difference being that SHOW ANALYZE also produces runtime statistics information.

Intended Usage

Imagine you're trying to troubleshoot a query that never finishes. Since it doesn't finish, it is not possible to get ANALYZE output for it. With SHOW ANALYZE, you can get the runtime statistics without waiting for the query to finish.

Examples

Example 1: Row Counts

Consider the tables `orders` and `customer` and a join query finding the total amount of orders from customers with Gold status:

```
explain format=json
select sum(orders.amount)
from
  customer join orders on customer.cust_id=orders.cust_id
where
  customer.status='GOLD';
```

The EXPLAIN for this query looks like this:

id	select_type	table	type	possible_keys	key	key_len	ref	rows
1	SIMPLE	customer	ALL	PRIMARY	NULL	NULL	NULL	1
1	SIMPLE	orders	ref	cust_id	cust_id	5	customer.cust_id	1

We run the SELECT, and it has been running for 30 seconds. Let's try SHOW ANALYZE :

```
show analyze format=json for 3;
| {
  "r_query_time_in_progress_ms": 32138,
```

^ this shows how long the query has been running.

```

"query_block": {
  "select_id": 1,
  "r_loops": 1,
  "nested_loop": [
    {
      "table": {
        "table_name": "customer",
        "access_type": "ALL",
        "possible_keys": ["PRIMARY"],
        "r_loops": 1,
        "rows": 199786,
        "r_rows": 110544,

```

^ `rows` shows the number of rows expected. `r_rows` in this example shows how many rows were processed so far (110K out of expected 200K). `r_loops` above shows we're doing the first table scan (which is obvious for this query plan).

```

      "filtered": 100,
      "r_filtered": 9.538283398,
      "attached_condition": "customer.`status` = 'GOLD'"
    }
  ],
  {
    "table": {
      "table_name": "orders",
      "access_type": "ref",
      "possible_keys": ["cust_id"],
      "key": "cust_id",
      "key_length": "5",
      "used_key_parts": ["cust_id"],
      "ref": ["test.customer.cust_id"],
      "r_loops": 10544,
      "rows": 1,
      "r_rows": 99.99222307,

```

^ here, `rows: 1` shows the optimizer was expecting 1 order per customer. But `r_rows: 99.9` shows that execution has found on average 100 orders per customer. This may be the reason the query is slower than expected!

The final chunk of the output doesn't have anything interesting but here it is:

```

      "filtered": 100,
      "r_filtered": 100
    }
  ]
}
}
}

```

Example 2: Timing Information

Regular `SELECT` queries collect row count information, so `SHOW ANALYZE` can display it. However, detailed timing information is not collected, as collecting it may have CPU overhead. But if the target query is collecting timing information, `SHOW ANALYZE` will display it. How does one get the target query to collect timing information? Currently there is one way: if the target is running `ANALYZE`, it IS collecting timing information. Re-running the previous example:

```

Connection 1> ANALYZE SELECT ... ;

```

```

Connection 2> SHOW ANALYZE FORMAT=JSON FOR <connection_id>;
ANALYZE
{
  "r_query_time_in_progress_ms": 30727,
  "query_block": {
    "select_id": 1,
    "r_loops": 1,
    "nested_loop": [
      {
        "table": {
          "table_name": "customer",
          "access_type": "ALL",
          "possible_keys": ["PRIMARY"],
          "r_loops": 1,
          "rows": 199786,
          "r_rows": 109994,
          "r_table_time_ms": 232.699,
          "r_other_time_ms": 46.355,

```

^ Now, `ANALYZE` prints timing information in members named `r_..._time_ms`. One can see that so far, out of 30 seconds, only 232 millisecond were spent in reading the customer table. The bottleneck is elsewhere...

```

    "filtered": 100,
    "r_filtered": 9.085950143,
    "attached_condition": "customer.`status` = 'GOLD'"
  }
},
{
  "table": {
    "table_name": "orders",
    "access_type": "ref",
    "possible_keys": ["cust_id"],
    "key": "cust_id",
    "key_length": "5",
    "used_key_parts": ["cust_id"],
    "ref": ["test.customer.cust_id"],
    "r_loops": 9994,
    "rows": 1,
    "r_rows": 99.99779868,
    "r_table_time_ms": 29460.609,
    "r_other_time_ms": 986.842,

```

^ 29.4 seconds were spent reading the orders table (and 0.986 seconds in processing the obtained rows). Now we can see where the query is spending time.

```

    "filtered": 100,
    "r_filtered": 100
  }
}
]
}
}

```

1.1.1.2.8.4 SHOW AUTHORS

Syntax

```
SHOW AUTHORS
```

Description

The `SHOW AUTHORS` statement displays information about the people who work on MariaDB. For each author, it displays Name, Location, and Comment values. All columns are encoded as latin1.

These include:

- First the active people in MariaDB are listed.
- Then the active people in MySQL.
- Last the people that have contributed to MariaDB/MySQL in the past.

The order is somewhat related to importance of the contribution given to the MariaDB project, but this is not 100% accurate. There is still room for improvement and debate...

Example

```
SHOW AUTHORS\G
***** 1. row *****
    Name: Michael (Monty) Widenius
Location: Tusby, Finland
    Comment: Lead developer and main author
***** 2. row *****
    Name: Sergei Golubchik
Location: Kerpen, Germany
    Comment: Architect, Full-text search, precision math, plugin framework, merges etc
***** 3. row *****
    Name: Igor Babaev
Location: Bellevue, USA
    Comment: Optimizer, keycache, core work
***** 4. row *****
    Name: Sergey Petrunia
Location: St. Petersburg, Russia
    Comment: Optimizer
***** 5. row *****
    Name: Oleksandr Byelkin
Location: Lugansk, Ukraine
    Comment: Query Cache (4.0), Subqueries (4.1), Views (5.0)
***** 6. row *****
    Name: Timour Katchaounov
Location: Sofia , Bulgaria
    Comment: Optimizer
***** 7. row *****
    Name: Kristian Nielsen
Location: Copenhagen, Denmark
    Comment: Replication, Async client protocol, General buildbot stuff
***** 8. row *****
    Name: Alexander (Bar) Barkov
Location: Izhevsk, Russia
    Comment: Unicode and character sets
***** 9. row *****
    Name: Alexey Botchkov (Holyfoot)
Location: Izhevsk, Russia
    Comment: GIS extensions, embedded server, precision math
***** 10. row *****
    Name: Daniel Bartholomew
Location: Raleigh, USA
    Comment: MariaDB documentation, Buildbot, releases
***** 11. row *****
    Name: Colin Charles
Location: Selangor, Malesia
    Comment: MariaDB documentation, talks at a LOT of conferences
***** 12. row *****
    Name: Sergey Vojtovich
Location: Izhevsk, Russia
    Comment: initial implementation of plugin architecture, maintained native storage engines
(MyISAM, MEMORY, ARCHIVE, etc), rewrite of table cache
***** 13. row *****
    Name: Vladislav Vaintroub
Location: Mannheim, Germany
    Comment: MariaDB Java connector, new thread pool, Windows optimizations
***** 14. row *****
    Name: Elena Stepanova
Location: Sankt Petersburg, Russia
    Comment: QA, test cases
***** 15. row *****
    Name: Georg Richter
Location: Heidelberg, Germany
    Comment: New LGPL C connector, PHP connector
***** 16. row *****
    Name: Jan Lindström
```

Comment: InnoDB core developer
...

```

1.1.1.2.8.5 SHOW BINARY LOGS

Syntax

```
SHOW BINARY LOGS  
SHOW MASTER LOGS
```

Description

Lists the [binary log](#) files on the server. This statement is used as part of the procedure described in [PURGE BINARY LOGS](#) [↗](#), that shows how to determine which logs can be purged.

This statement requires the [SUPER](#) privilege, the [REPLICATION_CLIENT](#) privilege, or, from [MariaDB 10.5.2](#), the [BINLOG MONITOR](#) privilege.

Examples

```
SHOW BINARY LOGS;  
+-----+-----+  
| Log_name          | File_size |  
+-----+-----+  
| mariadb-bin.000001 |    19039 |  
| mariadb-bin.000002 |   717389 |  
| mariadb-bin.000003 |     300 |  
| mariadb-bin.000004 |     333 |  
| mariadb-bin.000005 |     899 |  
| mariadb-bin.000006 |     125 |  
| mariadb-bin.000007 |    18907 |  
| mariadb-bin.000008 |    19530 |  
| mariadb-bin.000009 |     151 |  
| mariadb-bin.000010 |     151 |  
| mariadb-bin.000011 |     125 |  
| mariadb-bin.000012 |     151 |  
| mariadb-bin.000013 |     151 |  
| mariadb-bin.000014 |     125 |  
| mariadb-bin.000015 |     151 |  
| mariadb-bin.000016 |     314 |  
+-----+-----+
```

1.1.1.2.8.6 SHOW BINLOG EVENTS

Syntax

```
SHOW BINLOG EVENTS  
  [IN 'log_name'] [FROM pos] [LIMIT [offset,] row_count]
```

Description

Shows the events in the [binary log](#). If you do not specify ' log_name ', the first binary log is displayed.

Requires the [BINLOG MONITOR](#) privilege (\geq [MariaDB 10.5.2](#)) or the [REPLICATION SLAVE](#) privilege (\leq [MariaDB 10.5.1](#)).

Example

```
SHOW BINLOG EVENTS IN 'mysql_sandbox10019-bin.000002';
```

Log_name	Pos	Event_type	Server_id	End_log_pos	Info
mysql_sandbox10019-bin.000002	4	Format_desc	1	248	Server ver: 10.0.19-MariaDB-log, Binlog ver: 4
mysql_sandbox10019-bin.000002	248	Gtid_list	1	273	[]
mysql_sandbox10019-bin.000002	273	Binlog_checkpoint	1	325	
mysql_sandbox10019-bin.000002	325	Gtid	1	363	GTID 0-1-1
mysql_sandbox10019-bin.000002	363	Query	1	446	CREATE DATABASE blog
mysql_sandbox10019-bin.000002	446	Gtid	1	484	GTID 0-1-2
mysql_sandbox10019-bin.000002	484	Query	1	571	use `blog`; CREATE TABLE bb (id INT)

1.1.1.2.8.7 SHOW CHARACTER SET

Syntax

```
SHOW CHARACTER SET
  [LIKE 'pattern' | WHERE expr]
```

Contents

- [Syntax](#)
- [Description](#)
- [Examples](#)

Description

The `SHOW CHARACTER SET` statement shows all available [character sets](#). The `LIKE` clause, if present on its own, indicates which character set names to match. The `WHERE` and `LIKE` clauses can be given to select rows using more general conditions, as discussed in [Extended SHOW](#).

The same information can be queried from the [Information Schema CHARACTER_SETS](#) table.

See [Setting Character Sets and Collations](#) for details on specifying the character set at the server, database, table and column levels.

Examples

```
SHOW CHARACTER SET LIKE 'latin%';
```

Charset	Description	Default collation	Maxlen
latin1	cp1252 West European	latin1_swedish_ci	1
latin2	ISO 8859-2 Central European	latin2_general_ci	1
latin5	ISO 8859-9 Turkish	latin5_turkish_ci	1
latin7	ISO 8859-13 Baltic	latin7_general_ci	1

```
SHOW CHARACTER SET WHERE Maxlen LIKE '2';
```

Charset	Description	Default collation	Maxlen
big5	Big5 Traditional Chinese	big5_chinese_ci	2
sjis	Shift-JIS Japanese	sjis_japanese_ci	2
euckr	EUC-KR Korean	euckr_korean_ci	2
gb2312	GB2312 Simplified Chinese	gb2312_chinese_ci	2
gbk	GBK Simplified Chinese	gbk_chinese_ci	2
ucs2	UCS-2 Unicode	ucs2_general_ci	2
cp932	SJIS for Windows Japanese	cp932_japanese_ci	2

1.1.1.2.8.8 SHOW CLIENT_STATISTICS

Syntax

```
SHOW CLIENT_STATISTICS
```

Description

The `SHOW CLIENT_STATISTICS` statement is part of the [User Statistics](#) feature. It was removed as a separate statement in [MariaDB 10.1.1](#), but effectively replaced by the generic `SHOW information_schema_table` statement. The `information_schema.CLIENT_STATISTICS` table holds statistics about client connections.

The `userstat` system variable must be set to 1 to activate this feature. See the [User Statistics](#) and [information_schema.CLIENT_STATISTICS](#) articles for more information.

Example

```
SHOW CLIENT_STATISTICS\G
***** 1. row *****
      Client: localhost
    Total_connections: 35
  Concurrent_connections: 0
      Connected_time: 708
          Busy_time: 2.5557979999999985
          Cpu_time: 0.04123740000000002
    Bytes_received: 3883
      Bytes_sent: 21595
  Binlog_bytes_written: 0
      Rows_read: 18
      Rows_sent: 115
    Rows_deleted: 0
    Rows_inserted: 0
    Rows_updated: 0
  Select_commands: 70
  Update_commands: 0
    Other_commands: 0
  Commit_transactions: 1
  Rollback_transactions: 0
  Denied_connections: 0
  Lost_connections: 0
    Access_denied: 0
    Empty_queries: 35
```

5.2.6 SHOW COLLATION

1.1.1.2.1.16 SHOW COLUMNS

1.1.1.2.8.11 SHOW CONTRIBUTORS

Syntax

```
SHOW CONTRIBUTORS
```

Description

The `SHOW CONTRIBUTORS` statement displays information about the companies and people who financially contribute to MariaDB. For each contributor, it displays `Name`, `Location`, and `Comment` values. All columns are encoded as `latin1`.

It displays all [members and sponsors of the MariaDB Foundation](#) as well as other financial contributors.

Example

```
SHOW CONTRIBUTORS;
+-----+-----+-----+
| Name                | Location                | Comment                |
+-----+-----+-----+
| Alibaba Cloud       | https://www.alibabacloud.com/ | Platinum Sponsor of the MariaDB Foundation |
| Tencent Cloud       | https://cloud.tencent.com     | Platinum Sponsor of the MariaDB Foundation |
| Microsoft            | https://microsoft.com/       | Platinum Sponsor of the MariaDB Foundation |
| MariaDB Corporation | https://mariadb.com          | Founding member, Platinum Sponsor of the MariaDB Foundation |
| ServiceNow          | https://servicenow.com       | Platinum Sponsor of the MariaDB Foundation |
| Intel                | https://www.intel.com        | Platinum Sponsor of the MariaDB Foundation |
| SIT                  | https://sit.org              | Platinum Sponsor of the MariaDB Foundation |
| Visma                | https://visma.com            | Gold Sponsor of the MariaDB Foundation |
| DBS                  | https://dbs.com              | Gold Sponsor of the MariaDB Foundation |
| IBM                  | https://www.ibm.com          | Gold Sponsor of the MariaDB Foundation |
| Automattic          | https://automattic.com       | Silver Sponsor of the MariaDB Foundation |
| Percona              | https://www.percona.com/     | Sponsor of the MariaDB Foundation |
| Galera Cluster      | https://galeracluster.com    | Sponsor of the MariaDB Foundation |
| Google               | USA                          | Sponsoring encryption, parallel replication and GTID |
| Facebook             | USA                          | Sponsoring non-blocking API, LIMIT ROWS EXAMINED etc |
| Ronald Bradford      | Brisbane, Australia          | EFF contribution for UC2006 Auction |
| Sheeri Kritzer       | Boston, Mass. USA           | EFF contribution for UC2006 Auction |
| Mark Shuttleworth   | London, UK.                  | EFF contribution for UC2006 Auction |
+-----+-----+-----+
```

1.1.1.2.8.12 SHOW CREATE DATABASE

Syntax

```
SHOW CREATE {DATABASE | SCHEMA} db_name
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

Description

Shows the [CREATE DATABASE](#) statement that creates the given database. `SHOW CREATE SCHEMA` is a synonym for `SHOW CREATE DATABASE`. `SHOW CREATE DATABASE` quotes database names according to the value of the [sql_quote_show_create](#) server system variable.

Examples

```
SHOW CREATE DATABASE test;
+-----+-----+
| Database | Create Database |
+-----+-----+
| test    | CREATE DATABASE `test` /*!40100 DEFAULT CHARACTER SET latin1 */ |
+-----+-----+

SHOW CREATE SCHEMA test;
+-----+-----+
| Database | Create Database |
+-----+-----+
| test    | CREATE DATABASE `test` /*!40100 DEFAULT CHARACTER SET latin1 */ |
+-----+-----+
```

With [sql_quote_show_create](#) off:

```
SHOW CREATE DATABASE test;
+-----+-----+
| Database | Create Database |
+-----+-----+
| test    | CREATE DATABASE test /*!40100 DEFAULT CHARACTER SET latin1 */ |
+-----+-----+
```

With a comment, from [MariaDB 10.5](#):

```
SHOW CREATE DATABASE p;
+-----+-----+
| Database | Create Database |
+-----+-----+
| p        | CREATE DATABASE `p` /*!40100 DEFAULT CHARACTER SET latin1 */ COMMENT 'presentations' |
+-----+-----+
```

1.1.1.2.8.13 SHOW CREATE EVENT

Syntax

```
SHOW CREATE EVENT event_name
```

Description

This statement displays the [CREATE EVENT](#) statement that creates a given [event](#), as well as the [SQL_MODE](#) that was used when the trigger has been created and the character set used by the connection. To find out which events are present, use [SHOW EVENTS](#).

`SHOW CREATE EVENT` quotes identifiers according to the value of the [sql_quote_show_create](#) system variable. Prior to

MariaDB 10.6.5, MariaDB 10.5.13 and MariaDB 10.4.22 [↗](#), the output of this statement was unreliably affected by the `sql_quote_show_create` system variable.

The `information_schema.EVENTS` table provides similar, but more complete, information.

Examples

```
SHOW CREATE EVENT test.e_daily\G
***** 1. row *****
      Event: e_daily
      sql_mode:
      time_zone: SYSTEM
      Create Event: CREATE EVENT `e_daily`
                    ON SCHEDULE EVERY 1 DAY
                    STARTS CURRENT_TIMESTAMP + INTERVAL 6 HOUR
                    ON COMPLETION NOT PRESERVE
                    ENABLE
                    COMMENT 'Saves total number of sessions then
                             clears the table each day'
                    DO BEGIN
                        INSERT INTO site_activity.totals (time, total)
                        SELECT CURRENT_TIMESTAMP, COUNT(*)
                        FROM site_activity.sessions;
                        DELETE FROM site_activity.sessions;
                    END
      character_set_client: latin1
      collation_connection: latin1_swedish_ci
      Database Collation: latin1_swedish_ci
```

1.1.1.2.8.14 SHOW CREATE FUNCTION

Syntax

```
SHOW CREATE FUNCTION func_name
```

Description

This statement is similar to [SHOW CREATE PROCEDURE](#) but for [stored functions](#).

`SHOW CREATE FUNCTION` quotes identifiers according to the value of the `sql_quote_show_create` system variable. Prior to MariaDB 10.6.5, MariaDB 10.5.13 and MariaDB 10.4.22 [↗](#), the output of this statement was unreliably affected by the `sql_quote_show_create` system variable.

Example

```
SHOW CREATE FUNCTION VatCents\G
***** 1. row *****
      Function: VatCents
      sql_mode:
      Create Function: CREATE DEFINER=`root`@`localhost` FUNCTION `VatCents` (price
      DECIMAL(10,2)) RETURNS int(11)
      DETERMINISTIC
      BEGIN
      DECLARE x INT;
      SET x = price * 114;
      RETURN x;
      END
      character_set_client: utf8
      collation_connection: utf8_general_ci
      Database Collation: latin1_swedish_ci
```

1.1.1.2.8.15 SHOW CREATE PACKAGE

Syntax

```
SHOW CREATE PACKAGE [ db_name . ] package_name
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

Description

The `SHOW CREATE PACKAGE` statement can be used when [Oracle SQL_MODE](#) is set. It shows the `CREATE` statement that creates the given package specification.

`SHOW CREATE PACKAGE` quotes identifiers according to the value of the [sql_quote_show_create](#) system variable.

Examples

```
SHOW CREATE PACKAGE employee_tools\G
***** 1. row *****
      Package: employee_tools
      sql_mode:
PIPES_AS_CONCAT,ANSI_QUOTES,IGNORE_SPACE,ORACLE,NO_KEY_OPTIONS,NO_TABLE_OPTIONS,NO_FIELD_OPTIONS,NO_AUTO_CREATE_USER
      Create Package: CREATE DEFINER="root"@"localhost" PACKAGE "employee_tools" AS
      FUNCTION getSalary(eid INT) RETURN DECIMAL(10,2);
      PROCEDURE raiseSalary(eid INT, amount DECIMAL(10,2));
      PROCEDURE raiseSalaryStd(eid INT);
      PROCEDURE hire(ename TEXT, esalary DECIMAL(10,2));
END
character_set_client: utf8
collation_connection: utf8_general_ci
Database Collation: latin1_swedish_ci
```

1.1.1.2.8.16 SHOW CREATE PACKAGE BODY

Syntax

```
SHOW CREATE PACKAGE BODY [ db_name . ] package_name
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

Description

The `SHOW CREATE PACKAGE BODY` statement shows the `CREATE PACKAGE BODY` statement that creates the given package body (i.e. the implementation of the package). `CREATE PACKAGE BODY` can be used when [Oracle SQL_MODE](#) is set, or from [MariaDB 11.4](#).

`SHOW CREATE PACKAGE BODY` quotes identifiers according to the value of the [sql_quote_show_create](#) system variable.

Examples

```

SHOW CREATE PACKAGE BODY employee_tools\G
***** 1. row *****
      Package body: employee_tools
      sql_mode:
PIPES_AS_CONCAT,ANSI_QUOTES,IGNORE_SPACE,ORACLE,NO_KEY_OPTIONS,NO_TABLE_OPTIONS,NO_FIELD_OPTION
S,NO_AUTO_CREATE_USER
Create Package Body: CREATE DEFINER="root"@"localhost" PACKAGE BODY "employee_tools" AS

      stdRaiseAmount DECIMAL(10,2):=500;

PROCEDURE log (eid INT, ecmnt TEXT) AS
BEGIN
      INSERT INTO employee_log (id, cmnt) VALUES (eid, ecmnt);
END;

PROCEDURE hire(ename TEXT, esalary DECIMAL(10,2)) AS
      eid INT;
BEGIN
      INSERT INTO employee (name, salary) VALUES (ename, esalary);
      eid:= last_insert_id();
      log(eid, 'hire ' || ename);
END;

FUNCTION getSalary(eid INT) RETURN DECIMAL(10,2) AS
      nSalary DECIMAL(10,2);
BEGIN
      SELECT salary INTO nSalary FROM employee WHERE id=eid;
      log(eid, 'getSalary id=' || eid || ' salary=' || nSalary);
      RETURN nSalary;
END;

PROCEDURE raiseSalary(eid INT, amount DECIMAL(10,2)) AS
BEGIN
      UPDATE employee SET salary=salary+amount WHERE id=eid;
      log(eid, 'raiseSalary id=' || eid || ' amount=' || amount);
END;

PROCEDURE raiseSalaryStd(eid INT) AS
BEGIN
      raiseSalary(eid, stdRaiseAmount);
      log(eid, 'raiseSalaryStd id=' || eid);
END;

BEGIN
      log(0, 'Session ' || connection_id() || ' ' || current_user || ' started');
END
character_set_client: utf8
collation_connection: utf8_general_ci
Database Collation: latin1_swedish_ci

```

1.1.1.2.8.17 SHOW CREATE PROCEDURE

Syntax

```
SHOW CREATE PROCEDURE proc_name
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

Description

This statement is a MariaDB extension. It returns the exact string that can be used to re-create the named [stored procedure](#), as well as the [SQL_MODE](#) that was used when the trigger has been created and the character set used by the connection.. A similar statement, [SHOW CREATE FUNCTION](#), displays information about [stored functions](#).

Both statements require that:

- you are the owner of the routine;
- you have the [SHOW CREATE ROUTINE](#) privilege (from [MariaDB 11.3.0](#)); or
- have the [SELECT](#) privilege on the [mysql.proc](#) table.

When none of the above statements are true, the statements display `NULL` for the `Create Procedure` or `Create Function` field.

Warning Users with `SELECT` privileges on `mysql.proc` or `USAGE` privileges on `*.*` can view the text of routines, even when they do not have privileges for the function or procedure itself.

`SHOW CREATE PROCEDURE` quotes identifiers according to the value of the `sql_quote_show_create` system variable. Prior to [MariaDB 10.6.5](#), [MariaDB 10.5.13](#) and [MariaDB 10.4.22](#), the output of this statement was unreliably affected by the `sql_quote_show_create` system variable.

Examples

Here's a comparison of the `SHOW CREATE PROCEDURE` and `SHOW CREATE FUNCTION` statements.

```
SHOW CREATE PROCEDURE test.simpleproc\G
***** 1. row *****
      Procedure: simpleproc
      sql_mode:
  Create Procedure: CREATE PROCEDURE `simpleproc` (OUT param1 INT)
                    BEGIN
                    SELECT COUNT(*) INTO param1 FROM t;
                    END
character_set_client: latin1
collation_connection: latin1_swedish_ci
  Database Collation: latin1_swedish_ci

SHOW CREATE FUNCTION test.hello\G
***** 1. row *****
      Function: hello
      sql_mode:
  Create Function: CREATE FUNCTION `hello` (s CHAR(20))
                  RETURNS CHAR(50)
                  RETURN CONCAT('Hello, ',s, '!')
character_set_client: latin1
collation_connection: latin1_swedish_ci
  Database Collation: latin1_swedish_ci
```

When the user issuing the statement does not have privileges on the routine, attempting to `CALL` the procedure raises Error 1370.

```
CALL test.prcl();
Error 1370 (42000): execute command denied to
  user 'test_user'@'localhost' for routine 'test`.`prcl`
```

If the user neither has privilege to the routine nor the `SELECT` privilege on `mysql.proc` table, it raises Error 1305, informing them that the procedure does not exist.

```
SHOW CREATE TABLES test.prcl\G
Error 1305 (42000): PROCEDURE prcl does not exist
```

1.1.1.2.8.18 SHOW CREATE SEQUENCE

Syntax

```
SHOW CREATE SEQUENCE sequence_name;
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Example](#)
4. [Notes](#)

Description

Shows the [CREATE SEQUENCE](#) statement that creates the given [sequence](#). The statement requires the `SELECT` privilege for the table.

`SHOW CREATE SEQUENCE` quotes identifiers according to the value of the [sql_quote_show_create](#) system variable.

Example

```
CREATE SEQUENCE s1 START WITH 50;
SHOW CREATE SEQUENCE s1\G;
***** 1. row *****
      Table: s1
Create Table: CREATE SEQUENCE `s1` start with 50 minvalue 1 maxvalue 9223372036854775806
increment by 1 cache 1000 nocycle ENGINE=InnoDB
```

Notes

If you want to see the underlying table structure used for the `SEQUENCE` you can use [SHOW CREATE TABLE](#) on the `SEQUENCE`. You can also use `SELECT` to read the current recorded state of the `SEQUENCE`:

```
SHOW CREATE TABLE s1\G
***** 1. row *****
      Table: s1
Create Table: CREATE TABLE `s1` (
  `next_not_cached_value` bigint(21) NOT NULL,
  `minimum_value` bigint(21) NOT NULL,
  `maximum_value` bigint(21) NOT NULL,
  `start_value` bigint(21) NOT NULL COMMENT 'start value when sequences is created
or value if RESTART is used',
  `increment` bigint(21) NOT NULL COMMENT 'increment value',
  `cache_size` bigint(21) unsigned NOT NULL,
  `cycle_option` tinyint(1) unsigned NOT NULL COMMENT '0 if no cycles are allowed,
1 if the sequence should begin a new cycle when maximum_value is passed',
  `cycle_count` bigint(21) NOT NULL COMMENT 'How many cycles have been done'
) ENGINE=InnoDB SEQUENCE=1

SELECT * FROM s1\G
***** 1. row *****
next_not_cached_value: 50
  minimum_value: 1
  maximum_value: 9223372036854775806
  start_value: 50
  increment: 1
  cache_size: 1000
  cycle_option: 0
  cycle_count: 0
```

The [Information Schema SEQUENCES Table](#) also provides information about available sequences:

```

SELECT * FROM INFORMATION_SCHEMA.SEQUENCES\G
***** 1. row *****
      SEQUENCE_CATALOG: def
      SEQUENCE_SCHEMA: test
      SEQUENCE_NAME: s1
      DATA_TYPE: bigint
      NUMERIC_PRECISION: 64
NUMERIC_PRECISION_RADIX: 2
      NUMERIC_SCALE: 0
      START_VALUE: 50
      MINIMUM_VALUE: 1
      MAXIMUM_VALUE: 9223372036854775806
      INCREMENT: 1
      CYCLE_OPTION: 0

```

1.1.1.2.8.19 SHOW CREATE SERVER

MariaDB starting with [11.7](#)

The SHOW CREATE SERVER statement was introduced in [MariaDB 11.7](#).

Contents

1. [Syntax](#)
2. [Description](#)
3. [Example](#)

Syntax

```
SHOW CREATE SERVER server_name
```

Description

Shows the [CREATE SERVER](#) statement that created the given server definition.

Example

```

SHOW CREATE SERVER srv1\G
***** 1. row *****
      Server: srv1
Create Server: CREATE SERVER `srv1` FOREIGN DATA WRAPPER mysql
      OPTIONS (HOST '172.30.0.58', DATABASE 'db1', USER 'maxscale', PASSWORD 'password');

```

1.1.1.2.1.17 SHOW CREATE TABLE

1.1.1.2.8.21 SHOW CREATE TRIGGER

Syntax

```
SHOW CREATE TRIGGER trigger_name
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

Description

This statement shows a `CREATE TRIGGER` statement that creates the given trigger, as well as the `SQL_MODE` that was used when the trigger has been created and the character set used by the connection.

The `TRIGGER` privilege is required on the table the trigger is defined for to execute this statement.

`SHOW CREATE TRIGGER` quotes identifiers according to the value of the `sql_quote_show_create` system variable. Prior to [MariaDB 10.6.5](#), [MariaDB 10.5.13](#) and [MariaDB 10.4.22](#), the output of this statement was unreliably affected by the `sql_quote_show_create` system variable.

Examples

```
SHOW CREATE TRIGGER example\G
***** 1. row *****
      Trigger: example
      sql_mode: ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,STRICT_ALL_TABLES
,NO_ZERO_IN_DATE,NO_ZERO_DATE,ERROR_FOR_DIVISION_BY_ZERO,NO_AUTO_CREATE_USER,NO_
ENGINE_SUBSTITUTION
SQL Original Statement: CREATE DEFINER=`root`@`localhost` TRIGGER example BEFORE
INSERT ON t FOR EACH ROW
BEGIN
      SET NEW.c = NEW.c * 2;
END
      character_set_client: cp850
      collation_connection: cp850_general_ci
      Database Collation: utf8_general_ci
      Created: 2016-09-29 13:53:34.35
```

The `Created` column was added in [MariaDB 10.2.3](#) as part of introducing multiple trigger events per action.

1.1.1.1.13 SHOW CREATE USER

1.1.1.2.8.23 SHOW CREATE VIEW

Syntax

```
SHOW CREATE VIEW view_name
```

Description

This statement shows a `CREATE VIEW` statement that creates the given view, as well as the character set used by the connection when the view was created. This statement also works with views.

`SHOW CREATE VIEW` quotes table, column and stored function names according to the value of the `sql_quote_show_create` server system variable.

Examples

```
SHOW CREATE VIEW example\G
***** 1. row *****
      View: example
      Create View: CREATE ALGORITHM=UNDEFINED DEFINER=`root`@`localhost` SQL
SECURITY DEFINER VIEW `example` AS (select `t`.`id` AS `id`,`t`.`s` AS `s` from
`t`)
      character_set_client: cp850
      collation_connection: cp850_general_ci
```

With `sql_quote_show_create` off:

```
SHOW CREATE VIEW example\G
***** 1. row *****
      View: example
      Create View: CREATE ALGORITHM=UNDEFINED DEFINER=root@localhost SQL SECURITY DEFINER VIEW example AS (select t.id AS id,t.s AS s from t)
      character_set_client: cp850
      collation_connection: cp850_general_ci
```

Grants

To be able to see a view, you need to have the [SHOW VIEW](#) and the [SELECT](#) privilege on the view:

```
GRANT SHOW VIEW,SELECT ON test_database.test_view TO 'test'@'localhost';
```

1.1.1.2.8.24 SHOW DATABASES

Syntax

```
SHOW {DATABASES | SCHEMAS}
     [LIKE 'pattern' | WHERE expr]
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

Description

`SHOW DATABASES` lists the databases on the MariaDB server host. `SHOW SCHEMAS` is a synonym for `SHOW DATABASES`. The `LIKE` clause, if present on its own, indicates which database names to match. The `WHERE` and `LIKE` clauses can be given to select rows using more general conditions, as discussed in [Extended SHOW](#).

You see only those databases for which you have some kind of privilege, unless you have the global [SHOW DATABASES privilege](#). You can also get this list using the [mariadb-show](#) command.

If the server was started with the `--skip-show-database` option, you cannot use this statement at all unless you have the [SHOW DATABASES privilege](#).

The list of results returned by `SHOW DATABASES` is based on directories in the data directory, which is how MariaDB implements databases. It's possible that output includes directories that do not correspond to actual databases.

The [Information Schema SCHEMATA table](#) also contains database information.

Examples

```
SHOW DATABASES;
+-----+
| Database |
+-----+
| information_schema |
| mysql |
| performance_schema |
| test |
+-----+
```

```
SHOW DATABASES LIKE 'm%';
+-----+
| Database (m%) |
+-----+
| mysql |
+-----+
```

1.1.1.2.8.25 SHOW ENGINE

Contents

1. [Syntax](#)
2. [Description](#)
 1. [SHOW ENGINE INNODB STATUS](#)
 2. [SHOW ENGINE INNODB MUTEX](#)
 3. [SHOW ENGINE PERFORMANCE_SCHEMA STATUS](#)
 4. [SHOW ENGINE ROCKSDB STATUS](#)

Syntax

```
SHOW ENGINE engine_name {STATUS | MUTEX}
```

Description

`SHOW ENGINE` displays operational information about a storage engine. The following statements currently are supported:

```
SHOW ENGINE INNODB STATUS
SHOW ENGINE INNODB MUTEX
SHOW ENGINE PERFORMANCE_SCHEMA STATUS
SHOW ENGINE ROCKSDB STATUS
```

If the [Sphinx Storage Engine](#) is installed, the following is also supported:

```
SHOW ENGINE SPHINX STATUS
```

See [SHOW ENGINE SPHINX STATUS](#) .

Older (and now removed) synonyms were `SHOW INNODB STATUS` for `SHOW ENGINE INNODB STATUS` and `SHOW MUTEX STATUS` for `SHOW ENGINE INNODB MUTEX` .

SHOW ENGINE INNODB STATUS

`SHOW ENGINE INNODB STATUS` displays extensive information from the standard InnoDB Monitor about the state of the InnoDB storage engine. See [SHOW ENGINE INNODB STATUS](#) for more.

SHOW ENGINE INNODB MUTEX

`SHOW ENGINE INNODB MUTEX` displays InnoDB mutex statistics.

The statement displays the following output fields:

- **Type:** Always InnoDB.
- **Name:** The source file where the mutex is implemented, and the line number in the file where the mutex is created. The line number is dependent on the MariaDB version.
- **Status:** This field displays the following values if `UNIV_DEBUG` was defined at compilation time (for example, in `include/univ.h` in the InnoDB part of the source tree). Only the `os_waits` value is displayed if `UNIV_DEBUG` was not defined. Without `UNIV_DEBUG` , the information on which the output is based is insufficient to distinguish regular mutexes and mutexes that protect rw-locks (which allow multiple readers or a single writer). Consequently, the output may appear to contain multiple rows for the same mutex.
 - **count** indicates how many times the mutex was requested.
 - **spin_waits** indicates how many times the spinlock had to run.
 - **spin_rounds** indicates the number of spinlock rounds. (`spin_rounds` divided by `spin_waits` provides the average round count.)
 - **os_waits** indicates the number of operating system waits. This occurs when the spinlock did not work (the mutex was not locked during the spinlock and it was necessary to yield to the operating system and wait).
 - **os_yields** indicates the number of times a the thread trying to lock a mutex gave up its timeslice and yielded to the operating system (on the presumption that allowing other threads to run will free the mutex so that it can be locked).
 - **os_wait_times** indicates the amount of time (in ms) spent in operating system waits, if the `timed_mutexes` system variable is 1 (ON). If `timed_mutexes` is 0 (OFF), timing is disabled, so `os_wait_times` is 0. `timed_mutexes` is off by default.

Information from this statement can be used to diagnose system problems. For example, large values of `spin_waits` and `spin_rounds` may indicate scalability problems.

The `information_schema.INNODB_Mutexes` table provides similar information.

SHOW ENGINE PERFORMANCE_SCHEMA STATUS

This statement shows how much memory is used for `performance_schema` tables and internal buffers.

The output contains the following fields:

- **Type:** Always `performance_schema.`
- **Name:** The name of a table, the name of an internal buffer, or the `performance_schema` word, followed by a dot and an attribute. Internal buffers names are enclosed by parenthesis. `performance_schema` means that the attribute refers to the whole database (it is a total).
- **Status:** The value for the attribute.

The following attributes are shown, in this order, for all tables:

- **row_size:** The memory used for an individual record. This value will never change.
- **row_count:** The number of rows in the table or buffer. For some tables, this value depends on a server system variable.
- **memory:** For tables and `performance_schema`, this is the result of `row_size * row_count`.

For internal buffers, the attributes are:

- **count**
- **size**

SHOW ENGINE ROCKSDB STATUS

See also [MyRocks Performance Troubleshooting](#)

1.1.1.2.8.26 SHOW ENGINE INNODB STATUS

`SHOW ENGINE INNODB STATUS` is a specific form of the `SHOW ENGINE` statement that displays the [InnoDB Monitor](#) output, which is extensive InnoDB information which can be useful in diagnosing problems.

The following sections are displayed

- **Status:** Shows the timestamp, monitor name and the number of seconds, or the elapsed time between the current time and the time the InnoDB Monitor output was last displayed. The per-second averages are based upon this time.
- **BACKGROUND THREAD:** `srv_master_thread` lines show work performed by the main background thread.
- **SEMAPHORES:** Threads waiting for a semaphore and stats on how the number of times threads have needed a spin or a wait on a mutex or rw-lock semaphore. If this number of threads is large, there may be I/O or contention issues. Reducing the size of the `innodb_thread_concurrency` system variable may help if contention is related to thread scheduling. `Spin rounds per wait` shows the number of spinlock rounds per OS wait for a mutex.
- **LATEST FOREIGN KEY ERROR:** Only shown if there has been a foreign key constraint error, it displays the failed statement and information about the constraint and the related tables.
- **LATEST DETECTED DEADLOCK:** Only shown if there has been a deadlock, it displays the transactions involved in the deadlock and the statements being executed, held and required locked and the transaction rolled back to.
- **TRANSACTIONS:** The output of this section can help identify lock contention, as well as reasons for the deadlocks.
- **FILE I/O:** InnoDB thread information as well as pending I/O operations and I/O performance statistics.
- **INSERT BUFFER AND ADAPTIVE HASH INDEX:** InnoDB insert buffer (old name for the [change buffer](#)) and adaptive hash index status information, including the number of each type of operation performed, and adaptive hash index performance.
- **LOG:** InnoDB log information, including current log sequence number, how far the log has been flushed to disk, the position at which InnoDB last took a checkpoint, pending writes and write performance statistics.
- **BUFFER POOL AND MEMORY:** Information on buffer pool pages read and written, which allows you to see the number of data file I/O operations performed by your queries. See [InnoDB Buffer Pool](#) for more. Similar information is also available from the `INFORMATION_SCHEMA.INNODB_BUFFER_POOL_STATS` table.
- **ROW OPERATIONS:** Information about the main thread, including the number and performance rate for each type of row operation.

If the `innodb_status_output_locks` system variable is set to `1`, extended lock information will be displayed.

Example output:

```

=====

```

1.1.1.2.8.27 SHOW ENGINES

Syntax

```
SHOW [STORAGE] ENGINES
```

Description

`SHOW ENGINES` displays status information about the server's storage engines. This is particularly useful for checking whether a storage engine is supported, or to see what the default engine is. `SHOW TABLE TYPES` is a deprecated synonym.

The `information_schema.ENGINES` table provides the same information.

Since storage engines are plugins, different information about them is also shown in the `information_schema.PLUGINS` table and by the `SHOW PLUGINS` statement.

Note that both MySQL's InnoDB and Percona's XtraDB replacement are labeled as `InnoDB`. However, if XtraDB is in use, it will be specified in the `COMMENT` field. See [XtraDB and InnoDB](#). The same applies to [FederatedX](#).

The output consists of the following columns:

- `Engine` indicates the engine's name.
- `Support` indicates whether the engine is installed, and whether it is the default engine for the current session.
- `Comment` is a brief description.
- `Transactions`, `XA` and `Savepoints` indicate whether [transactions](#), [XA transactions](#) and [transaction savepoints](#) are supported by the engine.

Examples

```

SHOW ENGINES\G
***** 1. row *****
    Engine: InnoDB
    Support: DEFAULT
    Comment: Supports transactions, row-level locking, and foreign keys
Transactions: YES
    XA: YES
    Savepoints: YES
***** 2. row *****
    Engine: CSV
    Support: YES
    Comment: CSV storage engine
Transactions: NO
    XA: NO
    Savepoints: NO
***** 3. row *****
    Engine: MyISAM

Transactions: NO
    XA: NO
    Savepoints: NO
10 rows in set (0.00 sec)

```

1.1.1.2.8.28 SHOW ERRORS

Syntax

```
SHOW ERRORS [LIMIT [offset,] row_count]
SHOW ERRORS [LIMIT row_count OFFSET offset]
SHOW COUNT(*) ERRORS
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

Description

This statement is similar to [SHOW WARNINGS](#), except that instead of displaying errors, warnings, and notes, it displays only errors.

The `LIMIT` clause has the same syntax as for the [SELECT](#) statement.

The `SHOW COUNT(*) ERRORS` statement displays the number of errors. You can also retrieve this number from the `error_count` variable.

```
SHOW COUNT(*) ERRORS;
SELECT @@error_count;
```

The value of `error_count` might be greater than the number of messages displayed by [SHOW WARNINGS](#) if the `max_error_count` system variable is set so low that not all messages are stored.

For a list of MariaDB error codes, see [MariaDB Error Codes](#).

Examples

```
SELECT f();
ERROR 1305 (42000): FUNCTION f does not exist

SHOW COUNT(*) ERRORS;
+-----+
| @@session.error_count |
+-----+
|                      1 |
+-----+

SHOW ERRORS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Error | 1305 | FUNCTION f does not exist |
+-----+-----+-----+
```

1.1.1.2.8.29 SHOW EVENTS

Syntax

```
SHOW EVENTS [{FROM | IN} schema_name]
[LIKE 'pattern' | WHERE expr]
```

Description

Shows information about Event Manager [events](#) (created with [CREATE EVENT](#)). Requires the `EVENT` privilege. Without any

arguments, `SHOW EVENTS` lists all of the events in the current schema:

```
SELECT CURRENT_USER(), SCHEMA();
+-----+-----+
| CURRENT_USER() | SCHEMA() |
+-----+-----+
| jon@ghidora    | myschema |
+-----+-----+

SHOW EVENTS\G
***** 1. row *****
          Db: myschema
          Name: e_daily
          Definer: jon@ghidora
          Time zone: SYSTEM
          Type: RECURRING
          Execute at: NULL
          Interval value: 10
          Interval field: SECOND
          Starts: 2006-02-09 10:41:23
          Ends: NULL
          Status: ENABLED
          Originator: 0
character_set_client: latin1
collation_connection: latin1_swedish_ci
Database Collation: latin1_swedish_ci
```

To see the event action, use `SHOW CREATE EVENT` instead, or look at the `information_schema.EVENTS` table.

To see events for a specific schema, use the `FROM` clause. For example, to see events for the test schema, use the following statement:

```
SHOW EVENTS FROM test;
```

The `LIKE` clause, if present, indicates which event names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Extended Show](#).

4.2.2.8 SHOW FUNCTION CODE

1.1.1.2.8.31 SHOW FUNCTION STATUS

Syntax

```
SHOW FUNCTION STATUS
[LIKE 'pattern' | WHERE expr]
```

Description

This statement is similar to `SHOW PROCEDURE STATUS` but for [stored functions](#).

The `LIKE` clause, if present on its own, indicates which function names to match.

The `WHERE` and `LIKE` clauses can be given to select rows using more general conditions, as discussed in [Extended SHOW](#).

The `information_schema.ROUTINES` table contains more detailed information.

Examples

Showing all stored functions:

```

SHOW FUNCTION STATUS\G
***** 1. row *****
      Db: test
      Name: VatCents
      Type: FUNCTION
      Definer: root@localhost
      Modified: 2013-06-01 12:40:31
      Created: 2013-06-01 12:40:31
      Security_type: DEFINER
      Comment:
character_set_client: utf8
collation_connection: utf8_general_ci
Database Collation: latin1_swedish_ci

```

Stored functions whose name starts with 'V':

```

SHOW FUNCTION STATUS LIKE 'V%' \G
***** 1. row *****
      Db: test
      Name: VatCents
      Type: FUNCTION
      Definer: root@localhost
      Modified: 2013-06-01 12:40:31
      Created: 2013-06-01 12:40:31
      Security_type: DEFINER
      Comment:
character_set_client: utf8
collation_connection: utf8_general_ci
Database Collation: latin1_swedish_ci

```

Stored functions with a security type of 'DEFINER':

```

SHOW FUNCTION STATUS WHERE Security_type LIKE 'DEFINER' \G
***** 1. row *****
      Db: test
      Name: VatCents
      Type: FUNCTION
      Definer: root@localhost
      Modified: 2013-06-01 12:40:31
      Created: 2013-06-01 12:40:31
      Security_type: DEFINER
      Comment:
character_set_client: utf8
collation_connection: utf8_general_ci
Database Collation: latin1_swedish_ci

```

1.1.1.1.12 SHOW GRANTS

1.1.1.2.1.18 SHOW INDEX

1.1.1.2.8.34 SHOW INDEX_STATISTICS

Syntax

```
SHOW INDEX_STATISTICS
```

Description

The `SHOW INDEX_STATISTICS` statement was introduced in [MariaDB 5.2](#) as part of the [User Statistics](#) feature. It was removed as a separate statement in [MariaDB 10.1.1](#), but effectively replaced by the generic [SHOW information_schema_table](#) statement. The `information_schema.INDEX_STATISTICS` table shows statistics on index usage and makes it possible to do such things as locating unused indexes and generating the commands to remove them.

The `userstat` system variable must be set to 1 to activate this feature. See the [User Statistics](#) and [information_schema.INDEX_STATISTICS](#) table for more information.

Example

```
SHOW INDEX_STATISTICS;
+-----+-----+-----+-----+
| Table_schema | Table_name      | Index_name | Rows_read |
+-----+-----+-----+-----+
| test         | employees_example | PRIMARY   | 1         |
+-----+-----+-----+-----+
```

1.1.1.2.8.35 SHOW LOCALES

`SHOW LOCALES` was introduced as part of the [Information Schema plugin extension](#).

`SHOW LOCALES` is used to return [locales](#) information as part of the [Locales](#) plugin. It requires this plugin to be installed to work.

While the [information_schema.LOCALES](#) table has 8 columns, the `SHOW LOCALES` statement will only display 4 of them:

Example

```
SHOW LOCALES;
+-----+-----+-----+-----+
| Id | Name | Description | Error_Message_Language |
+-----+-----+-----+-----+
| 0 | en_US | English - United States | english |
| 1 | en_GB | English - United Kingdom | english |
| 2 | ja_JP | Japanese - Japan | japanese |
| 3 | sv_SE | Swedish - Sweden | swedish |
...

```

1.1.1.2.5.8 SHOW BINLOG STATUS

1.1.1.2.8.37 SHOW OPEN TABLES

Syntax

```
SHOW OPEN TABLES [FROM db_name]
[LIKE 'pattern' | WHERE expr]
```

Description

`SHOW OPEN TABLES` lists the non-`TEMPORARY` tables that are currently open in the table cache. See <http://dev.mysql.com/doc/refman/5.1/en/table-cache.html>.

The `FROM` and `LIKE` clauses may be used.

The `FROM` clause, if present, restricts the tables shown to those present in the `db_name` database.

The `LIKE` clause, if present on its own, indicates which table names to match. The `WHERE` and `LIKE` clauses can be given to select rows using more general conditions, as discussed in [Extended SHOW](#).

The following information is returned:

Column	Description
Database	Database name.
Name	Table name.

In_use	Number of table instances being used.
Name_locked	1 if the table is name-locked, e.g. if it is being dropped or renamed, otherwise 0.

Before [MariaDB 5.5](#), each use of, for example, `LOCK TABLE ... WRITE` would increment `In_use` for that table. With the implementation of the metadata locking improvements in [MariaDB 5.5](#), `LOCK TABLE... WRITE` acquires a strong MDL lock, and concurrent connections will wait on this MDL lock, so any subsequent `LOCK TABLE... WRITE` will not increment `In_use`.

Example

```
SHOW OPEN TABLES;
+-----+-----+-----+-----+
| Database | Table | In_use | Name_locked |
+-----+-----+-----+-----+
...
| test    | xjson | 0      | 0          |
| test    | jauthor | 0      | 0          |
| test    | locks  | 1      | 0          |
...
+-----+-----+-----+-----+
```

1.1.1.2.8.38 SHOW PACKAGE BODY STATUS

Syntax

```
SHOW PACKAGE BODY STATUS
  [LIKE 'pattern' | WHERE expr]
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

Description

The `SHOW PACKAGE BODY STATUS` statement returns characteristics of stored package bodies (implementations), such as the database, name, type, creator, creation and modification dates, and character set information. A similar statement, [SHOW PACKAGE STATUS](#), displays information about stored package specifications.

The `LIKE` clause, if present, indicates which package names to match. The `WHERE` and `LIKE` clauses can be given to select rows using more general conditions, as discussed in [Extended SHOW](#).

The [ROUTINES](#) table in the `INFORMATION_SCHEMA` database contains more detailed information.

Examples

```
SHOW PACKAGE BODY STATUS LIKE 'pkg1'\G
***** 1. row *****
      Db: test
      Name: pkg1
      Type: PACKAGE BODY
      Definer: root@localhost
      Modified: 2018-02-27 14:44:14
      Created: 2018-02-27 14:44:14
      Security_type: DEFINER
      Comment: This is my first package body
character_set_client: utf8
collation_connection: utf8_general_ci
Database Collation: latin1_swedish_ci
```

1.1.1.2.8.39 SHOW PACKAGE STATUS

Syntax

```
SHOW PACKAGE STATUS  
[LIKE 'pattern' | WHERE expr]
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

Description

The `SHOW PACKAGE STATUS` statement returns characteristics of stored package specifications, such as the database, name, type, creator, creation and modification dates, and character set information. A similar statement, [SHOW PACKAGE BODY STATUS](#), displays information about stored package bodies (i.e. implementations).

The `LIKE` clause, if present, indicates which package names to match. The `WHERE` and `LIKE` clauses can be given to select rows using more general conditions, as discussed in [Extended SHOW](#).

The [ROUTINES](#) table in the `INFORMATION_SCHEMA` database contains more detailed information.

Examples

```
SHOW PACKAGE STATUS LIKE 'pkg1'\G  
***** 1. row *****  
      Db: test  
      Name: pkg1  
      Type: PACKAGE  
      Definer: root@localhost  
      Modified: 2018-02-27 14:38:15  
      Created: 2018-02-27 14:38:15  
      Security_type: DEFINER  
      Comment: This is my first package  
character_set_client: utf8  
collation_connection: utf8_general_ci  
Database Collation: latin1_swedish_ci
```

1.1.1.2.6.1 SHOW PLUGINS

1.1.1.2.6.2 SHOW PLUGINS SONAME

1.1.1.2.8.42 SHOW PRIVILEGES

Syntax

```
SHOW PRIVILEGES
```

Description

`SHOW PRIVILEGES` shows the list of [system privileges](#) that the MariaDB server supports. The exact list of privileges depends on the version of your server.

Note that before [MariaDB 10.3.23](#), [MariaDB 10.4.13](#) and [MariaDB 10.5.2](#), the [Delete history](#) privilege displays as `Delete versioning rows` ([MDEV-20382](#)).

Example

From [MariaDB 10.5.9](#)

```
SHOW PRIVILEGES;
+-----+-----+-----+
| Privilege          | Context                               | Comment
+-----+-----+-----+
| Alter              | Tables                                | To alter the table
|
| Alter routine      | Functions,Procedures                 | To alter or drop stored
functions/procedures |
| Create             | Databases,Tables,Indexes             | To create new databases
and tables          |
| Create routine     | Databases                             | To use CREATE
FUNCTION/PROCEDURE |
| Create temporary tables | Databases                             | To use CREATE TEMPORARY
TABLE              |
| Create view        | Tables                                | To create new views
|
| Create user        | Server Admin                          | To create new users
|
| Delete            | Tables                                | To delete existing rows
|
| Delete history     | Tables                                | To delete versioning
table historical rows |
| Drop              | Databases,Tables                     | To drop databases,
tables, and views   |
| Event             | Server Admin                          | To create, alter, drop
and execute events |
| Execute           | Functions,Procedures                 | To execute stored routines
|
| File              | File access on server                | To read and write files
on the server      |
| Grant option      | Databases,Tables,Functions,Procedures | To give to other users
those privileges you possess |
| Index            | Tables                                | To create or drop indexes
|
| Insert            | Tables                                | To insert data into
tables              |
| Lock tables       | Databases                             | To use LOCK TABLES
(together with SELECT privilege) |
| Process          | Server Admin                          | To view the plain text of
currently executing queries |
| Proxy            | Server Admin                          | To make proxy user
possible           |
| References        | Databases,Tables                     | To have references on
tables              |
| Reload           | Server Admin                          | To reload or refresh
tables, logs and privileges |
| Binlog admin      | Server                                | To purge binary logs
|
| Binlog monitor    | Server                                | To use SHOW BINLOG STATUS
and SHOW BINARY LOG |
| Binlog replay     | Server                                | To use BINLOG (generated
by mariadb-binlog) |
| Replication master admin | Server                                | To monitor connected
slaves              |
| Replication slave admin | Server                                | To start/stop slave and
apply binlog events |
| Slave monitor     | Server                                | To use SHOW SLAVE STATUS
and SHOW RELAYLOG EVENTS |
| Replication slave | Server Admin                          | To read binary log events
from the master     |
| Select            | Tables                                | To retrieve rows from
table               |
| Show databases    | Server Admin                          | To see all databases with
SHOW DATABASES     |
| Show view         | Tables                                | To see views with SHOW
CREATE VIEW         |
| Shutdown          | Server Admin                          | To shut down the server
```

```

|
| Super                               | Server Admin                               | To use KILL thread, SET
GLOBAL, CHANGE MASTER, etc.          |
| Trigger                             | Tables                                     | To use triggers
|
| Create tablespace                   | Server Admin                               | To create/alter/drop
tablespaces                           |
| Update                             | Tables                                     | To update existing rows
|
| Set user                            | Server                                     | To create views and
stored routines with a different definer |
| Federated admin                    | Server                                     | To execute the CREATE
SERVER, ALTER SERVER, DROP SERVER statements |
| Connection admin                   | Server                                     | To bypass connection
limits and kill other users' connections |
| Read_only admin                    | Server                                     | To perform write
operations even if @@read_only=ON      |
| Usage                              | Server Admin                              | No privileges - allow
connect only                           |

1.1.1.2.8.43 SHOW PROCEDURE CODE

Syntax

```
SHOW PROCEDURE CODE proc_name
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

Description

This statement is a MariaDB extension that is available only for servers that have been built with debugging support. It displays a representation of the internal implementation of the named [stored procedure](#). A similar statement, [SHOW FUNCTION CODE](#), displays information about [stored functions](#).

Both statements require that you be the owner of the routine or have [SELECT](#) access to the `mysql.proc` table.

If the named routine is available, each statement produces a result set. Each row in the result set corresponds to one "instruction" in the routine. The first column is Pos, which is an ordinal number beginning with 0. The second column is Instruction, which contains an SQL statement (usually changed from the original source), or a directive which has meaning only to the stored-routine handler.

Examples

```

DELIMITER //

CREATE PROCEDURE p1 ()
BEGIN
    DECLARE fanta INT DEFAULT 55;
    DROP TABLE t2;
    LOOP
        INSERT INTO t3 VALUES (fanta);
    END LOOP;
END//
Query OK, 0 rows affected (0.00 sec)

```

```

SHOW PROCEDURE CODE p1//
+-----+-----+
| Pos | Instruction |
+-----+-----+
| 0 | set fanta@0 55 |
| 1 | stmt 9 "DROP TABLE t2" |
| 2 | stmt 5 "INSERT INTO t3 VALUES (fanta)" |
| 3 | jump 2 |
+-----+-----+

```

1.1.1.2.8.44 SHOW PROCEDURE STATUS

Syntax

```

SHOW PROCEDURE STATUS
[LIKE 'pattern' | WHERE expr]

```

Description

This statement is a MariaDB extension. It returns characteristics of a stored procedure, such as the database, name, type, creator, creation and modification dates, and character set information. A similar statement, [SHOW FUNCTION STATUS](#), displays information about stored functions.

The `LIKE` clause, if present, indicates which procedure or function names to match. The `WHERE` and `LIKE` clauses can be given to select rows using more general conditions, as discussed in [Extended SHOW](#).

The [ROUTINES](#) table in the `INFORMATION_SCHEMA` database contains more detailed information.

Examples

```

SHOW PROCEDURE STATUS LIKE 'p1'\G
***** 1. row *****
      Db: test
      Name: p1
      Type: PROCEDURE
      Definer: root@localhost
      Modified: 2010-08-23 13:23:03
      Created: 2010-08-23 13:23:03
      Security_type: DEFINER
      Comment:
character_set_client: latin1
collation_connection: latin1_swedish_ci
Database Collation: latin1_swedish_ci

```

1.1.1.2.8.45 SHOW PROCESSLIST

Syntax

Description

`SHOW PROCESSLIST` shows you which threads are running. You can also get this information from the [information_schema.PROCESSLIST](#) table or the [mariadb-admin processlist](#) command. If you have the [PROCESS privilege](#), you can see all threads. Otherwise, you can see only your own threads (that is, threads associated with the MariaDB account that you are using). If you do not use the `FULL` keyword, only the first 100 characters of each statement are shown in the Info field.

The columns shown in `SHOW PROCESSLIST` are:

Name	Description
ID	The client's process ID.
USER	The username associated with the process.
HOST	The host the client is connected to.
DB	The default database of the process (NULL if no default).
COMMAND	The command type. See Thread Command Values .
TIME	The amount of time, in seconds, the process has been in its current state. For a replica SQL thread before MariaDB 10.1 , this is the time in seconds between the last replicated event's timestamp and the replica machine's real time.
STATE	See Thread States .
INFO	The statement being executed.
PROGRESS	The total progress of the process (0-100%) (see Progress Reporting).

The [information_schema.PROCESSLIST](#) table contains a number of additional columns. See `TIME_MS` column in [information_schema.PROCESSLIST](#) for differences in the `TIME` column between MariaDB and MySQL.

Note that the `PROGRESS` field from the information schema, and the `PROGRESS` field from `SHOW PROCESSLIST` display different results. `SHOW PROCESSLIST` shows the total progress, while the information schema shows the progress for the current stage only.

Threads can be killed using their `thread_id` or their `query_id`, with the [KILL](#) statement.

Since queries on this table are locking, if the [performance_schema](#) is enabled, you may want to query the [THREADS](#) table instead.

Examples

```
SHOW PROCESSLIST;
+----+-----+-----+-----+-----+-----+-----+-----+
| Id | User           | Host           | db      | Command | Time | State           | Info           |
| Progress |
+----+-----+-----+-----+-----+-----+-----+-----+
| 2  | event_scheduler | localhost     | NULL    | Daemon  | 2693 | Waiting on empty queue | NULL          |
| 0.000 |
| 4  | root           | localhost     | NULL    | Query   | 0    | Table lock      | SHOW          |
PROCESSLIST | 0.000 |
+----+-----+-----+-----+-----+-----+-----+-----+
-----+-----+
```

1.1.1.2.8.46 SHOW PROFILE

Syntax

```
SHOW PROFILE [type [, type] ... ]
  [FOR QUERY n]
  [LIMIT row_count [OFFSET offset]]
```

```
type:
  ALL
| BLOCK IO
| CONTEXT SWITCHES
| CPU
| IPC
| MEMORY
| PAGE FAULTS
| SOURCE
| SWAPS
```

Description

The `SHOW PROFILE` and `SHOW PROFILES` statements display profiling information that indicates resource usage for statements executed during the course of the current session.

Profiling is controlled by the `profiling` session variable, which has a default value of `0` (`OFF`). Profiling is enabled by setting `profiling` to `1` or `ON`:

```
SET profiling = 1;
```

`SHOW PROFILES` displays a list of the most recent statements sent to the master. The size of the list is controlled by the `profiling_history_size` session variable, which has a default value of `15`. The maximum value is `100`. Setting the value to `0` has the practical effect of disabling profiling.

All statements are profiled except `SHOW PROFILES` and `SHOW PROFILE`, so you will find neither of those statements in the profile list. Malformed statements are profiled. For example, `SHOW PROFILING` is an illegal statement, and a syntax error occurs if you try to execute it, but it will show up in the profiling list.

`SHOW PROFILE` displays detailed information about a single statement. Without the `FOR QUERY n` clause, the output pertains to the most recently executed statement. If `FOR QUERY n` is included, `SHOW PROFILE` displays information for statement `n`. The values of `n` correspond to the `Query_ID` values displayed by `SHOW PROFILES`.

The `LIMIT row_count` clause may be given to limit the output to `row_count` rows. If `LIMIT` is given, `OFFSET offset` may be added to begin the output offset rows into the full set of rows.

By default, `SHOW PROFILE` displays Status and Duration columns. The Status values are like the State values displayed by `SHOW PROCESSLIST` (see [General Thread States](#)), although there might be some minor differences in interpretation for the two statements for some status values.

Optional type values may be specified to display specific additional types of information:

- `ALL` displays all information
- `BLOCK IO` displays counts for block input and output operations
- `CONTEXT SWITCHES` displays counts for voluntary and involuntary context switches
- `CPU` displays user and system CPU usage times
- `IPC` displays counts for messages sent and received
- `MEMORY` is not currently implemented
- `PAGE FAULTS` displays counts for major and minor page faults
- `SOURCE` displays the names of functions from the source code, together with the name and line number of the file in which the function occurs
- `SWAPS` displays swap counts

Profiling is enabled per session. When a session ends, its profiling information is lost.

The `information_schema.PROFILING` table contains similar information.

Examples

```

SELECT @@profiling;
+-----+
| @@profiling |
+-----+
|          0 |
+-----+

SET profiling = 1;

USE test;

DROP TABLE IF EXISTS t1;

CREATE TABLE T1 (id INT);

SHOW PROFILES;
+-----+-----+-----+
| Query_ID | Duration | Query |
+-----+-----+-----+
|      1 | 0.00009200 | SELECT DATABASE() |
|      2 | 0.00023800 | show databases |
|      3 | 0.00018900 | show tables |
|      4 | 0.00014700 | DROP TABLE IF EXISTS t1 |
|      5 | 0.24476900 | CREATE TABLE T1 (id INT) |
+-----+-----+-----+

SHOW PROFILE;
+-----+-----+
| Status | Duration |
+-----+-----+
| starting | 0.000042 |
| checking permissions | 0.000044 |
| creating table | 0.244645 |
| After create | 0.000013 |
| query end | 0.000003 |
| freeing items | 0.000016 |
| logging slow query | 0.000003 |
| cleaning up | 0.000003 |
+-----+-----+

SHOW PROFILE FOR QUERY 4;
+-----+-----+
| Status | Duration |
+-----+-----+
| starting | 0.000126 |
| query end | 0.000004 |
| freeing items | 0.000012 |
| logging slow query | 0.000003 |
| cleaning up | 0.000002 |
+-----+-----+

SHOW PROFILE CPU FOR QUERY 5;
+-----+-----+-----+-----+
| Status | Duration | CPU_user | CPU_system |
+-----+-----+-----+-----+
| starting | 0.000042 | 0.000000 | 0.000000 |
| checking permissions | 0.000044 | 0.000000 | 0.000000 |
| creating table | 0.244645 | 0.000000 | 0.000000 |
| After create | 0.000013 | 0.000000 | 0.000000 |
| query end | 0.000003 | 0.000000 | 0.000000 |
| freeing items | 0.000016 | 0.000000 | 0.000000 |
| logging slow query | 0.000003 | 0.000000 | 0.000000 |
| cleaning up | 0.000003 | 0.000000 | 0.000000 |
+-----+-----+-----+-----+

```

1.1.1.2.8.47 SHOW PROFILES

Syntax

Description

The `SHOW PROFILES` statement displays profiling information that indicates resource usage for statements executed during the course of the current session. It is used together with `SHOW PROFILE`.

1.1.1.2.8.48 SHOW QUERY_RESPONSE_TIME

It is possible to use `SHOW QUERY_RESPONSE_TIME` as an alternative for retrieving information from the `QUERY_RESPONSE_TIME` plugin.

This was introduced as part of the [Information Schema plugin extension](#).

Example

```
SHOW QUERY_RESPONSE_TIME;
+-----+-----+-----+
| Time          | Count | Total          |
+-----+-----+-----+
| 0.000001     | 0     | 0.000000     |
| 0.000010     | 17    | 0.000094     |
| 0.000100     | 4301  | 0.236555     |
| 0.001000     | 1499  | 0.824450     |
| 0.010000     | 14851 | 81.680502    |
| 0.100000     | 8066  | 443.635693   |
| 1.000000     | 0     | 0.000000     |
| 10.000000    | 0     | 0.000000     |
| 100.000000   | 1     | 55.937094    |
| 1000.000000  | 0     | 0.000000     |
| 10000.000000 | 0     | 0.000000     |
| 100000.000000| 0     | 0.000000     |
| 1000000.000000| 0     | 0.000000     |
| TOO LONG     | 0     | TOO LONG     |
+-----+-----+-----+
```

1.1.1.2.5.6 SHOW RELAYLOG EVENTS

1.1.1.2.5.9 SHOW REPLICA HOSTS

1.1.1.2.5.7 SHOW REPLICA STATUS

1.1.1.2.8.52 SHOW STATUS

Syntax

```
SHOW [GLOBAL | SESSION] STATUS
     [LIKE 'pattern' | WHERE expr]
```

Description

`SHOW STATUS` provides server status information. This information also can be obtained using the `mariadb-admin extended-status` command, or by querying the `Information Schema GLOBAL_STATUS` and `SESSION_STATUS` tables. The `LIKE` clause, if present, indicates which variable names to match. The `WHERE` clause can be given to select rows using more general conditions.

With the `GLOBAL` modifier, `SHOW STATUS` displays the status values for all connections to MariaDB. With `SESSION`, it displays the status values for the current connection. If no modifier is present, the default is `SESSION`. `LOCAL` is a synonym for `SESSION`. If you see a lot of 0 values, the reason is probably that you have used `SHOW STATUS` with a new connection instead of `SHOW GLOBAL STATUS`.

Some status variables have only a global value. For these, you get the same value for both `GLOBAL` and `SESSION`.

See [Server Status Variables](#) for a full list, scope and description of the variables that can be viewed with `SHOW STATUS`.

The `LIKE` clause, if present on its own, indicates which variable name to match.

The `WHERE` and `LIKE` clauses can be given to select rows using more general conditions, as discussed in [Extended SHOW](#).

Examples

```
SHOW GLOBAL STATUS;
+-----+-----+
| Variable_name                | Value                |
+-----+-----+
| Aborted_clients              | 0                    |
| Aborted_connects            | 0                    |
| Access_denied_errors        | 0                    |
| Acl_column_grants           | 0                    |
| Acl_database_grants         | 2                    |
| Acl_function_grants         | 0                    |
| Acl_procedure_grants        | 0                    |
| Acl_proxy_users             | 2                    |
| Acl_role_grants             | 0                    |
| Acl_roles                   | 0                    |
| Acl_table_grants            | 0                    |
| Acl_users                   | 6                    |
| Aria_pagecache_blocks_not_flushed | 0                    |
| Aria_pagecache_blocks_unused | 15706                |
| ...                          |                      |
| wsrep_local_index           | 18446744073709551615 |
| wsrep_provider_name         |                      |
| wsrep_provider_vendor       |                      |
| wsrep_provider_version      |                      |
| wsrep_ready                 | OFF                  |
| wsrep_thread_count          | 0                    |
+-----+-----+
516 rows in set (0.00 sec)
```

Example of filtered output:

```
SHOW STATUS LIKE 'Key%';
```

```
+-----+-----+
| Variable_name      | Value |
+-----+-----+
| Key_blocks_not_flushed | 0     |
| Key_blocks_unused   | 107163 |
| Key_blocks_used     | 0     |
| Key_blocks_warm     | 0     |
| Key_read_requests   | 0     |
| Key_reads          | 0     |
| Key_write_requests  | 0     |
| Key_writes         | 0     |
+-----+-----+
```

```
8 rows in set (0.00 sec)
```

1.1.1.2.8.53 SHOW TABLE STATUS

Syntax

```
SHOW TABLE STATUS [{FROM | IN} db_name]
                    [LIKE 'pattern' | WHERE expr]
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Views](#)
4. [Example](#)

Description

`SHOW TABLE STATUS` works like [SHOW TABLES](#), but provides more extensive information about each table (until [MariaDB 11.2.0](#), only non-TEMPORARY tables are shown).

The `LIKE` clause, if present on its own, indicates which table names to match. The `WHERE` and `LIKE` clauses can be given to select rows using more general conditions, as discussed in [Extended SHOW](#).

The following information is returned:

Column	Description
Name	Table name.
Engine	Table storage engine .
Version	Version number from the table's .frm file.
Row_format	Row format (see InnoDB , Aria and MyISAM row formats).
Rows	Number of rows in the table. Some engines, such as InnoDB may store an estimate.
Avg_row_length	Average row length in the table.
Data_length	For InnoDB , the index size, in pages, multiplied by the page size. For Aria and MyISAM , length of the data file, in bytes. For MEMORY , the approximate allocated memory.
Max_data_length	Maximum length of the data file, ie the total number of bytes that could be stored in the table. Not used in InnoDB .
Index_length	Length of the index file.
Data_free	Bytes allocated but unused. For InnoDB tables in a shared tablespace, the free space of the shared tablespace with small safety margin. An estimate in the case of partitioned tables - see the PARTITIONS table.
Auto_increment	Next AUTO_INCREMENT value.
Create_time	Time the table was created. Some engines just return the ctime information from the file system layer here, in that case the value is not necessarily the table creation time but rather the time the file system metadata for it had last changed.

Update_time	Time the table was last updated. On Windows, the timestamp is not updated on update, so MyISAM values will be inaccurate. In InnoDB , if shared tablespaces are used, will be <code>NULL</code> , while buffering can also delay the update, so the value will differ from the actual time of the last <code>UPDATE</code> , <code>INSERT</code> or <code>DELETE</code> .
Check_time	Time the table was last checked. Not kept by all storage engines, in which case will be <code>NULL</code> .
Collation	Character set and collation.
Checksum	Live checksum value, if any.
Create_options	Extra CREATE TABLE options.
Comment	Table comment provided when MariaDB created the table.
Max_index_length	Maximum index length (supported by MyISAM and Aria tables).
Temporary	Until MariaDB 11.2.0 , placeholder to signal that a table is a temporary table and always "N", except "Y" for generated information_schema tables and NULL for views. From MariaDB 11.2.0 , will also be set to "Y" for local temporary tables.

Similar information can be found in the [information_schema.TABLES](#) table as well as by using [mariadb-show](#):

```
mariadb-show --status db_name
```

Views

For views, all columns in `SHOW TABLE STATUS` are `NULL` except 'Name' and 'Comment'

Example

```
show table status\G
***** 1. row *****
      Name: bus_routes
      Engine: InnoDB
      Version: 10
      Row_format: Dynamic
      Rows: 5
      Avg_row_length: 3276
      Data_length: 16384
      Max_data_length: 0
      Index_length: 0
      Data_free: 0
      Auto_increment: NULL
      Create_time: 2017-05-24 11:17:46
      Update_time: NULL
      Check_time: NULL
      Collation: latin1_swedish_ci
      Checksum: NULL
      Create_options:
      Comment:
```

1.1.1.2.8.54 SHOW TABLES

Syntax

```
SHOW [FULL] TABLES [FROM db_name]
      [LIKE 'pattern' | WHERE expr]
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

Description

`SHOW TABLES` lists the tables (until [MariaDB 11.2.0](#), only non- `TEMPORARY` tables are shown), [sequences](#) and [views](#) in a given database.

The `LIKE` clause, if present on its own, indicates which table names to match. The `WHERE` and `LIKE` clauses can be given to select rows using more general conditions, as discussed in [Extended SHOW](#). For example, when searching for tables in the `test` database, the column name for use in the `WHERE` and `LIKE` clauses will be `Tables_in_test`

The `FULL` modifier is supported such that `SHOW FULL TABLES` displays a second output column. Values for the second column, `Table_type`, are `BASE TABLE` for a table, `VIEW` for a [view](#) and `SEQUENCE` for a [sequence](#).

You can also get this information using:

```
mariadb-show db_name
```

See [mariadb-show](#) for more details.

If you have no privileges for a base table or view, it does not show up in the output from `SHOW TABLES` or `mariadb-show db_name`.

The [information_schema.TABLES](#) table, as well as the `SHOW TABLE STATUS` statement, provide extended information about tables.

Examples

```
SHOW TABLES;
+-----+
| Tables_in_test |
+-----+
| animal_count   |
| animals        |
| are_the_moose |
| aria_test2     |
| t1             |
| view1          |
+-----+
```

Showing the tables beginning with `a` only.

```
SHOW TABLES WHERE Tables_in_test LIKE 'a%';
+-----+
| Tables_in_test |
+-----+
| animal_count   |
| animals        |
| are_the_moose |
| aria_test2     |
+-----+
```

Showing tables and table types:

```
SHOW FULL TABLES;
+-----+-----+
| Tables_in_test | Table_type |
+-----+-----+
| s1             | SEQUENCE   |
| student        | BASE TABLE|
| v1             | VIEW       |
+-----+-----+
```

Showing temporary tables: <= [MariaDB 11.1](#)

```

CREATE TABLE t (t int(11));
CREATE TEMPORARY TABLE t (t int(11));
CREATE TEMPORARY TABLE te (t int(11));

SHOW TABLES;
+-----+
| Tables_in_test |
+-----+
| t               |
+-----+

```

From [MariaDB 11.2.0](#):

```

CREATE TABLE t (t int(11));
CREATE TEMPORARY TABLE t (t int(11));
CREATE TEMPORARY TABLE te (t int(11));

SHOW TABLES;
+-----+
| Tables_in_test |
+-----+
| te             |
| t              |
| t              |
+-----+

```

1.1.1.2.8.55 SHOW TABLE_STATISTICS

Syntax

```
SHOW TABLE_STATISTICS
```

Description

The `SHOW TABLE_STATISTICS` statement is part of the [User Statistics](#) feature. It was removed as a separate statement in [MariaDB 10.1.1](#), but effectively replaced by the generic `SHOW information_schema_table` statement. The `information_schema.TABLE_STATISTICS` table shows statistics on table usage.

The `userstat` system variable must be set to 1 to activate this feature. See the [User Statistics](#) and [information_schema.TABLE_STATISTICS](#) articles for more information.

Example

```

SHOW TABLE_STATISTICS\G
***** 1. row *****
      Table_schema: mysql
      Table_name: proxies_priv
      Rows_read: 2
      Rows_changed: 0
Rows_changed_x_#indexes: 0
***** 2. row *****
      Table_schema: test
      Table_name: employees_example
      Rows_read: 7
      Rows_changed: 0
Rows_changed_x_#indexes: 0
***** 3. row *****
      Table_schema: mysql
      Table_name: user
      Rows_read: 16
      Rows_changed: 0
Rows_changed_x_#indexes: 0
***** 4. row *****
      Table_schema: mysql
      Table_name: db
      Rows_read: 2
      Rows_changed: 0
Rows_changed_x_#indexes: 0

```

1.1.1.2.8.56 SHOW TRIGGERS

Syntax

```

SHOW TRIGGERS [FROM db_name]
      [LIKE 'pattern' | WHERE expr]

```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

Description

`SHOW TRIGGERS` lists the triggers currently defined for tables in a database (the default database unless a `FROM` clause is given). This statement requires the `TRIGGER` privilege (prior to MySQL 5.1.22, it required the `SUPER` privilege).

The `LIKE` clause, if present on its own, indicates which table names to match and causes the statement to display triggers for those tables. The `WHERE` and `LIKE` clauses can be given to select rows using more general conditions, as discussed in [Extended SHOW](#).

Similar information is stored in the `information_schema.TRIGGERS` table.

If there are multiple triggers for the same action, then the triggers are shown in action order.

Examples

For the trigger defined at [Trigger Overview](#):

```

SHOW triggers Like 'animals' \G
***** 1. row *****
      Trigger: the_moosees_are_loose
      Event: INSERT
      Table: animals
      Statement: BEGIN
IF NEW.name = 'Moose' THEN
  UPDATE animal_count SET animal_count.animals = animal_count.animals+100;
ELSE
  UPDATE animal_count SET animal_count.animals = animal_count.animals+1;
END IF;
END

      Timing: AFTER
      Created: 2016-09-29 13:53:34.35
      sql_mode:
      Definer: root@localhost
character_set_client: utf8
collation_connection: utf8_general_ci
      Database Collation: latin1_swedish_ci

```

Listing all triggers associated with a certain table:

```

SHOW TRIGGERS FROM test WHERE `Table` = 'user' \G
***** 1. row *****
      Trigger: user_ai
      Event: INSERT
      Table: user
      Statement: BEGIN END
      Timing: AFTER
      Created: 2016-09-29 13:53:34.35
      sql_mode:
      Definer: root@%
character_set_client: utf8
collation_connection: utf8_general_ci
      Database Collation: latin1_swedish_ci

```

```

SHOW triggers WHERE Event Like 'Insert' \G
***** 1. row *****
      Trigger: the_moosees_are_loose
      Event: INSERT
      Table: animals
      Statement: BEGIN
IF NEW.name = 'Moose' THEN
  UPDATE animal_count SET animal_count.animals = animal_count.animals+100;
ELSE
  UPDATE animal_count SET animal_count.animals = animal_count.animals+1;
END IF;
END

      Timing: AFTER
      Created: 2016-09-29 13:53:34.35
      sql_mode:
      Definer: root@localhost
character_set_client: utf8
collation_connection: utf8_general_ci
      Database Collation: latin1_swedish_ci

```

- `character_set_client` is the session value of the `character_set_client` system variable when the trigger was created.
- `collation_connection` is the session value of the `collation_connection` system variable when the trigger was created.
- `Database Collation` is the collation of the database with which the trigger is associated.

These columns were added in MariaDB/MySQL 5.1.21.

Old triggers created before MySQL 5.7 and [MariaDB 10.2.3](#) have NULL in the `Created` column.

1.1.1.2.8.57 SHOW USER_STATISTICS

```
SHOW USER_STATISTICS
```

Description

The `SHOW USER_STATISTICS` statement is part of the [User Statistics](#) feature. It was removed as a separate statement in [MariaDB 10.1.1](#), but effectively replaced by the generic [SHOW information_schema_table](#) statement. The `information_schema.USER_STATISTICS` table holds statistics about user activity. You can use this table to find out such things as which user is causing the most load and which users are being abusive. You can also use this table to measure how close to capacity the server may be.

The `userstat` system variable must be set to 1 to activate this feature. See the [User Statistics](#) and `information_schema.USER_STATISTICS` table for more information.

Example

```
SHOW USER_STATISTICS\G
***** 1. row *****
      User: root
    Total_connections: 1
  Concurrent_connections: 0
      Connected_time: 3297
          Busy_time: 0.14113400000000006
          Cpu_time: 0.017637000000000003
      Bytes_received: 969
      Bytes_sent: 22355
  Binlog_bytes_written: 0
          Rows_read: 10
          Rows_sent: 67
      Rows_deleted: 0
      Rows_inserted: 0
      Rows_updated: 0
      Select_commands: 7
      Update_commands: 0
      Other_commands: 0
  Commit_transactions: 1
  Rollback_transactions: 0
  Denied_connections: 0
  Lost_connections: 0
      Access_denied: 0
      Empty_queries: 7
```

1.1.1.2.8.58 SHOW USER_VARIABLES

See the [User Variables Plugin](#) for details.

1.1.1.2.8.59 SHOW VARIABLES

Syntax

```
SHOW [GLOBAL | SESSION] VARIABLES
    [LIKE 'pattern' | WHERE expr]
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

Description

`SHOW VARIABLES` shows the values of MariaDB [system variables](#). This does not include user-defined variables - see [here](#)

for details on viewing those.

System variable information can also be obtained using the [mariadb-admin variables](#) command. The `LIKE` clause, if present, indicates which variable names to match. The `WHERE` clause can be given to select rows using more general conditions.

With the `GLOBAL` modifier, `SHOW VARIABLES` displays the values that are used for new connections to MariaDB. With `SESSION`, it displays the values that are in effect for the current connection. If no modifier is present, the default is `SESSION`. `LOCAL` is a synonym for `SESSION`. With a `LIKE` clause, the statement displays only rows for those variables with names that match the pattern. To obtain the row for a specific variable, use a `LIKE` clause as shown:

```
SHOW VARIABLES LIKE 'maria_group_commit';
SHOW SESSION VARIABLES LIKE 'maria_group_commit';
```

To get a list of variables whose name match a pattern, use the `%` wildcard character in a `LIKE` clause:

```
SHOW VARIABLES LIKE '%maria%';
SHOW GLOBAL VARIABLES LIKE '%maria%';
```

Wildcard characters can be used in any position within the pattern to be matched. Strictly speaking, because `_` is a wildcard that matches any single character, you should escape it as `_` to match it literally. In practice, this is rarely necessary.

The `WHERE` and `LIKE` clauses can be given to select rows using more general conditions, as discussed in [Extended SHOW](#).

See [SET](#) for information on setting server system variables.

See [Server System Variables](#) for a list of all the variables that can be set.

You can also see the server variables by querying the [Information Schema GLOBAL_VARIABLES](#) and [SESSION_VARIABLES](#) tables.

Examples

```
SHOW VARIABLES LIKE 'aria%';
+-----+-----+
| Variable_name          | Value          |
+-----+-----+
| aria_block_size        | 8192           |
| aria_checkpoint_interval | 30             |
| aria_checkpoint_log_activity | 1048576       |
| aria_force_start_after_recovery_failures | 0             |
| aria_group_commit      | none          |
| aria_group_commit_interval | 0             |
| aria_log_file_size     | 1073741824    |
| aria_log_purge_type    | immediate     |
| aria_max_sort_file_size | 9223372036853727232 |
| aria_page_checksum     | ON            |
| aria_pagecache_age_threshold | 300           |
| aria_pagecache_buffer_size | 134217728     |
| aria_pagecache_division_limit | 100           |
| aria_recover           | NORMAL        |
| aria_repair_threads    | 1             |
| aria_sort_buffer_size  | 134217728     |
| aria_stats_method      | nulls_unequal |
| aria_sync_log_dir      | NEWFILE       |
| aria_used_for_temp_tables | ON            |
+-----+-----+
```

```

SELECT VARIABLE_NAME, SESSION_VALUE, GLOBAL_VALUE FROM
INFORMATION_SCHEMA.SYSTEM_VARIABLES WHERE
VARIABLE_NAME LIKE 'max_error_count' OR
VARIABLE_NAME LIKE 'innodb_sync_spin_loops';
+-----+-----+
| VARIABLE_NAME          | SESSION_VALUE | GLOBAL_VALUE |
+-----+-----+
| MAX_ERROR_COUNT        | 64            | 64           |
| INNODB_SYNC_SPIN_LOOPS | NULL         | 30           |
+-----+-----+

SET GLOBAL max_error_count=128;

SELECT VARIABLE_NAME, SESSION_VALUE, GLOBAL_VALUE FROM
INFORMATION_SCHEMA.SYSTEM_VARIABLES WHERE
VARIABLE_NAME LIKE 'max_error_count' OR
VARIABLE_NAME LIKE 'innodb_sync_spin_loops';
+-----+-----+
| VARIABLE_NAME          | SESSION_VALUE | GLOBAL_VALUE |
+-----+-----+
| MAX_ERROR_COUNT        | 64            | 128          |
| INNODB_SYNC_SPIN_LOOPS | NULL         | 30           |
+-----+-----+

SET GLOBAL max_error_count=128;

SHOW VARIABLES LIKE 'max_error_count';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| max_error_count | 64   |
+-----+-----+

SHOW GLOBAL VARIABLES LIKE 'max_error_count';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| max_error_count | 128  |
+-----+-----+

```

Because the following variable only has a global scope, the global value is returned even when specifying SESSION (in this case by default):

```

SHOW VARIABLES LIKE 'innodb_sync_spin_loops';
+-----+-----+
| Variable_name          | Value |
+-----+-----+
| innodb_sync_spin_loops | 30    |
+-----+-----+

```

1.1.1.2.8.60 SHOW WARNINGS

Syntax

```

SHOW WARNINGS [LIMIT [offset,] row_count]
SHOW ERRORS [LIMIT row_count OFFSET offset]
SHOW COUNT(*) WARNINGS

```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
 1. [Stack Trace](#)

Description

`SHOW WARNINGS` shows the error, warning, and note messages that resulted from the last statement that generated messages in the current session. It shows nothing if the last statement used a table and generated no messages. (That is, a statement that uses a table but generates no messages clears the message list.) Statements that do not use tables and do not generate messages have no effect on the message list.

A note is different to a warning in that it only appears if the `sql_notes` variable is set to 1 (the default), and is not converted to an error if `strict mode` is enabled.

A related statement, `SHOW ERRORS`, shows only the errors.

The `SHOW COUNT(*) WARNINGS` statement displays the total number of errors, warnings, and notes. You can also retrieve this number from the `warning_count` variable:

```
SHOW COUNT(*) WARNINGS;
SELECT @@warning_count;
```

The value of `warning_count` might be greater than the number of messages displayed by `SHOW WARNINGS` if the `max_error_count` system variable is set so low that not all messages are stored.

The `LIMIT` clause has the same syntax as for the `SELECT` statement.

`SHOW WARNINGS` can be used after `EXPLAIN EXTENDED` to see how a query is internally rewritten by MariaDB.

If the `sql_notes` server variable is set to 1, Notes are included in the output of `SHOW WARNINGS`; if it is set to 0, this statement will not show (or count) Notes.

The results of `SHOW WARNINGS` and `SHOW COUNT(*) WARNINGS` are directly sent to the client. If you need to access those information in a stored program, you can use the `GET DIAGNOSTICS` statement instead.

For a list of MariaDB error codes, see [MariaDB Error Codes](#).

The `mariadb` client also has a number of options related to warnings. The `\w` command will show warnings after every statement, while `\w` will disable this. Starting the client with the `--show-warnings` option will show warnings after every statement.

MariaDB implements a stored routine error stack trace. `SHOW WARNINGS` can also be used to show more information. See the example below.

Examples

```
SELECT 1/0;
+-----+
| 1/0 |
+-----+
| NULL |
+-----+

SHOW COUNT(*) WARNINGS;
+-----+
| @@session.warning_count |
+-----+
| 1 |
+-----+

SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1365 | Division by 0 |
+-----+-----+-----+
```

Stack Trace

Displaying a stack trace:

```

DELIMITER $$
CREATE OR REPLACE PROCEDURE p1()
BEGIN
    DECLARE c CURSOR FOR SELECT * FROM not_existing;
    OPEN c;
    CLOSE c;
END;
$$
CREATE OR REPLACE PROCEDURE p2()
BEGIN
    CALL p1;
END;
$$
DELIMITER ;
CALL p2;
ERROR 1146 (42S02): Table 'test.not_existing' doesn't exist

SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Error | 1146 | Table 'test.not_existing' doesn't exist |
| Note | 4091 | At line 6 in test.p1 |
| Note | 4091 | At line 4 in test.p2 |
+-----+-----+-----+

```

`SHOW WARNINGS` displays a stack trace, showing where the error actually happened:

- Line 4 in test.p1 is the OPEN command which actually raised the error
- Line 3 in test.p2 is the CALL statement, calling p1 from p2.

1.1.1.2.8.61 SHOW WSREP_MEMBERSHIP

`SHOW WSREP_MEMBERSHIP` is part of the [WSREP_INFO](#) plugin.

Syntax

```
SHOW WSREP_MEMBERSHIP
```

Description

The `SHOW WSREP_MEMBERSHIP` statement returns [Galera](#) node cluster membership information. It returns the same information as found in the `information_schema.WSREP_MEMBERSHIP` table. Only users with the [SUPER](#) privilege can access this information.

Examples

```

SHOW WSREP_MEMBERSHIP;
+-----+-----+-----+-----+
| Index | Uuid | Name | Address |
+-----+-----+-----+-----+
| 0 | 19058073-8940-11e4-8570-16af7bf8fced | my_node1 | 10.0.2.15:16001 |
| 1 | 19f2b0e0-8942-11e4-9cb8-b39e8ee0b5dd | my_node3 | 10.0.2.15:16003 |
| 2 | d85e62db-8941-11e4-b1ef-4bc9980e476d | my_node2 | 10.0.2.15:16002 |
+-----+-----+-----+-----+

```

1.1.1.2.8.62 SHOW WSREP_STATUS

`SHOW WSREP_STATUS` is part of the [WSREP_INFO](#) plugin.

Syntax

Description

The `SHOW WSREP_STATUS` statement returns [Galera](#) node and cluster status information. It returns the same information as found in the `information_schema.WSREP_STATUS` table. Only users with the `SUPER` privilege can access this information.

Examples

```
SHOW WSREP_STATUS;
+-----+-----+-----+-----+
| Node_Index | Node_Status | Cluster_Status | Cluster_Size |
+-----+-----+-----+-----+
|          0 | Synced      | Primary        |             3 |
+-----+-----+-----+-----+
```

Information Schema INNODB_TABLESPACES_ENCRYPTION Table

Encryption metadata for InnoDB tablespaces.

Information Schema INNODB_TABLESPACES_SCRUBBING Table

Data scrubbing information.

Information Schema INNODB_TRX Table

Currently-executing InnoDB locks.

Information Schema TEMP_TABLES_INFO Table

Information about active InnoDB temporary tables.

1.1.1.2.9.1.1.1.1 Information Schema INNODB_BUFFER_PAGE Table

The [Information Schema](#) `INNODB_BUFFER_PAGE` table contains information about pages in the [buffer pool](#).

Querying this table can have a noticeable performance impact on a production server.

The `PROCESS` [privilege](#) is required to view the table.

It has the following columns:

Column	Description
<code>POOL_ID</code>	Buffer Pool identifier. From MariaDB 10.5.1 returns a value of 0, since multiple InnoDB buffer pool instances has been removed.
<code>BLOCK_ID</code>	Buffer Pool Block identifier.
<code>SPACE</code>	Tablespace identifier. Matches the <code>SPACE</code> value in the INNODB_SYS_TABLES table.
<code>PAGE_NUMBER</code>	Buffer pool page number.
<code>PAGE_TYPE</code>	Page type; one of <code>allocated</code> (newly-allocated page), <code>index</code> (B-tree node), <code>undo_log</code> (undo log page), <code>inode</code> (index node), <code>ibuf_free_list</code> (insert buffer free list), <code>ibuf_bitmap</code> (insert buffer bitmap), <code>system</code> (system page), <code>trx_system</code> (transaction system data), <code>file_space_header</code> (file space header), <code>extent_descriptor</code> (extent descriptor page), <code>blob</code> (uncompressed blob page), <code>compressed_blob</code> (first compressed blob page), <code>compressed_blob2</code> (subsequent compressed blob page) or <code>unknown</code> .
<code>FLUSH_TYPE</code>	Flush type.
<code>FIX_COUNT</code>	Count of the threads using this block in the buffer pool. When it is zero, the block can be evicted from the buffer pool.
<code>IS_HASHED</code>	Whether or not a hash index has been built on this page.
<code>NEWEST_MODIFICATION</code>	Most recent modification's Log Sequence Number.
<code>OLDEST_MODIFICATION</code>	Oldest modification's Log Sequence Number.
<code>ACCESS_TIME</code>	Abstract number representing the time the page was first accessed.
<code>TABLE_NAME</code>	Table that the page belongs to.
<code>INDEX_NAME</code>	Index that the page belongs to, either a clustered index or a secondary index.
<code>NUMBER_RECORDS</code>	Number of records the page contains.
<code>DATA_SIZE</code>	Size in bytes of all the records contained in the page.
<code>COMPRESSED_SIZE</code>	Compressed size in bytes of the page, or <code>NULL</code> for pages that aren't compressed.
<code>PAGE_STATE</code>	Page state; one of <code>FILE_PAGE</code> (page from a file) or <code>MEMORY</code> (page from an in-memory object) for valid data, or one of <code>NULL</code> , <code>READY_FOR_USE</code> , <code>NOT_USED</code> , <code>REMOVE_HASH</code> .
<code>IO_FIX</code>	Whether there is I/O pending for the page; one of <code>IO_NONE</code> (no pending I/O), <code>IO_READ</code> (read pending), <code>IO_WRITE</code> (write pending).
<code>IS_OLD</code>	Whether the page is old or not.
<code>FREE_PAGE_CLOCK</code>	<code>Freed_page_clock</code> counter, which tracks the number of blocks removed from the end of the least recently used (LRU) list, at the time the block was last placed at the head of the list.

The related [INFORMATION_SCHEMA.INNODB_BUFFER_PAGE_LRU](#) table contains the same information, but with an LRU (least recently used) position rather than block id.

Examples

```
DESC information_schema.innodb_buffer_page;
```

Field	Type	Null	Key	Default	Extra
POOL_ID	bigint(21) unsigned	NO		0	
BLOCK_ID	bigint(21) unsigned	NO		0	
SPACE	bigint(21) unsigned	NO		0	
PAGE_NUMBER	bigint(21) unsigned	NO		0	
PAGE_TYPE	varchar(64)	YES		NULL	
FLUSH_TYPE	bigint(21) unsigned	NO		0	
FIX_COUNT	bigint(21) unsigned	NO		0	
IS_HASHED	varchar(3)	YES		NULL	
NEWEST_MODIFICATION	bigint(21) unsigned	NO		0	
OLDEST_MODIFICATION	bigint(21) unsigned	NO		0	
ACCESS_TIME	bigint(21) unsigned	NO		0	
TABLE_NAME	varchar(1024)	YES		NULL	
INDEX_NAME	varchar(1024)	YES		NULL	
NUMBER_RECORDS	bigint(21) unsigned	NO		0	
DATA_SIZE	bigint(21) unsigned	NO		0	
COMPRESSED_SIZE	bigint(21) unsigned	NO		0	
PAGE_STATE	varchar(64)	YES		NULL	
IO_FIX	varchar(64)	YES		NULL	
IS_OLD	varchar(3)	YES		NULL	
FREE_PAGE_CLOCK	bigint(21) unsigned	NO		0	

```
SELECT * FROM INFORMATION_SCHEMA.INNOODB_BUFFER_PAGE\G
```

```
...
***** 6. row *****
      POOL_ID: 0
      BLOCK_ID: 5
      SPACE: 0
      PAGE_NUMBER: 11

      IO_FIX: IO_NONE
      IS_OLD: NO
      FREE_PAGE_CLOCK: 0
...

```

1.1.1.2.9.1.1.1.2 Information Schema INNODB_BUFFER_PAGE_LRU Table

The [Information Schema](#) `INNODB_BUFFER_PAGE_LRU` table contains information about pages in the [buffer pool](#) and how they are ordered for eviction purposes.

The `PROCESS` [privilege](#) is required to view the table.

It has the following columns:

Column	Description
POOL_ID	Buffer Pool identifier. From MariaDB 10.5.1 returns a value of 0, since multiple InnoDB buffer pool instances has been removed.

LRU_POSITION	LRU (Least recently-used), for determining eviction order from the buffer pool.
SPACE	Tablespace identifier. Matches the <code>SPACE</code> value on the <code>INNODB_SYS_TABLES</code> table.
PAGE_NUMBER	Buffer pool page number.
PAGE_TYPE	Page type; one of <code>allocated</code> (newly-allocated page), <code>index</code> (B-tree node), <code>undo_log</code> (undo log page), <code>inode</code> (index node), <code>ibuf_free_list</code> (insert buffer free list), <code>ibuf_bitmap</code> (insert buffer bitmap), <code>system</code> (system page), <code>trx_system</code> (transaction system data), <code>file_space_header</code> (file space header), <code>extent_descriptor</code> (extent descriptor page), <code>blob</code> (uncompressed blob page), <code>compressed_blob</code> (first compressed blob page), <code>compressed_blob2</code> (subsequent compressed blob page) or <code>unknown</code> .
FLUSH_TYPE	Flush type. 0= <code>FLUSH_KEEP</code> , 1= <code>FLUSH_RELEASE</code> , 2 = <code>FLUSH_IGNORE_CHANGED</code> , 3= <code>FLUSH_FORCE_WRITE</code>
FIX_COUNT	Count of the threads using this block in the buffer pool. When it is zero, the block can be evicted from the buffer pool.
IS_HASHED	Whether or not a hash index has been built on this page.
NEWEST_MODIFICATION	Most recent modification's Log Sequence Number.
OLDEST_MODIFICATION	Oldest modification's Log Sequence Number.
ACCESS_TIME	Abstract number representing the time the page was first accessed.
TABLE_NAME	Table that the page belongs to.
INDEX_NAME	Index that the page belongs to, either a clustered index or a secondary index.
NUMBER_RECORDS	Number of records the page contains.
DATA_SIZE	Size in bytes of all the records contained in the page.
COMPRESSED_SIZE	Compressed size in bytes of the page, or <code>NULL</code> for pages that aren't compressed.
PAGE_STATE	Page state; one of <code>FILE_PAGE</code> (page from a file) or <code>MEMORY</code> (page from an in-memory object) for valid data, or one of <code>NULL</code> , <code>READY_FOR_USE</code> , <code>NOT_USED</code> , <code>REMOVE_HASH</code> .
IO_FIX	Whether there is I/O pending for the page; one of <code>IO_NONE</code> (no pending I/O), <code>IO_READ</code> (read pending), <code>IO_WRITE</code> (write pending).
IS_OLD	Whether the page is old or not.
FREE_PAGE_CLOCK	<code>Freed_page_clock</code> counter, which tracks the number of blocks removed from the end of the LRU list, at the time the block was last placed at the head of the list.

The related [INFORMATION_SCHEMA.INNODB_BUFFER_PAGE](#) table contains the same information, but with a block id rather than LRU position.

Example

```
DESC information_schema.innodb_buffer_page_lru;
+-----+-----+-----+-----+-----+-----+
| Field          | Type          | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| POOL_ID        | bigint(21) unsigned | NO   |     | 0       |       |
| LRU_POSITION   | bigint(21) unsigned | NO   |     | 0       |       |
| SPACE         | bigint(21) unsigned | NO   |     | 0       |       |
| PAGE_NUMBER    | bigint(21) unsigned | NO   |     | 0       |       |
| PAGE_TYPE      | varchar(64)      | YES  |     | NULL    |       |
| FLUSH_TYPE     | bigint(21) unsigned | NO   |     | 0       |       |
| FIX_COUNT      | bigint(21) unsigned | NO   |     | 0       |       |
| IS_HASHED     | varchar(3)       | YES  |     | NULL    |       |

1.1.1.2.9.1.1.1.3 Information Schema INNODB_BUFFER_POOL_PAGES Table

The [Information Schema](#) `INNODB_BUFFER_POOL_PAGES` table is a Percona enhancement, and is only available for XtraDB, not InnoDB (see [XtraDB and InnoDB](#)). It contains a record for each page in the [buffer pool](#).

It has the following columns:

Column	Description
PAGE_TYPE	Type of page; one of <code>index</code> , <code>undo_log</code> , <code>inode</code> , <code>ibuf_free_list</code> , <code>allocated</code> , <code>bitmap</code> , <code>sys</code> , <code>trx_sys</code> , <code>fsp_hdr</code> , <code>xdes</code> , <code>blob</code> , <code>zblob</code> , <code>zblob2</code> and <code>unknown</code> .
SPACE_ID	Tablespace ID.
PAGE_NO	Page offset within tablespace.
LRU_POSITION	Page position in the LRU (least-recently-used) list.

FIX_COUNT	Page reference count, incremented each time the page is accessed. 0 if the page is not currently being accessed.
FLUSH_TYPE	Flush type of the most recent flush. 0 (LRU), 2 (flush_list)

1.1.1.2.9.1.1.1.4 Information Schema INNODB_BUFFER_POOL_PAGES_BLOB Table

The [Information Schema](#) `INNODB_BUFFER_POOL_PAGES_BLOB` table is a Percona enhancement, and is only available for XtraDB, not InnoDB (see [XtraDB and InnoDB](#)). It contains information about [buffer pool](#) blob pages.

It has the following columns:

Column	Description
SPACE_ID	Tablespace ID.
PAGE_NO	Page offset within tablespace.
COMPRESSED	1 if the blob contains compressed data, 0 if not.
PART_LEN	Page data length.
NEXT_PAGE_NO	Next page number.
LRU_POSITION	Page position in the LRU (least-recently-used) list.
FIX_COUNT	Page reference count, incremented each time the page is accessed. 0 if the page is not currently being accessed.
FLUSH_TYPE	Flush type of the most recent flush. 0 (LRU), 2 (flush_list)

1.1.1.2.9.1.1.1.5 Information Schema INNODB_BUFFER_POOL_PAGES_INDEX Table

The [Information Schema](#) `INNODB_BUFFER_POOL_PAGES` table is a Percona enhancement, and is only available for XtraDB, not InnoDB (see [XtraDB and InnoDB](#)). It contains information about [buffer pool](#) index pages.

It has the following columns:

Column	Description
INDEX_ID	Index name
SPACE_ID	Tablespace ID
PAGE_NO	Page offset within tablespace.
N_RECS	Number of user records on the page.
DATA_SIZE	Total data size in bytes of records in the page.
HASHED	1 if the block is in the adaptive hash index, 0 if not.
ACCESS_TIME	Page's last access time.
MODIFIED	1 if the page has been modified since being loaded, 0 if not.
DIRTY	1 if the page has been modified since it was last flushed, 0 if not
OLD	1 if the page in the in the <i>old</i> blocks of the LRU (least-recently-used) list, 0 if not.
LRU_POSITION	Position in the LRU (least-recently-used) list.
FIX_COUNT	Page reference count, incremented each time the page is accessed. 0 if the page is not currently being accessed.
FLUSH_TYPE	Flush type of the most recent flush. 0 (LRU), 2 (flush_list)

1.1.1.2.9.1.1.1.6 Information Schema INNODB_BUFFER_POOL_STATS Table

The [Information Schema](#) `INNODB_BUFFER_POOL_STATS` table contains information about pages in the [buffer pool](#), similar to what is returned with the `SHOW ENGINE INNODB STATUS` statement.

The `PROCESS` [privilege](#) is required to view the table.

It has the following columns:

Column	Description
<code>POOL_ID</code>	Buffer Pool identifier. From MariaDB 10.5.1 returns a value of 0, since multiple InnoDB buffer pool instances has been removed.
<code>POOL_SIZE</code>	Size in pages of the buffer pool.
<code>FREE_BUFFERS</code>	Number of free pages in the buffer pool.
<code>DATABASE_PAGES</code>	Total number of pages in the buffer pool.
<code>OLD_DATABASE_PAGES</code>	Number of pages in the <i>old</i> sublist.
<code>MODIFIED_DATABASE_PAGES</code>	Number of dirty pages.
<code>PENDING_DECOMPRESS</code>	Number of pages pending decompression.
<code>PENDING_READS</code>	Pending buffer pool level reads.
<code>PENDING_FLUSH_LRU</code>	Number of pages in the LRU pending flush.
<code>PENDING_FLUSH_LIST</code>	Number of pages in the flush list pending flush.
<code>PAGES_MADE_YOUNG</code>	Pages moved from the <i>old</i> sublist to the <i>new</i> sublist.
<code>PAGES_NOT_MADE_YOUNG</code>	Pages that have remained in the <i>old</i> sublist without moving to the <i>new</i> sublist.
<code>PAGES_MADE_YOUNG_RATE</code>	Hits that cause blocks to move to the top of the <i>new</i> sublist.
<code>PAGES_MADE_NOT_YOUNG_RATE</code>	Hits that do not cause blocks to move to the top of the <i>new</i> sublist due to the innodb_old_blocks delay not being met.
<code>NUMBER_PAGES_READ</code>	Number of pages read.
<code>NUMBER_PAGES_CREATED</code>	Number of pages created.
<code>NUMBER_PAGES_WRITTEN</code>	Number of pages written.
<code>PAGES_READ_RATE</code>	Number of pages read since the last printout divided by the time elapsed, giving pages read per second.
<code>PAGES_CREATE_RATE</code>	Number of pages created since the last printout divided by the time elapsed, giving pages created per second.
<code>PAGES_WRITTEN_RATE</code>	Number of pages written since the last printout divided by the time elapsed, giving pages written per second.
<code>NUMBER_PAGES_GET</code>	Number of logical read requests.
<code>HIT_RATE</code>	Buffer pool hit rate.
<code>YOUNG_MAKE_PER_THOUSAND_GETS</code>	For every 1000 gets, the number of pages made young.
<code>NOT_YOUNG_MAKE_PER_THOUSAND_GETS</code>	For every 1000 gets, the number of pages not made young.
<code>NUMBER_PAGES_READ_AHEAD</code>	Number of pages read ahead.
<code>NUMBER_READ_AHEAD_EVICTED</code>	Number of pages read ahead by the read-ahead thread that were later evicted without being accessed by any queries.
<code>READ_AHEAD_RATE</code>	Pages read ahead since the last printout divided by the time elapsed, giving read-ahead rate per second.
<code>READ_AHEAD_EVICTED_RATE</code>	Read-ahead pages not accessed since the last printout divided by time elapsed, giving the number of read-ahead pages evicted without access per second.
<code>LRU_IO_TOTAL</code>	Total least-recently used I/O.

LRU_IO_CURRENT	Least-recently used I/O for the current interval.
UNCOMPRESS_TOTAL	Total number of pages decompressed.
UNCOMPRESS_CURRENT	Number of pages decompressed in the current interval

Examples

```
DESC information_schema.innodb_buffer_pool_stats;
```

Field	Type	Null	Key	Default	Extra
POOL_ID	bigint(21) unsigned	NO		0	
POOL_SIZE	bigint(21) unsigned	NO		0	
FREE_BUFFERS	bigint(21) unsigned	NO		0	
DATABASE_PAGES	bigint(21) unsigned	NO		0

PAGES_WRITTEN_RATE	double	NO		0	
NUMBER_PAGES_GET	bigint(21) unsigned	NO		0	
HIT_RATE	bigint(21) unsigned	NO		0	
YOUNG_MAKE_PER_THOUSAND_GETS	bigint(21) unsigned	NO		0	
NOT_YOUNG_MAKE_PER_THOUSAND_GETS	bigint(21) unsigned	NO		0	
NUMBER_PAGES_READ_AHEAD	bigint(21) unsigned	NO		0	
NUMBER_READ_AHEAD_EVICTED	bigint(21) unsigned	NO		0	
READ_AHEAD_RATE	double	NO		0	
READ_AHEAD_EVICTED_RATE	double	NO		0	
LRU_IO_TOTAL	bigint(21) unsigned	NO		0	
LRU_IO_CURRENT	bigint(21) unsigned	NO		0	
UNCOMPRESS_TOTAL	bigint(21) unsigned	NO		0	
UNCOMPRESS_CURRENT	bigint(21) unsigned	NO		0	

1.1.1.2.9.1.1.1.7 Information Schema INNODB_CHANGED_PAGES Table

The [Information Schema](#) `INNODB_CHANGED_PAGES` Table contains data about modified pages from the bitmap file. It is updated at checkpoints by the log tracking thread parsing the log, so does not contain real-time data.

The number of records is limited by the value of the [innodb_max_changed_pages](#) system variable.

The `PROCESS` [privilege](#) is required to view the table.

It has the following columns:

Column	Description
SPACE_ID	Modified page space id
PAGE_ID	Modified page id
START_LSN	Interval start after which page was changed (equal to checkpoint LSN)
END_LSN	Interval end before which page was changed (equal to checkpoint LSN)

1.1.1.2.9.1.1.1.8 Information Schema INNODB_CMP and INNODB_CMP_RESET Tables

The `INNODB_CMP` and `INNODB_CMP_RESET` tables contain status information on compression operations related to [compressed XtraDB/InnoDB tables](#).

The `PROCESS` privilege is required to query this table.

These tables contain the following columns:

Column Name	Description
<code>PAGE_SIZE</code>	Compressed page size, in bytes. This value is unique in the table; other values are totals which refer to pages of this size.
<code>COMPRESS_OPS</code>	How many times a page of the size <code>PAGE_SIZE</code> has been compressed. This happens when a new page is created because the compression log runs out of space. This value includes both successful operations and <i>compression failures</i> .
<code>COMPRESS_OPS_OK</code>	How many times a page of the size <code>PAGE_SIZE</code> has been successfully compressed. This value should be as close as possible to <code>COMPRESS_OPS</code> . If it is notably lower, either avoid compressing some tables, or increase the <code>KEY_BLOCK_SIZE</code> for some compressed tables.
<code>COMPRESS_TIME</code>	Time (in seconds) spent to compress pages of the size <code>PAGE_SIZE</code> . This value includes time spent in <i>compression failures</i> .
<code>UNCOMPRESS_OPS</code>	How many times a page of the size <code>PAGE_SIZE</code> has been uncompressed. This happens when an uncompressed version of a page is created in the buffer pool, or when a <i>compression failure</i> occurs.
<code>UNCOMPRESS_TIME</code>	Time (in seconds) spent to uncompress pages of the size <code>PAGE_SIZE</code> .

These tables can be used to measure the effectiveness of XtraDB/InnoDB table compression. When you have to decide a value for `KEY_BLOCK_SIZE`, you can create more than one version of the table (one for each candidate value) and run a realistic workload on them. Then, these tables can be used to see how the operations performed with different page sizes.

`INNODB_CMP` and `INNODB_CMP_RESET` have the same columns and always contain the same values, but when `INNODB_CMP_RESET` is queried, both the tables are cleared. `INNODB_CMP_RESET` can be used, for example, if a script periodically logs the performances of compression in the last period of time. `INNODB_CMP` can be used to see the cumulated statistics.

Examples

```
SELECT * FROM information_schema.INNODB_CMP\G
***** 1. row *****
  page_size: 1024
  compress_ops: 0
  compress_ops_ok: 0
  compress_time: 0
  uncompress_ops: 0
  uncompress_time: 0
  ...
```

1.1.1.2.9.1.1.1.9 Information Schema INNODB_CMPMEM and INNODB_CMPMEM_RESET Tables

The `INNODB_CMPMEM` and `INNODB_CMPMEM_RESET` tables contain status information on compressed pages in the [buffer pool](#) (see InnoDB [COMPRESSED](#) format).

The `PROCESS` privilege is required to query this table.

These tables contain the following columns:

Column Name	Description
-------------	-------------

PAGE_SIZE	Compressed page size, in bytes. This value is unique in the table; other values are totals which refer to pages of this size.
BUFFER_POOL_INSTANCE	Buffer Pool identifier. From MariaDB 10.5.1 returns a value of 0, since multiple InnoDB buffer pool instances has been removed.
PAGES_USED	Number of pages of the size PAGE_SIZE which are currently in the buffer pool.
PAGES_FREE	Number of pages of the size PAGE_SIZE which are currently free, and thus are available for allocation. This value represents the buffer pool's fragmentation. A totally unfragmented buffer pool has at most 1 free page.
RELOCATION_OPS	How many times a page of the size PAGE_SIZE has been relocated. This happens when data exceeds a page (because a row must be copied into a new page) and when two pages are merged (because their data shrunk and can now be contained in one page).
RELOCATION_TIME	Time (in seconds) spent in relocation operations for pages of the size PAGE_SIZE . This column is reset when the INNODB_CMPMEM_RESET table is queried.

These tables can be used to measure the effectiveness of InnoDB table compression. When you have to decide a value for KEY_BLOCK_SIZE , you can create more than one version of the table (one for each candidate value) and run a realistic workload on them. Then, these tables can be used to see how the operations performed with different page sizes.

INNODB_CMPMEM and INNODB_CMPMEM_RESET have the same columns and always contain the same values, but when INNODB_CMPMEM_RESET is queried, the RELOCATION_TIME column from both the tables are cleared.

INNODB_CMPMEM_RESET can be used, for example, if a script periodically logs the performances of compression in the last period of time. INNODB_CMPMEM can be used to see the cumulated statistics.

Example

```
SELECT * FROM information_schema.INNODB_CMPMEM\G
***** 1. row *****
page_size: 1024
buffer_pool_instance: 0
pages_used: 0
pages_free: 0
relocation_ops: 0
relocation_time: 0
```

1.1.1.2.9.1.1.1.10 Information Schema INNODB_CMP_PER_INDEX and INNODB_CMP_PER_INDEX_RESET Tables

The INNODB_CMP_PER_INDEX and INNODB_CMP_PER_INDEX_RESET tables contain status information on compression operations related to [compressed XtraDB/InnoDB tables](#), grouped by individual indexes. These tables are only populated if the [innodb_cmp_per_index_enabled](#) system variable is set to ON .

The PROCESS privilege is required to query this table.

These tables contains the following columns:

Column Name	Description
DATABASE_NAME	Database containing the index.
TABLE_NAME	Table containing the index.
INDEX_NAME	Other values are totals which refer to this index's compression.
COMPRESS_OPS	How many times a page of INDEX_NAME has been compressed. This happens when a new page is created because the compression log runs out of space. This value includes both successful operations and <i>compression failures</i> .
COMPRESS_OPS_OK	How many times a page of INDEX_NAME has been successfully compressed. This value should be as close as possible to COMPRESS_OPS . If it is notably lower, either avoid compressing some tables, or increase the KEY_BLOCK_SIZE for some compressed tables.

COMPRESS_TIME	Time (in seconds) spent to compress pages of the size <code>PAGE_SIZE</code> . This value includes time spent in <i>compression failures</i> .
UNCOMPRESS_OPS	How many times a page of <code>INDEX_NAME</code> has been uncompressed. This happens when an uncompressed version of a page is created in the buffer pool, or when a <i>compression failure</i> occurs.
UNCOMPRESS_TIME	Time (in seconds) spent to uncompress pages of <code>INDEX_NAME</code> .

These tables can be used to measure the effectiveness of XtraDB/InnoDB compression, per table or per index. The values in these tables show which tables perform better with index compression, and which tables cause too many *compression failures* or perform too many compression/uncompression operations. When compression performs badly for a table, this might mean that you should change its `KEY_BLOCK_SIZE` , or that the table should not be compressed.

`INNODB_CMP_PER_INDEX` and `INNODB_CMP_PER_INDEX_RESET` have the same columns and always contain the same values, but when `INNODB_CMP_PER_INDEX_RESET` is queried, both the tables are cleared.

`INNODB_CMP_PER_INDEX_RESET` can be used, for example, if a script periodically logs the performances of compression in the last period of time. `INNODB_CMP_PER_INDEX` can be used to see the cumulated statistics.

1.1.1.2.9.1.1.1.11 Information Schema INNODB_FT_BEING_DELETED Table

The [Information Schema](#) `INNODB_FT_BEING_DELETED` table is only used while document ID's in the related [INNODB_FT_DELETED](#) are being removed from an InnoDB [fulltext index](#) while an [OPTIMIZE TABLE](#) is underway. At all other times the table will be empty.

The `SUPER` [privilege](#) is required to view the table, and it also requires the `innodb_ft_aux_table` system variable to be set.

It has the following column:

Column	Description
DOC_ID	Document ID of the row being deleted. Either an underlying ID value, or a sequence value generated by InnoDB if no usable option exists.

1.1.1.2.9.1.1.1.12 Information Schema INNODB_FT_CONFIG Table

The [Information Schema](#) `INNODB_FT_CONFIG` table contains InnoDB [fulltext index](#) metadata.

The `SUPER` [privilege](#) is required to view the table, and it also requires the `innodb_ft_aux_table` system variable to be set.

It has the following columns:

Column	Description
KEY	Metadata item name.
VALUE	Associated value.

Example

```
SELECT * FROM INNODB_FT_CONFIG;
+-----+-----+
| KEY          | VALUE |
+-----+-----+
| optimize_checkpoint_limit | 180 |
| synced_doc_id | 6 |
| last_optimized_word | |
| deleted_doc_count | 0 |
| total_word_count | |
| optimize_start_time | |
| optimize_end_time | |
| stopword_table_name | |
| use_stopword | 1 |
| table_state | 0 |
+-----+-----+
```

1.1.1.2.9.1.1.1.13 Information Schema INNODB_FT_DEFAULT_STOPWORD Table

The [Information Schema](#) `INNODB_FT_DEFAULT_STOPWORD` table contains a list of default [stopwords](#) used when creating an InnoDB [fulltext index](#).

The `PROCESS` [privilege](#) is required to view the table.

It has the following column:

Column	Description
VALUE	Default stopword for an InnoDB fulltext index . Setting either the innodb_ft_server_stopword_table or the innodb_ft_user_stopword_table system variable will override this.

Example

```
SELECT * FROM information_schema.INNODB_FT_DEFAULT_STOPWORD\G
***** 1. row *****
value: a
***** 2. row *****
value: about
***** 3. row *****
value: an
***** 4. row *****
value: are
...
***** 36. row *****
value: www
```

1.1.1.2.9.1.1.1.14 Information Schema INNODB_FT_DELETED Table

The [Information Schema](#) `INNODB_FT_DELETED` table contains rows that have been deleted from an InnoDB [fulltext index](#). This information is then used to filter results on subsequent searches, removing the need to expensively reorganise the index each time a row is deleted.

The fulltext index is then only reorganized when an [OPTIMIZE TABLE](#) statement is underway. The related [INNODB_FT_BEING_DELETED](#) table contains rows being deleted while an `OPTIMIZE TABLE` is in the process of running.

The `SUPER` [privilege](#) is required to view the table, and it also requires the [innodb_ft_aux_table](#) system variable to be set.

It has the following column:

Column	Description
DOC_ID	Document ID of the deleted row deleted. Either an underlying ID value, or a sequence value generated by InnoDB if no usable option exists.

Example

```

SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_DELETED;
+-----+
| DOC_ID |
+-----+
|      2 |
+-----+

DELETE FROM test.ft_innodb LIMIT 1;

SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_DELETED;
+-----+
| DOC_ID |
+-----+
|      2 |
|      3 |
+-----+

```

1.1.1.2.9.1.1.1.15 Information Schema INNODB_FT_INDEX_CACHE Table

The [Information Schema](#) `INNODB_FT_INDEX_CACHE` table contains information about rows that have recently been inserted into an InnoDB [fulltext index](#). To avoid re-organizing the fulltext index each time a change is made, which would be very expensive, new changes are stored separately and only integrated when an [OPTIMIZE TABLE](#) is run.

The `SUPER` [privilege](#) is required to view the table, and it also requires the `innodb_ft_aux_table` system variable to be set.

It has the following columns:

Column	Description
WORD	Word from the text of a newly added row. Words can appear multiple times in the table, once per <code>DOC_ID</code> and <code>POSITION</code> combination.
FIRST_DOC_ID	First document ID where this word appears in the index.
LAST_DOC_ID	Last document ID where this word appears in the index.
DOC_COUNT	Number of rows containing this word in the index.
DOC_ID	Document ID of the newly added row, either an appropriate ID column or an internal InnoDB value.
POSITION	Position of this word instance within the <code>DOC_ID</code> , as an offset added to the previous <code>POSITION</code> instance.

Note that for `OPTIMIZE TABLE` to process InnoDB fulltext index data, the `innodb_optimize_fulltext_only` system variable needs to be set to `1`. When this is done, and an `OPTIMIZE TABLE` statement run, the `INNODB_FT_INDEX_CACHE` table will be emptied, and the `INNODB_FT_INDEX_TABLE` table will be updated.

Examples

```

SELECT * FROM INNODB_FT_INDEX_CACHE;
+-----+-----+-----+-----+-----+-----+
| WORD          | FIRST_DOC_ID | LAST_DOC_ID | DOC_COUNT | DOC_ID | POSITION |
+-----+-----+-----+-----+-----+-----+
| and           | 4            | 4            | 1         | 4      | 0       |
| arrived       | 4            | 4            | 1         | 4      | 20      |
| ate           | 1            | 1            | 1         | 1      | 4       |
| everybody     | 1            | 1            | 1         | 1      | 8       |
| goldilocks    | 4            | 4            | 1         | 4      | 9       |
| hungry        | 3            | 3            | 1         | 3      | 8       |
| then          | 4            | 4            | 1         | 4      | 4       |
| wicked        | 2            | 2            | 1         | 2      | 4       |
| witch         | 2            | 2            | 1         | 2      | 11      |
+-----+-----+-----+-----+-----+-----+
9 rows in set (0.00 sec)

```

```

INSERT INTO test.ft_innodb VALUES(3,'And she ate a pear');

```

```

SELECT * FROM INNODB_FT_INDEX_CACHE;
+-----+-----+-----+-----+-----+-----+
| WORD          | FIRST_DOC_ID | LAST_DOC_ID | DOC_COUNT | DOC_ID | POSITION |
+-----+-----+-----+-----+-----+-----+
| and           | 4            | 5            | 2         | 4      | 0       |
| and           | 4            | 5            | 2         | 5      | 0       |

SELECT * FROM INNODB_FT_INDEX_CACHE;
Empty set (0.00 sec)

```

1.1.1.2.9.1.1.1.16 Information Schema INNODB_FT_INDEX_TABLE Table

The [Information Schema](#) `INNODB_FT_INDEX_TABLE` table contains information about InnoDB [fulltext indexes](#). To avoid re-organizing the fulltext index each time a change is made, which would be very expensive, new changes are stored separately and only integrated when an [OPTIMIZE TABLE](#) is run. See the [INNODB_FT_INDEX_CACHE](#) table.

The `SUPER` [privilege](#) is required to view the table, and it also requires the [innodb_ft_aux_table](#) system variable to be set.

It has the following columns:

Column	Description
<code>WORD</code>	Word from the text of a column with a fulltext index. Words can appear multiple times in the table, once per <code>DOC_ID</code> and <code>POSITION</code> combination.
<code>FIRST_DOC_ID</code>	First document ID where this word appears in the index.
<code>LAST_DOC_ID</code>	Last document ID where this word appears in the index.
<code>DOC_COUNT</code>	Number of rows containing this word in the index.
<code>DOC_ID</code>	Document ID of the newly added row, either an appropriate ID column or an internal InnoDB value.
<code>POSITION</code>	Position of this word instance within the <code>DOC_ID</code> , as an offset added to the previous <code>POSITION</code> instance.

Note that for `OPTIMIZE TABLE` to process InnoDB fulltext index data, the `innodb_optimize_fulltext_only` system variable needs to be set to `1`. When this is done, and an `OPTIMIZE TABLE` statement run, the `INNODB_FT_INDEX_CACHE` table will be emptied, and the `INNODB_FT_INDEX_TABLE` table will be updated.

Examples

```
SELECT * FROM INNODB_FT_INDEX_TABLE;
Empty set (0.00 sec)
```

```
SET GLOBAL innodb_optimize_fulltext_only =1;
```

```
OPTIMIZE TABLE test.ft_innodb;
```

```
+-----+-----+-----+
| Table          | Op          | Msg_type | Msg_text |
+-----+-----+-----+
| test.ft_innodb | optimize    | status   | OK       |
+-----+-----+-----+
```

```
SELECT * FROM INNODB_FT_INDEX_TABLE;
```

```
+-----+-----+-----+-----+-----+-----+
| WORD          | FIRST_DOC_ID | LAST_DOC_ID | DOC_COUNT | DOC_ID | POSITION |
+-----+-----+-----+-----+-----+-----+
| and           | 4            | 5            | 2         | 4      | 0       |
| and           | 4            | 5            | 2         | 5      | 0       |

+-----+-----+-----+-----+-----+-----+
```

1.1.1.2.9.1.1.1.17 Information Schema INNODB_LOCK_WAITS Table

The [Information Schema](#) `INNODB_LOCK_WAITS` table contains information about blocked InnoDB transactions. The `PROCESS` [privilege](#) is required to view the table.

It contains the following columns:

Column	Description
<code>REQUESTING_TRX_ID</code>	Requesting transaction ID from the INNODB_TRX table.
<code>REQUESTED_LOCK_ID</code>	Lock ID from the INNODB.LOCKS table for the waiting transaction.
<code>BLOCKING_TRX_ID</code>	Blocking transaction ID from the INNODB_TRX table.
<code>BLOCKING_LOCK_ID</code>	Lock ID from the INNODB.LOCKS table of a lock held by a transaction that is blocking another transaction.

The table is often used in conjunction with the [INNODB_LOCKS](#) and [INNODB_TRX](#) tables to diagnose problematic locks and transactions.

1.1.1.2.9.1.1.1.18 Information Schema INNODB_LOCKS Table

The [Information Schema](#) `INNODB_LOCKS` table stores information about locks that InnoDB transactions have requested but not yet acquired, or that are blocking another transaction.

It has the following columns:

Column	Description
<code>LOCK_ID</code>	Lock ID number - the format is not fixed, so do not rely upon the number for information.
<code>LOCK_TRX_ID</code>	Lock's transaction ID. Matches the INNODB_TRX.TRX_ID column.

LOCK_MODE	Lock mode . One of <code>S</code> (shared), <code>X</code> (exclusive), <code>IS</code> (intention shared), <code>IX</code> (intention exclusive row lock), <code>S_GAP</code> (shared gap lock), <code>X_GAP</code> (exclusive gap lock), <code>IS_GAP</code> (intention shared gap lock), <code>IX_GAP</code> (intention exclusive gap lock) or <code>AUTO_INC</code> (auto-increment table level lock).
LOCK_TYPE	Whether the lock is <code>RECORD</code> (row level) or <code>TABLE</code> level.
LOCK_TABLE	Name of the locked table, or table containing locked rows.
LOCK_INDEX	Index name if a <code>RECORD</code> <code>LOCK_TYPE</code> , or <code>NULL</code> if not.
LOCK_SPACE	Tablespace ID if a <code>RECORD</code> <code>LOCK_TYPE</code> , or <code>NULL</code> if not.
LOCK_PAGE	Locked record page number if a <code>RECORD</code> <code>LOCK_TYPE</code> , or <code>NULL</code> if not.
LOCK_REC	Locked record heap number if a <code>RECORD</code> <code>LOCK_TYPE</code> , or <code>NULL</code> if not.
LOCK_DATA	Locked record primary key as an SQL string if a <code>RECORD</code> <code>LOCK_TYPE</code> , or <code>NULL</code> if not. If no primary key exists, the internal InnoDB row_id number is instead used. To avoid unnecessary IO, also <code>NULL</code> if the locked record page is not in the buffer pool

The table is often used in conjunction with the [INNODB_LOCK_WAITS](#) and [INNODB_TRX](#) tables to diagnose problematic locks and transactions

Example

```
-- session 1
START TRANSACTION;
UPDATE t SET id = 15 WHERE id = 10;

-- session 2
DELETE FROM t WHERE id = 10;

-- session 1
USE information_schema;
SELECT l.*, t.*
  FROM information_schema.INNODB_LOCKS l
  JOIN information_schema.INNODB_TRX t
    ON l.lock_trx_id = t.trx_id
  WHERE trx_state = 'LOCK WAIT' \G
***** 1. row *****
      lock_id: 840:40:3:2
      lock_trx_id: 840
      lock_mode: X
      lock_type: RECORD
      lock_table: `test`.`t`
      lock_index: PRIMARY
      lock_space: 40
      lock_page: 3
      lock_rec: 2
      lock_data: 10
      trx_id: 840
      trx_state: LOCK WAIT
      trx_started: 2019-12-23 18:43:46
      trx_requested_lock_id: 840:40:3:2
      trx_wait_started: 2019-12-23 18:43:46
      trx_weight: 2
      trx_mysql_thread_id: 46
      trx_query: DELETE FROM t WHERE id = 10
      trx_operation_state: starting index read
      trx_tables_in_use: 1
      trx_tables_locked: 1
      trx_lock_structs: 2
      trx_lock_memory_bytes: 1136
      trx_rows_locked: 1
      trx_rows_modified: 0
      trx_concurrency_tickets: 0
      trx_isolation_level: REPEATABLE READ
      trx_unique_checks: 1
      trx_foreign_key_checks: 1
      trx_last_foreign_key_error: NULL
      trx_is_read_only: 0
      trx_autocommit_non_locking: 0
```

1.1.1.2.9.1.1.1.19 Information Schema INNODB_METRICS Table

Contents

1. [Enabling and Disabling Counters](#)
2. [Resetting Counters](#)
3. [Simplifying from MariaDB 10.6](#)
4. [Examples](#)

The [Information Schema](#) `INNODB_METRICS` table contains a list of useful InnoDB performance metrics. Each row in the table represents an instrumented counter that can be stopped, started and reset, and which can be grouped together by module.

The `PROCESS` [privilege](#) is required to view the table.

It has the following columns:

Column	Description
<code>NAME</code>	Unique counter name.
<code>SUBSYSTEM</code>	InnoDB subsystem. See below for the matching module to use to enable/disable monitoring this subsystem with the <code>innodb_monitor_enable</code> and <code>innodb_monitor_disable</code> system variables.
<code>COUNT</code>	Count since being enabled.
<code>MAX_COUNT</code>	Maximum value since being enabled.
<code>MIN_COUNT</code>	Minimum value since being enabled.
<code>AVG_COUNT</code>	Average value since being enabled.
<code>COUNT_RESET</code>	Count since last being reset.
<code>MAX_COUNT_RESET</code>	Maximum value since last being reset.
<code>MIN_COUNT_RESET</code>	Minimum value since last being reset.
<code>AVG_COUNT_RESET</code>	Average value since last being reset.
<code>TIME_ENABLED</code>	Time last enabled.
<code>TIME_DISABLED</code>	Time last disabled
<code>TIME_ELAPSED</code>	Time since enabled
<code>TIME_RESET</code>	Time last reset.
<code>ENABLED</code>	1 if enabled, 0 otherwise
<code>TYPE</code>	Item type; one of <code>counter</code> , <code>value</code> , <code>status_counter</code> , <code>set_owner</code> , <code>set_member</code> .
<code>COMMENT</code>	Counter description.

Note: In [MariaDB 10.4](#) and earlier the `ENABLED` column was called `STATUS`.

Enabling and Disabling Counters

Most of the counters are disabled by default. To enable them, use the `innodb_monitor_enable` system variable. You can either enable a variable by its name, for example:

```
SET GLOBAL innodb_monitor_enable = icp_match;
```

or enable a number of counters grouped by module. The `SUBSYSTEM` field indicates which counters are grouped together, but the following module names need to be used:

Module Name	Subsystem Field
<code>module_metadata</code>	<code>metadata</code>

module_lock	lock
module_buffer	buffer
module_buf_page	buffer_page_io
module_os	os
module_trx	transaction
module_purge	purge
module_compress	compression
module_file	file_system
module_index	index
module_adaptive_hash	adaptive_hash_index From MariaDB 10.6.2 , if <code>innodb_adaptive_hash_index</code> is disabled (the default), <code>adaptive_hash_index</code> will not be updated.
module_ibuf_system	change_buffer
module_srv	server
module_ddl	ddl
module_dml	dml
module_log	recovery
module_icp	icp

There are four counters in the `icp` subsystem:

```
SELECT NAME, SUBSYSTEM FROM INNODB_METRICS WHERE SUBSYSTEM='icp';
+-----+-----+
| NAME          | SUBSYSTEM |
+-----+-----+
| icp_attempts  | icp       |
| icp_no_match  | icp       |
| icp_out_of_range | icp       |
| icp_match     | icp       |
+-----+-----+
```

To enable them all, use the associated module name from the table above, `module_icp`.

```
SET GLOBAL innodb_monitor_enable = module_icp;
```

The `%` wildcard, used to represent any number of characters, can also be used when naming counters, for example:

```
SET GLOBAL innodb_monitor_enable = 'buffer%'
```

To disable counters, use the `innodb_monitor_disable` system variable, using the same naming rules as described above for enabling.

Counter status is not persistent, and will be reset when the server restarts. It is possible to use the options on the command line, or the `innodb_monitor_enable` option only in a configuration file.

Resetting Counters

Counters can also be reset. Resetting sets all the `*_COUNT_RESET` values to zero, while leaving the `*_COUNT` values, which perform counts since the counter was enabled, untouched. Resetting is performed with the `innodb_monitor_reset` (for individual counters) and `innodb_monitor_reset_all` (for all counters) system variables.

Simplifying from [MariaDB 10.6](#)

MariaDB starting with [10.6](#)

From [MariaDB 10.6](#), the interface was simplified by removing the following:

- `buffer_LRU_batches_flush`
- `buffer_LRU_batch_flush_pages`

- `buffer_LRU_batches_evict`
- `buffer_LRU_batch_evict_pages`

and by making the following reflect the status variables:

- `buffer_LRU_batch_flush_total_pages`: [innodb_buffer_pool_pages_LRU_flushed](#)
- `buffer_LRU_batch_evict_total_pages`: [innodb_buffer_pool_pages_LRU_freed](#)

The intention is to eventually remove the interface entirely (see [MDEV-15706](#) )

Examples

MariaDB 10.8:

```
SELECT name, subsystem, type, comment FROM INFORMATION_SCHEMA.INNODB_METRICS\G
***** 1. row *****
  name: metadata_table_handles_opened
subsystem: metadata
  type: counter
  comment: Number of table handles opened
***** 2. row *****
  name: lock_deadlocks
subsystem: lock
  type: value
  comment: Number of deadlocks
***** 3. row *****
  name: lock_timeouts
subsystem: lock
  type: value
  comment: Number of lock timeouts
***** 4. row *****
  name: lock_rec_lock_waits
subsystem: lock
  type: counter
  comment: Number of times enqueued into record lock wait queue
***** 5. row *****
  name: lock_table_lock_waits
subsystem: lock
  type: counter
  comment: Number of times enqueued into table lock wait queue
***** 6. row *****
  name: lock_rec_lock_requests
subsystem: lock
  type: counter
  comment: Number of record locks requested
***** 7. row *****
  name: lock_rec_lock_created
subsystem: lock
  type: counter
  comment: Number of record locks created
***** 8. row *****
  name: lock_rec_lock_removed
subsystem: lock
  type: counter
  comment: Number of record locks removed from the lock queue
***** 9. row *****
  name: lock_rec_locks
subsystem: lock
  type: counter
  comment: Current number of record locks on tables
***** 10. row *****
  name: lock_table_lock_created
subsystem: lock
  type: counter
  comment: Number of table locks created

...

***** 207. row *****
  name: icp_attempts
subsystem: icp
  type: counter
  comment: Number of attempts for index push-down condition checks
***** 208. row *****
```

```

name: icp_no_match
subsystem: icp
type: counter
comment: Index push-down condition does not match
***** 209. row *****
name: icp_out_of_range
subsystem: icp
type: counter
comment: Index push-down condition out of range
***** 210. row *****
name: icp_match
subsystem: icp
type: counter
comment: Index push-down condition matches

```

1.1.1.2.9.1.1.1.20 Information Schema INNODB_MUTEXES Table

The `INNODB_MUTEXES` table monitors mutex and rw locks waits. It has the following columns:

Column	Description
NAME	Name of the lock, as it appears in the source code.
CREATE_FILE	File name of the mutex implementation.
CREATE_LINE	Line number of the mutex implementation.
OS_WAITS	How many times the mutex occurred.

The `CREATE_FILE` and `CREATE_LINE` columns depend on the InnoDB/XtraDB version.

Note that since [MariaDB 10.2.2](#), the table has only been providing information about `rw_lock_t`, not any mutexes. From [MariaDB 10.2.2](#) until [MariaDB 10.2.32](#), [MariaDB 10.3.23](#), [MariaDB 10.4.13](#) and [MariaDB 10.5.1](#), the `NAME` column was not populated ([MDEV-21636](#)).

The `SHOW ENGINE INNODB STATUS` statement provides similar information.

Examples

```

SELECT * FROM INNODB_MUTEXES;
+-----+-----+-----+-----+
| NAME                | CREATE_FILE          | CREATE_LINE | OS_WAITS |
+-----+-----+-----+-----+
| &dict_sys->mutex     | dict0dict.cc        | 989         | 2         |
| &buf_pool->flush_state_mutex | buf0buf.cc          | 1388        | 1         |
| &log_sys->checkpoint_lock | log0log.cc          | 1014        | 2         |
| &bblock->lock         | combined buf0buf.cc | 1120        | 1         |
+-----+-----+-----+-----+

```

1.1.1.2.9.1.1.1.21 Information Schema INNODB_SYS_COLUMNS Table

The [Information Schema](#) `INNODB_SYS_COLUMNS` table contains information about InnoDB fields.

The `PROCESS` [privilege](#) is required to view the table.

It has the following columns:

Column	Description
TABLE_ID	Table identifier, matching the value from <code>INNODB_SYS_TABLES.TABLE_ID</code> .
NAME	Column name.

POS	Ordinal position of the column in the table, starting from 0. This value is adjusted when columns are added or removed.
MTYPE	Numeric column type identifier, (see the table below for an explanation of its values).
PRTYPE	Binary value of the InnoDB precise type, representing the data type, character set code and nullability.
LEN	Column length. For multi-byte character sets, represents the length in bytes.

The column `MTYPE` uses a numeric column type identifier, which has the following values:

Column Type Identifier	Description
1	VARCHAR
2	CHAR
3	FIXBINARY
4	BINARY
5	BLOB
6	INT
7	SYS_CHILD
8	SYS
9	FLOAT
10	DOUBLE
11	DECIMAL
12	VARMYSQL
13	MYSQL

Example

```

SELECT * FROM information_schema.INNODB_SYS_COLUMNS LIMIT 3\G
***** 1. row *****
TABLE_ID: 11
NAME: ID
POS: 0
MTYPE: 1
PRTYPE: 524292
LEN: 0
***** 2. row *****
TABLE_ID: 11
NAME: FOR_NAME
POS: 0
MTYPE: 1
PRTYPE: 524292
LEN: 0
***** 3. row *****
TABLE_ID: 11
NAME: REF_NAME
POS: 0
MTYPE: 1
PRTYPE: 524292
LEN: 0
3 rows in set (0.00 sec)

```

1.1.1.2.9.1.1.1.22 Information Schema INNODB_SYS_DATAFILES Table

MariaDB until [10.5](#)

The `INNODB_SYS_DATAFILES` table was added in [MariaDB 10.0.4](#), and removed in [MariaDB 10.6.0](#).

The [Information Schema](#) `INNODB_SYS_DATAFILES` table contains information about InnoDB datafile paths. It was intended to provide metadata for tablespaces inside InnoDB tables, which was never implemented in MariaDB and was removed in [MariaDB 10.6](#). The `PROCESS` [privilege](#) is required to view the table.

It contains the following columns:

Column	Description
SPACE	Numeric tablespace. Matches the <code>INNODB_SYS_TABLES.SPACE</code> value.
PATH	Tablespace datafile path.

Example

```
SELECT * FROM INNODB_SYS_DATAFILES;
+-----+-----+
| SPACE | PATH          |
+-----+-----+
|    19 | ./test/t2.ibd |
|    20 | ./test/t3.ibd |
| ...   |               |
|    68 | ./test/animals.ibd |
|    69 | ./test/animal_count.ibd |
|    70 | ./test/t.ibd   |
+-----+-----+
```

1.1.1.2.9.1.1.1.23 Information Schema INNODB_SYS_FIELDS Table

The [Information Schema](#) `INNODB_SYS_FIELDS` table contains information about fields that are part of an InnoDB index.

The `PROCESS` [privilege](#) is required to view the table.

It has the following columns:

Column	Description
INDEX_ID	Index identifier, matching the value from <code>INNODB_SYS_INDEXES.INDEX_ID</code> .
NAME	Field name, matching the value from <code>INNODB_SYS_COLUMNS.NAME</code> .
POS	Ordinal position of the field within the index, starting from 0. This is adjusted as columns are removed.

Example

```
SELECT * FROM information_schema.INNODB_SYS_FIELDS LIMIT 3\G
***** 1. row *****
INDEX_ID: 11
  NAME: ID
   POS: 0
***** 2. row *****
INDEX_ID: 12
  NAME: FOR_NAME
   POS: 0
***** 3. row *****
INDEX_ID: 13
  NAME: REF_NAME
   POS: 0
3 rows in set (0.00 sec)
```

1.1.1.2.9.1.1.1.24 Information Schema INNODB_SYS_FOREIGN Table

The [Information Schema](#) `INNODB_SYS_FOREIGN` table contains information about InnoDB [foreign keys](#).

The `PROCESS` [privilege](#) is required to view the table.

It has the following columns:

Column	Description
ID	Database name and foreign key name.
FOR_NAME	Database and table name of the foreign key child.
REF_NAME	Database and table name of the foreign key parent.
N_COLS	Number of foreign key index columns.
TYPE	Bit flag providing information about the foreign key.

The `TYPE` column provides a bit flag with information about the foreign key. This information is `OR`'ed together to read:

Bit Flag	Description
1	ON DELETE CASCADE
2	ON UPDATE SET NULL
4	ON UPDATE CASCADE
8	ON UPDATE SET NULL
16	ON DELETE NO ACTION
32	ON UPDATE NO ACTION

Example

```
SELECT * FROM INNODB_SYS_FOREIGN\G
***** 1. row *****
      ID: mysql/innodb_index_stats_ibfk_1
FOR_NAME: mysql/innodb_index_stats
REF_NAME: mysql/innodb_table_stats
      N_COLS: 2
      TYPE: 0
...

```

1.1.1.2.9.1.1.1.25 Information Schema INNODB_SYS_FOREIGN_COLS Table

The [Information Schema](#) `INNODB_SYS_FOREIGN_COLS` table contains information about InnoDB [foreign key](#) columns.

The `PROCESS` [privilege](#) is required to view the table.

It has the following columns:

Column	Description
ID	Foreign key index associated with this column, matching the <code>INNODB_SYS_FOREIGN.ID</code> field.
FOR_COL_NAME	Child column name.
REF_COL_NAME	Parent column name.
POS	Ordinal position of the column in the table, starting from 0.

1.1.1.2.9.1.1.1.26 Information Schema INNODB_SYS_INDEXES Table

The [Information Schema](#) `INNODB_SYS_INDEXES` table contains information about InnoDB indexes.

The `PROCESS` [privilege](#) is required to view the table.

It has the following columns:

Field	Type	Null	Key	Default	Description
INDEX_ID	bigint(21) unsigned	NO		0	A unique index identifier.
NAME	varchar(64)	NO			Index name, lowercase for all user-created indexes, or uppercase for implicitly-created indexes; <code>PRIMARY</code> (primary key), <code>GEN_CLUST_INDEX</code> (index representing primary key where there isn't one), <code>ID_IND</code> , <code>FOR_IND</code> (validating foreign key constraint), <code>REF_IND</code> .
TABLE_ID	bigint(21) unsigned	NO		0	Table identifier, matching the value from INNODB_SYS_TABLES.TABLE_ID .
TYPE	int(11)	NO		0	Numeric type identifier; one of 0 (secondary index), 1 (clustered index), 2 (unique index), 3 (primary index), 32 (full-text index).
N_FIELDS	int(11)	NO		0	Number of columns in the index. <code>GEN_CLUST_INDEX</code> 's have a value of 0 as the index is not based on an actual column in the table.
PAGE_NO	int(11)	NO		0	Index B-tree's root page number. -1 (unused) for full-text indexes, as they are laid out over several auxiliary tables.
SPACE	int(11)	NO		0	Tablespace identifier where the index resides. 0 represents the InnoDB system tablespace, while any other value represents a table created in file-per-table mode (see the innodb_file_per_table system variable). Remains unchanged after a <code>TRUNCATE TABLE</code> statement, and not necessarily unique.
MERGE_THRESHOLD	int(11)	NO		0	

Example

```

SELECT * FROM information_schema.INNODB_SYS_INDEXES LIMIT 3\G
***** 1. row *****
INDEX_ID: 11
NAME: ID_IND
TABLE_ID: 11
TYPE: 3
N_FIELDS: 1
PAGE_NO: 302
SPACE: 0
MERGE_THRESHOLD: 50
***** 2. row *****
INDEX_ID: 12
NAME: FOR_IND
TABLE_ID: 11
TYPE: 0
N_FIELDS: 1
PAGE_NO: 303
SPACE: 0
MERGE_THRESHOLD: 50
***** 3. row *****
INDEX_ID: 13
NAME: REF_IND
TABLE_ID: 11
TYPE: 3
N_FIELDS: 1
PAGE_NO: 304
SPACE: 0
MERGE_THRESHOLD: 50
3 rows in set (0.00 sec)

```

1.1.1.2.9.1.1.1.27 Information Schema INNODB_SYS_SEMAPHORE_WAITS Table

The [Information Schema](#) `INNODB_SYS_SEMAPHORE_WAITS` table is meant to contain information about current semaphore waits. At present it is not correctly populated. See [MDEV-21330](#).

The `PROCESS` privilege is required to view the table.

It contains the following columns:

Column	Description
<code>THREAD_ID</code>	Thread id waiting for semaphore
<code>OBJECT_NAME</code>	Semaphore name
<code>FILE</code>	File name where semaphore was requested
<code>LINE</code>	Line number on above file
<code>WAIT_TIME</code>	Wait time
<code>WAIT_OBJECT</code>	
<code>WAIT_TYPE</code>	Object type (mutex, rw-lock)
<code>HOLDER_THREAD_ID</code>	Holder thread id
<code>HOLDER_FILE</code>	File name where semaphore was acquired
<code>HOLDER_LINE</code>	Line number for above
<code>CREATED_FILE</code>	Creation file name
<code>CREATED_LINE</code>	Line number for above
<code>WRITER_THREAD</code>	Last write request thread id
<code>RESERVATION_MODE</code>	Reservation mode (shared, exclusive)
<code>READERS</code>	Number of readers if only shared mode
<code>WAITERS_FLAG</code>	Flags
<code>LOCK_WORD</code>	Lock word (for developers)
<code>LAST_READER_FILE</code>	Removed
<code>LAST_READER_LINE</code>	Removed
<code>LAST_WRITER_FILE</code>	Last writer file name
<code>LAST_WRITER_LINE</code>	Above line number
<code>OS_WAIT_COUNT</code>	Wait count

1.1.1.2.9.1.1.1.28 Information Schema `INNODB_SYS_TABLES` Table

The [Information Schema](#) `INNODB_SYS_TABLES` table contains information about InnoDB tables.

The `PROCESS` privilege is required to view the table.

It has the following columns:

Field	Type	Null	Key	Default	Description
<code>TABLE_ID</code>	<code>bigint(21) unsigned</code>	NO		0	Unique InnoDB table identifier.
<code>NAME</code>	<code>varchar(655)</code>	NO			Database and table name, or the uppercase InnoDB system table name.
<code>FLAG</code>	<code>int(11)</code>	NO		0	See Flag below
<code>N_COLS</code>	<code>int(11) unsigned (>= MariaDB 10.5)</code> <code>int(11) (<= MariaDB 10.4)</code>	NO		0	Number of columns in the table. The count includes two or three hidden InnoDB system columns, appended to the end of the column list: <code>DB_ROW_ID</code> (if there is no primary key or unique index on NOT NULL columns), <code>DB_TRX_ID</code> , <code>DB_ROLL_PTR</code> .

SPACE	int(11) unsigned (>= MariaDB 10.5) int(11) (<= MariaDB 10.4)	NO		0	Tablespace identifier where the index resides. 0 represents the InnoDB system tablespace, while any other value represents a table created in file-per-table mode (see the <code>innodb_file_per_table</code> system variable). Remains unchanged after a <code>TRUNCATE TABLE</code> statement.
FILE_FORMAT	varchar(10)	YES		NULL	InnoDB file format (Antelope or Barracuda). Removed in MariaDB 10.3 .
ROW_FORMAT	enum('Redundant', 'Compact', 'Compressed', 'Dynamic') (>= MariaDB 10.5) varchar(12) (<= MariaDB 10.4)	YES		NULL	InnoDB storage format (Compact, Redundant, Dynamic, or Compressed).
ZIP_PAGE_SIZE	int(11) unsigned	NO		0	For Compressed tables, the zipped page size.
SPACE_TYPE	enum('Single', 'System') (>= MariaDB 10.5) varchar(10) (<= MariaDB 10.4)	YES		NULL	

Flag

The flag field returns the `dict_table_t::flags` that correspond to the data dictionary record.

Bit	Description
0	Set if ROW_FORMAT is not REDUNDANT.
1 to 4	0, except for ROW_FORMAT=COMPRESSED, where they will determine the KEY_BLOCK_SIZE (the compressed page size).
5	Set for ROW_FORMAT=DYNAMIC or ROW_FORMAT=COMPRESSED.
6	Set if the DATA DIRECTORY attribute was present when the table was originally created.
7	Set if the page_compressed attribute is present.
8 to 11	Determine the page_compression_level.
12 to 13	Normally 00, but 11 for "no-rollback tables" (MariaDB 10.3 CREATE SEQUENCE). In MariaDB 10.1 , these bits could be 01 or 10 for ATOMIC_WRITES=ON or ATOMIC_WRITES=OFF.

Note that the table flags returned here are not the same as tablespace flags (`FSP_SPACE_FLAGS`).

Example

```

SELECT * FROM information_schema.INNODB_SYS_TABLES LIMIT 2\G
***** 1. row *****
    TABLE_ID: 14
      NAME: SYS_DATAFILES
      FLAG: 0
      N_COLS: 5
      SPACE: 0
    ROW_FORMAT: Redundant
    ZIP_PAGE_SIZE: 0
    SPACE_TYPE: System
***** 2. row *****
    TABLE_ID: 11
      NAME: SYS_FOREIGN
      FLAG: 0
      N_COLS: 7
      SPACE: 0
    ROW_FORMAT: Redundant
    ZIP_PAGE_SIZE: 0
    SPACE_TYPE: System
2 rows in set (0.00 sec)

```

1.1.1.2.9.1.1.1.29 Information Schema INNODB_SYS_TABLESPACES Table

The [Information Schema](#) `INNODB_SYS_TABLESPACES` table contains information about InnoDB tablespaces. Until [MariaDB 10.5](#) it was based on the internal `SYS_TABLESPACES` table. This internal table was removed in [MariaDB 10.6.0](#), so this Information Schema table has been repurposed to directly reflect the filesystem (`fil_system.space_list`).

The `PROCESS` [privilege](#) is required to view the table.

It has the following columns:

Column	Description
<code>SPACE</code>	Unique InnoDB tablespace identifier.
<code>NAME</code>	Database and table name separated by a backslash, or the uppercase InnoDB system table name.
<code>FLAG</code>	1 if a <code>DATA DIRECTORY</code> option has been specified in <code>CREATE TABLE</code> , otherwise 0.
<code>FILE_FORMAT</code>	InnoDB file format . Removed in MariaDB 10.3.1 ↗
<code>ROW_FORMAT</code>	InnoDB storage format used for this tablespace. If the Antelope file format is used, this value is always <code>Compact</code> or <code>Redundant</code> . When a table's checksum algorithm is <code>full_crc32</code> (the default from MariaDB 10.5), the value can only be <code>Compressed</code> or <code>NULL</code> .
<code>PAGE_SIZE</code>	Page size in bytes for this tablespace. Until MariaDB 10.5.0 , this was the value of the <code>innodb_page_size</code> variable. From MariaDB 10.6.0 , contains the physical page size of a page (previously <code>ZIP_PAGE_SIZE</code>).
<code>ZIP_PAGE_SIZE</code>	Zip page size for this tablespace. Removed in MariaDB 10.6.0 .
<code>SPACE_TYPE</code>	Tablespace type. Can be <code>General</code> for general tablespaces or <code>Single</code> for file-per-table tablespaces. Introduced MariaDB 10.2.1 ↗ . Removed MariaDB 10.5.0 .
<code>FS_BLOCK_SIZE</code>	File system block size. Introduced MariaDB 10.2.1 ↗ .
<code>FILE_SIZE</code>	Maximum size of the file, uncompressed. Introduced MariaDB 10.2.1 ↗ .
<code>ALLOCATED_SIZE</code>	Actual size of the file as per space allocated on disk. Introduced MariaDB 10.2.1 ↗ .
<code>FILENAME</code>	Tablespace datafile path, previously part of the <code>INNODB_SYS_DATAFILES</code> table. Added in MariaDB 10.6.0 .

Examples

[MariaDB 10.4:](#)

```
DESC information_schema.innodb_sys_tablespaces;
+-----+-----+-----+-----+-----+-----+
| Field | Type | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| SPACE | int(11) unsigned | NO | | 0 | |
| NAME | varchar(655) | NO | | | |
| FLAG | int(11) unsigned | NO | | 0 | |
| ROW_FORMAT | varchar(22) | YES | | NULL | |
| PAGE_SIZE | int(11) unsigned | NO | | 0 | |
| ZIP_PAGE_SIZE | int(11) unsigned | NO | | 0 | |
| SPACE_TYPE | varchar(10) | YES | | NULL | |
| FS_BLOCK_SIZE | int(11) unsigned | NO | | 0 | |
| FILE_SIZE | bigint(21) unsigned | NO | | 0 | |
| ALLOCATED_SIZE | bigint(21) unsigned | NO | | 0 | |
+-----+-----+-----+-----+-----+-----+
```

From [MariaDB 10.4](#):

```
SELECT * FROM information_schema.INNODB_SYS_TABLESPACES LIMIT 2\G
***** 1. row *****
SPACE: 2
NAME: mysql/innodb_table_stats
FLAG: 33
ROW_FORMAT: Dynamic
PAGE_SIZE: 16384
ZIP_PAGE_SIZE: 0
SPACE_TYPE: Single
FS_BLOCK_SIZE: 4096
FILE_SIZE: 98304
ALLOCATED_SIZE: 98304
***** 2. row *****
SPACE: 3
NAME: mysql/innodb_index_stats
FLAG: 33
ROW_FORMAT: Dynamic
PAGE_SIZE: 16384
ZIP_PAGE_SIZE: 0
SPACE_TYPE: Single
FS_BLOCK_SIZE: 4096
FILE_SIZE: 98304
ALLOCATED_SIZE: 98304
```

1.1.1.2.9.1.1.1.30 Information Schema INNODB_SYS_TABLESTATS Table

The [Information Schema](#) `INNODB_SYS_TABLESTATS` table contains InnoDB status information. It can be used for developing new performance-related extensions, or high-level performance monitoring.

The `PROCESS` [privilege](#) is required to view the table.

Note that the MySQL InnoDB and Percona XtraDB versions of the tables differ (see [XtraDB and InnoDB](#)).

It contains the following columns:

Column	Description
TABLE_ID	Table ID, matching the <code>INNODB_SYS_TABLES.TABLE_ID</code> value.
SCHEMA	Database name (XtraDB only).
NAME	Table name, matching the <code>INNODB_SYS_TABLES.NAME</code> value.
STATS_INITIALIZED	Initialized if statistics have already been collected, otherwise Uninitialized.
NUM_ROWS	Estimated number of rows currently in the table. Updated after each statement modifying the data, but uncommitted transactions mean it may not be accurate.
CLUST_INDEX_SIZE	Number of pages on disk storing the clustered index, holding InnoDB table data in primary key order, or NULL if not statistics yet collected.

OTHER_INDEX_SIZE	Number of pages on disk storing secondary indexes for the table, or <code>NULL</code> if not statistics yet collected.
MODIFIED_COUNTER	Number of rows modified by statements modifying data.
AUTOINC	Auto_increment value.
REF_COUNT	Countdown to zero, when table metadata can be removed from the table cache. (InnoDB only)
MYSQL_HANDLES_OPENED	(XtraDB only).

1.1.1.2.9.1.1.1.31 Information Schema INNODB_SYS_VIRTUAL Table

MariaDB starting with [10.2](#)

The `INNODB_SYS_VIRTUAL` table was added in [MariaDB 10.2](#).

The [Information Schema](#) `INNODB_SYS_VIRTUAL` table contains information about base columns of [virtual columns](#). The `PROCESS` [privilege](#) is required to view the table.

It contains the following columns:

Field	Type	Null	Key	Default	Description
TABLE_ID	bigint(21) unsigned	NO		0	
POS	int(11) unsigned	NO		0	
BASE_POS	int(11) unsigned	NO		0	

1.1.1.2.9.1.1.1.32 Information Schema INNODB_TABLESPACES_ENCRYPTION Table

The [Information Schema](#) `INNODB_TABLESPACES_ENCRYPTION` table contains metadata about [encrypted InnoDB tablespaces](#). When you [enable encryption for an InnoDB tablespace](#), an entry for the tablespace is added to this table. If you later [disable encryption for the InnoDB tablespace](#), then the row still remains in this table, but the `ENCRYPTION_SCHEME` and `CURRENT_KEY_VERSION` columns will be set to `0`.

Viewing this table requires the `PROCESS` privilege, although a bug in versions before [MariaDB 10.4.14](#) and [MariaDB 10.5.5](#) mean the `SUPER` privilege was required ([MDEV-23003](#)).

It contains the following columns:

Column	Description
SPACE	InnoDB tablespace ID.
NAME	Path to the InnoDB tablespace file, without the extension.
ENCRYPTION_SCHEME	Key derivation algorithm. Only <code>1</code> is currently used to represent an algorithm. If this value is <code>0</code> , then the tablespace is unencrypted.
KEYSERVER_REQUESTS	Number of times InnoDB has had to request a key from the encryption key management plugin . The three most recent keys are cached internally.
MIN_KEY_VERSION	Minimum key version used to encrypt a page in the tablespace. Different pages may be encrypted with different key versions.
CURRENT_KEY_VERSION	Key version that will be used to encrypt pages. If this value is <code>0</code> , then the tablespace is unencrypted.
KEY_ROTATION_PAGE_NUMBER	Page that a background encryption thread is currently rotating. If key rotation is not enabled, then the value will be <code>NULL</code> .
KEY_ROTATION_MAX_PAGE_NUMBER	When a background encryption thread starts rotating a tablespace, the field contains its current size. If key rotation is not enabled, then the value will be <code>NULL</code> .

CURRENT_KEY_ID	Key ID for the encryption key currently in use.
ROTATING_OR_FLUSHING	Current key rotation status. If this value is 1, then the background encryption threads are working on the tablespace. See MDEV-11738 .

When the [InnoDB system tablespace](#) is encrypted, it is represented in this table with the special name: `innodb_system`.

Example

```
SELECT * FROM information_schema.INNODB_TABLESPACES_ENCRYPTION
WHERE NAME LIKE 'db_encrypt%';
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| SPACE | NAME | ENCRYPTION_SCHEME |
KEYSERVER_REQUESTS | MIN_KEY_VERSION | CURRENT_KEY_VERSION | KEY_ROTATION_PAGE_NUMBER |
KEY_ROTATION_MAX_PAGE_NUMBER |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| 18 | db_encrypt/t_encrypted_existing_key | 1 |
1 | 1 | 1 | NULL |
NULL |
| 19 | db_encrypt/t_not_encrypted_existing_key | 1 |
0 | 1 | 1 | NULL |
NULL |
| 20 | db_encrypt/t_not_encrypted_non_existing_key | 1 |
0 | 4294967295 | 4294967295 | NULL |
NULL |
| 21 | db_encrypt/t_default_encryption_existing_key | 1 |
1 | 1 | 1 | NULL |
NULL |
| 22 | db_encrypt/t_encrypted_default_key | 1 |
1 | 1 | 1 | NULL |
NULL |
| 23 | db_encrypt/t_not_encrypted_default_key | 1 |
0 | 1 | 1 | NULL |
NULL |
| 24 | db_encrypt/t_defaults | 1 |
1 | 1 | 1 | NULL |
NULL |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
7 rows in set (0.00 sec)
```

1.1.1.2.9.1.1.1.33 Information Schema INNODB_TABLESPACES_SCRUBBING Table

MariaDB [10.1.3](#) - [10.5.1](#)

InnoDB and XtraDB data scrubbing was introduced in [MariaDB 10.1.3](#). The table was removed in [MariaDB 10.5.2](#) - see [MDEV-15528](#).

The [Information Schema](#) `INNODB_TABLESPACES_SCRUBBING` table contains [data scrubbing](#) information.

The `PROCESS` [privilege](#) is required to view the table.

It has the following columns:

Column	Description
SPACE	InnoDB table space id number.
NAME	Path to the table space file, without the extension.
COMPRESSED	The compressed page size, or zero if uncompressed.

LAST_SCRUB_COMPLETED	Date and time when the last scrub was completed, or <code>NULL</code> if never been performed.
CURRENT_SCRUB_STARTED	Date and time when the current scrub started, or <code>NULL</code> if never been performed.
CURRENT_SCRUB_ACTIVE_THREADS	Number of threads currently scrubbing the tablespace.
CURRENT_SCRUB_PAGE_NUMBER	Page that the scrubbing thread is currently scrubbing, or <code>NULL</code> if not enabled.
CURRENT_SCRUB_MAX_PAGE_NUMBER	When a scrubbing starts rotating a table space, the field contains its current size. <code>NULL</code> if not enabled.
ON_SSD	The field contains <code>1</code> when MariaDB detects that the table space is on a SSD based storage. <code>0</code> if not SSD or it could not be determined (since MariaDB 10.4.4 )

Example

```

SELECT * FROM information_schema.INNODB_TABLESPACES_SCRUBBING LIMIT 1\G
***** 1. ROW *****
      SPACE: 1
      NAME: mysql/innodb_table_stats
      COMPRESSED: 0
      LAST_SCRUB_COMPLETED: NULL
      CURRENT_SCRUB_STARTED: NULL
      CURRENT_SCRUB_PAGE_NUMBER: NULL
      CURRENT_SCRUB_MAX_PAGE_NUMBER: 0
      ROTATING_OR_FLUSHING: 0
1 rows in set (0.00 sec)

```

1.1.1.2.9.1.1.1.34 Information Schema INNODB_TRX Table

The [Information Schema](#) `INNODB_TRX` table stores information about all currently executing InnoDB transactions.

It has the following columns:

Column	Description
TRX_ID	Unique transaction ID number.
TRX_STATE	Transaction execution state; one of <code>RUNNING</code> , <code>LOCK WAIT</code> , <code>ROLLING BACK</code> or <code>COMMITTING</code> .
TRX_STARTED	Time that the transaction started.
TRX_REQUESTED_LOCK_ID	If <code>TRX_STATE</code> is <code>LOCK_WAIT</code> , the <code>INNODB_LOCKS.LOCK_ID</code> value of the lock being waited on. <code>NULL</code> if any other state.
TRX_WAIT_STARTED	If <code>TRX_STATE</code> is <code>LOCK_WAIT</code> , the time the transaction started waiting for the lock, otherwise <code>NULL</code> .
TRX_WEIGHT	Transaction weight, based on the number of locked rows and the number of altered rows. To resolve deadlocks, lower weighted transactions are rolled back first. Transactions that have affected non-transactional tables are always treated as having a heavier weight.
TRX_MYSQL_THREAD_ID	Thread ID from the <code>PROCESSLIST</code> table (note that the locking and transaction information schema tables use a different snapshot from the processlist, so records may appear in one but not the other).
TRX_QUERY	SQL that the transaction is currently running.
TRX_OPERATION_STATE	Transaction's current state, or <code>NULL</code> .
TRX_TABLES_IN_USE	Number of InnoDB tables currently being used for processing the current SQL statement.
TRX_TABLES_LOCKED	Number of InnoDB tables that that have row locks held by the current SQL statement.

TRX_LOCK_STRUCTS	Number of locks reserved by the transaction.
TRX_LOCK_MEMORY_BYTES	Total size in bytes of the memory used to hold the lock structures for the current transaction in memory.
TRX_ROWS_LOCKED	Number of rows the current transaction has locked. locked by this transaction. An approximation, and may include rows not visible to the current transaction that are delete-marked but physically present.
TRX_ROWS_MODIFIED	Number of rows added or changed in the current transaction.
TRX_CONCURRENCY_TICKETS	Indicates how much work the current transaction can do before being swapped out, see the innodb_concurrency_tickets system variable.
TRX_ISOLATION_LEVEL	Isolation level of the current transaction.
TRX_UNIQUE_CHECKS	Whether unique checks are <code>on</code> or <code>off</code> for the current transaction. Bulk data are a case where unique checks would be off.
TRX_FOREIGN_KEY_CHECKS	Whether foreign key checks are <code>on</code> or <code>off</code> for the current transaction. Bulk data are a case where foreign keys checks would be off.
TRX_LAST_FOREIGN_KEY_ERROR	Error message for the most recent foreign key error, or <code>NULL</code> if none.
TRX_ADAPTIVE_HASH_LATCHED	Whether the adaptive hash index is locked by the current transaction or not. One transaction at a time can change the adaptive hash index.
TRX_ADAPTIVE_HASH_TIMEOUT	Whether the adaptive hash index search latch should be relinquished immediately or reserved across all MariaDB calls. <code>0</code> if there is no contention on the adaptive hash index, in which case the latch is reserved until completion, otherwise counts down to zero and the latch is released after each row lookup.
TRX_IS_READ_ONLY	<code>1</code> if a read-only transaction, otherwise <code>0</code> .
TRX_AUTOCOMMIT_NON_LOCKING	<code>1</code> if the transaction only contains this one statement, that is, a <code>SELECT</code> statement not using <code>FOR UPDATE</code> or <code>LOCK IN SHARED MODE</code> , and with autocommit on. If this and <code>TRX_IS_READ_ONLY</code> are both <code>1</code> , the transaction can be optimized by the storage engine to reduce some overheads

The table is often used in conjunction with the [INNODB_LOCKS](#) and [INNODB_LOCK_WAITS](#) tables to diagnose problematic locks and transactions.

[XA transactions](#) are not stored in this table. To see them, `XA RECOVER` can be used.

Example

```

-- session 1
START TRANSACTION;
UPDATE t SET id = 15 WHERE id = 10;

-- session 2

1.1.1.2.9.1.1.1.35 Information Schema TEMP_TABLES_INFO Table

MariaDB [10.2.2](#) - [10.2.3](#)

The `TEMP_TABLES_INFO` table was introduced in [MariaDB 10.2.2](#) and was removed in [MariaDB 10.2.4](#). See [MDEV-12459](#) progress on an alternative.

The [Information Schema](#) `TEMP_TABLES_INFO` table contains information about active InnoDB temporary tables. All user and system-created temporary tables are reported when querying this table, with the exception of optimized internal temporary tables. The data is stored in memory.

Previously, InnoDB temp table metadata was rather stored in InnoDB system tables.

It has the following columns:

Column	Description
TABLE_ID	Table ID.
NAME	Table name.

N_COLS	Number of columns in the temporary table, including three hidden columns that InnoDB creates (DB_ROW_ID , DB_TRX_ID , and DB_ROLL_PTR).
SPACE	Numerical identifier for the tablespace identifier holding the temporary table. Compressed temporary tables are stored by default in separate per-table tablespaces in the temporary file directory. For non-compressed tables, the shared temporary table is named <code>ibtmp1</code> , found in the data directory. Always a non-zero value, and regenerated on server restart.
PER_TABLE_TABLESPACE	If <code>TRUE</code> , the temporary table resides in a separate per-table tablespace. If <code>FALSE</code> , it resides in the shared temporary tablespace.
IS_COMPRESSED	<code>TRUE</code> if the table is compressed.

The `PROCESS` [privilege](#) is required to view the table.

Examples

```
CREATE TEMPORARY TABLE t (i INT) ENGINE=INNODB;

SELECT * FROM INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO;
+-----+-----+-----+-----+-----+-----+
| TABLE_ID | NAME          | N_COLS | SPACE | PER_TABLE_TABLESPACE | IS_COMPRESSED |
+-----+-----+-----+-----+-----+-----+
| 39 | #sql11c93_3_1 | 4 | 64 | FALSE | FALSE |
+-----+-----+-----+-----+-----+-----+
```

Adding a compressed table:

```
SET GLOBAL innodb_file_format="Barracuda";

CREATE TEMPORARY TABLE t2 (i INT) ROW_FORMAT=COMPRESSED ENGINE=INNODB;

SELECT * FROM INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO;
+-----+-----+-----+-----+-----+-----+
| TABLE_ID | NAME          | N_COLS | SPACE | PER_TABLE_TABLESPACE | IS_COMPRESSED |
+-----+-----+-----+-----+-----+-----+
| 40 | #sql11c93_3_3 | 4 | 65 | TRUE | TRUE |
| 39 | #sql11c93_3_1 | 4 | 64 | FALSE | FALSE |
+-----+-----+-----+-----+-----+-----+
```

1.1.1.2.9.1.1.2.1 Information Schema ROCKSDB_CFSTATS Table

The [Information Schema ROCKSDB_CFSTATS](#) table is included as part of the [MyRocks](#) storage engine.

The `PROCESS` [privilege](#) is required to view the table.

It contains the following columns:

Column	Description
CF_NAME	
STAT_TYPE	
VALUE	

1.1.1.2.9.1.1.2.2 Information Schema ROCKSDB_CF_OPTIONS Table

The [Information Schema ROCKSDB_CF_OPTIONS](#) table is included as part of the [MyRocks](#) storage engine, and contains information about MyRocks [column families](#).

The `PROCESS` [privilege](#) is required to view the table.

It contains the following columns:

Column	Description
CF_NAME	Column family name.
OPTION_TYPE	
VALUE	

1.1.1.2.9.1.1.2.3 Information Schema ROCKSDB_COMPACTON_STATS Table

The [Information Schema ROCKSDB_COMPACTON_STATS](#) table is included as part of the [MyRocks](#) storage engine.

The `PROCESS` [privilege](#) is required to view the table.

It contains the following columns:

Column	Description
CF_NAME	
LEVEL	
TYPE	
VALUE	

1.1.1.2.9.1.1.2.4 Information Schema ROCKSDB_DBSTATS Table

The [Information Schema](#) `ROCKSDB_DBSTATS` table is included as part of the [MyRocks](#) storage engine.

The `PROCESS` [privilege](#) is required to view the table.

It contains the following columns:

Column	Description
STAT_TYPE	
VALUE	

1.1.1.2.9.1.1.2.5 Information Schema ROCKSDB_DDL Table

The [Information Schema](#) `ROCKSDB_DDL` table is included as part of the [MyRocks](#) storage engine.

The `PROCESS` [privilege](#) is required to view the table.

It contains the following columns:

Column	Description
TABLE_SCHEMA	
TABLE_NAME	
PARTITION_NAME	
INDEX_NAME	
COLUMN_FAMILY	
INDEX_NUMBER	
INDEX_TYPE	
KV_FORMAT_VERSION	
TTL_DURATION	
INDEX_FLAGS	
CF	
AUTO_INCREMENT	

1.1.1.2.9.1.1.2.6 Information Schema ROCKSDB_DEADLOCK Table

The [Information Schema](#) `ROCKSDB_DEADLOCK` table is included as part of the [MyRocks](#) storage engine.

The `PROCESS` [privilege](#) is required to view the table.

It contains the following columns:

Column	Description
--------	-------------

DEADLOCK_ID	
TIMESTAMP	
TRANSACTION_ID	
CF_NAME	
WAITING_KEY	
LOCK_TYPE	
INDEX_NAME	
TABLE_NAME	
ROLLED_BACK	

1.1.1.2.9.1.1.2.7 Information Schema ROCKSDB_GLOBAL_INFO Table

The [Information Schema](#) `ROCKSDB_GLOBAL_INFO` table is included as part of the [MyRocks](#) storage engine.

The `PROCESS` [privilege](#) is required to view the table.

It contains the following columns:

Column	Description
TYPE	
NAME	
VALUE	

1.1.1.2.9.1.1.2.8 Information Schema ROCKSDB_INDEX_FILE_MAP Table

The [Information Schema](#) `ROCKSDB_INDEX_FILE_MAP` table is included as part of the [MyRocks](#) storage engine.

The `PROCESS` [privilege](#) is required to view the table.

It contains the following columns:

Column	Description
COLUMN_FAMILY	
INDEX_NUMBER	
SST_NAME	
NUM_ROWS	
DATA_SIZE	
ENTRY_DELETES	
ENTRY_SINGLEDELETES	
ENTRY_MERGES	
ENTRY_OTHERS	
DISTINCT_KEYS_PREFIX	

1.1.1.2.9.1.1.2.9 Information Schema ROCKSDB_LOCKS Table

The [Information Schema](#) `ROCKSDB_LOCKS` table is included as part of the [MyRocks](#) storage engine.

The `PROCESS` [privilege](#) is required to view the table.

It contains the following columns:

Column	Description
COLUMN_FAMILY_ID	
TRANSACTION_ID	
KEY	
MODE	

1.1.1.2.9.1.1.2.10 Information Schema ROCKSDB_PERF_CONTEXT Table

The [Information Schema](#) `ROCKSDB_PERF_CONTEXT` table is included as part of the [MyRocks](#) storage engine and includes per-table/partition counters .

The `PROCESS` [privilege](#) is required to view the table.

It contains the following columns:

Column	Description
TABLE_SCHEMA	
TABLE_NAME	
PARTITION_NAME	
STAT_TYPE	
VALUE	

Note: for multi-table queries, all counter increments are "billed" to the first table in the query:

<https://github.com/facebook/mysql-5.6/issues/1018> [↗](#)

1.1.1.2.9.1.1.2.11 Information Schema ROCKSDB_PERF_CONTEXT_GLOBAL Table

The [Information Schema](#) `ROCKSDB_PERF_CONTEXT_GLOBAL` table is included as part of the [MyRocks](#) storage engine and includes global counter information.

The `PROCESS` [privilege](#) is required to view the table.

It contains the following columns:

Column	Description
STAT_TYPE	
VALUE	

1.1.1.2.9.1.1.2.12 Information Schema ROCKSDB_SST_PROPS Table

The [Information Schema](#) `ROCKSDB_SST_PROPS` table is included as part of the [MyRocks](#) storage engine.

The `PROCESS` [privilege](#) is required to view the table.

It contains the following columns:

Column	Description
SST_NAME	
COLUMN_FAMILY	

DATA_BLOCKS	
ENTRIES	
RAW_KEY_SIZE	
RAW_VALUE_SIZE	
DATA_BLOCK_SIZE	
INDEX_BLOCK_SIZE	
INDEX_PARTITIONS	
TOP_LEVEL_INDEX_SIZE	
FILTER_BLOCK_SIZE	
COMPRESSION_ALGO	
CREATION_TIME	

1.1.1.2.9.1.1.2.13 Information Schema ROCKSDB_TRX Table

The [Information Schema](#) `ROCKSDB_TRX` table is included as part of the [MyRocks](#) storage engine.

The `PROCESS` [privilege](#) is required to view the table.

It contains the following columns:

Column	Description
TRANSACTION_ID	
STATE	
NAME	
WRITE_COUNT	
LOCK_COUNT	
TIMEOUT_SEC	
WAITING_KEY	
WAITING_COLUMN_FAMILY_ID	
IS_REPLICATION	
SKIP_TRX_API	
READ_ONLY	
HAS_DEADLOCK_DETECTION	
NUM_ONGOING_BULKLOAD	
THREAD_ID	
QUERY	

1.1.1.2.9.1.1.3 ColumnStore Information Schema Tables

1. [COLUMNSTORE_TABLES](#)
2. [COLUMNSTORE_COLUMNS](#)
3. [COLUMNSTORE_EXTENTS](#)
4. [COLUMNSTORE_FILES](#)
5. [Stored Procedures](#)
 1. [total_usage\(\)](#)
 2. [table_usage\(\)](#)
 3. [compression_ratio\(\)](#)

MariaDB ColumnStore has four Information Schema tables that expose information about the table and column storage. These tables were added in version 1.0.5 of ColumnStore and were heavily modified for 1.0.6.

COLUMNSTORE_TABLES

The first table is the INFORMATION_SCHEMA.COLUMNSTORE_TABLES. This contains information about the tables inside ColumnStore. The table layout is as follows:

Column	Description
TABLE_SCHEMA	The database schema for the table
TABLE_NAME	The table name
OBJECT_ID	The ColumnStore object ID for the table
CREATION_DATE	The date the table was created
COLUMN_COUNT	The number of columns in the table
AUTOINCREMENT	The start autoincrement value for the table set during CREATE TABLE

Note: Tables created with ColumnStore 1.0.4 or lower will have the year field of the creation data set incorrectly by 1900 years.

COLUMNSTORE_COLUMNS

The INFORMATION_SCHEMA.COLUMNSTORE_COLUMNS table contains information about every single column inside ColumnStore. The table layout is as follows:

Column	Description
TABLE_SCHEMA	The database schema for the table
TABLE_NAME	The table name for the column
COLUMN_NAME	The column name
OBJECT_ID	The object ID for the column
DICTIONARY_OBJECT_ID	The dictionary object ID for the column (NULL if there is no dictionary object)
LIST_OBJECT_ID	Placeholder for future information
TREE_OBJECT_ID	Placeholder for future information
DATA_TYPE	The data type for the column
COLUMN_LENGTH	The data length for the column
COLUMN_POSITION	The position of the column in the table, starting at 0
COLUMN_DEFAULT	The default value for the column
IS_NULLABLE	Whether or not the column can be set to NULL
NUMERIC_PRECISION	The numeric precision for the column
NUMERIC_SCALE	The numeric scale for the column
IS_AUTOINCREMENT	Set to 1 if the column is an autoincrement column
COMPRESSION_TYPE	The type of compression (either "None" or "Snappy")

COLUMNSTORE_EXTENTS

This table displays the extent map in a user consumable form. An extent is a collection of details about a section of data related to a columnstore column. A majority of columns in ColumnStore will have multiple extents and the columns table above can be joined to this one to filter results by table or column. The table layout is as follows:

Column	Description
OBJECT_ID	The object ID for the extent
OBJECT_TYPE	Whether this is a "Column" or "Dictionary" extent
LOGICAL_BLOCK_START	ColumnStore's internal start LBID for this extent
LOGICAL_BLOCK_END	ColumnStore's internal end LBID for this extent
MIN_VALUE	This minimum value stored in this extent
MAX_VALUE	The maximum value stored in this extent
WIDTH	The data width for the extent
DBROOT	The DBRoot number for the extent
PARTITION_ID	The partition ID for the extent
SEGMENT_ID	The segment ID for the extent
BLOCK_OFFSET	The block offset for the data file, each data file can contain multiple extents for a column
MAX_BLOCKS	The maximum number of blocks for the extent
HIGH_WATER_MARK	The last block committed to the extent (starting at 0)
STATE	The state of the extent (see below)
STATUS	The availability status for the column which is either "Available", "Unavailable" or "Out of service"
DATA_SIZE	The uncompressed data size for the extent calculated as $(HWM + 1) * BLOCK_SIZE$

Notes:

1. The state is "Valid" for a normal state, "Invalid" if a cpimport has completed but the table has not yet been accessed (min/max values will be invalid) or "Updating" if there is a DML statement writing to the column
2. In ColumnStore the block size is 8192 bytes
3. By default ColumnStore will write create an extent file of $256 * 1024 * WIDTH$ bytes for the first partition, if this is too small then for uncompressed data it will create a file of the maximum size for the extent ($MAX_BLOCKS * BLOCK_SIZE$). Snappy always compression adds a header block.
4. Object IDs of less than 3000 are for internal tables and will not appear in any of the information schema tables
5. Prior to 1.0.12 / 1.1.2 DATA_SIZE was incorrectly calculated
6. HWM is set to zero for the lower segments when there are multiple segments in an extent file, these can be observed when $BLOCK_OFFSET > 0$
7. When HWM is 0 the DATA_SIZE will show 0 instead of 8192 to avoid confusion when there is multiple segments in an extent file

COLUMNSTORE_FILES

The columnstore_files table provides information about each file associated with extensions. Each extension can reuse a file at different block offsets so this is not a 1:1 relationship to the columnstore_extents table.

Column	Description
OBJECT_ID	The object ID for the extent
SEGMENT_ID	The segment ID for the extent
PARTITION_ID	The partition ID for the extent
FILENAME	The full path and filename for the extent file, multiple extents for the same column can point to this file with different BLOCK_OFFSETs
FILE_SIZE	The disk file size for the extent

COMPRESSED_DATA_SIZE	The amount of the compressed file used, NULL if this is an uncompressed file
----------------------	--

Stored Procedures

A few stored procedures were added in 1.0.6 to provide summaries based on the information schema tables. These can be accessed from the COLUMNSTORE_INFO schema.

total_usage()

The total_usage() procedure gives a total disk usage summary for all the columns in ColumnStore with the exception of the columns used for internal maintenance. It is executed using the following query:

```
> call columnstore_info.total_usage();
```

table_usage()

The table_usage() procedure gives a the total data disk usage, dictionary disk usage and grand total disk usage per-table. It can be called in several ways, the first gives a total for each table:

```
> call columnstore_info.table_usage(NULL, NULL);
```

Or for a specific table, my_table in my_schema in this example:

```
> call columnstore_info.table_usage('my_schema', 'my_table');
```

You can also request all tables for a specified schema:

```
> call columnstore_info.table_usage('my_schema', NULL);
```

Note: The quotes around the table name are required, an error will occur without them.

compression_ratio()

The compression_ratio() procedure calculates the average compression ratio across all the compressed extents in ColumnStore. It is called using:

```
> call columnstore_info.compression_ratio();
```

Note: The compression ratio is incorrectly calculated before versions 1.0.12 / 1.1.2

1.1.1.2.9.1.1.4 Information Schema ALL_PLUGINS Table

Description

The [Information Schema](#) ALL_PLUGINS table contains information about [server plugins](#), whether installed or not.

It contains the following columns:

Column	Description
PLUGIN_NAME	Name of the plugin.
PLUGIN_VERSION	Version from the plugin's general type descriptor.
PLUGIN_STATUS	Plugin status, one of ACTIVE, INACTIVE, DISABLED, DELETED or NOT INSTALLED.

PLUGIN_TYPE	Plugin type; STORAGE ENGINE , INFORMATION_SCHEMA , AUTHENTICATION , REPLICATION , DAEMON or AUDIT .
PLUGIN_TYPE_VERSION	Version from the plugin's type-specific descriptor.
PLUGIN_LIBRARY	Plugin's shared object file name, located in the directory specified by the <code>plugin_dir</code> system variable, and used by the <code>INSTALL PLUGIN</code> and <code>UNINSTALL PLUGIN</code> statements. <code>NULL</code> if the plugin is compiled in and cannot be uninstalled.
PLUGIN_LIBRARY_VERSION	Version from the plugin's API interface.
PLUGIN_AUTHOR	Author of the plugin.
PLUGIN_DESCRIPTION	Description.
PLUGIN_LICENSE	Plugin's licence.
LOAD_OPTION	How the plugin was loaded; one of <code>OFF</code> , <code>ON</code> , <code>FORCE</code> or <code>FORCE_PLUS_PERMANENT</code> . See Installing Plugins .
PLUGIN_MATURITY	Plugin's maturity level; one of <code>Unknown</code> , <code>Experimental</code> , <code>Alpha</code> , <code>Beta</code> , <code>'Gamma</code> , and <code>Stable</code> .
PLUGIN_AUTH_VERSION	Plugin's version as determined by the plugin author. An example would be '0.99 beta 1'.

It provides a superset of the information shown by the `SHOW PLUGINS SONAME` statement, as well as the `information_schema.PLUGINS` table. For specific information about storage engines (a particular type of plugin), see the [Information Schema ENGINES](#) table and the `SHOW ENGINES` statement.

The table is not a standard Information Schema table, and is a MariaDB extension.

Example

```

SELECT * FROM information_schema.all_plugins\G
***** 1. row *****
    PLUGIN_NAME: binlog

```

1.1.1.2.9.1.1.5 Information Schema APPLICABLE_ROLES Table

The [Information Schema](#) `APPLICABLE_ROLES` table shows the [role authorizations](#) that the current user may use.

It contains the following columns:

Column	Description	Added
GRANTEE	Account that the role was granted to.	
ROLE_NAME	Name of the role.	
IS_GRANTABLE	Whether the role can be granted or not.	
IS_DEFAULT	Whether the role is the user's default role or not	MariaDB 10.1.3

The current role is in the [ENABLED_ROLES](#) Information Schema table.

Example

```
SELECT * FROM information_schema.APPLICABLE_ROLES;
+-----+-----+-----+-----+
| GRANTEE          | ROLE_NAME  | IS_GRANTABLE | IS_DEFAULT |
+-----+-----+-----+-----+
| root@localhost  | journalist | YES          | NO         |
| root@localhost  | staff      | YES          | NO         |
| root@localhost  | dd         | YES          | NO         |
| root@localhost  | dog        | YES          | NO         |
+-----+-----+-----+-----+
```

1.1.1.2.9.1.1.6 Information Schema CHARACTER_SETS Table

The [Information Schema](#) `CHARACTER_SETS` table contains a list of supported [character sets](#), their default collations and maximum lengths.

It contains the following columns:

Column	Description
CHARACTER_SET_NAME	Name of the character set.
DEFAULT_COLLATE_NAME	Default collation used.
DESCRIPTION	Character set description.
MAXLEN	Maximum length.

The [SHOW CHARACTER SET](#) statement returns the same results (although in a different order), and both can be refined in the same way. For example, the following two statements return the same results:

```
SHOW CHARACTER SET WHERE Maxlen LIKE '2';
```

and

```
SELECT * FROM information_schema.CHARACTER_SETS
WHERE MAXLEN LIKE '2';
```

See [Setting Character Sets and Collations](#) for details on specifying the character set at the server, database, table and column levels, and [Supported Character Sets and Collations](#) for a full list of supported characters sets and collations.

Example

```

SELECT CHARACTER_SET_NAME FROM information_schema.CHARACTER_SETS
WHERE DEFAULT_COLLATE_NAME LIKE '%chinese%';
+-----+
| CHARACTER_SET_NAME |
+-----+
| big5                |
| gb2312              |
| gbk                 |
+-----+

```

1.1.1.2.9.1.1.7 Information Schema CHECK_CONSTRAINTS Table

The [Information Schema](#) `CHECK_CONSTRAINTS` table stores metadata about the [constraints](#) defined for tables in all databases.

It contains the following columns:

Column	Description
CONSTRAINT_CATALOG	Always contains the string 'def'.
CONSTRAINT_SCHEMA	Database name.
CONSTRAINT_NAME	Constraint name.
TABLE_NAME	Table name.
LEVEL	Type of the constraint ('Column' or 'Table'). From MariaDB 10.5.10
CHECK_CLAUSE	Constraint clause.

Example

A table with a numeric table check constraint and with a default check constraint name:

```
CREATE TABLE t ( a int, CHECK (a>10));
```

To see check constraint call `check_constraints` table from [information schema](#).

```
SELECT * from INFORMATION_SCHEMA.CHECK_CONSTRAINTS\G
```

```

***** 1. row *****
CONSTRAINT_CATALOG: def
CONSTRAINT_SCHEMA: test
  CONSTRAINT_NAME: CONSTRAINT_1
    TABLE_NAME: t
      CHECK_CLAUSE: `a` > 10

```

A new table check constraint called `a_upper` :

```
ALTER TABLE t ADD CONSTRAINT a_upper CHECK (a<100);
```

```
SELECT * from INFORMATION_SCHEMA.CHECK_CONSTRAINTS\G
```

```

***** 1. row *****
CONSTRAINT_CATALOG: def
CONSTRAINT_SCHEMA: test
CONSTRAINT_NAME: CONSTRAINT_1
TABLE_NAME: t
CHECK_CLAUSE: `a` > 10
***** 2. row *****
CONSTRAINT_CATALOG: def
CONSTRAINT_SCHEMA: test
CONSTRAINT_NAME: a_upper
TABLE_NAME: t
CHECK_CLAUSE: `a` < 100

```

A new table `tt` with a field check constraint called `b`, as well as a table check constraint called `b_upper`:

```

CREATE TABLE tt(b int CHECK(b>0),CONSTRAINT b_upper CHECK(b<50));

SELECT * from INFORMATION_SCHEMA.CHECK_CONSTRAINTS;
+-----+-----+-----+-----+-----+
| CONSTRAINT_CATALOG | CONSTRAINT_SCHEMA | CONSTRAINT_NAME | TABLE_NAME | CHECK_CLAUSE |
+-----+-----+-----+-----+-----+
| def                | test              | b               | tt          | `b` > 0      |
| def                | test              | b_upper        | tt          | `b` < 50     |
| def                | test              | CONSTRAINT_1   | t           | `a` > 10     |
| def                | test              | a_upper        | t           | `a` < 100    |
+-----+-----+-----+-----+-----+

```

Note: The name of the field constraint is the same as the field name.

After dropping the default table constraint called `CONSTRAINT_1`:

```

ALTER TABLE t DROP CONSTRAINT CONSTRAINT_1;

SELECT * from INFORMATION_SCHEMA.CHECK_CONSTRAINTS;
+-----+-----+-----+-----+-----+
| CONSTRAINT_CATALOG | CONSTRAINT_SCHEMA | CONSTRAINT_NAME | TABLE_NAME | CHECK_CLAUSE |
+-----+-----+-----+-----+-----+
| def                | test              | b               | tt          | `b` > 0      |
| def                | test              | b_upper        | tt          | `b` < 50     |
| def                | test              | a_upper        | t           | `a` < 100    |
+-----+-----+-----+-----+-----+

```

Trying to insert invalid arguments into table `t` and `tt` generates an error.

```

INSERT INTO t VALUES (10),(20),(100);
ERROR 4025 (23000): CONSTRAINT `a_upper` failed for `test`.`t`

INSERT INTO tt VALUES (10),(-10),(100);
ERROR 4025 (23000): CONSTRAINT `b` failed for `test`.`tt`

INSERT INTO tt VALUES (10),(20),(100);
ERROR 4025 (23000): CONSTRAINT `b_upper` failed for `test`.`tt`

```

From [MariaDB 10.5.10](#):

```

create table majra(check(x>0), x int, y int check(y < 0), z int,
                  constraint z check(z>0), constraint xyz check(x<10 and y<10 and
z<10));
Query OK, 0 rows affected (0.036 sec)

show create table majra;
+-----+-----+
| Table | Create Table
+-----+-----+

4 rows in set (0.001 sec)

```

1.1.1.2.9.1.1.8 Information Schema CLIENT_STATISTICS Table

The [Information Schema](#) `CLIENT_STATISTICS` table holds statistics about client connections. This is part of the [User Statistics](#) feature, which is not enabled by default.

It contains the following columns:

Field	Type	Notes
CLIENT	VARCHAR(64)	The IP address or hostname the connection originated from.
TOTAL_CONNECTIONS	BIGINT(21)	The number of connections created for this client.
CONCURRENT_CONNECTIONS	BIGINT(21)	The number of concurrent connections for this client.
CONNECTED_TIME	BIGINT(21)	The cumulative number of seconds elapsed while there were connections from this client.

BUSY_TIME	DOUBLE	The cumulative number of seconds there was activity on connections from this client.
CPU_TIME	DOUBLE	The cumulative CPU time elapsed while servicing this client's connections. Note that this number may be wrong on SMP system if there was a CPU migration for the thread during the execution of the query.
BYTES_RECEIVED	BIGINT (21)	The number of bytes received from this client's connections.
BYTES_SENT	BIGINT (21)	The number of bytes sent to this client's connections.
BINLOG_BYTES_WRITTEN	BIGINT (21)	The number of bytes written to the binary log from this client's connections.
ROWS_READ	BIGINT (21)	The number of rows read by this client's connections.
ROWS_SENT	BIGINT (21)	The number of rows sent by this client's connections.
ROWS_DELETED	BIGINT (21)	The number of rows deleted by this client's connections.
ROWS_INSERTED	BIGINT (21)	The number of rows inserted by this client's connections.
ROWS_UPDATED	BIGINT (21)	The number of rows updated by this client's connections.
KEY_READ_HITS	BIGINT (21)	From MariaDB 11.5
KEY_READ_MISSES	BIGINT (21)	From MariaDB 11.5
SELECT_COMMANDS	BIGINT (21)	The number of SELECT commands executed from this client's connections.
UPDATE_COMMANDS	BIGINT (21)	The number of UPDATE commands executed from this client's connections.
OTHER_COMMANDS	BIGINT (21)	The number of other commands executed from this client's connections.
COMMIT_TRANSACTIONS	BIGINT (21)	The number of COMMIT commands issued by this client's connections.
ROLLBACK_TRANSACTIONS	BIGINT (21)	The number of ROLLBACK commands issued by this client's connections.
DENIED_CONNECTIONS	BIGINT (21)	The number of connections denied to this client.
LOST_CONNECTIONS	BIGINT (21)	The number of this client's connections that were terminated uncleanly.
ACCESS_DENIED	BIGINT (21)	The number of times this client's connections issued commands that were denied.
EMPTY_QUERIES	BIGINT (21)	The number of times this client's connections sent queries that returned no results to the server.
TOTAL_SSL_CONNECTIONS	BIGINT (21)	The number of TLS connections created for this client. (>= MariaDB 10.1.1)
MAX_STATEMENT_TIME_EXCEEDED	BIGINT (21)	The number of times a statement was aborted, because it was executed longer than its MAX_STATEMENT_TIME threshold. (>= MariaDB 10.1.1)

Example

```

SELECT * FROM information_schema.CLIENT_STATISTICS\G
***** 1. row *****
      CLIENT: localhost
      TOTAL_CONNECTIONS: 3
      CONCURRENT_CONNECTIONS: 0
      CONNECTED_TIME: 4883
      BUSY_TIME: 0.009722
      CPU_TIME: 0.0102131
      BYTES_RECEIVED: 841
      BYTES_SENT: 13897
      BINLOG_BYTES_WRITTEN: 0
      ROWS_READ: 0
      ROWS_SENT: 214
      ROWS_DELETED: 0
      ROWS_INSERTED: 207
      ROWS_UPDATED: 0
      SELECT_COMMANDS: 10
      UPDATE_COMMANDS: 0
      OTHER_COMMANDS: 13
      COMMIT_TRANSACTIONS: 0
      ROLLBACK_TRANSACTIONS: 0
      DENIED_CONNECTIONS: 0
      LOST_CONNECTIONS: 0
      ACCESS_DENIED: 0
      EMPTY_QUERIES: 1

```

1.1.1.2.9.1.1.9 Information Schema COLLATION_CHARACTER_SET_APPLICABILITY Table

The [Information Schema](#) `COLLATION_CHARACTER_SET_APPLICABILITY` table shows which [character sets](#) are associated with which collations.

It contains the following columns:

Column	Description
<code>COLLATION_NAME</code>	Collation name.
<code>CHARACTER_SET_NAME</code>	Name of the associated character set.
<code>FULL_COLLATION_NAME</code>	Name of the associated character set/collation combination. Added in MariaDB 10.10.1 .
<code>ID</code>	The unique identifier of this character set/collation combination. Added in MariaDB 10.10.1 .
<code>IS_DEFAULT</code>	If the collation is the default for this character set. Added in MariaDB 10.10.1 .

The `COLLATIONS` table is table of the base `COLLATION_NAMES` in the same way that `CHARACTER_SETS` table is table of the base `CHARACTER_SET_NAMES`. The `COLLATION_CHARACTER_SET_APPLICABILITY` table is the mapping between collations and character sets.

When joining the `information_schema.TABLES` table with its field `TABLE_COLLATIONS`, this should be joined to `FULL_COLLATION_NAME` in the `COLLATION_CHARACTER_SET_APPLICABILITY` table.

See [Setting Character Sets and Collations](#) for details on specifying the character set at the server, database, table and column levels.

Example

```
SELECT * FROM information_schema.COLLATION_CHARACTER_SET_APPLICABILITY WHERE
CHARACTER_SET_NAME='utf32' ORDER BY IS_DEFAULT DESC, ID LIMIT 10;
```

COLLATION_NAME	CHARACTER_SET_NAME	FULL_COLLATION_NAME	ID	IS_DEFAULT
utf32_general_ci	utf32	utf32_general_ci	60	Yes
utf32_bin	utf32	utf32_bin	61	
utf32_unicode_ci	utf32	utf32_unicode_ci	160	
utf32_icelandic_ci	utf32	utf32_icelandic_ci	161	
utf32_latvian_ci	utf32	utf32_latvian_ci	162	
utf32_romanian_ci	utf32	utf32_romanian_ci	163	
utf32_slovenian_ci	utf32	utf32_slovenian_ci	164	
utf32_polish_ci	utf32	utf32_polish_ci	165	
utf32_estonian_ci	utf32	utf32_estonian_ci	166	
utf32_spanish_ci	utf32	utf32_spanish_ci	167	

10 rows in set (0.004 sec)

1.1.1.2.9.1.1.10 Information Schema COLLATIONS Table

Contents

- [NO PAD collations](#)
- [Example](#)

The [Information Schema](#) `COLLATIONS` table contains a list of supported [collations](#).

It contains the following columns:

Column	Description
<code>COLLATION_NAME</code>	Name of the collation.
<code>CHARACTER_SET_NAME</code>	Associated character set.
<code>ID</code>	Collation id.
<code>IS_DEFAULT</code>	Whether the collation is the character set's default.
<code>IS_COMPILED</code>	Whether the collation is compiled into the server.
<code>SORTLEN</code>	Sort length, used for determining the memory used to sort strings in this collation.
<code>COMMENT</code>	For utf8mb4_0900 collations, contains the corresponding alias collation. From MariaDB 11.4.5 , MariaDB 11.7.2 , MariaDB 11.8.1 .

The `SHOW COLLATION` statement returns the same results and both can be reduced in a similar way.

For example, in [MariaDB 10.6](#), the following two statements return the same results:

```
SHOW COLLATION WHERE Charset LIKE 'utf8mb3';
```

and

```
SELECT * FROM information_schema.COLLATIONS
WHERE CHARACTER_SET_NAME LIKE 'utf8mb3';
```

In [MariaDB 10.5](#) and before, `utf8` should be specified instead of `utf8mb3`.

NO PAD collations

`NO PAD` collations regard trailing spaces as normal characters. You can get a list of all `NO PAD` collations as follows:

```
SELECT collation_name FROM information_schema.COLLATIONS
WHERE collation_name LIKE "%nopad%";
```

```
+-----+
| collation_name |
+-----+
| big5_chinese_nopad_ci |
| big5_nopad_bin |
...

```

Example

```
SELECT * FROM information_schema.COLLATIONS;
```

```
+-----+-----+-----+-----+-----+-----+
| COLLATION_NAME | CHARACTER_SET_NAME | ID | IS_DEFAULT | IS_COMPILED | SORTLEN |
+-----+-----+-----+-----+-----+-----+
| big5_chinese_ci | big5 | 1 | Yes | Yes | 1 |
| big5_bin | big5 | 84 | | Yes | 1 |
| big5_chinese_nopad_ci | big5 | 1025 | | Yes | 1 |
| big5_nopad_bin | big5 | 1108 | | Yes | 1 |
| dec8_swedish_ci | dec8 | 3 | Yes | Yes | 1 |
| dec8_bin | dec8 | 69 | | Yes | 1 |
| dec8_swedish_nopad_ci | dec8 | 1027 | | Yes | 1 |
| dec8_nopad_bin | dec8 | 1093 | | Yes | 1 |
| cp850_general_ci | cp850 | 4 | Yes | Yes | 1 |
| cp850_bin | cp850 | 80 | | Yes | 1 |
...

```

1.1.1.2.9.1.1.11 Information Schema COLUMN_PRIVILEGES Table

The [Information Schema](#) `COLUMN_PRIVILEGES` table contains column privilege information derived from the `mysql.columns_priv` grant table.

It has the following columns:

Column	Description
GRANTEE	In the format <code>user_name@host_name</code> .
TABLE_CATALOG	Always <code>def</code> .
TABLE_SCHEMA	Database name.
TABLE_NAME	Table name.
COLUMN_NAME	Column name.
PRIVILEGE_TYPE	One of <code>SELECT</code> , <code>INSERT</code> , <code>UPDATE</code> or <code>REFERENCES</code> .
IS_GRANTABLE	Whether the user has the GRANT OPTION for this privilege.

Similar information can be accessed with the `SHOW FULL COLUMNS` and `SHOW GRANTS` statements. See the [GRANT](#) article for more about privileges.

This information is also stored in the `columns_priv` table, in the `mysql` system database.

For a description of the privileges that are shown in this table, see [column privileges](#).

Example

In the following example, no column-level privilege has been explicitly assigned:

```
SELECT * FROM information_schema.COLUMN_PRIVILEGES;
Empty set
```

1.1.1.2.9.1.1.12 Information Schema COLUMNS Table

The [Information Schema COLUMNS](#) table provides information about columns in each table on the server.

It contains the following columns:

Column	Description
TABLE_CATALOG	Always contains the string 'def'.
TABLE_SCHEMA	Database name.
TABLE_NAME	Table name.
COLUMN_NAME	Column name.
ORDINAL_POSITION	Column position in the table. Can be used for ordering.
COLUMN_DEFAULT	Default value for the column. Literals are quoted to distinguish them from expressions. <code>NULL</code> means that the column has no default. In MariaDB 10.2.6 and earlier, no quotes were used for any type of default and <code>NULL</code> can either mean that there is no default, or that the default column value is <code>NULL</code> .
IS_NULLABLE	Whether the column can contain <code>NULL</code> s.
DATA_TYPE	The column's data type .
CHARACTER_MAXIMUM_LENGTH	Maximum length.
CHARACTER_OCTET_LENGTH	Same as the <code>CHARACTER_MAXIMUM_LENGTH</code> except for multi-byte character sets .
NUMERIC_PRECISION	For numeric types, the precision (number of significant digits) for the column. <code>NULL</code> if not a numeric field.
NUMERIC_SCALE	For numeric types, the scale (significant digits to the right of the decimal point). <code>NULL</code> if not a numeric field.
DATETIME_PRECISION	Fractional-seconds precision, or <code>NULL</code> if not a time data type .
CHARACTER_SET_NAME	Character set if a non-binary string data type , otherwise <code>NULL</code> .
COLLATION_NAME	Collation if a non-binary string data type , otherwise <code>NULL</code> .
COLUMN_TYPE	Column definition, a MySQL and MariaDB extension.
COLUMN_KEY	Index type. <code>PRI</code> for primary key, <code>UNI</code> for unique index, <code>MUL</code> for multiple index. A MySQL and MariaDB extension.
EXTRA	Additional information about a column, for example whether the column is an invisible column , or <code>WITHOUT SYSTEM VERSIONING</code> if the table is not a system-versioned table . A MySQL and MariaDB extension.
PRIVILEGES	Which privileges you have for the column. A MySQL and MariaDB extension.
COLUMN_COMMENT	Column comments.
IS_GENERATED	Indicates whether the column value is generated (virtual, or computed) . Can be <code>ALWAYS</code> or <code>NEVER</code> .
GENERATION_EXPRESSION	The expression used for computing the column value in a generated (virtual, or computed) column.
IS_SYSTEM_TIME_PERIOD_START	From MariaDB 11.4.1 .
IS_SYSTEM_TIME_PERIOD_END	From MariaDB 11.4.1 .

It provides information similar to, but more complete, than [SHOW COLUMNS](#) and [mariadb-show](#).

Examples

```

SELECT * FROM information_schema.COLUMNS\G
...
***** 9. row *****
      TABLE_CATALOG: def
      TABLE_SCHEMA: test
      TABLE_NAME: t2
      COLUMN_NAME: j
      ORDINAL_POSITION: 1
      COLUMN_DEFAULT: NULL
      IS_NULLABLE: YES
      DATA_TYPE: longtext
CHARACTER_MAXIMUM_LENGTH: 4294967295
CHARACTER_OCTET_LENGTH: 4294967295
      NUMERIC_PRECISION: NULL
      NUMERIC_SCALE: NULL
      DATETIME_PRECISION: NULL
      CHARACTER_SET_NAME: utf8mb4
      COLLATION_NAME: utf8mb4_bin
      COLUMN_TYPE: longtext
      COLUMN_KEY:
      EXTRA:
      PRIVILEGES: select,insert,update,references
      COLUMN_COMMENT:
      IS_GENERATED: NEVER
      GENERATION_EXPRESSION: NULL
...

```

```

CREATE TABLE t (
  s1 VARCHAR(20) DEFAULT 'ABC',
  s2 VARCHAR(20) DEFAULT (concat('A','B')),
  s3 VARCHAR(20) DEFAULT ("concat('A','B')"),
  s4 VARCHAR(20),
  s5 VARCHAR(20) DEFAULT NULL,
  s6 VARCHAR(20) NOT NULL,
  s7 VARCHAR(20) DEFAULT 'NULL' NULL,
  s8 VARCHAR(20) DEFAULT 'NULL' NOT NULL
);

```

```

SELECT
  table_name,
  column_name,
  ordinal_position,
  column_default,
  column_default IS NULL
FROM information_schema.COLUMNS
WHERE table_schema=DATABASE()
AND TABLE_NAME='t';

```

table_name	column_name	ordinal_position	column_default	column_default IS NULL
t	s1	1	'ABC'	0
t	s2	2	concat('A','B')	0
t	s3	3	'concat('A','B')'	0
t	s4	4	NULL	0
t	s5	5	NULL	0
t	s6	6	NULL	1
t	s7	7	'NULL'	0
t	s8	8	'NULL'	0

In the results above, the two single quotes in `concat('A','B')` indicate an escaped single quote - see [string-literals](#). Note that while [mariadb client](#) appears to show the same default value for columns `s5` and `s6`, the first is a 4-character string "NULL", while the second is the SQL NULL value.

From [MariaDB 11.3](#):

```

CREATE TABLE t(
  x INT,
  start_timestamp TIMESTAMP(6) GENERATED ALWAYS AS ROW START,
  end_timestamp TIMESTAMP(6) GENERATED ALWAYS AS ROW END,
  PERIOD FOR SYSTEM_TIME(start_timestamp, end_timestamp)
) WITH SYSTEM VERSIONING;

SELECT TABLE_NAME, COLUMN_NAME, ORDINAL_POSITION,
       IS_SYSTEM_TIME_PERIOD_START, IS_SYSTEM_TIME_PERIOD_END
FROM INFORMATION_SCHEMA.COLUMNS WHERE TABLE_NAME='t'\G
***** 1. row *****
      TABLE_NAME: t
      COLUMN_NAME: x
      ORDINAL_POSITION: 1
IS_SYSTEM_TIME_PERIOD_START: NO
IS_SYSTEM_TIME_PERIOD_END: NO
***** 2. row *****
      TABLE_NAME: t
      COLUMN_NAME: start_timestamp
      ORDINAL_POSITION: 2
IS_SYSTEM_TIME_PERIOD_START: YES
IS_SYSTEM_TIME_PERIOD_END: NO
***** 3. row *****
      TABLE_NAME: t
      COLUMN_NAME: end_timestamp
      ORDINAL_POSITION: 3
IS_SYSTEM_TIME_PERIOD_START: NO
IS_SYSTEM_TIME_PERIOD_END: YES

```

1.1.1.2.9.1.1.13 Information Schema DISKS Table

Contents

1. [Description](#)
2. [Example](#)

Description

The `DISKS` table is created when the `DISKS` plugin is enabled, and shows metadata about disks on the system.

Before [MariaDB 10.4.7](#), [MariaDB 10.3.17](#), [MariaDB 10.2.26](#) and [MariaDB 10.1.41](#), this plugin did **not** check [user privileges](#). When it is enabled, **any** user can query the `INFORMATION_SCHEMA.DISKS` table and see all the information it provides.

Since [MariaDB 10.4.7](#), [MariaDB 10.3.17](#), [MariaDB 10.2.26](#) and [MariaDB 10.1.41](#), it requires the [FILE privilege](#).

The plugin only works on Linux.

The table contains the following columns:

Column	Description
<code>DISK</code>	Name of the disk itself.
<code>PATH</code>	Mount point of the disk.
<code>TOTAL</code>	Total space in KiB.
<code>USED</code>	Used amount of space in KiB.
<code>AVAILABLE</code>	Amount of space in KiB available to non-root users.

Note that as the amount of space available to root (OS user) may be more than what is available to non-root users, 'available' + 'used' may be less than 'total'.

All paths to which a particular disk has been mounted are reported. The rationale is that someone might want to take different action e.g. depending on which disk is relevant for a particular path. This leads to the same disk being reported multiple times.

Example

```
SELECT * FROM information_schema.DISKS;

+-----+-----+-----+-----+-----+
| Disk      | Path  | Total  | Used   | Available |
+-----+-----+-----+-----+-----+
| /dev/vda1 | /      | 26203116 | 2178424 | 24024692 |
| /dev/vda1 | /boot  | 26203116 | 2178424 | 24024692 |
| /dev/vda1 | /etc   | 26203116 | 2178424 | 24024692 |
+-----+-----+-----+-----+-----+
```

1.1.1.2.9.1.1.14 Information Schema ENABLED_ROLES Table

The [Information Schema](#) `ENABLED_ROLES` table shows the enabled [roles](#) for the current session.

It contains the following column:

Column	Description
<code>ROLE_NAME</code>	The enabled role name, or <code>NULL</code> .

This table lists all roles that are currently enabled, one role per row — the current role, roles granted to the current role, roles granted to these roles and so on. If no role is set, the row contains a `NULL` value.

The roles that the current user can enable are listed in the [APPLICABLE_ROLES](#) Information Schema table.

See also [CURRENT_ROLE\(\)](#).

Examples

```
SELECT * FROM information_schema.ENABLED_ROLES;

+-----+
| ROLE_NAME |
+-----+
| NULL      |
+-----+

SET ROLE staff;

SELECT * FROM information_schema.ENABLED_ROLES;

+-----+
| ROLE_NAME |
+-----+
| staff     |
+-----+
```

1.1.1.2.9.1.1.15 Information Schema ENGINES Table

The [Information Schema](#) `ENGINES` table displays status information about the server's [storage engines](#).

It contains the following columns:

Column	Description
<code>ENGINE</code>	Name of the storage engine.
<code>SUPPORT</code>	Whether the engine is the default, or is supported or not.
<code>COMMENT</code>	Storage engine comments.
<code>TRANSACTIONS</code>	Whether or not the engine supports transactions .
<code>XA</code>	Whether or not the engine supports XA transactions .

SAVEPOINTS	Whether or not savepoints are supported.
------------	--

It provides identical information to the `SHOW ENGINES` statement. Since storage engines are plugins, different information about them is also shown in the `information_schema.PLUGINS` table and by the `SHOW PLUGINS` statement.

The table is not a standard Information Schema table, and is a MySQL and MariaDB extension.

Note that both MySQL's InnoDB and Percona's XtraDB replacement are labeled as `InnoDB`. However, if XtraDB is in use, it will be specified in the `COMMENT` field. See [XtraDB and InnoDB](#). The same applies to [FederatedX](#).

Example

```

SELECT * FROM information_schema.ENGINES\G;
***** 1. row *****
ENGINE: InnoDB
SUPPORT: DEFAULT
COMMENT: Supports transactions, row-level locking, and foreign keys
TRANSACTIONS: YES
XA: YES
SAVEPOINTS: YES
***** 2. row *****

10 rows in set (0.00 sec)

```

Check if a given storage engine is available:

```
SELECT SUPPORT FROM information_schema.ENGINES WHERE ENGINE LIKE 'tokudb';
Empty set
```

Check which storage engine supports XA transactions:

```
SELECT ENGINE FROM information_schema.ENGINES WHERE XA = 'YES';
+-----+
| ENGINE |
+-----+
| InnoDB |
+-----+
```

1.1.1.2.9.1.1.16 Information Schema EVENTS Table

The [Information Schema](#) `EVENTS` table stores information about [Events](#) on the server.

It contains the following columns:

Column	Description
EVENT_CATALOG	Always <code>def</code> .
EVENT_SCHEMA	Database where the event was defined.
EVENT_NAME	Event name.
DEFINER	Event definer.
TIME_ZONE	Time zone used for the event's scheduling and execution, by default <code>SYSTEM</code> .
EVENT_BODY	<code>SQL</code> .
EVENT_DEFINITION	The <code>SQL</code> defining the event.
EVENT_TYPE	Either <code>ONE TIME</code> or <code>RECURRING</code> .
EXECUTE_AT	DATETIME when the event is set to execute, or <code>NULL</code> if recurring.
INTERVAL_VALUE	Numeric interval between event executions for a recurring event, or <code>NULL</code> if not recurring.
INTERVAL_FIELD	Interval unit (e.g., <code>hour</code>)
SQL_MODE	The SQL_MODE at the time the event was created.
STARTS	Start DATETIME for a recurring event, <code>NULL</code> if not defined or not recurring.
ENDS	End DATETIME for a recurring event, <code>NULL</code> if not defined or not recurring.
STATUS	One of <code>ENABLED</code> , <code>DISABLED</code> or <code>SLAVESIDE_DISABLED</code> .
ON_COMPLETION	The <code>ON COMPLETION</code> clause, either <code>PRESERVE</code> or <code>NOT PRESERVE</code> .
CREATED	When the event was created.
LAST_ALTERED	When the event was last changed.
LAST_EXECUTED	When the event was last run.
EVENT_COMMENT	The comment provided in the <code>CREATE EVENT</code> statement, or an empty string if none.
ORIGINATOR	MariaDB server ID on which the event was created.
CHARACTER_SET_CLIENT	character_set_client system variable session value at the time the event was created.
COLLATION_CONNECTION	collation_connection system variable session value at the time the event was created.
DATABASE_COLLATION	Database collation with which the event is linked.

The `SHOW EVENTS` and `SHOW CREATE EVENT` statements provide similar information.

1.1.1.2.9.1.1.17 Information Schema FEEDBACK Table

The [Information Schema FEEDBACK](#) table is created when the [Feedback Plugin](#) is enabled, and contains the complete contents submitted by the plugin.

It contains two columns:

Column	Description
VARIABLE_NAME	Name of the item of information being collected.
VARIABLE_VALUE	Contents of the item of information being collected.

It is possible to disable automatic collection, by setting the `feedback_url` variable to an empty string, and to submit the contents manually, as follows:

```
$ mysql -e 'SELECT * FROM information_schema.FEEDBACK' > report.txt
```

Then you can send it by opening https://mariadb.org/feedback_plugin/post in your browser, and uploading your generated `report.txt`. Or you can do it from the command line with (for example):

```
$ curl -F [email protected] https://mariadb.org/feedback_plugin/post
```

Manual uploading allows you to be absolutely sure that we receive only the data shown in the `information_schema.FEEDBACK` table and that no private or sensitive information is being sent.

Example

```
SELECT * FROM information_schema.FEEDBACK\G
...
***** 906. row *****
VARIABLE_NAME: Uname_sysname
VARIABLE_VALUE: Linux
***** 907. row *****
VARIABLE_NAME: Uname_release
VARIABLE_VALUE: 3.13.0-53-generic
***** 908. row *****
VARIABLE_NAME: Uname_version
VARIABLE_VALUE: #89-Ubuntu SMP Wed May 20 10:34:39 UTC 2015
***** 909. row *****
VARIABLE_NAME: Uname_machine
VARIABLE_VALUE: x86_64
***** 910. row *****
VARIABLE_NAME: Uname_distribution
VARIABLE_VALUE: lsb: Ubuntu 14.04.2 LTS
***** 911. row *****

VARIABLE_VALUE: 1
***** 915. row *****
VARIABLE_NAME: Collation used binary
VARIABLE_VALUE: 16
***** 916. row *****
VARIABLE_NAME: Collation used utf8_bin
VARIABLE_VALUE: 4044
```

1.1.1.2.9.1.1.18 Information Schema FILES

Table

The `FILES` tables is unused in MariaDB. See [MDEV-11426](#).

1.1.1.2.9.1.1.19 Information Schema GEOMETRY_COLUMNS Table

Description

The [Information Schema](#) `GEOMETRY_COLUMNS` table provides support for Spatial Reference systems for GIS data.

It contains the following columns:

Column	Type	Null	Description
<code>F_TABLE_CATALOG</code>	<code>VARCHAR(512)</code>	NO	Together with <code>F_TABLE_SCHEMA</code> and <code>F_TABLE_NAME</code> , the fully qualified name of the featured table containing the geometry column.
<code>F_TABLE_SCHEMA</code>	<code>VARCHAR(64)</code>	NO	Together with <code>F_TABLE_CATALOG</code> and <code>F_TABLE_NAME</code> , the fully qualified name of the featured table containing the geometry column.
<code>F_TABLE_NAME</code>	<code>VARCHAR(64)</code>	NO	Together with <code>F_TABLE_CATALOG</code> and <code>F_TABLE_SCHEMA</code> , the fully qualified name of the featured table containing the geometry column.
<code>F_GEOMETRY_COLUMN</code>	<code>VARCHAR(64)</code>	NO	Name of the column in the featured table that is the geometry golumn.
<code>G_TABLE_CATALOG</code>	<code>VARCHAR(512)</code>	NO	
<code>G_TABLE_SCHEMA</code>	<code>VARCHAR(64)</code>	NO	Database name of the table implementing the geometry column.
<code>G_TABLE_NAME</code>	<code>VARCHAR(64)</code>	NO	Table name that is implementing the geometry column.
<code>G_GEOMETRY_COLUMN</code>	<code>VARCHAR(64)</code>	NO	
<code>STORAGE_TYPE</code>	<code>TINYINT(2)</code>	NO	Binary geometry implementation. Always 1 in MariaDB.
<code>GEOMETRY_TYPE</code>	<code>INT(7)</code>	NO	Integer reflecting the type of geometry stored in this column (see table below).
<code>COORD_DIMENSION</code>	<code>TINYINT(2)</code>	NO	Number of dimensions in the spatial reference system. Always 2 in MariaDB.
<code>MAX_PPR</code>	<code>TINYINT(2)</code>	NO	Always 0 in MariaDB.
<code>SRID</code>	<code>SMALLINT(5)</code>	NO	ID of the Spatial Reference System used for the coordinate geometry in this table. It is a foreign key reference to the <code>SPATIAL_REF_SYS</code> table.

Storage_type

The integers in the `storage_type` field match the geometry types as follows:

Integer	Type
0	GEOMETRY
1	POINT
3	LINestring
5	POLYGON
7	MULTIPOINT
9	MULTILINestring
11	MULTIPOLYGON

Example

```
CREATE TABLE g1(g GEOMETRY(9,4) REF_SYSTEM_ID=101);

SELECT * FROM information_schema.GEOMETRY_COLUMNS\G
***** 1. row *****
F_TABLE_CATALOG: def
F_TABLE_SCHEMA: test
F_TABLE_NAME: g1
F_GEOMETRY_COLUMN:
G_TABLE_CATALOG: def
G_TABLE_SCHEMA: test
G_TABLE_NAME: g1
G_GEOMETRY_COLUMN: g
STORAGE_TYPE: 1
GEOMETRY_TYPE: 0
COORD_DIMENSION: 2
MAX_PPR: 0
SRID: 101
```

1.1.1.2.9.1.1.20 Information Schema GLOBAL_STATUS and SESSION_STATUS Tables

The [Information Schema](#) GLOBAL_STATUS and SESSION_STATUS tables store a record of all [status variables](#) and their global and session values respectively. This is the same information as displayed by the [SHOW STATUS](#) commands SHOW GLOBAL STATUS and SHOW SESSION STATUS.

They contain the following columns:

Column	Description
VARIABLE_NAME	Status variable name.
VARIABLE_VALUE	Global or session value.

Example

```
SELECT * FROM information_schema.GLOBAL_STATUS;
+-----+-----+
| VARIABLE_NAME | VARIABLE_VALUE |
+-----+-----+
...
| BINLOG_SNAPSHOT_FILE | mariadb-bin.000208 |
| BINLOG_SNAPSHOT_POSITION | 369 |
...
| THREADS_CONNECTED | 1 |
| THREADS_CREATED | 1 |
| THREADS_RUNNING | 1 |
| UPTIME | 57358 |
| UPTIME_SINCE_FLUSH_STATUS | 57358 |
+-----+-----+
```

1.1.1.2.9.1.1.21 Information Schema GLOBAL_VARIABLES and SESSION_VARIABLES Tables

The [Information Schema](#) GLOBAL_VARIABLES and SESSION_VARIABLES tables stores a record of all [system variables](#) and their global and session values respectively. This is the same information as displayed by the [SHOW VARIABLES](#) commands SHOW GLOBAL VARIABLES and SHOW SESSION VARIABLES.

It contains the following columns:

Column	Description
--------	-------------

VARIABLE_NAME	System variable name.
VARIABLE_VALUE	Global or session value.

Example

```
SELECT * FROM information_schema.GLOBAL_VARIABLES ORDER BY VARIABLE_NAME\G
***** 1. row *****
VARIABLE_NAME: ARIA_BLOCK_SIZE
VARIABLE_VALUE: 8192
***** 2. row *****
VARIABLE_NAME: ARIA_CHECKPOINT_LOG_ACTIVITY
VARIABLE_VALUE: 1048576
***** 3. row *****
VARIABLE_NAME: ARIA_CHECKPOINT_INTERVAL
VARIABLE_VALUE: 30
...
***** 455. row *****
VARIABLE_NAME: VERSION_COMPILE_MACHINE
VARIABLE_VALUE: x86_64
***** 456. row *****
VARIABLE_NAME: VERSION_COMPILE_OS
VARIABLE_VALUE: debian-linux-gnu
***** 457. row *****
VARIABLE_NAME: WAIT_TIMEOUT
VARIABLE_VALUE: 600
```

1.1.1.2.9.1.1.22 Information Schema INDEX_STATISTICS Table

The [Information Schema](#) `INDEX_STATISTICS` table shows statistics on index usage and makes it possible to do such things as locating unused indexes and generating the commands to remove them.

This is part of the [User Statistics](#) feature, which is not enabled by default.

It contains the following columns:

Field	Type	Notes
TABLE_SCHEMA	VARCHAR(192)	The schema (database) name.
TABLE_NAME	VARCHAR(192)	The table name.
INDEX_NAME	VARCHAR(192)	The index name (as visible in SHOW CREATE TABLE).
ROWS_READ	BIGINT(21)	The number of rows read from this index.
QUERIES	BIGINT(21)	Incremented for each index the query is part of. This assists one to see how effective the index is. From MariaDB 11.5

Example

```
SELECT * FROM information_schema.INDEX_STATISTICS
WHERE TABLE_NAME = "author";
+-----+-----+-----+-----+
| TABLE_SCHEMA | TABLE_NAME | INDEX_NAME | ROWS_READ |
+-----+-----+-----+-----+
| books        | author      | by_name    | 15        |
+-----+-----+-----+-----+
```

1.1.1.2.9.1.1.23 Information Schema KEY_CACHES Table

The [Information Schema](#) `KEY_CACHES` table shows statistics about the [segmented key cache](#).

It contains the following columns:

Column Name	Description
KEY_CACHE_NAME	The name of the key cache
SEGMENTS	total number of segments (set to <code>NULL</code> for regular key caches)
SEGMENT_NUMBER	segment number (set to <code>NULL</code> for any regular key caches and for rows containing aggregation statistics for segmented key caches)
FULL_SIZE	memory for cache buffers/auxiliary structures
BLOCK_SIZE	size of the blocks
USED_BLOCKS	number of currently used blocks
UNUSED_BLOCKS	number of currently unused blocks
DIRTY_BLOCKS	number of currently dirty blocks
READ_REQUESTS	number of read requests
READS	number of actual reads from files into buffers
WRITE_REQUESTS	number of write requests
WRITES	number of actual writes from buffers into files

Example

```
SELECT * FROM information_schema.KEY_CACHES \G
***** 1. row *****
KEY_CACHE_NAME: default
SEGMENTS: NULL
SEGMENT_NUMBER: NULL
    FULL_SIZE: 134217728
    BLOCK_SIZE: 1024
    USED_BLOCKS: 36
    UNUSED_BLOCKS: 107146
    DIRTY_BLOCKS: 0
    READ_REQUESTS: 40305
        READS: 21
    WRITE_REQUESTS: 19239
        WRITES: 358
```

1.1.1.2.9.1.1.24 Information Schema KEY_COLUMN_USAGE Table

The [Information Schema](#) `KEY_COLUMN_USAGE` table shows which key columns have constraints.

It contains the following columns:

Column	Description
CONSTRAINT_CATALOG	Always <code>def</code> .
CONSTRAINT_SCHEMA	Database name of the constraint.
CONSTRAINT_NAME	Name of the constraint (<code>PRIMARY</code> for the primary key).
TABLE_CATALOG	Always <code>#def</code> .
TABLE_SCHEMA	Database name of the column constraint.
TABLE_NAME	Table name of the column constraint.
COLUMN_NAME	Column name of the constraint.
ORDINAL_POSITION	Position of the column within the constraint.
POSITION_IN_UNIQUE_CONSTRAINT	For foreign keys , the position in the unique constraint.

REFERENCED_TABLE_SCHEMA	For foreign keys, the referenced database name.
REFERENCED_TABLE_NAME	For foreign keys, the referenced table name.
REFERENCED_COLUMN_NAME	For foreign keys, the referenced column name.

Example

```
SELECT * FROM information_schema.KEY_COLUMN_USAGE LIMIT 1 \G
***** 1. row *****
      CONSTRAINT_CATALOG: def
      CONSTRAINT_SCHEMA: my_website
      CONSTRAINT_NAME: PRIMARY
      TABLE_CATALOG: def
      TABLE_SCHEMA: users
      COLUMN_NAME: user_id
      ORDINAL_POSITION: 1
POSITION_IN_UNIQUE_CONSTRAINT: NULL
REFERENCED_TABLE_SCHEMA: NULL
REFERENCED_TABLE_NAME: NULL
REFERENCED_COLUMN_NAME: NULL
```

1.1.1.2.9.1.1.25 Information Schema KEY_PERIOD_USAGE Table

MariaDB starting with [11.4.1](#)

The [Information Schema](#) `KEY_PERIOD_USAGE` table shows information about [Application-Time Periods](#).

It contains the following columns:

Column	Description
CONSTRAINT_CATALOG	
CONSTRAINT_SCHEMA	
CONSTRAINT_NAME	
TABLE_CATALOG	
TABLE_SCHEMA	
TABLE_NAME	
PERIOD_NAME	

Example

1.1.1.2.9.1.1.26 Information Schema KEYWORDS Table

MariaDB starting with [10.6.3](#)

The `KEYWORDS` table was added in [MariaDB 10.6.3](#).

Description

The [Information Schema](#) `KEYWORDS` table contains the list of MariaDB keywords.

It contains a single column:

Column	Description
--------	-------------

WORD	Keyword
------	---------

The table is not a standard Information Schema table, and is a MariaDB extension.

Example

```
SELECT * FROM INFORMATION_SCHEMA.KEYWORDS;
```

```
+-----+
| WORD |
+-----+
| &&   |
| <=   |
| <>   |
| !=   |

1.1.1.2.9.1.1.27 Information Schema LOCALES Table

Description

The [Information Schema](#) `LOCALES` table contains a list of all compiled-in locales. It is only available if the [LOCALES plugin](#) has been installed.

It contains the following columns:

Column	Description
ID	Row ID.
NAME	Locale name, for example <code>en_GB</code> .
DESCRIPTION	Locale description, for example <code>English - United Kingdom</code> .
MAX_MONTH_NAME_LENGTH	Numeric length of the longest month in the locale
MAX_DAY_NAME_LENGTH	Numeric length of the longest day name in the locale.
DECIMAL_POINT	Decimal point character (some locales use a comma).
THOUSAND_SEP	Thousand's character separator,
ERROR_MESSAGE_LANGUAGE	Error message language.

The table is not a standard Information Schema table, and is a MariaDB extension.

The [SHOW LOCALES](#) statement returns a subset of the information.

Example

```

SELECT * FROM information_schema.LOCALES;
+-----+-----+-----+-----+-----+-----+-----+-----+
| ID | NAME | DESCRIPTION | MAX_MONTH_NAME_LENGTH |
MAX_DAY_NAME_LENGTH | DECIMAL_POINT | THOUSAND_SEP | ERROR_MESSAGE_LANGUAGE |
+-----+-----+-----+-----+-----+-----+-----+-----+
| 0 | en_US | English - United States | 9 |
9 | . | | , | | english |
| 1 | en_GB | English - United Kingdom | 9 |
9 | . | | , | | english |
| 2 | ja_JP | Japanese - Japan | 3 |
3 | . | | , | | japanese |
| 3 | sv_SE | Swedish - Sweden | 9 |

1.1.1.2.9.1.1.28 Information Schema METADATA_LOCK_INFO Table

The [Information Schema](#) `METADATA_LOCK_INFO` table is created by the `metadata_lock_info` plugin. It shows active [metadata locks](#) and user locks (the locks acquired with `GET_LOCK`).

It has the following columns:

Column	Description
THREAD_ID	
LOCK_MODE	One of MDL_INTENTION_EXCLUSIVE, MDL_SHARED, MDL_SHARED_HIGH_PRIO, MDL_SHARED_READ, MDL_SHARED_READ_ONLY, MDL_SHARED_WRITE, MDL_SHARED_NO_WRITE, MDL_SHARED_NO_READ_WRITE, MDL_SHARED_UPGRADABLE or MDL_EXCLUSIVE.
LOCK_DURATION	One of MDL_STATEMENT, MDL_TRANSACTION or MDL_EXPLICIT
LOCK_TYPE	One of Global read lock, Schema metadata lock, Table metadata lock, Stored function metadata lock, Stored procedure metadata lock, Trigger metadata lock, Event metadata lock, Commit lock or User lock.
TABLE_SCHEMA	
TABLE_NAME	

"LOCK_MODE" Descriptions

The `LOCK_MODE` column can have the following values:

Value	Description
-------	-------------

MDL_INTENTION_EXCLUSIVE	An intention exclusive metadata lock (IX). Used only for scoped locks. Owner of this type of lock can acquire upgradable exclusive locks on individual objects. Compatible with other IX locks, but is incompatible with scoped S and X locks. IX lock is taken in SCHEMA namespace when we intend to modify object metadata. Object may refer table, stored procedure, trigger, view/etc.
MDL_SHARED	A shared metadata lock (S). To be used in cases when we are interested in object metadata only and there is no intention to access object data (e.g. for stored routines or during preparing prepared statements). We also mis-use this type of lock for open HANDLERS, since lock acquired by this statement has to be compatible with lock acquired by LOCK TABLES ... WRITE statement, i.e. SNRW (We can't get by by acquiring S lock at HANDLER ... OPEN time and upgrading it to SR lock for HANDLER ... READ as it doesn't solve problem with need to abort DML statements which wait on table level lock while having open HANDLER in the same connection). To avoid deadlock which may occur when SNRW lock is being upgraded to X lock for table on which there is an active S lock which is owned by thread which waits in its turn for table-level lock owned by thread performing upgrade we have to use thr_abort_locks_for_thread() facility in such situation. This problem does not arise for locks on stored routines as we don't use SNRW locks for them. It also does not arise when S locks are used during PREPARE calls as table-level locks are not acquired in this case. This lock is taken for global read lock, when caching a stored procedure in memory for the duration of the transaction and for tables used by prepared statements.
MDL_SHARED_HIGH_PRIO	A high priority shared metadata lock. Used for cases when there is no intention to access object data (i.e. data in the table). "High priority" means that, unlike other shared locks, it is granted ignoring pending requests for exclusive locks. Intended for use in cases when we only need to access metadata and not data, e.g. when filling an INFORMATION_SCHEMA table. Since SH lock is compatible with SNRW lock, the connection that holds SH lock should not try to acquire any kind of table-level or row-level lock, as this can lead to a deadlock. Moreover, after acquiring SH lock, the connection should not wait for any other resource, as it might cause starvation for X locks and a potential deadlock during upgrade of SNW or SNRW to X lock (e.g. if the upgrading connection holds the resource that is being waited for).
MDL_SHARED_READ	A shared metadata lock (SR) for cases when there is an intention to read data from table. A connection holding this kind of lock can read table metadata and read table data (after acquiring appropriate table and row-level locks). This means that one can only acquire TL_READ, TL_READ_NO_INSERT, and similar table-level locks on table if one holds SR MDL lock on it. To be used for tables in SELECTs, subqueries, and LOCK TABLE ... READ statements.
MDL_SHARED_WRITE	A shared metadata lock (SW) for cases when there is an intention to modify (and not just read) data in the table. A connection holding SW lock can read table metadata and modify or read table data (after acquiring appropriate table and row-level locks). To be used for tables to be modified by INSERT, UPDATE, DELETE statements, but not LOCK TABLE ... WRITE or DDL). Also taken by SELECT ... FOR UPDATE.
MDL_SHARED_UPGRADABLE	An upgradable shared metadata lock for cases when there is an intention to modify (and not just read) data in the table. Can be upgraded to MDL_SHARED_NO_WRITE and MDL_EXCLUSIVE. A connection holding SU lock can read table metadata and modify or read table data (after acquiring appropriate table and row-level locks). To be used for the first phase of ALTER TABLE.
MDL_SHARED_READ_ONLY	A shared metadata lock for cases when we need to read data from table and block all concurrent modifications to it (for both data and metadata). Used by LOCK TABLES READ statement.
MDL_SHARED_NO_WRITE	An upgradable shared metadata lock which blocks all attempts to update table data, allowing reads. A connection holding this kind of lock can read table metadata and read table data. Can be upgraded to X metadata lock. Note, that since this type of lock is not compatible with SNRW or SW lock types, acquiring appropriate engine-level locks for reading (TL_READ* for MyISAM, shared row locks in InnoDB) should be contention-free. To be used for the first phase of ALTER TABLE, when copying data between tables, to allow concurrent SELECTs from the table, but not UPDATEs.

MDL_SHARED_NO_READ_WRITE	An upgradable shared metadata lock which allows other connections to access table metadata, but not data. It blocks all attempts to read or update table data, while allowing INFORMATION_SCHEMA and SHOW queries. A connection holding this kind of lock can read table metadata modify and read table data. Can be upgraded to X metadata lock. To be used for LOCK TABLES WRITE statement. Not compatible with any other lock type except S and SH.
MDL_EXCLUSIVE	An exclusive metadata lock (X). A connection holding this lock can modify both table's metadata and data. No other type of metadata lock can be granted while this lock is held. To be used for CREATE/DROP/RENAME TABLE statements and for execution of certain phases of other DDL statements.

Examples

First, install the `metadata_lock_info` plugin, if it is not already installed:

```
install plugin if not exists METADATA_LOCK_INFO soname "metadata_lock_info.so";
```

User lock:

```
SELECT GET_LOCK('abc',1000);
+-----+
| GET_LOCK('abc',1000) |
+-----+
|          1          |
+-----+

SELECT * FROM information_schema.METADATA_LOCK_INFO;
+-----+-----+-----+-----+-----+-----+
| THREAD_ID | LOCK_MODE          | LOCK_DURATION | LOCK_TYPE | TABLE_SCHEMA | TABLE_NAME |
+-----+-----+-----+-----+-----+-----+
|          61 | MDL_SHARED_NO_READ_WRITE | MDL_EXPLICIT | User lock | abc           |             |
+-----+-----+-----+-----+-----+-----+

```

Table metadata lock:

```
START TRANSACTION;

INSERT INTO t VALUES (1,2);

SELECT * FROM information_schema.METADATA_LOCK_INFO \G
***** 1. row *****
  THREAD_ID: 4
  LOCK_MODE: MDL_SHARED_WRITE
LOCK_DURATION: MDL_TRANSACTION
  LOCK_TYPE: Table metadata lock
  TABLE_SCHEMA: test
  TABLE_NAME: t
```

```
SELECT * FROM information_schema.METADATA_LOCK_INFO;
+-----+-----+-----+-----+-----+-----+
| THREAD_ID | LOCK_MODE | LOCK_DURATION | LOCK_TYPE | TABLE_SCHEMA | TABLE_NAME |
+-----+-----+-----+-----+-----+-----+
| 31 | MDL_INTENTION_EXCLUSIVE | MDL_EXPLICIT | Global read lock | | |
| 31 | MDL_INTENTION_EXCLUSIVE | MDL_EXPLICIT | Commit lock | | |
| 31 | MDL_INTENTION_EXCLUSIVE | MDL_EXPLICIT | Schema metadata lock | dbname | |
| 31 | MDL_SHARED_NO_READ_WRITE | MDL_EXPLICIT | Table metadata lock | dbname | exotics |
+-----+-----+-----+-----+-----+-----+

```

1.1.1.2.9.1.1.29 Information Schema

MROONGA_STATS Table

The [Information Schema](#) `MROONGA_STATS` table only exists if the [Mroonga](#) storage engine is installed, and contains information about its activities.

Column	Description
VERSION	Mroonga version.
rows_written	Number of rows written into Mroonga tables.
rows_read	Number of rows read from all Mroonga tables.

This table always contains 1 row.

1.1.1.2.9.1.1.30 Information Schema OPTIMIZER_TRACE Table

Description

The [Information Schema](#) `OPTIMIZER_TRACE` table contains [Optimizer Trace](#) information.

It contains the following columns:

Column	Description
QUERY	Displays the query that was asked to be traced.
TRACE	A JSON document displaying the stats we collected when the query was run.
MISSING_BYTES_BEYOND_MAX_MEM_SIZE	For huge trace, where the trace is truncated due to the <code>optimizer_trace_max_mem_size</code> limit being reached, displays the bytes that are missing in the trace
INSUFFICIENT_PRIVILEGES	Set to 1 if the user running the trace does not have the privileges to see the trace.

Structure:

```
SHOW CREATE TABLE INFORMATION_SCHEMA.OPTIMIZER_TRACE \G
***** 1. row *****
      Table: OPTIMIZER_TRACE
Create Table: CREATE TEMPORARY TABLE `OPTIMIZER_TRACE` (
  `QUERY` longtext NOT NULL DEFAULT '',
  `TRACE` longtext NOT NULL DEFAULT '',
  `MISSING_BYTES_BEYOND_MAX_MEM_SIZE` int(20) NOT NULL DEFAULT 0,
  `INSUFFICIENT_PRIVILEGES` tinyint(1) NOT NULL DEFAULT 0
) ENGINE=Aria DEFAULT CHARSET=utf8 PAGE_CHECKSUM=0
```

1.1.1.2.9.1.1.31 Information Schema PARAMETERS Table

The [Information Schema](#) `PARAMETERS` table stores information about [stored procedures](#) and [stored functions](#) parameters.

It contains the following columns:

Column	Description
SPECIFIC_CATALOG	Always <code>def</code> .
SPECIFIC_SCHEMA	Database name containing the stored routine parameter.
SPECIFIC_NAME	Stored routine name.
ORDINAL_POSITION	Ordinal position of the parameter, starting at <code>1</code> for a function RETURNS clause.
PARAMETER_MODE	One of <code>IN</code> , <code>OUT</code> , <code>INOUT</code> or <code>NULL</code> for RETURNS.

PARAMETER_NAME	Name of the parameter, or <code>NULL</code> for RETURNS.
DATA_TYPE	The column's data type .
CHARACTER_MAXIMUM_LENGTH	Maximum length.
CHARACTER_OCTET_LENGTH	Same as the <code>CHARACTER_MAXIMUM_LENGTH</code> except for multi-byte character sets .
NUMERIC_PRECISION	For numeric types, the precision (number of significant digits) for the column. <code>NULL</code> if not a numeric field.
NUMERIC_SCALE	For numeric types, the scale (significant digits to the right of the decimal point). <code>NULL</code> if not a numeric field.
DATETIME_PRECISION	Fractional-seconds precision, or <code>NULL</code> if not a time data type .
CHARACTER_SET_NAME	Character set if a non-binary string data type , otherwise <code>NULL</code> .
COLLATION_NAME	Collation if a non-binary string data type , otherwise <code>NULL</code> .
DTD_IDENTIFIER	Description of the data type.
ROUTINE_TYPE	PROCEDURE or FUNCTION.

Information from this table is similar to that found in the `param_list` column in the [mysql.proc](#) table, and the output of the [SHOW CREATE PROCEDURE](#) and [SHOW CREATE FUNCTION](#) statements.

To obtain information about the routine itself, you can query the [Information Schema ROUTINES table](#).

Example

```
SELECT * FROM information_schema.PARAMETERS
LIMIT 1 \G
***** 1. row *****
      SPECIFIC_CATALOG: def
      SPECIFIC_SCHEMA: accounts
      SPECIFIC_NAME: user_counts
      ORDINAL_POSITION: 1
      PARAMETER_MODE: IN
      PARAMETER_NAME: user_order
      DATA_TYPE: varchar
CHARACTER_MAXIMUM_LENGTH: 255
CHARACTER_OCTET_LENGTH: 765
      NUMERIC_PRECISION: NULL
      NUMERIC_SCALE: NULL
      DATETIME_PRECISION: NULL
      CHARACTER_SET_NAME: utf8
      COLLATION_NAME: utf8_general_ci
      DTD_IDENTIFIER: varchar(255)
      ROUTINE_TYPE: PROCEDURE
```

1.1.1.2.9.1.1.32 Information Schema PARTITIONS Table

The [Information Schema PARTITIONS](#) contains information about [table partitions](#), with each record corresponding to a single partition or subpartition of a partitioned table. Each non-partitioned table also has a record in the `PARTITIONS` table, but most of the values are `NULL`.

It contains the following columns:

Column	Description
TABLE_CATALOG	Always <code>def</code> .
TABLE_SCHEMA	Database name.
TABLE_NAME	Table name containing the partition.
PARTITION_NAME	Partition name.
SUBPARTITION_NAME	Subpartition name, or <code>NULL</code> if not a subpartition.

PARTITION_ORDINAL_POSITION	Order of the partition starting from 1.
SUBPARTITION_ORDINAL_POSITION	Order of the subpartition starting from 1.
PARTITION_METHOD	The partitioning type; one of RANGE , LIST , HASH , LINEAR HASH , KEY or LINEAR KEY .
SUBPARTITION_METHOD	Subpartition type; one of HASH , LINEAR HASH , KEY or LINEAR KEY , or NULL if not a subpartition.
PARTITION_EXPRESSION	Expression used to create the partition by the CREATE TABLE or ALTER TABLE statement.
SUBPARTITION_EXPRESSION	Expression used to create the subpartition by the CREATE TABLE or ALTER TABLE statement, or NULL if not a subpartition.
PARTITION_DESCRIPTION	For a RANGE partition, contains either MAXINTEGER or an integer, as set in the VALUES LESS THAN clause. For a LIST partition, contains a comma-separated list of integers, as set in the VALUES IN . For a SYSTEM_TIME INTERVAL partition, shows a defined upper boundary timestamp for historical values (the last history partition can contain values above the upper boundary). NULL if another type of partition.
TABLE_ROWS	Number of rows in the table (may be an estimate for some storage engines).
AVG_ROW_LENGTH	Average row length, that is DATA_LENGTH divided by TABLE_ROWS
DATA_LENGTH	Total number of bytes stored in all rows of the partition.
MAX_DATA_LENGTH	Maximum bytes that could be stored in the partition.
INDEX_LENGTH	Size in bytes of the partition index file.
DATA_FREE	Unused bytes allocated to the partition.
CREATE_TIME	Time the partition was created
UPDATE_TIME	Time the partition was last modified.
CHECK_TIME	Time the partition was last checked, or NULL for storage engines that don't record this information.
CHECKSUM	Checksum value, or NULL if none.
PARTITION_COMMENT	Partition comment, truncated to 80 characters, or an empty string if no comment.
NODEGROUP	Node group, only used for MySQL Cluster, defaults to 0 .
TABLESPACE_NAME	Always default .

1.1.1.2.9.1.1.33 Information Schema PERIODS Table

MariaDB starting with [11.4.1](#)

The [Information Schema](#) [PERIODS](#) table provides information about [Application-Time Periods](#).

It contains the following columns:

Column	Description
TABLE_CATALOG	Always contains the string 'def'.
TABLE_SCHEMA	Database name.
TABLE_NAME	Table name.
PERIOD	Period name.
START_COLUMN_NAME	Name of the column that starts the period.
END_COLUMN_NAME	Name of the column that ends the period.

Example

```
CREATE OR REPLACE TABLE t1(  
  name VARCHAR(50),  
  date_1 DATE,  
  date_2 DATE,  
  PERIOD FOR date_period(date_1, date_2)  
);  
  
SELECT * FROM INFORMATION_SCHEMA.PERIODS;  
+-----+-----+-----+-----+-----+-----+  
| TABLE_CATALOG | TABLE_SCHEMA | TABLE_NAME | PERIOD      | START_COLUMN_NAME | END_COLUMN_NAME |  
+-----+-----+-----+-----+-----+-----+  
| def            | test          | t1          | date_period | date_1            | date_2          |  
+-----+-----+-----+-----+-----+-----+
```

1.1.1.2.9.1.1.34 Information Schema PLUGINS Table

The [Information Schema](#) `PLUGINS` table contains information about [server plugins](#).

It contains the following columns:

Column	Description
PLUGIN_NAME	Name of the plugin.
PLUGIN_VERSION	Version from the plugin's general type descriptor.
PLUGIN_STATUS	Plugin status, one of <code>ACTIVE</code> , <code>INACTIVE</code> , <code>DISABLED</code> or <code>DELETED</code> .
PLUGIN_TYPE	Plugin type; <code>STORAGE ENGINE</code> , <code>INFORMATION_SCHEMA</code> , <code>AUTHENTICATION</code> , <code>REPLICATION</code> , <code>DAEMON</code> or <code>AUDIT</code> .
PLUGIN_TYPE_VERSION	Version from the plugin's type-specific descriptor.
PLUGIN_LIBRARY	Plugin's shared object file name, located in the directory specified by the <code>plugin_dir</code> system variable, and used by the <code>INSTALL PLUGIN</code> and <code>UNINSTALL PLUGIN</code> statements. <code>NULL</code> if the plugin is compiled in and cannot be uninstalled.
PLUGIN_LIBRARY_VERSION	Version from the plugin's API interface.
PLUGIN_AUTHOR	Author of the plugin.
PLUGIN_DESCRIPTION	Description.
PLUGIN_LICENSE	Plugin's licence.
LOAD_OPTION	How the plugin was loaded; one of <code>OFF</code> , <code>ON</code> , <code>FORCE</code> or <code>FORCE_PLUS_PERMANENT</code> . See Installing Plugins .
PLUGIN_MATURITY	Plugin's maturity level; one of <code>Unknown</code> , <code>Experimental</code> , <code>Alpha</code> , <code>Beta</code> , <code>'Gamma</code> , and <code>Stable</code> .
PLUGIN_AUTH_VERSION	Plugin's version as determined by the plugin author. An example would be '0.99 beta 1'.

It provides a superset of the information shown by the `SHOW PLUGINS` statement. For specific information about storage engines (a particular type of plugins), see the `information_schema.ENGINES` table and the `SHOW ENGINES` statement.

This table provides a subset of the Information Schema `information_schema.ALL_PLUGINS` table, which contains all available plugins, installed or not.

The table is not a standard Information Schema table, and is a MariaDB extension.

Examples

The easiest way to get basic information on plugins is with `SHOW PLUGINS`:

```
SHOW PLUGINS;
```

Name	Status	Type	Library	License
binlog	ACTIVE	STORAGE ENGINE	NULL	GPL
mysql_native_password	ACTIVE	AUTHENTICATION	NULL	GPL
mysql_old_password	ACTIVE	AUTHENTICATION	NULL	GPL
MRG_MyISAM	ACTIVE	STORAGE ENGINE	NULL	GPL
MyISAM	ACTIVE	STORAGE ENGINE	NULL	GPL
CSV	ACTIVE	STORAGE ENGINE	NULL	GPL
MEMORY	ACTIVE	STORAGE ENGINE	NULL	GPL
FEDERATED	ACTIVE	STORAGE ENGINE	NULL	GPL
PERFORMANCE_SCHEMA	ACTIVE	STORAGE ENGINE	NULL	GPL
Aria	ACTIVE	STORAGE ENGINE	NULL	GPL
InnoDB	ACTIVE	STORAGE ENGINE	NULL	GPL
INNODB_TRX	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_LOCKS	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_LOCK_WAITS	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_CMP	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_CMP_RESET	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_CMPMEM	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_CMPMEM_RESET	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_BUFFER_PAGE	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_BUFFER_PAGE_LRU	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_BUFFER_POOL_STATS	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_METRICS	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_FT_DEFAULT_STOPWORD	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_FT_INSERTED	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_FT_DELETED	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_FT_BEING_DELETED	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_FT_CONFIG	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_FT_INDEX_CACHE	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_FT_INDEX_TABLE	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_SYS_TABLES	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_SYS_TABLESTATS	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_SYS_INDEXES	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_SYS_COLUMNS	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_SYS_FIELDS	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_SYS_FOREIGN	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_SYS_FOREIGN_COLS	ACTIVE	INFORMATION SCHEMA	NULL	GPL
SPHINX	ACTIVE	STORAGE ENGINE	NULL	GPL
ARCHIVE	ACTIVE	STORAGE ENGINE	NULL	GPL
BLACKHOLE	ACTIVE	STORAGE ENGINE	NULL	GPL
FEEDBACK	DISABLED	INFORMATION SCHEMA	NULL	GPL
partition	ACTIVE	STORAGE ENGINE	NULL	GPL
pam	ACTIVE	AUTHENTICATION	auth_pam.so	GPL

```
SELECT LOAD_OPTION
FROM INFORMATION_SCHEMA.PLUGINS
WHERE PLUGIN_NAME LIKE 'tokudb';
Empty set
```

The equivalent **SELECT** query would be:

```
SELECT PLUGIN_NAME, PLUGIN_STATUS,
PLUGIN_TYPE, PLUGIN_LIBRARY, PLUGIN_LICENSE
FROM INFORMATION_SCHEMA.PLUGINS;
```

Other **SELECT** queries can be used to see additional information. For example:

```

SELECT PLUGIN_NAME, PLUGIN_DESCRIPTION,
PLUGIN_MATURITY, PLUGIN_AUTH_VERSION
FROM INFORMATION_SCHEMA.PLUGINS
WHERE PLUGIN_TYPE='STORAGE ENGINE'
ORDER BY PLUGIN_MATURITY \G

***** 1. row *****
      PLUGIN_NAME: FEDERATED
      PLUGIN_DESCRIPTION: FederatedX pluggable storage engine
      PLUGIN_MATURITY: Beta
      PLUGIN_AUTH_VERSION: 2.1
***** 2. row *****
      PLUGIN_NAME: Aria
      PLUGIN_DESCRIPTION: Crash-safe tables with MyISAM heritage
      PLUGIN_MATURITY: Gamma
      PLUGIN_AUTH_VERSION: 1.5
***** 3. row *****
      PLUGIN_NAME: PERFORMANCE_SCHEMA
      PLUGIN_DESCRIPTION: Performance Schema
      PLUGIN_MATURITY: Gamma
      PLUGIN_AUTH_VERSION: 0.1
***** 4. row *****
      PLUGIN_NAME: binlog
      PLUGIN_DESCRIPTION: This is a pseudo storage engine to represent the binlog in a transaction
      PLUGIN_MATURITY: Stable
      PLUGIN_AUTH_VERSION: 1.0
***** 5. row *****
      PLUGIN_NAME: MEMORY
      PLUGIN_DESCRIPTION: Hash based, stored in memory, useful for temporary tables
      PLUGIN_MATURITY: Stable

      PLUGIN_NAME: partition
      PLUGIN_DESCRIPTION: Partition Storage Engine Helper
      PLUGIN_MATURITY: Stable
      PLUGIN_AUTH_VERSION: 1.0

```

Check if a given plugin is available:

```

SELECT LOAD_OPTION
FROM INFORMATION_SCHEMA.PLUGINS
WHERE PLUGIN_NAME LIKE 'tokudb';
Empty set

```

Show authentication plugins:

```

SELECT PLUGIN_NAME, LOAD_OPTION
FROM INFORMATION_SCHEMA.PLUGINS
WHERE PLUGIN_TYPE LIKE 'authentication'

```

```

***** 1. row *****
PLUGIN_NAME: mysql_native_password
LOAD_OPTION: FORCE
***** 2. row *****
PLUGIN_NAME: mysql_old_password
LOAD_OPTION: FORCE

```

1.1.1.2.9.1.1.35 Information Schema PROCESSLIST Table

Contents

1. Example

The [Information Schema](#) `PROCESSLIST` table contains information about running threads.

Similar information can also be returned with the [SHOW \[FULL\] PROCESSLIST](#) statement, or the [mariadb-admin processlist](#) command.

It contains the following columns:

Column	Description
ID	Connection identifier.
USER	MariaDB User.
HOST	The hostname from which this thread is connected. For Unix socket connections, <code>localhost</code> . For TCP/IP connections, the TCP port is appended (e.g. <code>192.168.1.17:58061</code> or <code>other-host.company.com:58061</code>). For <code>system user</code> , this column is blank (<code>'</code>).
DB	Default database, or <code>NULL</code> if none.
COMMAND	Type of command running, corresponding to the <code>Com_ status variables</code> . See Thread Command Values .
TIME	Seconds that the thread has spent on the current <code>COMMAND</code> so far.
STATE	Current state of the thread. See Thread States .
INFO	Statement the thread is executing, or <code>NULL</code> if none.
TIME_MS	Time in milliseconds with microsecond precision that the thread has spent on the current <code>COMMAND</code> so far (see more).
STAGE	The stage the process is currently in.
MAX_STAGE	The maximum number of stages.
PROGRESS	The progress of the process within the current stage (0-100%).
MEMORY_USED	Memory in bytes used by the thread.
MAX_MEMORY_USED	Maximum memory in bytes used by the thread.
EXAMINED_ROWS	Rows examined by the thread. Only updated by UPDATE, DELETE, and similar statements. For SELECT and other statements, the value remains zero.
SENT_ROWS	Number of rows sent by the statement being executed. From MariaDB 11.3.0 .

QUERY_ID	Query ID.
INFO_BINARY	Binary data information
TID	Thread ID (MDEV-6756)
TMP_SPACE_USED	See Limiting Size of Created Disk Temporary Files and Tables Overview . From MariaDB 11.5 .

Note that as a difference to MySQL, in MariaDB the `TIME` column (and also the `TIME_MS` column) are not affected by any setting of `@TIMESTAMP` . This means that it can be reliably used also for threads that change `@TIMESTAMP` (such as the [replication SQL thread](#)). See also [MySQL Bug #22047](#) .

As a consequence of this, the `TIME` column of `SHOW FULL PROCESSLIST` and `INFORMATION_SCHEMA.PROCESSLIST` can not be used to determine if a slave is lagging behind. For this, use instead the `Seconds_Behind_Master` column in the output of `SHOW SLAVE STATUS` .

Note that the `PROGRESS` field from the information schema, and the `PROGRESS` field from `SHOW PROCESSLIST` display different results. `SHOW PROCESSLIST` shows the total progress, while the information schema shows the progress for the current stage only.. To retrieve a similar "total" Progress value from `information_schema.PROCESSLIST` as the one from `SHOW PROCESSLIST` , use

```
SELECT CASE WHEN Max_Stage < 2 THEN Progress ELSE (Stage-1)/Max_Stage*100+Progress/Max_Stage END
AS Progress FROM INFORMATION_SCHEMA.PROCESSLIST;
```

Example

```
SELECT * FROM INFORMATION_SCHEMA.PROCESSLIST\G
***** 1. row *****
      ID: 9
      USER: msandbox
      HOST: localhost
      DB: NULL
      COMMAND: Query
      TIME: 0
      STATE: Filling schema table
      INFO: SELECT * FROM INFORMATION_SCHEMA.PROCESSLIST
      TIME_MS: 0.351

1.1.1.2.9.1.1.36 Information Schema

PROFILING Table

The [Information Schema](#) `PROFILING` table contains information about statement resource usage. Profiling information is only recorded if the `profiling` session variable is set to 1.

It contains the following columns:

Column Name	Description
QUERY_ID	Query_ID.
SEQ	Sequence number showing the display order for rows with the same <code>QUERY_ID</code> .
STATE	Profiling state.
DURATION	Time in seconds that the statement has been in the current state.
CPU_USER	User CPU usage in seconds.
CPU_SYSTEM	System CPU usage in seconds.
CONTEXT_VOLUNTARY	Number of voluntary context switches.
CONTEXT_INVOLUNTARY	Number of involuntary context switches.
BLOCK_OPS_IN	Number of block input operations.
BLOCK_OPS_OUT	Number of block output operations.
MESSAGES_SENT	Number of communications sent.
MESSAGES_RECEIVED	Number of communications received.
PAGE_FAULTS_MAJOR	Number of major page faults.
PAGE_FAULTS_MINOR	Number of minor page faults.
SWAPS	Number of swaps.
SOURCE_FUNCTION	Function in the source code executed by the profiled state.
SOURCE_FILE	File in the source code executed by the profiled state.
SOURCE_LINE	Line in the source code executed by the profiled state.

It contains similar information to the `SHOW PROFILE` and `SHOW PROFILES` statements.

Profiling is enabled per session. When a session ends, its profiling information is lost.

1.1.1.2.9.1.1.37 Information Schema QUERY_CACHE_INFO Table

Description

The table is not a standard Information Schema table, and is a MariaDB extension.

The `QUERY_CACHE_INFO` table is created by the `QUERY_CACHE_INFO` plugin, and allows you to see the contents of the [query cache](#). It creates a table in the `information_schema` database that shows all queries that are in the cache. You must have the `PROCESS` privilege (see [GRANT](#)) to use this table.

It contains the following columns:

Column	Description
STATEMENT_SCHEMA	Database used when query was included
STATEMENT_TEXT	Query text
RESULT_BLOCKS_COUNT	Number of result blocks
RESULT_BLOCKS_SIZE	Size in bytes of result blocks
RESULT_BLOCKS_SIZE_USED	Size in bytes of used blocks

LIMIT	Added MariaDB 10.1.8 .
MAX_SORT_LENGTH	Added MariaDB 10.1.8 .
GROUP_CONCAT_MAX_LENGTH	Added MariaDB 10.1.8 .
CHARACTER_SET_CLIENT	Added MariaDB 10.1.8 .
CHARACTER_SET_RESULT	Added MariaDB 10.1.8 .
COLLATION	Added MariaDB 10.1.8 .
TIMEZONE	Added MariaDB 10.1.8 .
DEFAULT_WEEK_FORMAT	Added MariaDB 10.1.8 .
DIV_PRECISION_INCREMENT	Added MariaDB 10.1.8 .
SQL_MODE	Added MariaDB 10.1.8 .
LC_TIME_NAMES	Added MariaDB 10.1.8 .
CLIENT_LONG_FLAG	Added MariaDB 10.1.8 .
CLIENT_PROTOCOL_41	Added MariaDB 10.1.8 .
PROTOCOL_TYPE	Added MariaDB 10.1.8 .
MORE_RESULTS_EXISTS	Added MariaDB 10.1.8 .
IN_TRANS	Added MariaDB 10.1.8 .
AUTOCOMMIT	Added MariaDB 10.1.8 .
PACKET_NUMBER	Added MariaDB 10.1.8 .
HITS	Incremented each time the query cache is hit. Added MariaDB 10.3.2 .

For example:

```
SELECT * FROM information_schema.QUERY_CACHE_INFO;
+-----+-----+-----+-----+-----+
| STATEMENT_SCHEMA | STATEMENT_TEXT | RESULT_BLOCKS_COUNT | RESULT_BLOCKS_SIZE |
RESULT_BLOCKS_SIZE_USED |
+-----+-----+-----+-----+-----+
...
| test           | SELECT * FROM a | 1 | 512 |
143 |
| test           | select * FROM a | 1 | 512 |
143 |
...
+-----+-----+-----+-----+-----+
-----
```

1.1.1.2.9.1.1.38 Information Schema QUERY_RESPONSE_TIME Table

Description

The [Information Schema](#) `QUERY_RESPONSE_TIME` table contains information about queries that take a long time to execute . It is only available if the [QUERY_RESPONSE_TIME](#) plugin has been installed.

It contains the following columns:

Column	Description
TIME	Time interval
COUNT	Count of queries falling into the time interval

TOTAL	Total execution time of all queries for this interval
-------	---

See [QUERY_RESPONSE_TIME](#) plugin for a full description.

The table is not a standard Information Schema table, and is a MariaDB extension.

[SHOW QUERY_RESPONSE_TIME](#) is available as an alternative for retrieving the data.

Example

```
SELECT * FROM information_schema.QUERY_RESPONSE_TIME;
+-----+-----+-----+
| TIME          | COUNT | TOTAL          |
+-----+-----+-----+
| 0.000001     | 0     | 0.000000     |
| 0.000010     | 17    | 0.000094     |
| 0.000100     | 4301  | 0.236555     |
| 0.001000     | 1499  | 0.824450     |
| 0.010000     | 14851 | 81.680502    |
| 0.100000     | 8066  | 443.635693   |
| 1.000000     | 0     | 0.000000     |
| 10.000000    | 0     | 0.000000     |
| 100.000000   | 1     | 55.937094    |
| 1000.000000  | 0     | 0.000000     |
| 10000.000000 | 0     | 0.000000     |
| 100000.000000| 0     | 0.000000     |
| 1000000.000000| 0     | 0.000000     |
| TOO LONG     | 0     | TOO LONG     |
+-----+-----+-----+
```

1.1.1.2.9.1.1.39 Information Schema REFERENTIAL_CONSTRAINTS Table

The [Information Schema](#) `REFERENTIAL_CONSTRAINTS` table contains information about [foreign keys](#). The single columns are listed in the [KEY_COLUMN_USAGE](#) table.

It has the following columns:

Column	Description
CONSTRAINT_CATALOG	Always <code>def</code> .
CONSTRAINT_SCHEMA	Database name, together with <code>CONSTRAINT_NAME</code> identifies the foreign key.
CONSTRAINT_NAME	Foreign key name, together with <code>CONSTRAINT_SCHEMA</code> identifies the foreign key.
UNIQUE_CONSTRAINT_CATALOG	Always <code>def</code> .
UNIQUE_CONSTRAINT_SCHEMA	Database name, together with <code>UNIQUE_CONSTRAINT_NAME</code> and <code>REFERENCED_TABLE_NAME</code> identifies the referenced key.
UNIQUE_CONSTRAINT_NAME	Referenced key name, together with <code>UNIQUE_CONSTRAINT_SCHEMA</code> and <code>REFERENCED_TABLE_NAME</code> identifies the referenced key.
MATCH_OPTION	Always <code>NONE</code> .
UPDATE_RULE	The Update Rule; one of <code>CASCADE</code> , <code>SET NULL</code> , <code>SET DEFAULT</code> , <code>RESTRICT</code> , <code>NO ACTION</code> .
DELETE_RULE	The Delete Rule; one of <code>CASCADE</code> , <code>SET NULL</code> , <code>SET DEFAULT</code> , <code>RESTRICT</code> , <code>NO ACTION</code> .
TABLE_NAME	Table name from the <code>TABLE_CONSTRAINTS</code> table.
REFERENCED_TABLE_NAME	Referenced key table name, together with <code>UNIQUE_CONSTRAINT_SCHEMA</code> and <code>UNIQUE_CONSTRAINT_NAME</code> identifies the referenced key.

1.1.1.2.9.1.1.40 Information Schema

ROUTINES Table

The [Information Schema](#) `ROUTINES` table stores information about [stored procedures](#) and [stored functions](#).

It contains the following columns:

Column	Description
<code>SPECIFIC_NAME</code>	
<code>ROUTINE_CATALOG</code>	Always <code>def</code> .
<code>ROUTINE_SCHEMA</code>	Database name associated with the routine.
<code>ROUTINE_NAME</code>	Name of the routine.
<code>ROUTINE_TYPE</code>	Whether the routine is a <code>PROCEDURE</code> or a <code>FUNCTION</code> .
<code>DATA_TYPE</code>	The return value's data type (for stored functions).
<code>CHARACTER_MAXIMUM_LENGTH</code>	Maximum length.
<code>CHARACTER_OCTET_LENGTH</code>	Same as the <code>CHARACTER_MAXIMUM_LENGTH</code> except for multi-byte character sets .
<code>NUMERIC_PRECISION</code>	For numeric types, the precision (number of significant digits) for the column. <code>NULL</code> if not a numeric field.
<code>NUMERIC_SCALE</code>	For numeric types, the scale (significant digits to the right of the decimal point). <code>NULL</code> if not a numeric field.
<code>DATETIME_PRECISION</code>	Fractional-seconds precision, or <code>NULL</code> if not a time data type .
<code>CHARACTER_SET_NAME</code>	Character set if a non-binary string data type , otherwise <code>NULL</code> .
<code>COLLATION_NAME</code>	Collation if a non-binary string data type , otherwise <code>NULL</code> .
<code>DATA_TYPE</code>	The column's data type .
<code>ROUTINE_BODY</code>	Always <code>SQL</code> .
<code>ROUTINE_DEFINITION</code>	Definition of the routine.
<code>EXTERNAL_NAME</code>	Always <code>NULL</code> .
<code>EXTERNAL_LANGUAGE</code>	Always <code>SQL</code> .
<code>PARAMETER_STYLE</code>	Always <code>SQL</code> .
<code>IS_DETERMINISTIC</code>	Whether the routine is deterministic (can produce only one result for a given list of parameters) or not.
<code>SQL_DATA_ACCESS</code>	One of <code>READS SQL DATA</code> , <code>MODIFIES SQL DATA</code> , <code>CONTAINS SQL</code> , or <code>NO SQL</code> .
<code>SQL_PATH</code>	Always <code>NULL</code> .
<code>SECURITY_TYPE</code>	<code>INVOKER</code> or <code>DEFINER</code> . Indicates which user's privileges apply to this routine.
<code>CREATED</code>	Date and time the routine was created.
<code>LAST_ALTERED</code>	Date and time the routine was last changed.
<code>SQL_MODE</code>	The <code>SQL_MODE</code> at the time the routine was created.
<code>ROUTINE_COMMENT</code>	Comment associated with the routine.
<code>DEFINER</code>	If the <code>SECURITY_TYPE</code> is <code>DEFINER</code> , this value indicates which user defined this routine.
<code>CHARACTER_SET_CLIENT</code>	The character set used by the client that created the routine.
<code>COLLATION_CONNECTION</code>	The collation (and character set) used by the connection that created the routine.
<code>DATABASE_COLLATION</code>	The default collation (and character set) for the database, at the time the routine was created.

It provides information similar to, but more complete, than the `SHOW PROCEDURE STATUS` and `SHOW FUNCTION STATUS` statements.

For information about the parameters accepted by the routine, you can query the `information_schema.PARAMETERS` table.

1.1.1.2.9.1.1.41 Information Schema SCHEMA_PRIVILEGES Table

The [Information Schema](#) `SCHEMA_PRIVILEGES` table contains information about [database privileges](#).

It contains the following columns:

Column	Description
GRANTEE	Account granted the privilege in the format <code>user_name@host_name .</code>
TABLE_CATALOG	Always <code>def</code>
TABLE_SCHEMA	Database name.
PRIVILEGE_TYPE	The granted privilege.
IS_GRANTABLE	Whether the privilege can be granted.

The same information in a different format can be found in the [mysql.db](#) table.

1.1.1.2.9.1.1.42 Information Schema SCHEMATA Table

The [Information Schema](#) `SCHEMATA` table stores information about databases on the server.

It contains the following columns:

Column	Description
CATALOG_NAME	Always <code>def .</code>
SCHEMA_NAME	Database name.
DEFAULT_CHARACTER_SET_NAME	Default character set for the database.
DEFAULT_COLLATION_NAME	Default collation .
SQL_PATH	Always <code>NULL .</code>
SCHEMA_COMMENT	Database comment. From MariaDB 10.5.0 .

Example

```
SELECT * FROM INFORMATION_SCHEMA.SCHEMATA\G
***** 1. row *****
      CATALOG_NAME: def
      SCHEMA_NAME: information_schema
DEFAULT_CHARACTER_SET_NAME: utf8
      DEFAULT_COLLATION_NAME: utf8_general_ci
      SQL_PATH: NULL
***** 2. row *****
      CATALOG_NAME: def
      SCHEMA_NAME: mysql
DEFAULT_CHARACTER_SET_NAME: latin1
      DEFAULT_COLLATION_NAME: latin1_swedish_ci
      SQL_PATH: NULL
***** 3. row *****
      CATALOG_NAME: def
      SCHEMA_NAME: performance_schema
DEFAULT_CHARACTER_SET_NAME: utf8
      DEFAULT_COLLATION_NAME: utf8_general_ci
      SQL_PATH: NULL
***** 4. row *****
      CATALOG_NAME: def
      SCHEMA_NAME: test
DEFAULT_CHARACTER_SET_NAME: latin1
      DEFAULT_COLLATION_NAME: latin1_swedish_ci
      SQL_PATH: NULL
...

```

From [MariaDB 10.5.0](#):

```
SELECT * FROM INFORMATION_SCHEMA.SCHEMATA\G
...
***** 2. row *****
      CATALOG_NAME: def
      SCHEMA_NAME: presentations
DEFAULT_CHARACTER_SET_NAME: latin1
DEFAULT_COLLATION_NAME: latin1_swedish_ci
      SQL_PATH: NULL
      SCHEMA_COMMENT: Presentations for conferences
...
```

1.1.1.2.9.1.1.43 Information Schema SEQUENCES Table

MariaDB starting with [11.5](#)
The [Information Schema SEQUENCES](#) table stores information about [sequences](#) on the server.

It contains the following columns. See [CREATE SEQUENCE](#) for details.

Column	Description
SEQUENCE_CATALOG	Catalog name
SEQUENCE_SCHEMA	Database name
SEQUENCE_NAME	Sequence name
DATA_TYPE	Data type, for example <code>BIGINT</code> or <code>TINYINT UNSIGNED</code>
NUMERIC_PRECISION	
NUMERIC_PRECISION_RADIX	
NUMERIC_SCALE	
START_VALUE	
MINIMUM_VALUE	
MAXIMUM_VALUE	
INCREMENT	
CYCLE_OPTION	1 if the <code>CYCLE OPTION</code> is set, otherwise 0

Example

```
CREATE SEQUENCE s START WITH 100 INCREMENT BY 10;

SELECT * FROM INFORMATION_SCHEMA.SEQUENCES\G
***** 1. row *****
      SEQUENCE_CATALOG: def
      SEQUENCE_SCHEMA: test
      SEQUENCE_NAME: s
      DATA_TYPE: bigint
      NUMERIC_PRECISION: 64
NUMERIC_PRECISION_RADIX: 2
      NUMERIC_SCALE: 0
      START_VALUE: 100
      MINIMUM_VALUE: 1
      MAXIMUM_VALUE: 9223372036854775806
      INCREMENT: 10
      CYCLE_OPTION: 0
```

1.1.1.2.9.1.1.44 Information Schema SLAVE_STATUS Table

MariaDB starting with [11.6](#)

The [Information Schema](#) `SLAVE_STATUS` table contains replica status information, similar to [SHOW REPLICATION STATUS](#).

See [SHOW REPLICATION STATUS](#) for column descriptions.

1.1.1.2.9.1.1.45 Information Schema SPATIAL_REF_SYS Table

Description

The [Information Schema](#) `SPATIAL_REF_SYS` table stores information on each spatial reference system used in the database.

It contains the following columns:

Column	Type	Null	Description
SRID	smallint(5)	NO	An integer value that uniquely identifies each Spatial Reference System within a database.
AUTH_NAME	varchar(512)	NO	The name of the standard or standards body that is being cited for this reference system.
AUTH_SRID	smallint(5)	NO	The numeric ID of the coordinate system in the above authority's catalog.
SRTEXT	varchar(2048)	NO	The Well-known Text Representation of the Spatial Reference System.

Note: See [MDEV-7540](#).

See Also

- [information_schema.GEOMETRY_COLUMNS](#) table.

1.1.1.2.9.1.1.46 Information Schema SPIDER_ALLOC_MEM Table

The [Information Schema](#) `SPIDER_ALLOC_MEM` table is installed along with the [Spider](#) storage engine. It shows information about Spider's memory usage.

It contains the following columns:

Column	Description
ID	
FUNC_NAME	
FILE_NAME	
LINE_NO	
TOTAL_ALLOC_MEM	
CURRENT_ALLOC_MEM	
ALLOC_MEM_COUNT	
FREE_MEM_COUNT	

1.1.1.2.9.1.1.47 Information Schema SPIDER_WRAPPER_PROTOCOLS Table

MariaDB starting with [10.5.4](#)

The [Information Schema](#) `SPIDER_WRAPPER_PROTOCOLS` table is installed along with the [Spider](#) storage engine from [MariaDB 10.5.4](#).

It contains the following columns:

Column	Type	Description
WRAPPER_NAME	varchar(64)	
WRAPPER_VERSION	varchar(20)	
WRAPPER_DESCRIPTION	longtext	
WRAPPER_MATURITY	varchar(12)	

1.1.1.2.9.1.1.48 Information Schema SQL_FUNCTIONS Table

MariaDB starting with [10.5.12](#)

The `SQL_FUNCTIONS` table was added in [MariaDB 10.2.40](#), [MariaDB 10.3.31](#), [MariaDB 10.4.21](#), [MariaDB 10.5.12](#) and [MariaDB 10.6.3](#).

Description

The [Information Schema](#) `SQL_FUNCTIONS` table contains the list of [MariaDB functions](#).

It contains a single column:

Column	Description
FUNCTION	Function name

The table is not a standard Information Schema table, and is a MariaDB extension.

Example

```
SELECT * FROM INFORMATION_SCHEMA.SQL_FUNCTIONS;
```

```
+-----+
| FUNCTION          |
+-----+
| ADDDATE           |
| ADD_MONTHS        |
| BIT_AND           |
| BIT_OR            |
| BIT_XOR           |
| CAST              |
| COUNT             |
| CUME_DIST         |
| CURDATE           |
| CURTIME           |
| DATE_ADD          |
| DATE_SUB          |
| DATE_FORMAT       |
| DECODE            |
| DENSE_RANK        |
| EXTRACT           |
| FIRST_VALUE       |
| GROUP_CONCAT      |
| JSON_ARRAYAGG     |
| JSON_OBJECTAGG    |
| LAG               |

1.1.1.2.9.1.1.49 Information Schema STATISTICS Table

The [Information Schema](#) `STATISTICS` table provides information about table indexes.

It contains the following columns:

Column	Description
TABLE_CATALOG	Always <code>def</code> .
TABLE_SCHEMA	Database name.
TABLE_NAME	Table name.
NON_UNIQUE	1 if the index can have duplicates, 0 if not.
INDEX_SCHEMA	Database name.
INDEX_NAME	Index name. The primary key is always named <code>PRIMARY</code> .
SEQ_IN_INDEX	The column sequence number, starting at 1.
COLUMN_NAME	Column name.
COLLATION	A for sorted in ascending order, or <code>NULL</code> for unsorted.
CARDINALITY	Estimate of the number of unique values stored in the index based on statistics stored as integers. Higher cardinalities usually mean a greater chance of the index being used in a join. Updated by the ANALYZE TABLE statement or <code>mysamchk -a</code> .
SUB_PART	<code>NULL</code> if the whole column is indexed, or the number of indexed characters if partly indexed.
PACKED	<code>NULL</code> if not packed, otherwise how the index is packed.
NULLABLE	<code>YES</code> if the column may contain <code>NULL</code> s, empty string if not.
INDEX_TYPE	Index type, one of <code>BTREE</code> , <code>RTREE</code> , <code>HASH</code> or <code>FULLTEXT</code> . See Storage Engine Index Types .
COMMENT	Index comments from the CREATE INDEX statement.
IGNORED	Whether or not an index will be ignored by the optimizer. See Ignored Indexes . From MariaDB 10.6.0 .

The `SHOW INDEX` statement produces similar output.

Example

```
SELECT * FROM INFORMATION_SCHEMA.STATISTICS\G
...
***** 85. row *****
TABLE_CATALOG: def
TABLE_SCHEMA: test
TABLE_NAME: table1
NON_UNIQUE: 1
INDEX_SCHEMA: test
INDEX_NAME: col2
SEQ_IN_INDEX: 1
COLUMN_NAME: col2
COLLATION: A
CARDINALITY: 6
SUB_PART: NULL
PACKED: NULL
NULLABLE:
INDEX_TYPE: BTREE
COMMENT:
INDEX_COMMENT:
...
```

1.1.1.2.9.1.1.50 Information Schema SYSTEM_VARIABLES Table

The [Information Schema](#) `SYSTEM_VARIABLES` table shows current values and various metadata of all [system variables](#).

It contains the following columns:

Column	Description
--------	-------------

VARIABLE_NAME	System variable name.
SESSION_VALUE	Session value of the variable or NULL if the variable only has a global scope.
GLOBAL_VALUE	Global value of the variable or NULL if the variable only has a session scope.
GLOBAL_VALUE_ORIGIN	How the global value was set — a compile-time default, auto-configured by the server, configuration file (or a command line), with the SQL statement.
DEFAULT_VALUE	Compile-time default value of the variable.
VARIABLE_SCOPE	Global, session, or session-only.
VARIABLE_TYPE	Data type of the variable value.
VARIABLE_COMMENT	Help text, usually shown in <code>mariadb --help --verbose</code> .
NUMERIC_MIN_VALUE	For numeric variables — minimal allowed value.
NUMERIC_MAX_VALUE	For numeric variables — maximal allowed value.
NUMERIC_BLOCK_SIZE	For numeric variables — a valid value must be a multiple of the "block size".
ENUM_VALUE_LIST	For <code>ENUM</code> , <code>SET</code> , and <code>FLAGSET</code> variables — the list of recognized values.
READ_ONLY	Whether a variable can be set with the SQL statement. Note that many "read only" variables can still be set on the command line.
COMMAND_LINE_ARGUMENT	Whether an argument is required when setting the variable on the command line. <code>NULL</code> when a variable can not be set on the command line.
GLOBAL_VALUE_PATH	Which config file the variable got its value from. <code>NULL</code> if not set in any config file. Added in MariaDB 10.5.0 .

Example

```

SELECT * FROM information_schema.SYSTEM_VARIABLES
WHERE VARIABLE_NAME='JOIN_BUFFER_SIZE'\G
***** 1. row *****
VARIABLE_NAME: JOIN_BUFFER_SIZE
SESSION_VALUE: 131072
GLOBAL_VALUE: 131072
GLOBAL_VALUE_ORIGIN: COMPILE-TIME
DEFAULT_VALUE: 131072
VARIABLE_SCOPE: SESSION
VARIABLE_TYPE: BIGINT UNSIGNED
VARIABLE_COMMENT: The size of the buffer that is used for joins
NUMERIC_MIN_VALUE: 128
NUMERIC_MAX_VALUE: 18446744073709551615
NUMERIC_BLOCK_SIZE: 128
ENUM_VALUE_LIST: NULL
READ_ONLY: NO
COMMAND_LINE_ARGUMENT: REQUIRED

```

1.1.1.2.9.1.1.51 Information Schema TABLE_CONSTRAINTS Table

The [Information Schema](#) `TABLE_CONSTRAINTS` table contains information about tables that have [constraints](#).

It has the following columns:

Column	Description
CONSTRAINT_CATALOG	Always <code>def</code> .
CONSTRAINT_SCHEMA	Database name containing the constraint.
CONSTRAINT_NAME	Constraint name.
TABLE_SCHEMA	Database name.
TABLE_NAME	Table name.

The [REFERENTIAL_CONSTRAINTS](#) table has more information about foreign keys.

1.1.1.2.9.1.1.52 Information Schema TABLE_PRIVILEGES Table

The [Information Schema](#) `TABLE_PRIVILEGES` table contains table privilege information derived from the `mysql.tables_priv` grant table.

It has the following columns:

Column	Description
GRANTEE	In the format <code>user_name@host_name</code> .
TABLE_CATALOG	Always <code>def</code> .
TABLE_SCHEMA	Database name.
TABLE_NAME	Table name.
PRIVILEGE_TYPE	One of <code>SELECT</code> , <code>INSERT</code> , <code>UPDATE</code> , <code>REFERENCES</code> , <code>ALTER</code> , <code>INDEX</code> , <code>DROP</code> or <code>CREATE VIEW</code> .
IS_GRANTABLE	Whether the user has the GRANT OPTION for this privilege.

Similar information can be accessed with the [SHOW GRANTS](#) statement. See the [GRANT](#) article for more about privileges.

The table only shows privileges granted on the table level. This differs from the Sys Schema [privileges_by_table_by_level](#) view, which shows all privileges, broken down by table.

For a description of the privileges that are shown in this table, see [table privileges](#).

1.1.1.2.9.1.1.53 Information Schema TABLE_STATISTICS Table

The [Information Schema](#) `TABLE_STATISTICS` table shows statistics on table usage.

This is part of the [User Statistics](#) feature, which is not enabled by default.

It contains the following columns:

Field	Type	Notes
TABLE_SCHEMA	<code>varchar(192)</code>	The schema (database) name.
TABLE_NAME	<code>varchar(192)</code>	The table name.
ROWS_READ	<code>bigint(21)</code>	The number of rows read from the table.
ROWS_CHANGED	<code>bigint(21)</code>	The number of rows changed in the table.
ROWS_CHANGED_X_INDEXES	<code>bigint(21)</code>	The number of rows changed in the table, multiplied by the number of indexes changed.
ROWS_INSERTED	<code>bigint(21)</code>	From MariaDB 11.5
ROWS_UPDATED	<code>bigint(21)</code>	From MariaDB 11.5
ROWS_DELETED	<code>bigint(21)</code>	From MariaDB 11.5
KEY_READ_HITS	<code>bigint(21)</code>	From MariaDB 11.5
KEY_READ_MISSES	<code>bigint(21)</code>	From MariaDB 11.5

Example

```
SELECT * FROM INFORMATION_SCHEMA.TABLE_STATISTICS WHERE TABLE_NAME='user';
```

TABLE_SCHEMA	TABLE_NAME	ROWS_READ	ROWS_CHANGED	ROWS_CHANGED_X_INDEXES
mysql	user	5	2	2

1.1.1.2.9.1.1.54 Information Schema TABLES Table

Contents

- Examples
 - View Tables in Order of Size

The [Information Schema](#) table shows information about the various tables (until [MariaDB 11.2.0](#), only non- `TEMPORARY` tables, except for tables from the `Information Schema` database) and [views](#) on the server.

It contains the following columns:

Column	Description
<code>TABLE_CATALOG</code>	Always <code>def.</code>
<code>TABLE_SCHEMA</code>	Database name.
<code>TABLE_NAME</code>	Table name.
<code>TABLE_TYPE</code>	One of <code>BASE TABLE</code> for a regular table, <code>VIEW</code> for a view , <code>SYSTEM VIEW</code> for Information Schema tables, <code>SYSTEM VERSIONED</code> for system-versioned tables , <code>SEQUENCE</code> for sequences or, from MariaDB 11.2.0 , <code>TEMPORARY</code> for local temporary tables.
<code>ENGINE</code>	Storage Engine .
<code>VERSION</code>	Version number from the table's <code>.frm</code> file
<code>ROW_FORMAT</code>	Row format (see InnoDB , Aria and MyISAM row formats).
<code>TABLE_ROWS</code>	Number of rows in the table. Some engines, such as XtraDB and InnoDB may store an estimate.
<code>AVG_ROW_LENGTH</code>	Average row length in the table.
<code>DATA_LENGTH</code>	For InnoDB/XtraDB , the index size, in pages, multiplied by the page size. For Aria and MyISAM , length of the data file, in bytes. For MEMORY , the approximate allocated memory.
<code>MAX_DATA_LENGTH</code>	Maximum length of the data file, ie the total number of bytes that could be stored in the table. Not used in XtraDB and InnoDB .
<code>INDEX_LENGTH</code>	Length of the index file.
<code>DATA_FREE</code>	Bytes allocated but unused. For InnoDB tables in a shared tablespace, the free space of the shared tablespace with small safety margin. An estimate in the case of partitioned tables - see the PARTITIONS table.
<code>AUTO_INCREMENT</code>	Next AUTO_INCREMENT value.
<code>CREATE_TIME</code>	Time the table was created. Some engines just return the <code>ctime</code> information from the file system layer here, in that case the value is not necessarily the table creation time but rather the time the file system metadata for it had last changed.
<code>UPDATE_TIME</code>	Time the table was last updated. On Windows, the timestamp is not updated on update, so MyISAM values will be inaccurate. In InnoDB , if shared tablespaces are used, will be <code>NULL</code> , while buffering can also delay the update, so the value will differ from the actual time of the last <code>UPDATE</code> , <code>INSERT</code> or <code>DELETE</code> .
<code>CHECK_TIME</code>	Time the table was last checked. Not kept by all storage engines, in which case will be <code>NULL</code> .
<code>TABLE_COLLATION</code>	Character set and collation .
<code>CHECKSUM</code>	Live checksum value, if any.
<code>CREATE_OPTIONS</code>	Extra CREATE TABLE options.
<code>TABLE_COMMENT</code>	Table comment provided when MariaDB created the table.

MAX_INDEX_LENGTH	Maximum index length (supported by MyISAM and Aria tables). Added in MariaDB 10.3.5 .
TEMPORARY	Until MariaDB 11.2.0 , placeholder to signal that a table is a temporary table and always "N", except "Y" for generated information_schema tables and NULL for views. From MariaDB 11.2.0 , will also be set to "Y" for local temporary tables. Added in MariaDB 10.3.5 .

Although the table is standard in the Information Schema, all but `TABLE_CATALOG`, `TABLE_SCHEMA`, `TABLE_NAME`, `TABLE_TYPE`, `ENGINE` and `VERSION` are MySQL and MariaDB extensions.

`SHOW TABLES` lists all tables in a database.

Examples

From [MariaDB 10.3.5](#):

```
SELECT * FROM information_schema.tables WHERE table_schema='test'\G
***** 1. row *****
TABLE_CATALOG: def
TABLE_SCHEMA: test
TABLE_NAME: xx5
TABLE_TYPE: BASE TABLE
ENGINE: InnoDB
VERSION: 10
ROW_FORMAT: Dynamic
TABLE_ROWS: 0
AVG_ROW_LENGTH: 0
DATA_LENGTH: 16384
MAX_DATA_LENGTH: 0
INDEX_LENGTH: 0
DATA_FREE: 0
AUTO_INCREMENT: NULL
CREATE_TIME: 2020-11-18 15:57:10
UPDATE_TIME: NULL
CHECK_TIME: NULL
TABLE_COLLATION: latin1_swedish_ci
CHECKSUM: NULL
CREATE_OPTIONS:
TABLE_COMMENT:
MAX_INDEX_LENGTH: 0
TEMPORARY: N
***** 2. row *****
TABLE_CATALOG: def
TABLE_SCHEMA: test
TABLE_NAME: xx4
TABLE_TYPE: BASE TABLE
ENGINE: MyISAM
VERSION: 10
ROW_FORMAT: Fixed
TABLE_ROWS: 0
AVG_ROW_LENGTH: 0
DATA_LENGTH: 0
MAX_DATA_LENGTH: 1970324836974591
INDEX_LENGTH: 1024
DATA_FREE: 0
AUTO_INCREMENT: NULL
CREATE_TIME: 2020-11-18 15:56:57
UPDATE_TIME: 2020-11-18 15:56:57
CHECK_TIME: NULL
TABLE_COLLATION: latin1_swedish_ci
CHECKSUM: NULL
CREATE_OPTIONS:
TABLE_COMMENT:
MAX_INDEX_LENGTH: 17179868160
TEMPORARY: N
...
```

Example with temporary = 'y', from [MariaDB 10.3.5](#):

```

SELECT * FROM information_schema.tables WHERE temporary='y'\G
***** 1. row *****
TABLE_CATALOG: def
TABLE_SCHEMA: information_schema
TABLE_NAME: INNODB_FT_DELETED
TABLE_TYPE: SYSTEM VIEW
ENGINE: MEMORY
VERSION: 11
ROW_FORMAT: Fixed
TABLE_ROWS: NULL
AVG_ROW_LENGTH: 9
DATA_LENGTH: 0
MAX_DATA_LENGTH: 9437184
INDEX_LENGTH: 0
DATA_FREE: 0
AUTO_INCREMENT: NULL
CREATE_TIME: 2020-11-17 21:54:02
UPDATE_TIME: NULL
CHECK_TIME: NULL
TABLE_COLLATION: utf8_general_ci
CHECKSUM: NULL
CREATE_OPTIONS: max_rows=1864135
TABLE_COMMENT:
MAX_INDEX_LENGTH: 0
TEMPORARY: Y
...

```

View Tables in Order of Size

Returns a list of all tables in the database, ordered by size:

```

SELECT table_schema as `DB`, table_name AS `Table`,
ROUND(((data_length + index_length) / 1024 / 1024), 2) `Size (MB)`
FROM information_schema.TABLES
ORDER BY (data_length + index_length) DESC;

```

```

+-----+-----+-----+
| DB          | Table                               | Size (MB) |
+-----+-----+-----+
| wordpress   | wp_simple_history_contexts          | 7.05 |
| wordpress   | wp_posts                            | 6.59 |
| wordpress   | wp_simple_history                   | 3.05 |
| wordpress   | wp_comments                         | 2.73 |
| wordpress   | wp_commentmeta                     | 2.47 |
| wordpress   | wp_simple_login_log                 | 2.03 |
...

```

From [MariaDB 11.2.0](#)

```

CREATE TEMPORARY TABLE foo.t1 (a int);

SELECT * FROM INFORMATION_SCHEMA.TABLES WHERE TABLE_SCHEMA='foo' AND TEMPORARY='y'\G
***** 1. row *****
TABLE_CATALOG: def
TABLE_SCHEMA: foo
TABLE_NAME: t1
TABLE_TYPE: TEMPORARY
...
TEMPORARY: Y

```

1.1.1.2.9.1.1.55 Information Schema TABLESPACES Table

The [Information Schema](#) TABLESPACES table contains information about active tablespaces..

The table is a MariaDB and MySQL extension, and does not include information about InnoDB tablespaces.

Column	Description
--------	-------------

TABLESPACE_NAME	
ENGINE	
TABLESPACE_TYPE	
LOGFILE_GROUP_NAME	
EXTENT_SIZE	
AUTOEXTEND_SIZE	
MAXIMUM_SIZE	
NODEGROUP_ID	
TABLESPACE_COMMENT	

1.1.1.2.9.1.1.56 Information Schema THREAD_POOL_GROUPS Table

MariaDB starting with [10.5](#)

The [Information Schema](#) `THREAD_POOL_GROUPS` table was introduced in [MariaDB 10.5.0](#).

The table provides information about [thread pool](#) groups, and contains the following columns:

Column	Description
GROUP_ID	the thread group this row is showing data for
CONNECTIONS	the number of clients currently connected to this thread group
THREADS	total number of threads in this group (ACTIVE+STANDBY+LISTENER)
ACTIVE_THREADS	number of threads currently executing a query
STANDBY_THREADS	number of threads in reserve that do not currently execute anything
QUEUE_LENGTH	number of client requests waiting for execution
HAS_LISTENER	whether there is an active listener thread right now, always 1 if thread_pool_dedicated_listener is ON
IS_STALLED	whether there's currently an active worker thread in this group that has exceeded thread_pool_stall_limit time

Setting [thread_pool_dedicated_listener](#) will give each group its own dedicated listener, and the listener thread will not pick up work items. As a result, the actual queue size in the table will be more exact, since IO requests are immediately dequeued from poll, without delay.

1.1.1.2.9.1.1.57 Information Schema THREAD_POOL_QUEUES Table

MariaDB starting with [10.5](#)

The [Information Schema](#) `THREAD_POOL_QUEUES` table was introduced in [MariaDB 10.5.0](#).

The table provides information about [thread pool](#) queues, and contains the following columns:

Column	Description
GROUP_ID	the thread group this row is showing data for
POSITION	position in the groups queue
PRIORITY	request priority, see priority scheduling
CONNECTION_ID	ID of the client connection that submitted the queued request

QUEUEING_TIME_MICROSECONDS	how long the request has already been waiting in the queue in microseconds
----------------------------	--

Setting [thread_poll_exact_stats](#) will provides better queueing time statistics by using a high precision timestamp, at a small performance cost, for the time when the connection was added to the queue. This timestamp helps calculate the queueing time shown in the table.

Setting [thread_pool_dedicated_listener](#) will give each group its own dedicated listener, and the listener thread will not pick up work items. As a result, the queueing time in the table will be more exact, since IO requests are immediately dequeued from poll, without delay.

1.1.1.2.9.1.1.58 Information Schema THREAD_POOL_STATS Table

MariaDB starting with [10.5](#)

The [Information Schema](#) `THREAD_POOL_STATS` table was introduced in [MariaDB 10.5.0](#).

The table provides performance counter information for the [thread pool](#), and contains the following columns:

Column	Description
GROUP_ID	the thread group this row is showing data for
THREAD_CREATIONS	number of threads created for this group so far
THREAD_CREATIONS_DUE_TO_STALL	number of threads created due to detected stalls
WAKES	standby thread wakeups
WAKES_DUE_TO_STALL	wakeups due to stalls
THROTTLES	how often thread creation was throttled, see also: thread-creation-throttling
STALLS	number of detected stalls
POLLS_BY_LISTENER	
POLLS_BY_WORKER	
DEQUEUEES_BY_LISTENER	
DEQUEUEES_BY_WORKER	

1.1.1.2.9.1.1.59 Information Schema THREAD_POOL_WAITS Table

MariaDB starting with [10.5](#)

The [Information Schema](#) `THREAD_POOL_WAITS` table was introduced in [MariaDB 10.5.0](#).

The table provides wait counters for the [thread pool](#), and contains the following columns:

Column	Description
REASON	name of the reason for waiting, e.g. ROW_LOCK, DISKIO, NET ...
COUNT	how often a wait for this specific reason has happened so far

1.1.1.2.9.1.1.60 Information Schema TRIGGERS Table

Contents

The [Information Schema](#) `TRIGGERS` table contains information about [triggers](#).

It has the following columns:

Column	Description
TRIGGER_CATALOG	Always <code>def</code> .
TRIGGER_SCHEMA	Database name in which the trigger occurs.
TRIGGER_NAME	Name of the trigger.
EVENT_MANIPULATION	The event that activates the trigger. One of <code>INSERT</code> , <code>UPDATE</code> or <code>'DELETE</code> .
EVENT_OBJECT_CATALOG	Always <code>def</code> .
EVENT_OBJECT_SCHEMA	Database name on which the trigger acts.
EVENT_OBJECT_TABLE	Table name on which the trigger acts.
ACTION_ORDER	Indicates the order that the action will be performed in (of the list of a table's triggers with identical <code>EVENT_MANIPULATION</code> and <code>ACTION_TIMING</code> values). Before MariaDB 10.2.3 introduced the <code>FOLLOWS</code> and <code>PRECEDES</code> clauses, always <code>0</code> .
ACTION_CONDITION	<code>NULL</code> .
ACTION_STATEMENT	Trigger body, UTF-8 encoded.
ACTION_ORIENTATION	Always <code>ROW</code> .
ACTION_TIMING	Whether the trigger acts <code>BEFORE</code> or <code>AFTER</code> the event that triggers it.
ACTION_REFERENCE_OLD_TABLE	Always <code>NULL</code> .
ACTION_REFERENCE_NEW_TABLE	Always <code>NULL</code> .
ACTION_REFERENCE_OLD_ROW	Always <code>OLD</code> .
ACTION_REFERENCE_NEW_ROW	Always <code>NEW</code> .
CREATED	Always <code>NULL</code> .
SQL_MODE	The <code>SQL_MODE</code> when the trigger was created, and which it uses for execution.
DEFINER	The account that created the trigger, in the form <code>user_name@host_name</code> .
CHARACTER_SET_CLIENT	The client <code>character set</code> when the trigger was created, from the session value of the <code>character_set_client</code> system variable.
COLLATION_CONNECTION	The client <code>collation</code> when the trigger was created, from the session value of the <code>collation_connection</code> system variable.
DATABASE_COLLATION	<code>Collation</code> of the associated database.

Queries to the `TRIGGERS` table will return information only for databases and tables for which you have the `TRIGGER` privilege. Similar information is returned by the `SHOW TRIGGERS` statement.

1.1.1.2.9.1.1.61 Information Schema USER_PRIVILEGES Table

The [Information Schema](#) `USER_PRIVILEGES` table contains global user privilege information derived from the `mysql.global_priv` grant table.

It contains the following columns:

Column	Description
GRANTEE	In the format <code>user_name@host_name</code> .
TABLE_CATALOG	Always <code>def</code> .
PRIVILEGE_TYPE	The specific privilege, for example <code>CREATE USER</code> , <code>RELOAD</code> , <code>SHUTDOWN</code> , <code>SELECT</code> , <code>INSERT</code> , <code>UPDATE</code> or <code>REFERENCES</code> .
IS_GRANTABLE	Whether the user has the <code>GRANT OPTION</code> for this privilege.

The database, table and column privileges returned here are the ones granted on all databases and tables, and by implication all columns.

Similar information can be accessed with the `SHOW GRANTS` statement. See the [GRANT](#) article for more about privileges.

This information is also stored in the [mysql.global_priv](#) table, in the `mysql` system database.

1.1.1.2.9.1.1.62 Information Schema USER_STATISTICS Table

The [Information Schema](#) `USER_STATISTICS` table holds statistics about user activity. This is part of the [User Statistics](#) feature, which is not enabled by default.

You can use this table to find out such things as which user is causing the most load and which users are being abusive. You can also use this table to measure how close to capacity the server may be.

It contains the following columns:

Field	Type	Notes
USER	<code>varchar(48)</code>	The username. The value <code>'#mysql_system_user#'</code> appears when there is no username (such as for the slave SQL thread).
TOTAL_CONNECTIONS	<code>int(11)</code>	The number of connections created for this user.
CONCURRENT_CONNECTIONS	<code>int(11)</code>	The number of concurrent connections for this user.
CONNECTED_TIME	<code>int(11)</code>	The cumulative number of seconds elapsed while there were connections from this user.
BUSY_TIME	<code>double</code>	The cumulative number of seconds there was activity on connections from this user.
CPU_TIME	<code>double</code>	The cumulative CPU time elapsed while servicing this user's connections.
BYTES_RECEIVED	<code>bigint(21)</code>	The number of bytes received from this user's connections.
BYTES_SENT	<code>bigint(21)</code>	The number of bytes sent to this user's connections.
BINLOG_BYTES_WRITTEN	<code>bigint(21)</code>	The number of bytes written to the binary log from this user's connections.
ROWS_READ	<code>bigint(21)</code>	The number of rows read by this user's connections.
ROWS_SENT	<code>bigint(21)</code>	The number of rows sent by this user's connections.
ROWS_DELETED	<code>int(21)</code>	The number of rows deleted by this user's connections.
ROWS_INSERTED	<code>bigint(21)</code>	The number of rows inserted by this user's connections.
ROWS_UPDATED	<code>bigint(21)</code>	The number of rows updated by this user's connections.
KEY_READ_HITS	<code>bigint(21)</code>	From MariaDB 11.5
KEY_READ_MISSES	<code>bigint(21)</code>	From MariaDB 11.5
SELECT_COMMANDS	<code>bigint(21)</code>	The number of <code>SELECT</code> commands executed from this user's connections.
UPDATE_COMMANDS	<code>bigint(21)</code>	The number of <code>UPDATE</code> commands executed from this user's connections.
OTHER_COMMANDS	<code>bigint(21)</code>	The number of other commands executed from this user's connections.
COMMIT_TRANSACTIONS	<code>bigint(21)</code>	The number committed transactions. Note that in autocommit mode every statement is a separate transaction.
ROLLBACK_TRANSACTIONS	<code>bigint(21)</code>	The number of transactions that were rolled back.
DENIED_CONNECTIONS	<code>bigint(21)</code>	The number of connections denied to this user.
LOST_CONNECTIONS	<code>bigint(21)</code>	The number of this user's connections that were terminated uncleanly.
ACCESS_DENIED	<code>bigint(21)</code>	The number of times this user's connections issued commands that were denied.

EMPTY_QUERIES	bigint (21)	The number of times this user's connections sent queries to the server that did not return data to the client (a per-user aggregate of the empty_queries status variable).
TOTAL_SSL_CONNECTIONS	bigint (21)	The number of TLS connections created for this user.
MAX_STATEMENT_TIME_EXCEEDED	bigint (21)	The number of times a statement was aborted, because it was executed longer than its MAX_STATEMENT_TIME threshold.

Example

```

SELECT * FROM information_schema.USER_STATISTICS\G
***** 1. row *****
      USER: root
      TOTAL_CONNECTIONS: 1
      CONCURRENT_CONNECTIONS: 0
      CONNECTED_TIME: 297
      BUSY_TIME: 0.001725
      CPU_TIME: 0.001982
      BYTES_RECEIVED: 388
      BYTES_SENT: 2327
      BINLOG_BYTES_WRITTEN: 0
      ROWS_READ: 0
      ROWS_SENT: 12
      ROWS_DELETED: 0
      ROWS_INSERTED: 13
      ROWS_UPDATED: 0
      SELECT_COMMANDS: 4
      UPDATE_COMMANDS: 0
      OTHER_COMMANDS: 3
      COMMIT_TRANSACTIONS: 0
      ROLLBACK_TRANSACTIONS: 0
      DENIED_CONNECTIONS: 0
      LOST_CONNECTIONS: 0
      ACCESS_DENIED: 0
      EMPTY_QUERIES: 1

```

1.1.1.2.9.1.1.63 Information Schema USER_VARIABLES Table

Contents

1. [Description](#)
2. [Example](#)

Description

The `USER_VARIABLES` table is created when the [user_variables](#) plugin is enabled, and contains information about [user-defined variables](#).

The table contains the following columns:

Column	Description
VARIABLE_NAME	Variable name.
VARIABLE_VALUE	Variable value.
VARIABLE_TYPE	Variable type .
CHARACTER_SET_NAME	Character set .

User variables are reset and the table emptied with the [FLUSH USER_VARIABLES](#) statement. `SHOW USER_VARIABLES` displays a subset of the data.

Example

```

SET @v1 = 0;
SET @v2 = 'abc';
SET @v3 = CAST(123 AS CHAR(5));

SELECT * FROM information_schema.USER_VARIABLES ORDER BY VARIABLE_NAME;
+-----+-----+-----+-----+
| VARIABLE_NAME | VARIABLE_VALUE | VARIABLE_TYPE | CHARACTER_SET_NAME |
+-----+-----+-----+-----+
| v1            | 0              | INT           | latin1              |
| v2            | abc            | VARCHAR       | utf8                 |
| v3            | 123            | VARCHAR       | utf8                 |
+-----+-----+-----+-----+

SHOW USER_VARIABLES;
+-----+-----+
| Variable_name | Value |
+-----+-----+
| v3            | 123   |
| v2            | abc   |
| v1            | 0     |
+-----+-----+

```

1.1.1.2.9.1.1.64 Information Schema VIEWS Table

The [Information Schema](#) `VIEWS` table contains information about [views](#). The `SHOW VIEW` [privilege](#) is required to view the table.

It has the following columns:

Column	Description
TABLE_CATALOG	Always <code>def</code> .
TABLE_SCHEMA	Database name containing the view.
TABLE_NAME	View table name.
VIEW_DEFINITION	Definition of the view.
CHECK_OPTION	<code>YES</code> if the <code>WITH CHECK_OPTION</code> clause has been specified, <code>NO</code> otherwise.
IS_UPDATABLE	Whether the view is updatable or not.
DEFINER	Account specified in the <code>DEFINER</code> clause (or the default when created).
SECURITY_TYPE	SQL SECURITY characteristic, either <code>DEFINER</code> or <code>INVOKER</code> .
CHARACTER_SET_CLIENT	The client character set when the view was created, from the session value of the character_set_client system variable.
COLLATION_CONNECTION	The client collation when the view was created, from the session value of the collation_connection system variable.
ALGORITHM	The algorithm used in the view. See View Algorithms .

Example

```

SELECT * FROM information_schema.VIEWS\G
***** 1. row *****
      TABLE_CATALOG: def
      TABLE_SCHEMA: test
      TABLE_NAME: v
      VIEW_DEFINITION: select `test`.`t`.`qty` AS `qty`,`test`.`t`.`price` AS `price`,
('test`.`t`.`qty` * `test`.`t`.`price`) AS `value` from `test`.`t`
      CHECK_OPTION: NONE
      IS_UPDATABLE: YES
      DEFINER: root@localhost
      SECURITY_TYPE: DEFINER
CHARACTER_SET_CLIENT: utf8
COLLATION_CONNECTION: utf8_general_ci
      ALGORITHM: UNDEFINED

```

1.1.1.2.9.1.1.65 Information Schema WSREP_MEMBERSHIP Table

The `WSREP_STATUS` table makes [Galera](#) node cluster membership information available through the [Information Schema](#). The same information can be returned using the `SHOW WSREP_MEMBERSHIP` statement. Only users with the `SUPER` can access information from this table.

The `WSREP_MEMBERSHIP` table is part of the [WSREP_INFO](#) plugin.

Example

```

SELECT * FROM information_schema.WSREP_MEMBERSHIP;
+-----+-----+-----+-----+
| INDEX | UUID                               | NAME | ADDRESS          |
+-----+-----+-----+-----+
| 0     | 46da96e3-6e9e-11e4-95a2-f609aa5444b3 | node1 | 10.0.2.15:16000 |
| 1     | 5f6bc72a-6e9e-11e4-84ed-57ec6780a3d3 | node2 | 10.0.2.15:16001 |
| 2     | 7473fd75-6e9e-11e4-91de-0b541ad91bd0 | node3 | 10.0.2.15:16002 |
+-----+-----+-----+-----+

```

1.1.1.2.9.1.1.66 Information Schema WSREP_STATUS Table

The `WSREP_STATUS` table makes [Galera](#) node cluster status information available through the [Information Schema](#). The same information can be returned using the `SHOW WSREP_STATUS` statement. Only users with the `SUPER` privilege can access information from this table.

The `WSREP_STATUS` table is part of the [WSREP_INFO](#) plugin.

Example

```

SELECT * FROM information_schema.WSREP_STATUS\G
***** 1. row *****
      NODE_INDEX: 0

```

1.1.1.2.8.2 Extended SHOW

1.1.1.2.9.1.3 TIME_MS column in INFORMATION_SCHEMA.PROCESSLIST

In MariaDB, an extra column `TIME_MS` has been added to the `INFORMATION_SCHEMA.PROCESSLIST` table. This column shows the same information as the column `'TIME'`, but in units of milliseconds with microsecond precision (the unit and precision of the `TIME` column is one second).

For details about microseconds support in MariaDB, see [microseconds in MariaDB](#).

The value displayed in the `TIME` and `TIME_MS` columns is the period of time that the given thread has been in its current state. Thus it can be used to check for example how long a thread has been executing the current query, or for how long it has been idle.

```
select id, time, time_ms, command, state from
  information_schema.processlist, (select sleep(2)) t;
+-----+-----+-----+-----+-----+
| id | time | time_ms | command | state |
+-----+-----+-----+-----+-----+
| 37 | 2 | 2000.493 | Query | executing |
+-----+-----+-----+-----+-----+
```

Note that as a difference to MySQL, in MariaDB the `TIME` column (and also the `TIME_MS` column) are not affected by any setting of `@TIMESTAMP`. This means that it can be reliably used also for threads that change `@TIMESTAMP` (such as the [replication SQL thread](#)). See also [MySQL Bug #22047](#).

As a consequence of this, the `TIME` column of `SHOW FULL PROCESSLIST` and `INFORMATION_SCHEMA.PROCESSLIST` can not be used to determine if a slave is lagging behind. For this, use instead the `Seconds_Behind_Master` column in the output of `SHOW SLAVE STATUS`.

The addition of the `TIME_MS` column is based on the `microsec_process` patch, developed by [Percona](#).

1.1.1.2.9.2 Performance Schema

The MariaDB Performance Schema is a feature for monitoring the performance of your MariaDB server. It is not enabled by default - see [the overview](#) for details on activating.

Performance Schema Overview

[Quick overview of the Performance Schema.](#)

Performance Schema Tables

[Tables making up the MariaDB Performance Schema.](#)

Performance Schema Status Variables

[Performance Schema status variables.](#)

Performance Schema System Variables

[Performance Schema system variables.](#)

Performance Schema Digests

[Normalized statements with data values removed](#)

PERFORMANCE_SCHEMA Storage Engine

[PERFORMANCE_SCHEMA storage engine, a mechanism for implementing the feature.](#)

There are [4 related questions](#).

1.1.1.2.9.2.1 Performance Schema Tables

Tables that are part of the [MariaDB Performance Schema](#), a feature for monitoring the performance of MariaDB server.

List of Performance Schema Tables

[List and short description of all performance_schema tables.](#)

Performance Schema accounts Table

Account connection information.

Performance Schema cond_instances Table

List of instrumented condition objects.

Performance Schema events_stages_current Table

Current stage events.

Performance Schema events_stages_history Table

Most recent stage events per thread.

Performance Schema events_stages_history_long Table

Most recent completed stage events.

Performance Schema events_stages_summary_by_account_by_event_name Table

Stage events, summarized by account and event name.

Performance Schema events_stages_summary_by_host_by_event_name Table

Stage events summarized by host and event name.

Performance Schema events_stages_summary_by_thread_by_event_name Table

Stage events summarized by thread and event name.

Performance Schema events_stages_summary_by_user_by_event_name Table

Stage events summarized by user and event name.

Performance Schema events_stages_summary_global_by_event_name Table

Event summaries.

Performance Schema events_statements_current Table

Current statement events.

Performance Schema events_statements_history Table

Most recent statement events per thread

Performance Schema events_statements_history_long Table

Most recent statement events.

Performance Schema events_statements_summary_by_account_by_event_name Table

Statement events summarized by account and event name.

Performance Schema events_statements_summary_by_digest Table

Statement events summarized by schema and digest.

Performance Schema events_statements_summary_by_host_by_event_name Table

Statement events summarized by host and event name.

Performance Schema events_statements_summary_by_program Table

Summarizes events for a particular stored program.

Performance Schema events_statements_summary_by_thread_by_event_name Table

Statement events summarized by thread and event name.

Performance Schema events_statements_summary_by_user_by_event_name Table

Statement events summarized by user and event name.

Performance Schema events_statements_summary_global_by_event_name Table

Statement events summarized by event name.

**Performance Schema events_transactions_current Table**

Current transaction events for each thread.

**Performance Schema events_transactions_history Table**

Most recent completed transaction events for each thread.

**Performance Schema events_transactions_history_long Table**

Most recent completed transaction events that have ended globally.

**Performance Schema events_transactions_summary_by_account_by_event_name Table**

Transaction events aggregated by account and event name.

**Performance Schema events_transactions_summary_by_host_by_event_name Table**

Transaction events aggregated by host and event name.

**Performance Schema events_transactions_summary_by_thread_by_event_name Table**

Transaction events aggregated by thread and event name.

**Performance Schema events_transactions_summary_by_user_by_event_name Table**

Transaction events aggregated by user and event name.

**Performance Schema events_transactions_summary_global_by_event_name Table**

Transaction events aggregated by event name.

**Performance Schema events_waits_current Table**

Current wait events

**Performance Schema events_waits_history Table**

Most recent wait events per thread

**Performance Schema events_waits_history_long Table**

Most recent completed wait events

**Performance Schema events_waits_summary_by_account_by_event_name Table**

Wait events summarized by account and event name.

**Performance Schema events_waits_summary_by_host_by_event_name Table**

Wait events summarized by host and event name.

**Performance Schema events_waits_summary_by_instance Table**

Wait events summarized by instance

**Performance Schema events_waits_summary_by_thread_by_event_name Table**

Wait events summarized by thread and event name.

**Performance Schema events_waits_summary_by_user_by_event_name Table**

Wait events summarized by user and event name.

**Performance Schema events_waits_summary_global_by_event_name Table**

Wait events summarized by event name.

**Performance Schema file_instances Table**

List of file instruments.

**Performance Schema file_summary_by_event_name Table**

File events summarized by event name.

**Performance Schema file_summary_by_instance Table**

File events summarized by instance.

Performance Schema global_status Table

Status variables and their global values.

Performance Schema hosts Table

Hosts used to connect to the server.

Performance Schema host_cache Table

Host_cache information.

Performance Schema memory_summary_by_account_by_event_name Table

Memory usage statistics aggregated by account and event.

Performance Schema memory_summary_by_host_by_event_name Table

Memory usage statistics aggregated by host and event.

Performance Schema memory_summary_by_thread_by_event_name Table

Memory usage statistics aggregated by thread and event.

Performance Schema memory_summary_by_user_by_event_name Table

Memory usage statistics aggregated by user and event.

Performance Schema memory_summary_global_by_event_name Table

Memory usage statistics aggregated by event and event.

Performance Schema metadata_locks Table

Metadata lock information.

Performance Schema mutex_instances Table

Seen mutexes

Performance Schema objects_summary_global_by_type Table

Aggregates object wait events.

Performance Schema performance_timers Table

Available event timers

Performance Schema prepared_statements_instances Table

Aggregated statistics of prepared statements.

Performance Schema replication_applier_configuration Table

Configuration settings affecting replica transactions.

Performance Schema replication_applier_status Table

Information about the general transaction execution status on the slave.

Performance Schema replication_applier_status_by_coordinator Table

Coordinator thread status used in multi-threaded replicas to manage multiple workers.

Performance Schema replication_applier_status_by_worker Table

Slave worker thread specific information.

Performance Schema replication_connection_configuration Table

Replica configuration settings used for connecting to the primary.

Performance Schema rwlock_instances Table

Seen read-write locks

Performance Schema session_account_connect_attrs Table

Connection attributes for the current session.

Performance Schema session_connect_attrs Table

Connection attributes for all sessions.

**Performance Schema session_status Table**

Status variables and their session values.

**Performance Schema setup_actors Table**

Determines whether monitoring is enabled for host/user combinations.

**Performance Schema setup_consumers Table**

Lists the types of consumers for which event information is available.

**Performance Schema setup_instruments Table**

List of instrumented object classes

**Performance Schema setup_objects Table**

Which objects are monitored.

**Performance Schema setup_timers Table**

Currently selected event timers

**Performance Schema socket_instances Table**

Active server connections.

**Performance Schema socket_summary_by_event_name Table**

Aggregates timer and byte count statistics for all socket I/O operations by socket instrument.

**Performance Schema socket_summary_by_instance Table**

Aggregates timer and byte count statistics for all socket I/O operations by socket instance.

**Performance Schema status_by_account Table**

Status variable information by user/host account.

**Performance Schema status_by_host Table**

Status variable information by host.

**Performance Schema status_by_thread Table**

Status variable information about active foreground threads.

**Performance Schema status_by_user Table**

Status variable information by user.

**Performance Schema table_handles Table**

Table lock information.

**Performance Schema table_io_waits_summary_by_index_usage Table**

Table I/O waits by index.

**Performance Schema table_io_waits_summary_by_table Table**

Table I/O waits by table.

**Performance Schema table_lock_waits_summary_by_table Table**

Table lock waits by table.

**Performance Schema threads Table**

Each server thread is represented as a row in the threads table.

**Performance Schema users Table**

User connection information.

**Performance Schema user_variables_by_thread Table**

User-defined variables and the threads that defined them.

1.1.1.2.9.2.1.1 List of Performance Schema

Tables

Below is a list of all [Performance Schema](#) tables as well as a brief description of each of them.

Table	Description
accounts	Client account connection statistics.
cond_instances	Synchronization object instances.
events_stages_current	Current stage events.
events_stages_history	Ten most recent stage events per thread.
events_stages_history_long	Ten thousand most recent stage events.
events_stages_summary_by_account_by_event_name	Summarized stage events per account and event name.
events_stages_summary_by_host_by_event_name	Summarized stage events per host and event name.
events_stages_summary_by_thread_by_event_name	Summarized stage events per thread and event name.
events_stages_summary_by_user_by_event_name	Summarized stage events per user name and event name.
events_stages_summary_global_by_event_name	Summarized stage events per event name.
events_statements_current	Current statement events.
events_statements_history	Ten most recent events per thread.
events_statements_history_long	Ten thousand most recent stage events.
events_statements_summary_by_account_by_event_name	Summarized statement events per account and event name.
events_statements_summary_by_digest	Summarized statement events by scheme and digest.
events_statements_summary_by_host_by_event_name	Summarized statement events by host and event name.
events_statements_summary_by_program	Events for a particular stored program.
events_statements_summary_by_thread_by_event_name	Summarized statement events by thread and event name.
events_statements_summary_by_user_by_event_name	Summarized statement events by user and event name.
events_statements_summary_global_by_event_name	Summarized statement events by event name.
events_transactions_current	Current transaction events for each thread.
events_transactions_history	Most recent completed transaction events for each thread.
events_transactions_history_long	Most recent completed transaction events that have ended globally.
events_transactions_summary_by_account_by_event_name	Transaction events aggregated by account and event.
events_transactions_summary_by_host_by_event_name	Transaction events aggregated by host and event..
events_transactions_summary_by_thread_by_event_name	Transaction events aggregated by thread and event..
events_transactions_summary_by_user_by_event_name	Transaction events aggregated by user and event..
events_transactions_summary_global_by_event_name	Transaction events aggregated by event name.
events_waits_current	Current wait events.
events_waits_history	Ten most recent wait events per thread.
events_waits_history_long	Ten thousand most recent wait events per thread.

<code>events_waits_summary_by_account_by_event_name</code>	Summarized wait events by account and event name.
<code>events_waits_summary_by_host_by_event_name</code>	Summarized wait events by host and event name.
<code>events_waits_summary_by_instance</code>	Summarized wait events by instance.
<code>events_waits_summary_by_thread_by_event_name</code>	Summarized wait events by thread and event name.
<code>events_waits_summary_by_user_by_event_name</code>	Summarized wait events by user and event name.
<code>events_waits_summary_global_by_event_name</code>	Summarized wait events by event name.
<code>file_instances</code>	Seen files.
<code>file_summary_by_event_name</code>	File events summarized by event name.
<code>file_summary_by_instance</code>	File events summarized by instance.
<code>global_status</code>	Global status variables and values.
<code>host_cache</code>	Host and IP information.
<code>hosts</code>	Connections by host.
<code>memory_summary_by_account_by_event_name</code>	Memory usage statistics aggregated by account and event.
<code>memory_summary_by_host_by_event_name</code>	Memory usage statistics aggregated by host. and event.
<code>memory_summary_by_thread_by_event_name</code>	Memory usage statistics aggregated by thread and event..
<code>memory_summary_by_user_by_event_name</code>	Memory usage statistics aggregated by user and event..
<code>memory_summary_global_by_event_name</code>	Memory usage statistics aggregated by event.
<code>metadata_locks</code>	Metadata locks.
<code>mutex_instances</code>	Seen mutexes.
<code>objects_summary_global_by_type</code>	Object wait events.
<code>performance_timers</code>	Available event timers.
<code>prepared_statements_instances</code>	Aggregate statistics of prepared statements.
<code>replication_applier_configuration</code>	Configuration settings affecting replica transactions.
<code>replication_applier_status</code>	General transaction execution status on the replica.
<code>replication_applier_status_by_coordinator</code>	Coordinator thread specific information.
<code>replication_applier_status_by_worker</code>	Replica worker thread specific information.
<code>replication_connection_configuration</code>	Rreplica's configuration settings used for connecting to the primary.
<code>rwlock_instances</code>	Seen read-write locks.
<code>session_account_connect_attrs</code>	Current session connection attributes.
<code>session_connect_attrs</code>	All session connection attributes.
<code>session_status</code>	Session status variables and values.
<code>setup_actors</code>	Details on foreground thread monitoring.
<code>setup_consumers</code>	Consumers for which event information is stored.
<code>setup_instruments</code>	Instrumented objects for which events are collected.
<code>setup_objects</code>	Objects to be monitored.
<code>setup_timers</code>	Currently selected event timers.
<code>socket_instances</code>	Active connections.
<code>socket_summary_by_event_name</code>	Timer and byte count statistics by socket instrument.

<code>socket_summary_by_instance</code>	Timer and byte count statistics by socket instance.
<code>status_by_account</code>	Status variable info by host/user account.
<code>status_by_host</code>	Status variable info by host.
<code>status_by_thread</code>	Status variable info about active foreground threads.
<code>status_by_user</code>	Status variable info by user.
<code>table_handles</code>	Table lock information.
<code>table_io_waits_summary_by_index_usage</code>	Aggregate table I/O wait events by index.
<code>table_io_waits_summary_by_table</code>	Aggregate table I/O wait events by table.
<code>table_lock_waits_summary_by_table</code>	Aggregate table lock wait events by table.
<code>threads</code>	Server thread information.
<code>user_variables_by_thread</code>	User-defined variables by thread.
<code>users</code>	Connection statistics by user.

1.1.1.2.9.2.1.2 Performance Schema accounts Table

Description

Each account that connects to the server is stored as a row in the accounts table, along with current and total connections.

The table size is determined at startup by the value of the `performance_schema_accounts_size` system variable. If this is set to 0, account statistics will be disabled.

Column	Description
<code>USER</code>	The connection's client user name for the connection, or NULL if an internal thread.
<code>HOST</code>	The connection client's host name, or NULL if an internal thread.
<code>CURRENT_CONNECTIONS</code>	Current connections for the account.
<code>TOTAL_CONNECTIONS</code>	Total connections for the account.

The `USER` and `HOST` values shown here are the username and host used for user connections, not the patterns used to check permissions.

Example

```
SELECT * FROM performance_schema.accounts;
+-----+-----+-----+-----+
| USER          | HOST          | CURRENT_CONNECTIONS | TOTAL_CONNECTIONS |
+-----+-----+-----+-----+
| root          | localhost    | 1                   | 2                 |
| NULL         | NULL         | 20                  | 23                |
| debian-sys-maint | localhost    | 0                   | 35                |
+-----+-----+-----+-----+
```

1.1.1.2.9.2.1.3 Performance Schema cond_instances Table

Description

The `cond_instances` table lists all conditions while the server is executing. A condition, or instrumented condition object, is an internal code mechanism used for signalling that a specific event has occurred so that any threads waiting for this

condition can continue.

The maximum number of conditions stored in the performance schema is determined by the [performance_schema_max_cond_instances](#) system variable.

Column	Description
NAME	Client user name for the connection, or <code>NULL</code> if an internal thread.
OBJECT_INSTANCE_BEGIN	Address in memory of the instrumented condition.

1.1.1.2.9.2.1.4 Performance Schema `events_stages_current` Table

The `events_stages_current` table contains current stage events, with each row being a record of a thread and its most recent stage event.

The table contains the following columns:

Column	Description
THREAD_ID	Thread associated with the event. Together with <code>EVENT_ID</code> uniquely identifies the row.
EVENT_ID	Thread's current event number at the start of the event. Together with <code>THREAD_ID</code> uniquely identifies the row.
END_EVENT_ID	<code>NULL</code> when the event starts, set to the thread's current event number at the end of the event.
EVENT_NAME	Event instrument name and a <code>NAME</code> from the <code>setup_instruments</code> table
SOURCE	Name and line number of the source file containing the instrumented code that produced the event.
TIMER_START	Value in picoseconds when the event timing started or <code>NULL</code> if timing is not collected. Relative to the server start, not to the epoch, so cannot directly be converted to a timestamp.
TIMER_END	Value in picoseconds when the event timing ended, or <code>NULL</code> if the event has not ended or timing is not collected. Relative to the server start, not to the epoch, so cannot directly be converted to a timestamp.
TIMER_WAIT	Value in picoseconds of the event's duration or <code>NULL</code> if the event has not ended or timing is not collected.
NESTING_EVENT_ID	<code>EVENT_ID</code> of event within which this event nests.
NESTING_EVENT_TYPE	Nesting event type. One of <code>transaction</code> , <code>statement</code> , <code>stage</code> or <code>wait</code> .

It is possible to empty this table with a `TRUNCATE TABLE` statement.

The related tables, [events_stages_history](#) and [events_stages_history_long](#) derive their values from the current events.

1.1.1.2.9.2.1.5 Performance Schema `events_stages_history` Table

The `events_stages_history` table by default contains the ten most recent completed stage events per thread. This number can be adjusted by setting the [performance_schema_events_stages_history_size](#) system variable when the server starts up.

The table structure is identical to the [events_stage_current](#) table structure, and contains the following columns:

Column	Description
THREAD_ID	Thread associated with the event. Together with <code>EVENT_ID</code> uniquely identifies the row.
EVENT_ID	Thread's current event number at the start of the event. Together with <code>THREAD_ID</code> uniquely identifies the row.
END_EVENT_ID	<code>NULL</code> when the event starts, set to the thread's current event number at the end of the event.
EVENT_NAME	Event instrument name and a <code>NAME</code> from the <code>setup_instruments</code> table

SOURCE	Name and line number of the source file containing the instrumented code that produced the event.
TIMER_START	Value in picoseconds when the event timing started or <code>NULL</code> if timing is not collected. Relative to the server start, not to the epoch, so cannot directly be converted to a timestamp.
TIMER_END	Value in picoseconds when the event timing ended, or <code>NULL</code> if timing is not collected. Relative to the server start, not to the epoch, so cannot directly be converted to a timestamp.
TIMER_WAIT	Value in picoseconds of the event's duration or <code>NULL</code> if timing is not collected.
NESTING_EVENT_ID	<code>EVENT_ID</code> of event within which this event nests.
NESTING_EVENT_TYPE	Nesting event type. One of <code>transaction</code> , <code>statement</code> , <code>stage</code> or <code>wait</code> .

It is possible to empty this table with a `TRUNCATE TABLE` statement.

[events_stages_current](#) and [events_stages_history_long](#) are related tables.

1.1.1.2.9.2.1.6 Performance Schema `events_stages_history_long` Table

The `events_stages_history_long` table by default contains the ten thousand most recent completed stage events. This number can be adjusted by setting the `performance_schema_events_stages_history_long_size` system variable when the server starts up.

The table structure is identical to the `events_stage_current` table structure, and contains the following columns:

Column	Description
THREAD_ID	Thread associated with the event. Together with <code>EVENT_ID</code> uniquely identifies the row.
EVENT_ID	Thread's current event number at the start of the event. Together with <code>THREAD_ID</code> uniquely identifies the row.
END_EVENT_ID	<code>NULL</code> when the event starts, set to the thread's current event number at the end of the event.
EVENT_NAME	Event instrument name and a <code>NAME</code> from the <code>setup_instruments</code> table
SOURCE	Name and line number of the source file containing the instrumented code that produced the event.
TIMER_START	Value in picoseconds when the event timing started or <code>NULL</code> if timing is not collected. Relative to the server start, not to the epoch, so cannot directly be converted to a timestamp.
TIMER_END	Value in picoseconds when the event timing ended, or <code>NULL</code> if timing is not collected. Relative to the server start, not to the epoch, so cannot directly be converted to a timestamp.
TIMER_WAIT	Value in picoseconds of the event's duration or <code>NULL</code> if timing is not collected.
NESTING_EVENT_ID	<code>EVENT_ID</code> of event within which this event nests.
NESTING_EVENT_TYPE	Nesting event type. One of <code>transaction</code> , <code>statement</code> , <code>stage</code> or <code>wait</code> .

It is possible to empty this table with a `TRUNCATE TABLE` statement.

[events_stages_current](#) and [events_stages_history](#) are related tables.

1.1.1.2.9.2.1.7 Performance Schema `events_stages_summary_by_account_by_event` Table

The table lists stage events, summarized by account and event name.

It contains the following columns:

Column	Description
USER	User. Used together with <code>HOST</code> and <code>EVENT_NAME</code> for grouping events.

HOST	Host. Used together with <code>USER</code> and <code>EVENT_NAME</code> for grouping events.
EVENT_NAME	Event name. Used together with <code>USER</code> and <code>HOST</code> for grouping events.
COUNT_STAR	Number of summarized events, which includes all timed and untimed events.
SUM_TIMER_WAIT	Total wait time of the timed summarized events.
MIN_TIMER_WAIT	Minimum wait time of the timed summarized events.
AVG_TIMER_WAIT	Average wait time of the timed summarized events.
MAX_TIMER_WAIT	Maximum wait time of the timed summarized events.

Example

```

SELECT * FROM events_stages_summary_by_account_by_event_name\G
...
***** 325. row *****
      USER: NULL
      HOST: NULL
      EVENT_NAME: stage/sql/Waiting for event metadata lock
      COUNT_STAR: 0
      SUM_TIMER_WAIT: 0
      MIN_TIMER_WAIT: 0
      AVG_TIMER_WAIT: 0
      MAX_TIMER_WAIT: 0
***** 326. row *****
      USER: NULL
      HOST: NULL
      EVENT_NAME: stage/sql/Waiting for commit lock
      COUNT_STAR: 0
      SUM_TIMER_WAIT: 0
      MIN_TIMER_WAIT: 0
      AVG_TIMER_WAIT: 0
      MAX_TIMER_WAIT: 0
***** 327. row *****
      USER: NULL
      HOST: NULL
      EVENT_NAME: stage/aria/Waiting for a resource
      COUNT_STAR: 0
      SUM_TIMER_WAIT: 0
      MIN_TIMER_WAIT: 0
      AVG_TIMER_WAIT: 0
      MAX_TIMER_WAIT: 0

```

1.1.1.2.9.2.1.8 Performance Schema `events_stages_summary_by_host_by_event_name` Table

The table lists stage events, summarized by host and event name.

It contains the following columns:

Column	Description
HOST	Host. Used together with <code>EVENT_NAME</code> for grouping events.
EVENT_NAME	Event name. Used together with <code>HOST</code> for grouping events.
COUNT_STAR	Number of summarized events, which includes all timed and untimed events.
SUM_TIMER_WAIT	Total wait time of the timed summarized events.
MIN_TIMER_WAIT	Minimum wait time of the timed summarized events.
AVG_TIMER_WAIT	Average wait time of the timed summarized events.
MAX_TIMER_WAIT	Maximum wait time of the timed summarized events.

Example

```
SELECT * FROM events_stages_summary_by_host_by_event_name\G
...
***** 216. row *****
      HOST: NULL
      EVENT_NAME: stage/sql/Waiting for event metadata lock
      COUNT_STAR: 0
      SUM_TIMER_WAIT: 0
      MIN_TIMER_WAIT: 0
      AVG_TIMER_WAIT: 0
      MAX_TIMER_WAIT: 0
***** 217. row *****
      HOST: NULL
      EVENT_NAME: stage/sql/Waiting for commit lock
      COUNT_STAR: 0
      SUM_TIMER_WAIT: 0
      MIN_TIMER_WAIT: 0
      AVG_TIMER_WAIT: 0
      MAX_TIMER_WAIT: 0
***** 218. row *****
      HOST: NULL
      EVENT_NAME: stage/aria/Waiting for a resource
      COUNT_STAR: 0
      SUM_TIMER_WAIT: 0
      MIN_TIMER_WAIT: 0
      AVG_TIMER_WAIT: 0
      MAX_TIMER_WAIT: 0
```

1.1.1.2.9.2.1.9 Performance Schema events_stages_summary_by_thread_by_event_name Table

The table lists stage events, summarized by thread and event name.

It contains the following columns:

Column	Description
THREAD_ID	Thread associated with the event. Together with <code>EVENT_NAME</code> uniquely identifies the row.
EVENT_NAME	Event name. Used together with <code>THREAD_ID</code> for grouping events.
COUNT_STAR	Number of summarized events, which includes all timed and untimed events.
SUM_TIMER_WAIT	Total wait time of the timed summarized events.
MIN_TIMER_WAIT	Minimum wait time of the timed summarized events.
AVG_TIMER_WAIT	Average wait time of the timed summarized events.
MAX_TIMER_WAIT	Maximum wait time of the timed summarized events.

Example

```

SELECT * FROM events_stages_summary_by_thread_by_event_name\G
...
***** 2287. row *****
  THREAD_ID: 64
  EVENT_NAME: stage/sql/Waiting for event metadata lock
  COUNT_STAR: 0
  SUM_TIMER_WAIT: 0
  MIN_TIMER_WAIT: 0
  AVG_TIMER_WAIT: 0
  MAX_TIMER_WAIT: 0
***** 2288. row *****
  THREAD_ID: 64
  EVENT_NAME: stage/sql/Waiting for commit lock
  COUNT_STAR: 0
  SUM_TIMER_WAIT: 0
  MIN_TIMER_WAIT: 0
  AVG_TIMER_WAIT: 0
  MAX_TIMER_WAIT: 0
***** 2289. row *****
  THREAD_ID: 64
  EVENT_NAME: stage/aria/Waiting for a resource
  COUNT_STAR: 0
  SUM_TIMER_WAIT: 0
  MIN_TIMER_WAIT: 0
  AVG_TIMER_WAIT: 0
  MAX_TIMER_WAIT: 0

```

1.1.1.2.9.2.1.10 Performance Schema events_stages_summary_by_user_by_event_name Table

The table lists stage events, summarized by user and event name.

It contains the following columns:

Column	Description
USER	User. Used together with <code>EVENT_NAME</code> for grouping events.
EVENT_NAME	Event name. Used together with <code>USER</code> for grouping events.
COUNT_STAR	Number of summarized events, which includes all timed and untimed events.
SUM_TIMER_WAIT	Total wait time of the timed summarized events.
MIN_TIMER_WAIT	Minimum wait time of the timed summarized events.
AVG_TIMER_WAIT	Average wait time of the timed summarized events.
MAX_TIMER_WAIT	Maximum wait time of the timed summarized events.

Example

```

SELECT * FROM events_stages_summary_by_user_by_event_name\G
...
***** 325. row *****
      USER: NULL
      EVENT_NAME: stage/sql/Waiting for event metadata lock
      COUNT_STAR: 0
      SUM_TIMER_WAIT: 0
      MIN_TIMER_WAIT: 0
      AVG_TIMER_WAIT: 0
      MAX_TIMER_WAIT: 0
***** 326. row *****
      USER: NULL
      EVENT_NAME: stage/sql/Waiting for commit lock
      COUNT_STAR: 0
      SUM_TIMER_WAIT: 0
      MIN_TIMER_WAIT: 0
      AVG_TIMER_WAIT: 0
      MAX_TIMER_WAIT: 0
***** 327. row *****
      USER: NULL
      EVENT_NAME: stage/aria/Waiting for a resource
      COUNT_STAR: 0
      SUM_TIMER_WAIT: 0
      MIN_TIMER_WAIT: 0
      AVG_TIMER_WAIT: 0
      MAX_TIMER_WAIT: 0

```

1.1.1.2.9.2.1.11 Performance Schema events_stages_summary_global_by_event_name Table

The table lists stage events, summarized by thread and event name.

It contains the following columns:

Column	Description
EVENT_NAME	Event name.
COUNT_STAR	Number of summarized events, which includes all timed and untimed events.
SUM_TIMER_WAIT	Total wait time of the timed summarized events.
MIN_TIMER_WAIT	Minimum wait time of the timed summarized events.
AVG_TIMER_WAIT	Average wait time of the timed summarized events.
MAX_TIMER_WAIT	Maximum wait time of the timed summarized events.

Example

```

SELECT * FROM events_stages_summary_global_by_event_name\G
...
***** 106. row *****
EVENT_NAME: stage/sql/Waiting for trigger metadata lock
COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
***** 107. row *****
EVENT_NAME: stage/sql/Waiting for event metadata lock
COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
***** 108. row *****
EVENT_NAME: stage/sql/Waiting for commit lock
COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
***** 109. row *****
EVENT_NAME: stage/aria/Waiting for a resource
COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0

```

1.1.1.2.9.2.1.12 Performance Schema events_statements_current Table

The `events_statements_current` table contains current statement events, with each row being a record of a thread and its most recent statement event.

The table contains the following columns:

Column	Description
THREAD_ID	Thread associated with the event. Together with <code>EVENT_ID</code> uniquely identifies the row.
EVENT_ID	Thread's current event number at the start of the event. Together with <code>THREAD_ID</code> uniquely identifies the row.
END_EVENT_ID	<code>NULL</code> when the event starts, set to the thread's current event number at the end of the event.
EVENT_NAME	Event instrument name and a <code>NAME</code> from the <code>setup_instruments</code> table
SOURCE	Name and line number of the source file containing the instrumented code that produced the event.
TIMER_START	Value in picoseconds when the event timing started or <code>NULL</code> if timing is not collected. Relative to the server start, not to the epoch, so cannot directly be converted to a timestamp.
TIMER_END	Value in picoseconds when the event timing ended, or <code>NULL</code> if the event has not ended or timing is not collected. Relative to the server start, not to the epoch, so cannot directly be converted to a timestamp.
TIMER_WAIT	Value in picoseconds of the event's duration or <code>NULL</code> if the event has not ended or timing is not collected.
LOCK_TIME	Time in picoseconds spent waiting for locks. The time is calculated in microseconds but stored in picoseconds for compatibility with other timings.
SQL_TEXT	The SQL statement, or <code>NULL</code> if the command is not associated with an SQL statement.
DIGEST	Statement digest .

DIGEST_TEXT	Statement digest text.
CURRENT_SCHEMA	Statement's default database for the statement, or <code>NULL</code> if there was none.
OBJECT_SCHEMA	Reserved, currently <code>NULL</code>
OBJECT_NAME	Reserved, currently <code>NULL</code>
OBJECT_TYPE	Reserved, currently <code>NULL</code>
OBJECT_INSTANCE_BEGIN	Address in memory of the statement object.
MYSQL_ERRNO	Error code. See MariaDB Error Codes for a full list.
RETURNED_SQLSTATE	The <code>SQLSTATE</code> value.
MESSAGE_TEXT	Statement error message. See MariaDB Error Codes .
ERRORS	0 if <code>SQLSTATE</code> signifies completion (starting with 00) or warning (01), otherwise 1.
WARNINGS	Number of warnings from the diagnostics area.
ROWS_AFFECTED	Number of rows affected the statement affected.
ROWS_SENT	Number of rows returned.
ROWS_EXAMINED	Number of rows read during the statement's execution.
CREATED_TMP_DISK_TABLES	Number of on-disk temp tables created by the statement.
CREATED_TMP_TABLES	Number of temp tables created by the statement.
SELECT_FULL_JOIN	Number of joins performed by the statement which did not use an index.
SELECT_FULL_RANGE_JOIN	Number of joins performed by the statement which used a range search of the first table.
SELECT_RANGE	Number of joins performed by the statement which used a range of the first table.
SELECT_RANGE_CHECK	Number of joins without keys performed by the statement that check for key usage after each row.
SELECT_SCAN	Number of joins performed by the statement which used a full scan of the first table.
SORT_MERGE_PASSES	Number of merge passes by the sort algorithm performed by the statement. If too high, you may need to increase the <code>sort_buffer_size</code> .
SORT_RANGE	Number of sorts performed by the statement which used a range.
SORT_ROWS	Number of rows sorted by the statement.
SORT_SCAN	Number of sorts performed by the statement which used a full table scan.
NO_INDEX_USED	0 if the statement performed a table scan with an index, 1 if without an index.
NO_GOOD_INDEX_USED	0 if a good index was found for the statement, 1 if no good index was found. See the Range checked for each record description in the EXPLAIN article.
NESTING_EVENT_ID	Reserved, currently <code>NULL</code> .
NESTING_EVENT_TYPE	Reserved, currently <code>NULL</code> .

It is possible to empty this table with a `TRUNCATE TABLE` statement.

The related tables, [events_statements_history](#) and [events_statements_history_long](#) derive their values from the current events table.

1.1.1.2.9.2.1.13 Performance Schema `events_statements_history` Table

The `events_statements_history` table by default contains the ten most recent completed statement events per thread. This number can be adjusted by setting the `performance_schema_events_statements_history_size` system variable when the server starts up.

The table structure is identical to the [events_statements_current](#) table structure, and contains the following columns:

The table contains the following columns:

Column	Description
THREAD_ID	Thread associated with the event. Together with <code>EVENT_ID</code> uniquely identifies the row.
EVENT_ID	Thread's current event number at the start of the event. Together with <code>THREAD_ID</code> uniquely identifies the row.
END_EVENT_ID	<code>NULL</code> when the event starts, set to the thread's current event number at the end of the event.
EVENT_NAME	Event instrument name and a <code>NAME</code> from the <code>setup_instruments</code> table
SOURCE	Name and line number of the source file containing the instrumented code that produced the event.
TIMER_START	Value in picoseconds when the event timing started or <code>NULL</code> if timing is not collected. Relative to the server start, not to the epoch, so cannot directly be converted to a timestamp.
TIMER_END	Value in picoseconds when the event timing ended, or <code>NULL</code> if timing is not collected. Relative to the server start, not to the epoch, so cannot directly be converted to a timestamp.
TIMER_WAIT	Value in picoseconds of the event's duration or <code>NULL</code> if timing is not collected.
LOCK_TIME	Time in picoseconds spent waiting for locks. The time is calculated in microseconds but stored in picoseconds for compatibility with other timings.
SQL_TEXT	The SQL statement, or <code>NULL</code> if the command is not associated with an SQL statement.
DIGEST	Statement digest .
DIGEST_TEXT	Statement digest text.
CURRENT_SCHEMA	Statement's default database for the statement, or <code>NULL</code> if there was none.
OBJECT_SCHEMA	Reserved, currently <code>NULL</code>
OBJECT_NAME	Reserved, currently <code>NULL</code>
OBJECT_TYPE	Reserved, currently <code>NULL</code>
OBJECT_INSTANCE_BEGIN	Address in memory of the statement object.
MYSQL_ERRNO	Error code. See MariaDB Error Codes for a full list.
RETURNED_SQLSTATE	The SQLSTATE value.
MESSAGE_TEXT	Statement error message. See MariaDB Error Codes .
ERRORS	0 if <code>SQLSTATE</code> signifies completion (starting with 00) or warning (01), otherwise 1.
WARNINGS	Number of warnings from the diagnostics area.
ROWS_AFFECTED	Number of rows affected the statement affected.
ROWS_SENT	Number of rows returned.
ROWS_EXAMINED	Number of rows read during the statement's execution.
CREATED_TMP_DISK_TABLES	Number of on-disk temp tables created by the statement.
CREATED_TMP_TABLES	Number of temp tables created by the statement.
SELECT_FULL_JOIN	Number of joins performed by the statement which did not use an index.
SELECT_FULL_RANGE_JOIN	Number of joins performed by the statement which used a range search of the first table.
SELECT_RANGE	Number of joins performed by the statement which used a range of the first table.
SELECT_RANGE_CHECK	Number of joins without keys performed by the statement that check for key usage after each row.
SELECT_SCAN	Number of joins performed by the statement which used a full scan of the first table.
SORT_MERGE_PASSES	Number of merge passes by the sort algorithm performed by the statement. If too high, you may need to increase the sort_buffer_size .
SORT_RANGE	Number of sorts performed by the statement which used a range.

<code>SORT_ROWS</code>	Number of rows sorted by the statement.
<code>SORT_SCAN</code>	Number of sorts performed by the statement which used a full table scan.
<code>NO_INDEX_USED</code>	0 if the statement performed a table scan with an index, 1 if without an index.
<code>NO_GOOD_INDEX_USED</code>	0 if a good index was found for the statement, 1 if no good index was found. See the Range checked for each record description in the EXPLAIN article.
<code>NESTING_EVENT_ID</code>	Reserved, currently <code>NULL</code> .
<code>NESTING_EVENT_TYPE</code>	Reserved, currently <code>NULL</code> .

It is possible to empty this table with a `TRUNCATE TABLE` statement.

[events_statements_current](#) and [events_statements_history_long](#) are related tables.

1.1.1.2.9.2.1.14 Performance Schema `events_statements_history_long` Table

The `events_statements_history_long` table by default contains the ten thousand most recent completed statement events. This number can be adjusted by setting the `performance_schema_events_statements_history_long_size` system variable when the server starts up.

The table structure is identical to the `events_statements_current` table structure, and contains the following columns:

Column	Description
<code>THREAD_ID</code>	Thread associated with the event. Together with <code>EVENT_ID</code> uniquely identifies the row.
<code>EVENT_ID</code>	Thread's current event number at the start of the event. Together with <code>THREAD_ID</code> uniquely identifies the row.
<code>END_EVENT_ID</code>	<code>NULL</code> when the event starts, set to the thread's current event number at the end of the event.
<code>EVENT_NAME</code>	Event instrument name and a <code>NAME</code> from the <code>setup_instruments</code> table
<code>SOURCE</code>	Name and line number of the source file containing the instrumented code that produced the event.
<code>TIMER_START</code>	Value in picoseconds when the event timing started or <code>NULL</code> if timing is not collected. Relative to the server start, not to the epoch, so cannot directly be converted to a timestamp.
<code>TIMER_END</code>	Value in picoseconds when the event timing ended, or <code>NULL</code> if timing is not collected. Relative to the server start, not to the epoch, so cannot directly be converted to a timestamp.
<code>TIMER_WAIT</code>	Value in picoseconds of the event's duration or <code>NULL</code> if timing is not collected.
<code>LOCK_TIME</code>	Time in picoseconds spent waiting for locks. The time is calculated in microseconds but stored in picoseconds for compatibility with other timings.
<code>SQL_TEXT</code>	The SQL statement, or <code>NULL</code> if the command is not associated with an SQL statement.
<code>DIGEST</code>	Statement digest .
<code>DIGEST_TEXT</code>	Statement digest text .
<code>CURRENT_SCHEMA</code>	Statement's default database for the statement, or <code>NULL</code> if there was none.
<code>OBJECT_SCHEMA</code>	Reserved, currently <code>NULL</code>
<code>OBJECT_NAME</code>	Reserved, currently <code>NULL</code>
<code>OBJECT_TYPE</code>	Reserved, currently <code>NULL</code>
<code>OBJECT_INSTANCE_BEGIN</code>	Address in memory of the statement object.
<code>MYSQL_ERRNO</code>	Error code. See MariaDB Error Codes for a full list.
<code>RETURNED_SQLSTATE</code>	The SQLSTATE value.
<code>MESSAGE_TEXT</code>	Statement error message. See MariaDB Error Codes .

ERRORS	0 if <code>SQLSTATE</code> signifies completion (starting with 00) or warning (01), otherwise 1 .
WARNINGS	Number of warnings from the diagnostics area.
ROWS_AFFECTED	Number of rows affected the statement affected.
ROWS_SENT	Number of rows returned.
ROWS_EXAMINED	Number of rows read during the statement's execution.
CREATED_TMP_DISK_TABLES	Number of on-disk temp tables created by the statement.
CREATED_TMP_TABLES	Number of temp tables created by the statement.
SELECT_FULL_JOIN	Number of joins performed by the statement which did not use an index.
SELECT_FULL_RANGE_JOIN	Number of joins performed by the statement which used a range search of the first table.
SELECT_RANGE	Number of joins performed by the statement which used a range of the first table.
SELECT_RANGE_CHECK	Number of joins without keys performed by the statement that check for key usage after each row.
SELECT_SCAN	Number of joins performed by the statement which used a full scan of the first table.
SORT_MERGE_PASSES	Number of merge passes by the sort algorithm performed by the statement. If too high, you may need to increase the sort_buffer_size .
SORT_RANGE	Number of sorts performed by the statement which used a range.
SORT_ROWS	Number of rows sorted by the statement.
SORT_SCAN	Number of sorts performed by the statement which used a full table scan.
NO_INDEX_USED	0 if the statement performed a table scan with an index, 1 if without an index.
NO_GOOD_INDEX_USED	0 if a good index was found for the statement, 1 if no good index was found. See the Range checked for each record description in the EXPLAIN article.
NESTING_EVENT_ID	Reserved, currently <code>NULL</code> .
NESTING_EVENT_TYPE	Reserved, currently <code>NULL</code> .

It is possible to empty this table with a `TRUNCATE TABLE` statement.

[events_statements_current](#) and [events_statements_history](#) are related tables.

1.1.1.2.9.2.1.15 Performance Schema `events_statements_summary_by_account_by_event_name` Table

The [Performance Schema](#) `events_statements_summary_by_account_by_event_name` table contains statement events summarized by account and event name. It contains the following columns:

Column	Description
USER	User. Used together with <code>HOST</code> and <code>EVENT_NAME</code> for grouping events.
HOST	Host. Used together with <code>USER</code> and <code>EVENT_NAME</code> for grouping events.
EVENT_NAME	Event name. Used together with <code>USER</code> and <code>HOST</code> for grouping events.
COUNT_STAR	Number of summarized events
SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.
MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.
AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.
MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.
SUM_LOCK_TIME	Sum of the <code>LOCK_TIME</code> column in the <code>events_statements_current</code> table.
SUM_ERRORS	Sum of the <code>ERRORS</code> column in the <code>events_statements_current</code> table.

SUM_WARNINGS	Sum of the WARNINGS column in the events_statements_current table.
SUM_ROWS_AFFECTED	Sum of the ROWS_AFFECTED column in the events_statements_current table.
SUM_ROWS_SENT	Sum of the ROWS_SENT column in the events_statements_current table.
SUM_ROWS_EXAMINED	Sum of the ROWS_EXAMINED column in the events_statements_current table.
SUM_CREATED_TMP_DISK_TABLES	Sum of the CREATED_TMP_DISK_TABLES column in the events_statements_current table.
SUM_CREATED_TMP_TABLES	Sum of the CREATED_TMP_TABLES column in the events_statements_current table.
SUM_SELECT_FULL_JOIN	Sum of the SELECT_FULL_JOIN column in the events_statements_current table.
SUM_SELECT_FULL_RANGE_JOIN	Sum of the SELECT_FULL_RANGE_JOIN column in the events_statements_current table.
SUM_SELECT_RANGE	Sum of the SELECT_RANGE column in the events_statements_current table.
SUM_SELECT_RANGE_CHECK	Sum of the SELECT_RANGE_CHECK column in the events_statements_current table.
SUM_SELECT_SCAN	Sum of the SELECT_SCAN column in the events_statements_current table.
SUM_SORT_MERGE_PASSES	Sum of the SORT_MERGE_PASSES column in the events_statements_current table.
SUM_SORT_RANGE	Sum of the SORT_RANGE column in the events_statements_current table.
SUM_SORT_ROWS	Sum of the SORT_ROWS column in the events_statements_current table.
SUM_SORT_SCAN	Sum of the SORT_SCAN column in the events_statements_current table.
SUM_NO_INDEX_USED	Sum of the NO_INDEX_USED column in the events_statements_current table.
SUM_NO_GOOD_INDEX_USED	Sum of the NO_GOOD_INDEX_USED column in the events_statements_current table.

The *_TIMER_WAIT columns only calculate results for timed events, as non-timed events have a NULL wait time.

Example

```

SELECT * FROM events_statements_summary_by_account_by_event_name\G
...
***** 521. row *****
      USER: NULL
      HOST: NULL
      EVENT_NAME: statement/com/Error

      SUM_CREATED_TMP_TABLES: 0
      SUM_SELECT_FULL_JOIN: 0
SUM_SELECT_FULL_RANGE_JOIN: 0
      SUM_SELECT_RANGE: 0
SUM_SELECT_RANGE_CHECK: 0
      SUM_SELECT_SCAN: 0
      SUM_SORT_MERGE_PASSES: 0
      SUM_SORT_RANGE: 0
      SUM_SORT_ROWS: 0
      SUM_SORT_SCAN: 0
      SUM_NO_INDEX_USED: 0
      SUM_NO_GOOD_INDEX_USED: 0

```

1.1.1.2.9.2.1.16 Performance Schema events_statements_summary_by_digest Table

The [Performance Schema digest](#) is a hashed, normalized form of a statement with the specific data values removed. It allows statistics to be gathered for similar kinds of statements.

The [Performance Schema](#) `events_statements_summary_by_digest` table records statement events summarized by schema and digest. It contains the following columns:

Column	Description
--------	-------------

SCHEMA_NAME	Database name. Records are summarised together with DIGEST .
DIGEST	Performance Schema digest . Records are summarised together with SCHEMA_NAME .
DIGEST_TEXT	The unhashed form of the digest.
COUNT_STAR	Number of summarized events
SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.
MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.
AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.
MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.
SUM_LOCK_TIME	Sum of the LOCK_TIME column in the events_statements_current table.
SUM_ERRORS	Sum of the ERRORS column in the events_statements_current table.
SUM_WARNINGS	Sum of the WARNINGS column in the events_statements_current table.
SUM_ROWS_AFFECTED	Sum of the ROWS_AFFECTED column in the events_statements_current table.
SUM_ROWS_SENT	Sum of the ROWS_SENT column in the events_statements_current table.
SUM_ROWS_EXAMINED	Sum of the ROWS_EXAMINED column in the events_statements_current table.
SUM_CREATED_TMP_DISK_TABLES	Sum of the CREATED_TMP_DISK_TABLES column in the events_statements_current table.
SUM_CREATED_TMP_TABLES	Sum of the CREATED_TMP_TABLES column in the events_statements_current table.
SUM_SELECT_FULL_JOIN	Sum of the SELECT_FULL_JOIN column in the events_statements_current table.
SUM_SELECT_FULL_RANGE_JOIN	Sum of the SELECT_FULL_RANGE_JOIN column in the events_statements_current table.
SUM_SELECT_RANGE	Sum of the SELECT_RANGE column in the events_statements_current table.
SUM_SELECT_RANGE_CHECK	Sum of the SELECT_RANGE_CHECK column in the events_statements_current table.
SUM_SELECT_SCAN	Sum of the SELECT_SCAN column in the events_statements_current table.
SUM_SORT_MERGE_PASSES	Sum of the SORT_MERGE_PASSES column in the events_statements_current table.
SUM_SORT_RANGE	Sum of the SORT_RANGE column in the events_statements_current table.
SUM_SORT_ROWS	Sum of the SORT_ROWS column in the events_statements_current table.
SUM_SORT_SCAN	Sum of the SORT_SCAN column in the events_statements_current table.
SUM_NO_INDEX_USED	Sum of the NO_INDEX_USED column in the events_statements_current table.
SUM_NO_GOOD_INDEX_USED	Sum of the NO_GOOD_INDEX_USED column in the events_statements_current table.
FIRST_SEEN	Time at which the digest was first seen.
LAST_SEEN	Time at which the digest was most recently seen.

The *_TIMER_WAIT columns only calculate results for timed events, as non-timed events have a NULL wait time.

The events_statements_summary_by_digest table is limited in size by the [performance_schema_digests_size](#) system variable. Once the limit has been reached and the table is full, all entries are aggregated in a row with a NULL digest. The COUNT_STAR value of this NULL row indicates how many digests are recorded in the row and therefore gives an indication of whether [performance_schema_digests_size](#) should be increased to provide more accurate statistics.

1.1.1.2.9.2.1.17 Performance Schema events_statements_summary_by_host_by_event

Table

The [Performance Schema](#) `events_statements_summary_by_host_by_event_name` table contains statement events summarized by host and event name. It contains the following columns:

Column	Description
<code>HOST</code>	Host. Used together with <code>EVENT_NAME</code> for grouping events.
<code>EVENT_NAME</code>	Event name. Used together with <code>HOST</code> for grouping events.
<code>COUNT_STAR</code>	Number of summarized events
<code>SUM_TIMER_WAIT</code>	Total wait time of the summarized events that are timed.
<code>MIN_TIMER_WAIT</code>	Minimum wait time of the summarized events that are timed.
<code>AVG_TIMER_WAIT</code>	Average wait time of the summarized events that are timed.
<code>MAX_TIMER_WAIT</code>	Maximum wait time of the summarized events that are timed.
<code>SUM_LOCK_TIME</code>	Sum of the <code>LOCK_TIME</code> column in the <code>events_statements_current</code> table.
<code>SUM_ERRORS</code>	Sum of the <code>ERRORS</code> column in the <code>events_statements_current</code> table.
<code>SUM_WARNINGS</code>	Sum of the <code>WARNINGS</code> column in the <code>events_statements_current</code> table.
<code>SUM_ROWS_AFFECTED</code>	Sum of the <code>ROWS_AFFECTED</code> column in the <code>events_statements_current</code> table.
<code>SUM_ROWS_SENT</code>	Sum of the <code>ROWS_SENT</code> column in the <code>events_statements_current</code> table.
<code>SUM_ROWS_EXAMINED</code>	Sum of the <code>ROWS_EXAMINED</code> column in the <code>events_statements_current</code> table.
<code>SUM_CREATED_TMP_DISK_TABLES</code>	Sum of the <code>CREATED_TMP_DISK_TABLES</code> column in the <code>events_statements_current</code> table.
<code>SUM_CREATED_TMP_TABLES</code>	Sum of the <code>CREATED_TMP_TABLES</code> column in the <code>events_statements_current</code> table.
<code>SUM_SELECT_FULL_JOIN</code>	Sum of the <code>SELECT_FULL_JOIN</code> column in the <code>events_statements_current</code> table.
<code>SUM_SELECT_FULL_RANGE_JOIN</code>	Sum of the <code>SELECT_FULL_RANGE_JOIN</code> column in the <code>events_statements_current</code> table.
<code>SUM_SELECT_RANGE</code>	Sum of the <code>SELECT_RANGE</code> column in the <code>events_statements_current</code> table.
<code>SUM_SELECT_RANGE_CHECK</code>	Sum of the <code>SELECT_RANGE_CHECK</code> column in the <code>events_statements_current</code> table.
<code>SUM_SELECT_SCAN</code>	Sum of the <code>SELECT_SCAN</code> column in the <code>events_statements_current</code> table.
<code>SUM_SORT_MERGE_PASSES</code>	Sum of the <code>SORT_MERGE_PASSES</code> column in the <code>events_statements_current</code> table.
<code>SUM_SORT_RANGE</code>	Sum of the <code>SORT_RANGE</code> column in the <code>events_statements_current</code> table.
<code>SUM_SORT_ROWS</code>	Sum of the <code>SORT_ROWS</code> column in the <code>events_statements_current</code> table.
<code>SUM_SORT_SCAN</code>	Sum of the <code>SORT_SCAN</code> column in the <code>events_statements_current</code> table.
<code>SUM_NO_INDEX_USED</code>	Sum of the <code>NO_INDEX_USED</code> column in the <code>events_statements_current</code> table.
<code>SUM_NO_GOOD_INDEX_USED</code>	Sum of the <code>NO_GOOD_INDEX_USED</code> column in the <code>events_statements_current</code> table.

The `*_TIMER_WAIT` columns only calculate results for timed events, as non-timed events have a `NULL` wait time.

Example

```

SELECT * FROM events_statements_summary_by_host_by_event_name\G
...
***** 347. row *****
      HOST: NULL
      EVENT_NAME: statement/com/Error
      COUNT_STAR: 0
      SUM_TIMER_WAIT: 0
      MIN_TIMER_WAIT: 0
      AVG_TIMER_WAIT: 0
      MAX_TIMER_WAIT: 0
      SUM_LOCK_TIME: 0
      SUM_ERRORS: 0
      SUM_WARNINGS: 0
      SUM_ROWS_AFFECTED: 0
      SUM_ROWS_SENT: 0
      SUM_ROWS_EXAMINED: 0
SUM_CREATED_TMP_DISK_TABLES: 0
      SUM_CREATED_TMP_TABLES: 0
      SUM_SELECT_FULL_JOIN: 0

1.1.1.2.9.2.1.18 Performance Schema events_statements_summary_by_program Table

MariaDB starting with [10.5.2](#)

The `events_statements_summary_by_program` table, along with many other new [Performance Schema tables](#), was added in [MariaDB 10.5.2](#).

Each row in the the [Performance Schema](#) `events_statements_summary_by_program` table summarizes events for a particular stored program (stored procedure, stored function, trigger or event).

It contains the following fields.

Column	Type	Null	Description
OBJECT_TYPE	enum('EVENT', 'FUNCTION', 'PROCEDURE', 'TABLE', 'TRIGGER')	YES	Object type for which the summary is generated.
OBJECT_SCHEMA	varchar(64)	NO	The schema of the object for which the summary is generated.
OBJECT_NAME	varchar(64)	NO	The name of the object for which the summary is generated.
COUNT_STAR	bigint(20) unsigned	NO	The number of summarized events (from events_statements_current). This value includes all events, whether timed or nontimed.
SUM_TIMER_WAIT	bigint(20) unsigned	NO	The number of summarized events (from events_statements_current). This value includes all events, whether timed or nontimed.
MIN_TIMER_WAIT	bigint(20) unsigned	NO	The minimum wait time of the summarized timed events.
AVG_TIMER_WAIT	bigint(20) unsigned	NO	The average wait time of the summarized timed events.
MAX_TIMER_WAIT	bigint(20) unsigned	NO	The maximum wait time of the summarized timed events.
COUNT_STATEMENTS	bigint(20) unsigned	NO	Total number of nested statements invoked during stored program execution.
SUM_STATEMENTS_WAIT	bigint(20) unsigned	NO	The total wait time of the summarized timed statements. This value is calculated only for timed statements because nontimed statements have a wait time of NULL. The same is true for the other xxx_STATEMENT_WAIT values.
MIN_STATEMENTS_WAIT	bigint(20) unsigned	NO	The minimum wait time of the summarized timed statements.
AVG_STATEMENTS_WAIT	bigint(20) unsigned	NO	The average wait time of the summarized timed statements.
MAX_STATEMENTS_WAIT	bigint(20) unsigned	NO	The maximum wait time of the summarized timed statements.
SUM_LOCK_TIME	bigint(20) unsigned	NO	The total time spent (in picoseconds) waiting for table locks for the summarized statements.
SUM_ERRORS	bigint(20) unsigned	NO	The total number of errors that occurred for the summarized statements.
SUM_WARNINGS	bigint(20) unsigned	NO	The total number of warnings that occurred for the summarized statements.
SUM_ROWS_AFFECTED	bigint(20) unsigned	NO	The total number of affected rows by the summarized statements.
SUM_ROWS_SENT	bigint(20) unsigned	NO	The total number of rows returned by the summarized statements.
SUM_ROWS_EXAMINED	bigint(20) unsigned	NO	The total number of rows examined by the summarized statements. The total number of affected rows by the summarized statements.
SUM_CREATED_TMP_DISK_TABLES	bigint(20) unsigned	NO	The total number of on-disk temporary tables created by the summarized statements.
SUM_CREATED_TMP_TABLES	bigint(20) unsigned	NO	The total number of in-memory temporary tables created by the summarized statements.

SUM_SELECT_FULL_JOIN	bigint(20) unsigned	NO	The total number of full joins executed by the summarized statements.
SUM_SELECT_FULL_RANGE_JOIN	bigint(20) unsigned	NO	The total number of range search joins executed by the summarized statements.
SUM_SELECT_RANGE	bigint(20) unsigned	NO	The total number of joins that used ranges on the first table executed by the summarized statements.
SUM_SELECT_RANGE_CHECK	bigint(20) unsigned	NO	The total number of joins that check for key usage after each row executed by the summarized statements.
SUM_SELECT_SCAN	bigint(20) unsigned	NO	The total number of joins that did a full scan of the first table executed by the summarized statements.
SUM_SORT_MERGE_PASSES	bigint(20) unsigned	NO	The total number of merge passes that the sort algorithm has had to do for the summarized statements.
SUM_SORT_RANGE	bigint(20) unsigned	NO	The total number of sorts that were done using ranges for the summarized statements.
SUM_SORT_ROWS	bigint(20) unsigned	NO	The total number of sorted rows that were sorted by the summarized statements.
SUM_SORT_SCAN	bigint(20) unsigned	NO	The total number of sorts that were done by scanning the table by the summarized statements.
SUM_NO_INDEX_USED	bigint(20) unsigned	NO	The total number of statements that performed a table scan without using an index.
SUM_NO_GOOD_INDEX_USED	bigint(20) unsigned	NO	The total number of statements where no good index was found.

1.1.1.2.9.2.1.19 Performance Schema events_statements_summary_by_thread_by_event Table

The [Performance Schema](#) `events_statements_summary_by_thread_by_event_name` table contains statement events summarized by thread and event name. It contains the following columns:

Column	Description
THREAD_ID	Thread associated with the event. Together with <code>EVENT_NAME</code> uniquely identifies the row.
EVENT_NAME	Event name. Used together with <code>THREAD_ID</code> for grouping events.
COUNT_STAR	Number of summarized events
SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.
MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.
AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.
MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.
SUM_LOCK_TIME	Sum of the <code>LOCK_TIME</code> column in the <code>events_statements_current</code> table.
SUM_ERRORS	Sum of the <code>ERRORS</code> column in the <code>events_statements_current</code> table.
SUM_WARNINGS	Sum of the <code>WARNINGS</code> column in the <code>events_statements_current</code> table.
SUM_ROWS_AFFECTED	Sum of the <code>ROWS_AFFECTED</code> column in the <code>events_statements_current</code> table.
SUM_ROWS_SENT	Sum of the <code>ROWS_SENT</code> column in the <code>events_statements_current</code> table.
SUM_ROWS_EXAMINED	Sum of the <code>ROWS_EXAMINED</code> column in the <code>events_statements_current</code> table.
SUM_CREATED_TMP_DISK_TABLES	Sum of the <code>CREATED_TMP_DISK_TABLES</code> column in the <code>events_statements_current</code> table.
SUM_CREATED_TMP_TABLES	Sum of the <code>CREATED_TMP_TABLES</code> column in the <code>events_statements_current</code> table.

SUM_SELECT_FULL_JOIN	Sum of the SELECT_FULL_JOIN column in the events_statements_current table.
SUM_SELECT_FULL_RANGE_JOIN	Sum of the SELECT_FULL_RANGE_JOIN column in the events_statements_current table.
SUM_SELECT_RANGE	Sum of the SELECT_RANGE column in the events_statements_current table.
SUM_SELECT_RANGE_CHECK	Sum of the SELECT_RANGE_CHECK column in the events_statements_current table.
SUM_SELECT_SCAN	Sum of the SELECT_SCAN column in the events_statements_current table.
SUM_SORT_MERGE_PASSES	Sum of the SORT_MERGE_PASSES column in the events_statements_current table.
SUM_SORT_RANGE	Sum of the SORT_RANGE column in the events_statements_current table.
SUM_SORT_ROWS	Sum of the SORT_ROWS column in the events_statements_current table.
SUM_SORT_SCAN	Sum of the SORT_SCAN column in the events_statements_current table.
SUM_NO_INDEX_USED	Sum of the NO_INDEX_USED column in the events_statements_current table.
SUM_NO_GOOD_INDEX_USED	Sum of the NO_GOOD_INDEX_USED column in the events_statements_current table.

The *_TIMER_WAIT columns only calculate results for timed events, as non-timed events have a NULL wait time.

Example

```

SELECT * FROM events_statements_summary_by_thread_by_event_name\G

1.1.1.2.9.2.1.20 Performance Schema events_statements_summary_by_user_by_event Table

The [Performance Schema](#) `events_statements_summary_by_user_by_event_name` table contains statement events summarized by user and event name. It contains the following columns:

Column	Description
USER	User. Used together with <code>EVENT_NAME</code> for grouping events.
EVENT_NAME	Event name. Used together with <code>USER</code> for grouping events.

COUNT_STAR	Number of summarized events
SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.
MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.
AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.
MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.
SUM_LOCK_TIME	Sum of the LOCK_TIME column in the events_statements_current table.
SUM_ERRORS	Sum of the ERRORS column in the events_statements_current table.
SUM_WARNINGS	Sum of the WARNINGS column in the events_statements_current table.
SUM_ROWS_AFFECTED	Sum of the ROWS_AFFECTED column in the events_statements_current table.
SUM_ROWS_SENT	Sum of the ROWS_SENT column in the events_statements_current table.
SUM_ROWS_EXAMINED	Sum of the ROWS_EXAMINED column in the events_statements_current table.
SUM_CREATED_TMP_DISK_TABLES	Sum of the CREATED_TMP_DISK_TABLES column in the events_statements_current table.
SUM_CREATED_TMP_TABLES	Sum of the CREATED_TMP_TABLES column in the events_statements_current table.
SUM_SELECT_FULL_JOIN	Sum of the SELECT_FULL_JOIN column in the events_statements_current table.
SUM_SELECT_FULL_RANGE_JOIN	Sum of the SELECT_FULL_RANGE_JOIN column in the events_statements_current table.
SUM_SELECT_RANGE	Sum of the SELECT_RANGE column in the events_statements_current table.
SUM_SELECT_RANGE_CHECK	Sum of the SELECT_RANGE_CHECK column in the events_statements_current table.
SUM_SELECT_SCAN	Sum of the SELECT_SCAN column in the events_statements_current table.
SUM_SORT_MERGE_PASSES	Sum of the SORT_MERGE_PASSES column in the events_statements_current table.
SUM_SORT_RANGE	Sum of the SORT_RANGE column in the events_statements_current table.
SUM_SORT_ROWS	Sum of the SORT_ROWS column in the events_statements_current table.
SUM_SORT_SCAN	Sum of the SORT_SCAN column in the events_statements_current table.
SUM_NO_INDEX_USED	Sum of the NO_INDEX_USED column in the events_statements_current table.
SUM_NO_GOOD_INDEX_USED	Sum of the NO_GOOD_INDEX_USED column in the events_statements_current table.

The *_TIMER_WAIT columns only calculate results for timed events, as non-timed events have a NULL wait time.

Example

```

SELECT * FROM events_statements_summary_by_user_by_event_name\G
...

1.1.1.2.9.2.1.21 Performance Schema events_statements_summary_global_by_event_n Table

The [Performance Schema](#) `events_statements_summary_global_by_event_name` table contains statement events summarized by event name. It contains the following columns:

Column	Description
EVENT_NAME	Event name.
COUNT_STAR	Number of summarized events

SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.
MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.
AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.
MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.
SUM_LOCK_TIME	Sum of the LOCK_TIME column in the events_statements_current table.
SUM_ERRORS	Sum of the ERRORS column in the events_statements_current table.
SUM_WARNINGS	Sum of the WARNINGS column in the events_statements_current table.
SUM_ROWS_AFFECTED	Sum of the ROWS_AFFECTED column in the events_statements_current table.
SUM_ROWS_SENT	Sum of the ROWS_SENT column in the events_statements_current table.
SUM_ROWS_EXAMINED	Sum of the ROWS_EXAMINED column in the events_statements_current table.
SUM_CREATED_TMP_DISK_TABLES	Sum of the CREATED_TMP_DISK_TABLES column in the events_statements_current table.
SUM_CREATED_TMP_TABLES	Sum of the CREATED_TMP_TABLES column in the events_statements_current table.
SUM_SELECT_FULL_JOIN	Sum of the SELECT_FULL_JOIN column in the events_statements_current table.
SUM_SELECT_FULL_RANGE_JOIN	Sum of the SELECT_FULL_RANGE_JOIN column in the events_statements_current table.
SUM_SELECT_RANGE	Sum of the SELECT_RANGE column in the events_statements_current table.
SUM_SELECT_RANGE_CHECK	Sum of the SELECT_RANGE_CHECK column in the events_statements_current table.
SUM_SELECT_SCAN	Sum of the SELECT_SCAN column in the events_statements_current table.
SUM_SORT_MERGE_PASSES	Sum of the SORT_MERGE_PASSES column in the events_statements_current table.
SUM_SORT_RANGE	Sum of the SORT_RANGE column in the events_statements_current table.
SUM_SORT_ROWS	Sum of the SORT_ROWS column in the events_statements_current table.
SUM_SORT_SCAN	Sum of the SORT_SCAN column in the events_statements_current table.
SUM_NO_INDEX_USED	Sum of the NO_INDEX_USED column in the events_statements_current table.
SUM_NO_GOOD_INDEX_USED	Sum of the NO_GOOD_INDEX_USED column in the events_statements_current table.

The *_TIMER_WAIT columns only calculate results for timed events, as non-timed events have a NULL wait time.

Example

```

1.1.1.2.9.2.1.22 Performance Schema events_transactions_current Table

MariaDB starting with [10.5.2](#)

The events_transactions_current table was introduced in [MariaDB 10.5.2](#).

The `events_transactions_current` table contains current transaction events for each thread.

The table size cannot be figured, and always stores one row for each thread, showing the current status of the thread's most recent monitored transaction event.

The table contains the following columns:

Column	Type	Description
--------	------	-------------

THREAD_ID	bigint(20) unsigned	The thread associated with the event.
EVENT_ID	bigint(20) unsigned	The event id associated with the event.
END_EVENT_ID	bigint(20) unsigned	This column is set to NULL when the event starts and updated to the thread current event number when the event ends.
EVENT_NAME	varchar(128)	The name of the instrument from which the event was collected. This is a NAME value from the setup_instruments table.
STATE	enum('ACTIVE', 'COMMITTED', 'ROLLED BACK')	The current transaction state. The value is ACTIVE (after START TRANSACTION or BEGIN), COMMITTED (after COMMIT), or ROLLED BACK (after ROLLBACK).
TRX_ID	bigint(20) unsigned	Unused.
GTID	varchar(64)	Transaction GTID , using the format DOMAIN-SERVER_ID-SEQUENCE_NO.
XID_FORMAT_ID	int(11)	XA transaction format ID for GTRID and BQUAL values.
XID_GTRID	varchar(130)	XA global transaction ID.
XID_BQUAL	varchar(130)	XA transaction branch qualifier.
XA_STATE	varchar(64)	The state of the XA transaction. The value is ACTIVE (after XA START), IDLE (after XA END), PREPARED (after XA PREPARE), ROLLED BACK (after XA ROLLBACK), or COMMITTED (after XA COMMIT).
SOURCE	varchar(64)	The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs.
TIMER_START	bigint(20) unsigned	The unit is picoseconds. When event timing started. NULL if event has no timing information.
TIMER_END	bigint(20) unsigned	The unit is picoseconds. When event timing ended. NULL if event has no timing information.
TIMER_WAIT	bigint(20) unsigned	The unit is picoseconds. Event duration. NULL if event has not timing information.
ACCESS_MODE	enum('READ ONLY', 'READ WRITE')	Transaction access mode.
ISOLATION_LEVEL	varchar(64)	Transaction isolation level. One of: REPEATABLE READ, READ COMMITTED, READ UNCOMMITTED, or SERIALIZABLE.
AUTOCOMMIT	enum('YES', 'NO')	Whether autocommit mode was enabled when the transaction started.
NUMBER_OF_SAVEPOINTS	bigint(20) unsigned	The number of SAVEPOINT statements issued during the transaction.
NUMBER_OF_ROLLBACK_TO_SAVEPOINT	bigint(20) unsigned	The number of ROLLBACK_TO_SAVEPOINT statements issued during the transaction.
NUMBER_OF_RELEASE_SAVEPOINT	bigint(20) unsigned	The number of RELEASE_SAVEPOINT statements issued during the transaction.
OBJECT_INSTANCE_BEGIN	bigint(20) unsigned	Unused.
NESTING_EVENT_ID	bigint(20) unsigned	The EVENT_ID value of the event within which this event is nested.
NESTING_EVENT_TYPE	enum('TRANSACTION', 'STATEMENT', 'STAGE', 'WAIT')	The nesting event type.

1.1.1.2.9.2.1.23 Performance Schema events_transactions_history Table

MariaDB starting with [10.5.2](#)

The events_transactions_history table was introduced in [MariaDB 10.5.2](#).

The events_transactions_history table contains the most recent completed transaction events for each thread.

The number of records stored per thread in the table is determined by the performance_schema_events_transactions_history_size system variable, which is autosized on startup.

If adding a completed transaction event would cause the table to exceed this limit, the oldest thread row is discarded.

All of a thread's rows are discarded when the thread ends.

The table contains the following columns:

Column	Type	Description
THREAD_ID	bigint(20) unsigned	The thread associated with the event.
EVENT_ID	bigint(20) unsigned	The event id associated with the event.
END_EVENT_ID	bigint(20) unsigned	This column is set to NULL when the event starts and updated to the thread current event number when the event ends.
EVENT_NAME	varchar(128)	The name of the instrument from which the event was collected. This is a NAME value from the setup_instruments table.
STATE	enum('ACTIVE', 'COMMITTED', 'ROLLED BACK')	The current transaction state. The value is ACTIVE (after START TRANSACTION or BEGIN), COMMITTED (after COMMIT), or ROLLED BACK (after ROLLBACK).
TRX_ID	bigint(20) unsigned	Unused.
GTID	varchar(64)	Transaction GTID, using the format DOMAIN-SERVER_ID-SEQUENCE_NO.
XID_FORMAT_ID	int(11)	XA transaction format ID for GTRID and BQUAL values.
XID_GTRID	varchar(130)	XA global transaction ID.
XID_BQUAL	varchar(130)	XA transaction branch qualifier.
XA_STATE	varchar(64)	The state of the XA transaction. The value is ACTIVE (after XA START), IDLE (after XA END), PREPARED (after XA PREPARE), ROLLED BACK (after XA ROLLBACK), or COMMITTED (after XA COMMIT).
SOURCE	varchar(64)	The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs.
TIMER_START	bigint(20) unsigned	The unit is picoseconds. When event timing started. NULL if event has no timing information.
TIMER_END	bigint(20) unsigned	The unit is picoseconds. When event timing ended. NULL if event has no timing information.
TIMER_WAIT	bigint(20) unsigned	The unit is picoseconds. Event duration. NULL if event has not timing information.
ACCESS_MODE	enum('READ ONLY', 'READ WRITE')	Transaction access mode.

ISOLATION_LEVEL	varchar(64)	Transaction isolation level. One of: REPEATABLE READ, READ COMMITTED, READ UNCOMMITTED, or SERIALIZABLE.
AUTOCOMMIT	enum('YES', 'NO')	NO
NUMBER_OF_SAVEPOINTS	bigint(20) unsigned	The number of SAVEPOINT statements issued during the transaction.
NUMBER_OF_ROLLBACK_TO_SAVEPOINT	bigint(20) unsigned	The number of ROLLBACK_TO_SAVEPOINT statements issued during the transaction.
NUMBER_OF_RELEASE_SAVEPOINT	bigint(20) unsigned	The number of RELEASE_SAVEPOINT statements issued during the transaction.
OBJECT_INSTANCE_BEGIN	bigint(20) unsigned	Unused.
NESTING_EVENT_ID	bigint(20) unsigned	The EVENT_ID value of the event within which this event is nested.
NESTING_EVENT_TYPE	enum('TRANSACTION', 'STATEMENT', 'STAGE', 'WAIT')	The nesting event type.

1.1.1.2.9.2.1.24 Performance Schema events_transactions_history_long Table

MariaDB starting with [10.5.2](#)

The events_transactions_history_long table was introduced in [MariaDB 10.5.2](#).

The `events_transactions_history_long` table contains the most recent completed transaction events that have ended globally, across all threads.

The number of records stored in the table is determined by the `performance_schema_events_transactions_history_long_size` system variable, which is autosized on startup.

If adding a completed transaction would cause the table to exceed this limit, the oldest row, regardless of thread, is discarded.

The table contains the following columns:

Column	Type	Description
THREAD_ID	bigint(20) unsigned	The thread associated with the event.
EVENT_ID	bigint(20) unsigned	The event id associated with the event.
END_EVENT_ID	bigint(20) unsigned	This column is set to NULL when the event starts and updated to the thread current event number when the event ends.
EVENT_NAME	varchar(128)	The name of the instrument from which the event was collected. This is a NAME value from the setup_instruments table.
STATE	enum('ACTIVE', 'COMMITTED', 'ROLLED BACK')	The current transaction state. The value is ACTIVE (after START TRANSACTION or BEGIN), COMMITTED (after COMMIT), or ROLLED BACK (after ROLLBACK).
TRX_ID	bigint(20) unsigned	Unused.
GTID	varchar(64)	Transaction GTID , using the format DOMAIN-SERVER_ID-SEQUENCE_NO.
XID_FORMAT_ID	int(11)	XA transaction format ID for GTRID and BQUAL values.
XID_GTRID	varchar(130)	XA global transaction ID.
XID_BQUAL	varchar(130)	XA transaction branch qualifier.

XA_STATE	varchar(64)	The state of the XA transaction. The value is ACTIVE (after XA START), IDLE (after XA END), PREPARED (after XA PREPARE), ROLLED BACK (after XA ROLLBACK), or COMMITTED (after XA COMMIT).
SOURCE	varchar(64)	The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs.
TIMER_START	bigint(20) unsigned	The unit is picoseconds. When event timing started. NULL if event has no timing information.
TIMER_END	bigint(20) unsigned	The unit is picoseconds. When event timing ended. NULL if event has no timing information.
TIMER_WAIT	bigint(20) unsigned	The unit is picoseconds. Event duration. NULL if event has not timing information.
ACCESS_MODE	enum('READ ONLY', 'READ WRITE')	Transaction access mode.
ISOLATION_LEVEL	varchar(64)	Transaction isolation level. One of: REPEATABLE READ, READ COMMITTED, READ UNCOMMITTED, or SERIALIZABLE.
AUTOCOMMIT	enum('YES', 'NO')	NO
NUMBER_OF_SAVEPOINTS	bigint(20) unsigned	The number of SAVEPOINT statements issued during the transaction.
NUMBER_OF_ROLLBACK_TO_SAVEPOINT	bigint(20) unsigned	The number of ROLLBACK_TO_SAVEPOINT statements issued during the transaction.
NUMBER_OF_RELEASE_SAVEPOINT	bigint(20) unsigned	The number of RELEASE_SAVEPOINT statements issued during the transaction.
OBJECT_INSTANCE_BEGIN	bigint(20) unsigned	Unused.
NESTING_EVENT_ID	bigint(20) unsigned	The EVENT_ID value of the event within which this event is nested.
NESTING_EVENT_TYPE	enum('TRANSACTION', 'STATEMENT', 'STAGE', 'WAIT')	The nesting event type.

1.1.1.2.9.2.1.25 Performance Schema events_transactions_summary_by_account_by_event_name Table

MariaDB starting with [10.5.2](#)

The events_transactions_summary_by_account_by_event_name table was introduced in [MariaDB 10.5.2](#).

The events_transactions_summary_by_account_by_event_name table contains information on transaction events aggregated by account and event name.

The table contains the following columns:

Column	Type	Description
USER	char(32)	User for which summary is generated.
HOST	char(60)	Host for which summary is generated.
EVENT_NAME	varchar(128)	Event name for which summary is generated.
COUNT_STAR	bigint(20) unsigned	The number of summarized events. This value includes all events, whether timed or nontimed.

SUM_TIMER_WAIT	bigint(20) unsigned	The total wait time of the summarized timed events. This value is calculated only for timed events because nontimed events have a wait time of NULL. The same is true for the other xxx_TIMER_WAIT values.
MIN_TIMER_WAIT	bigint(20) unsigned	The minimum wait time of the summarized timed events.
AVG_TIMER_WAIT	bigint(20) unsigned	The average wait time of the summarized timed events.
MAX_TIMER_WAIT	bigint(20) unsigned	The maximum wait time of the summarized timed events.
COUNT_READ_WRITE	bigint(20) unsigned	The total number of only READ/WRITE transaction events.
SUM_TIMER_READ_WRITE	bigint(20) unsigned	The total wait time of only READ/WRITE transaction events.
MIN_TIMER_READ_WRITE	bigint(20) unsigned	The minimum wait time of only READ/WRITE transaction events.
AVG_TIMER_READ_WRITE	bigint(20) unsigned	The average wait time of only READ/WRITE transaction events.
MAX_TIMER_READ_WRITE	bigint(20) unsigned	The maximum wait time of only READ/WRITE transaction events.
COUNT_READ_ONLY	bigint(20) unsigned	The total number of only READ ONLY transaction events.
SUM_TIMER_READ_ONLY	bigint(20) unsigned	The total wait time of only READ ONLY transaction events.
MIN_TIMER_READ_ONLY	bigint(20) unsigned	The minimum wait time of only READ ONLY transaction events.
AVG_TIMER_READ_ONLY	bigint(20) unsigned	The average wait time of only READ ONLY transaction events.
MAX_TIMER_READ_ONLY	bigint(20) unsigned	The maximum wait time of only READ ONLY transaction events.

1.1.1.2.9.2.1.26 Performance Schema events_transactions_summary_by_host_by_event Table

MariaDB starting with [10.5.2](#)

The events_transactions_summary_by_host_by_event_name table was introduced in [MariaDB 10.5.2](#).

The events_transactions_summary_by_host_by_event_name table contains information on transaction events aggregated by host and event name.

The table contains the following columns:

Column	Type	Description
HOST	char(60)	Host for which summary is generated.
EVENT_NAME	varchar(128)	Event name for which summary is generated.
COUNT_STAR	bigint(20) unsigned	The number of summarized events. This value includes all events, whether timed or nontimed.
SUM_TIMER_WAIT	bigint(20) unsigned	The total wait time of the summarized timed events. This value is calculated only for timed events because nontimed events have a wait time of NULL. The same is true for the other xxx_TIMER_WAIT values.
MIN_TIMER_WAIT	bigint(20) unsigned	The minimum wait time of the summarized timed events.

AVG_TIMER_WAIT	bigint(20) unsigned	The average wait time of the summarized timed events.
MAX_TIMER_WAIT	bigint(20) unsigned	The maximum wait time of the summarized timed events.
COUNT_READ_WRITE	bigint(20) unsigned	The total number of only READ/WRITE transaction events.
SUM_TIMER_READ_WRITE	bigint(20) unsigned	The total wait time of only READ/WRITE transaction events.
MIN_TIMER_READ_WRITE	bigint(20) unsigned	The minimum wait time of only READ/WRITE transaction events.
AVG_TIMER_READ_WRITE	bigint(20) unsigned	The average wait time of only READ/WRITE transaction events.
MAX_TIMER_READ_WRITE	bigint(20) unsigned	The maximum wait time of only READ/WRITE transaction events.
COUNT_READ_ONLY	bigint(20) unsigned	The total number of only READ ONLY transaction events.
SUM_TIMER_READ_ONLY	bigint(20) unsigned	The total wait time of only READ ONLY transaction events.
MIN_TIMER_READ_ONLY	bigint(20) unsigned	The minimum wait time of only READ ONLY transaction events.
AVG_TIMER_READ_ONLY	bigint(20) unsigned	The average wait time of only READ ONLY transaction events.
MAX_TIMER_READ_ONLY	bigint(20) unsigned	The maximum wait time of only READ ONLY transaction events.

1.1.1.2.9.2.1.27 Performance Schema events_transactions_summary_by_thread_by_event Table

MariaDB starting with [10.5.2](#)

The events_transactions_summary_by_thread_by_event_name table was introduced in [MariaDB 10.5.2](#).

The events_transactions_summary_by_thread_by_event_name table contains information on transaction events aggregated by thread and event name.

The table contains the following columns:

```

+-----+-----+-----+-----+-----+-----+
| Field          | Type                | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| THREAD_ID      | bigint(20) unsigned | NO   |     | NULL    |       |
| EVENT_NAME     | varchar(128)        | NO   |     | NULL    |       |
| COUNT_STAR     | bigint(20) unsigned | NO   |     | NULL    |       |
| SUM_TIMER_WAIT | bigint(20) unsigned | NO   |     | NULL    |       |
| MIN_TIMER_WAIT | bigint(20) unsigned | NO   |     | NULL    |       |
| AVG_TIMER_WAIT | bigint(20) unsigned | NO   |     | NULL    |       |
| MAX_TIMER_WAIT | bigint(20) unsigned | NO   |     | NULL    |       |
| COUNT_READ_WRITE | bigint(20) unsigned | NO   |     | NULL    |       |
| SUM_TIMER_READ_WRITE | bigint(20) unsigned | NO   |     | NULL    |       |
| MIN_TIMER_READ_WRITE | bigint(20) unsigned | NO   |     | NULL    |       |
| AVG_TIMER_READ_WRITE | bigint(20) unsigned | NO   |     | NULL    |       |
| MAX_TIMER_READ_WRITE | bigint(20) unsigned | NO   |     | NULL    |       |
| COUNT_READ_ONLY | bigint(20) unsigned | NO   |     | NULL    |       |
| SUM_TIMER_READ_ONLY | bigint(20) unsigned | NO   |     | NULL    |       |
| MIN_TIMER_READ_ONLY | bigint(20) unsigned | NO   |     | NULL    |       |
| AVG_TIMER_READ_ONLY | bigint(20) unsigned | NO   |     | NULL    |       |
| MAX_TIMER_READ_ONLY | bigint(20) unsigned | NO   |     | NULL    |       |
+-----+-----+-----+-----+-----+-----+

```

1.1.1.2.9.2.1.28 Performance Schema events_transactions_summary_by_user_by_event Table

MariaDB starting with [10.5.2](#)

The events_transactions_summary_by_user_by_event_name table was introduced in [MariaDB 10.5.2](#).

The events_transactions_summary_by_user_by_event_name table contains information on transaction events aggregated by user and event name.

The table contains the following columns:

Field	Type	Null	Key	Default	Extra
USER	char(32)	YES		NULL	
EVENT_NAME	varchar(128)	NO		NULL	
COUNT_STAR	bigint(20) unsigned	NO		NULL	
SUM_TIMER_WAIT	bigint(20) unsigned	NO		NULL	
MIN_TIMER_WAIT	bigint(20) unsigned	NO		NULL	
AVG_TIMER_WAIT	bigint(20) unsigned	NO		NULL	
MAX_TIMER_WAIT	bigint(20) unsigned	NO		NULL	
COUNT_READ_WRITE	bigint(20) unsigned	NO		NULL	
SUM_TIMER_READ_WRITE	bigint(20) unsigned	NO		NULL	
MIN_TIMER_READ_WRITE	bigint(20) unsigned	NO		NULL	
AVG_TIMER_READ_WRITE	bigint(20) unsigned	NO		NULL	
MAX_TIMER_READ_WRITE	bigint(20) unsigned	NO		NULL	
COUNT_READ_ONLY	bigint(20) unsigned	NO		NULL	
SUM_TIMER_READ_ONLY	bigint(20) unsigned	NO		NULL	
MIN_TIMER_READ_ONLY	bigint(20) unsigned	NO		NULL	
AVG_TIMER_READ_ONLY	bigint(20) unsigned	NO		NULL	
MAX_TIMER_READ_ONLY	bigint(20) unsigned	NO		NULL	

1.1.1.2.9.2.1.29 Performance Schema events_transactions_summary_global_by_event_ Table

MariaDB starting with [10.5.2](#)

The events_transactions_summary_global_by_event_name table was introduced in [MariaDB 10.5.2](#).

The events_transactions_summary_global_by_event_name table contains information on transaction events aggregated by event name.

The table contains the following columns:

Field	Type	Null	Key	Default	Extra
EVENT_NAME	varchar(128)	NO		NULL	
COUNT_STAR	bigint(20) unsigned	NO		NULL	
SUM_TIMER_WAIT	bigint(20) unsigned	NO		NULL	
MIN_TIMER_WAIT	bigint(20) unsigned	NO		NULL	
AVG_TIMER_WAIT	bigint(20) unsigned	NO		NULL	
MAX_TIMER_WAIT	bigint(20) unsigned	NO		NULL	
COUNT_READ_WRITE	bigint(20) unsigned	NO		NULL	
SUM_TIMER_READ_WRITE	bigint(20) unsigned	NO		NULL	
MIN_TIMER_READ_WRITE	bigint(20) unsigned	NO		NULL	
AVG_TIMER_READ_WRITE	bigint(20) unsigned	NO		NULL	
MAX_TIMER_READ_WRITE	bigint(20) unsigned	NO		NULL	
COUNT_READ_ONLY	bigint(20) unsigned	NO		NULL	
SUM_TIMER_READ_ONLY	bigint(20) unsigned	NO		NULL	
MIN_TIMER_READ_ONLY	bigint(20) unsigned	NO		NULL	
AVG_TIMER_READ_ONLY	bigint(20) unsigned	NO		NULL	
MAX_TIMER_READ_ONLY	bigint(20) unsigned	NO		NULL	

1.1.1.2.9.2.1.30 Performance Schema events_waits_current Table

The `events_waits_current` table contains the status of a thread's most recently monitored wait event, listing one event per thread.

The table contains the following columns:

Column	Description
THREAD_ID	Thread associated with the event. Together with <code>EVENT_ID</code> uniquely identifies the row.
EVENT_ID	Thread's current event number at the start of the event. Together with <code>THREAD_ID</code> uniquely identifies the row.
END_EVENT_ID	<code>NULL</code> when the event starts, set to the thread's current event number at the end of the event.
EVENT_NAME	Event instrument name and a <code>NAME</code> from the <code>setup_instruments</code> table
SOURCE	Name and line number of the source file containing the instrumented code that produced the event.
TIMER_START	Value in picoseconds when the event timing started or <code>NULL</code> if timing is not collected.
TIMER_END	Value in picoseconds when the event timing ended, or <code>NULL</code> if the event has not ended or timing is not collected.
TIMER_WAIT	Value in picoseconds of the event's duration or <code>NULL</code> if the event has not ended or timing is not collected.
SPINS	Number of spin rounds for a mutex, or <code>NULL</code> if spin rounds are not used, or spinning is not instrumented.
OBJECT_SCHEMA	Name of the schema that contains the table for table I/O objects, otherwise <code>NULL</code> for file I/O and synchronization objects.
OBJECT_NAME	File name for file I/O objects, table name for table I/O objects, the socket's <code>IP:PORT</code> value for a socket object or <code>NULL</code> for a synchronization object.
INDEX_NAME	Name of the index, <code>PRIMARY</code> for the primary key, or <code>NULL</code> for no index used.
OBJECT_TYPE	<code>FILE</code> for a file object, <code>TABLE</code> or <code>TEMPORARY TABLE</code> for a table object, or <code>NULL</code> for a synchronization object.
OBJECT_INSTANCE_BEGIN	Address in memory of the object.
NESTING_EVENT_ID	<code>EVENT_ID</code> of event within which this event nests.
NESTING_EVENT_TYPE	Nesting event type. Either <code>statement</code> , <code>stage</code> or <code>wait</code> .

OPERATION	Operation type, for example read, write or lock
NUMBER_OF_BYTES	Number of bytes that the operation read or wrote, or <code>NULL</code> for table I/O waits.
FLAGS	Reserved for use in the future.

It is possible to empty this table with a `TRUNCATE TABLE` statement.

The related tables, [events_waits_history](#) and [events_waits_history_long](#) derive their values from the current events.

1.1.1.2.9.2.1.31 Performance Schema `events_waits_history` Table

The `events_waits_history` table by default contains the ten most recent completed wait events per thread. This number can be adjusted by setting the [performance_schema_events_waits_history_size](#) system variable when the server starts up.

The table structure is identical to the [events_waits_current](#) table structure, and contains the following columns:

Column	Description
THREAD_ID	Thread associated with the event. Together with <code>EVENT_ID</code> uniquely identifies the row.
EVENT_ID	Thread's current event number at the start of the event. Together with <code>THREAD_ID</code> uniquely identifies the row.
END_EVENT_ID	<code>NULL</code> when the event starts, set to the thread's current event number at the end of the event.
EVENT_NAME	Event instrument name and a <code>NAME</code> from the <code>setup_instruments</code> table
SOURCE	Name and line number of the source file containing the instrumented code that produced the event.
TIMER_START	Value in picoseconds when the event timing started or <code>NULL</code> if timing is not collected.
TIMER_END	Value in picoseconds when the event timing ended, or <code>NULL</code> if timing is not collected.
TIMER_WAIT	Value in picoseconds of the event's duration or <code>NULL</code> if timing is not collected.
SPINS	Number of spin rounds for a mutex, or <code>NULL</code> if spin rounds are not used, or spinning is not instrumented.
OBJECT_SCHEMA	Name of the schema that contains the table for table I/O objects, otherwise <code>NULL</code> for file I/O and synchronization objects.
OBJECT_NAME	File name for file I/O objects, table name for table I/O objects, the socket's <code>IP:PORT</code> value for a socket object or <code>NULL</code> for a synchronization object.
INDEX_NAME	Name of the index, <code>PRIMARY</code> for the primary key, or <code>NULL</code> for no index used.
OBJECT_TYPE	<code>FILE</code> for a file object, <code>TABLE</code> or <code>TEMPORARY TABLE</code> for a table object, or <code>NULL</code> for a synchronization object.
OBJECT_INSTANCE_BEGIN	Address in memory of the object.
NESTING_EVENT_ID	<code>EVENT_ID</code> of event within which this event nests.
NESTING_EVENT_TYPE	Nesting event type. Either <code>statement</code> , <code>stage</code> or <code>wait</code> .
OPERATION	Operation type, for example read, write or lock
NUMBER_OF_BYTES	Number of bytes that the operation read or wrote, or <code>NULL</code> for table I/O waits.
FLAGS	Reserved for use in the future.

It is possible to empty this table with a `TRUNCATE TABLE` statement.

[events_waits_current](#) and [events_waits_history_long](#) are related tables.

1.1.1.2.9.2.1.32 Performance Schema `events_waits_history_long` Table

The `events_waits_history_long` table by default contains the ten thousand most recent completed wait events. This

number can be adjusted by setting the [performance_schema_events_waits_history_long_size](#) system variable when the server starts up.

The table structure is identical to the [events_waits_current](#) table structure, and contains the following columns:

Column	Description
THREAD_ID	Thread associated with the event. Together with <code>EVENT_ID</code> uniquely identifies the row.
EVENT_ID	Thread's current event number at the start of the event. Together with <code>THREAD_ID</code> uniquely identifies the row.
END_EVENT_ID	<code>NULL</code> when the event starts, set to the thread's current event number at the end of the event.
EVENT_NAME	Event instrument name and a NAME from the <code>setup_instruments</code> table
SOURCE	Name and line number of the source file containing the instrumented code that produced the event.
TIMER_START	Value in picoseconds when the event timing started or <code>NULL</code> if timing is not collected.
TIMER_END	Value in picoseconds when the event timing ended, or <code>NULL</code> if timing is not collected.
TIMER_WAIT	Value in picoseconds of the event's duration or <code>NULL</code> if timing is not collected.
SPINS	Number of spin rounds for a mutex, or <code>NULL</code> if spin rounds are not used, or spinning is not instrumented.
OBJECT_SCHEMA	Name of the schema that contains the table for table I/O objects, otherwise <code>NULL</code> for file I/O and synchronization objects.
OBJECT_NAME	File name for file I/O objects, table name for table I/O objects, the socket's IP:PORT value for a socket object or <code>NULL</code> for a synchronization object.
INDEX_NAME	Name of the index, PRIMARY for the primary key, or <code>NULL</code> for no index used.
OBJECT_TYPE	FILE for a file object, TABLE or TEMPORARY TABLE for a table object, or <code>NULL</code> for a synchronization object.
OBJECT_INSTANCE_BEGIN	Address in memory of the object.
NESTING_EVENT_ID	<code>EVENT_ID</code> of event within which this event nests.
NESTING_EVENT_TYPE	Nesting event type. Either <code>statement</code> , <code>stage</code> or <code>wait</code> .
OPERATION	Operation type, for example read, write or lock
NUMBER_OF_BYTES	Number of bytes that the operation read or wrote, or <code>NULL</code> for table I/O waits.
FLAGS	Reserved for use in the future.

It is possible to empty this table with a `TRUNCATE TABLE` statement.

`events_waits_current` and `events_waits_history` are related tables.

1.1.1.2.9.2.1.33 Performance Schema `events_waits_summary_by_account_by_event_name` Table

The [Performance Schema](#) `events_waits_summary_by_account_by_event_name` table contains wait events summarized by account and event name. It contains the following columns:

Column	Description
USER	User. Used together with <code>HOST</code> and <code>EVENT_NAME</code> for grouping events.
HOST	Host. Used together with <code>USER</code> and <code>EVENT_NAME</code> for grouping events.
EVENT_NAME	Event name. Used together with <code>USER</code> and <code>HOST</code> for grouping events.
COUNT_STAR	Number of summarized events
SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.

MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.
AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.
MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.

The *_TIMER_WAIT columns only calculate results for timed events, as non-timed events have a NULL wait time.

Example

```

SELECT * FROM events_waits_summary_by_account_by_event_name\G
...
***** 915. row *****
      USER: NULL
      HOST: NULL
      EVENT_NAME: wait/io/socket/sql/server_tcpip_socket
      COUNT_STAR: 0
      SUM_TIMER_WAIT: 0
      MIN_TIMER_WAIT: 0
      AVG_TIMER_WAIT: 0
      MAX_TIMER_WAIT: 0
***** 916. row *****
      USER: NULL
      HOST: NULL
      EVENT_NAME: wait/io/socket/sql/server_unix_socket
      COUNT_STAR: 0
      SUM_TIMER_WAIT: 0
      MIN_TIMER_WAIT: 0
      AVG_TIMER_WAIT: 0
      MAX_TIMER_WAIT: 0
***** 917. row *****
      USER: NULL
      HOST: NULL
      EVENT_NAME: wait/io/socket/sql/client_connection
      COUNT_STAR: 0
      SUM_TIMER_WAIT: 0
      MIN_TIMER_WAIT: 0
      AVG_TIMER_WAIT: 0
      MAX_TIMER_WAIT: 0
***** 918. row *****
      USER: NULL
      HOST: NULL
      EVENT_NAME: idle
      COUNT_STAR: 0
      SUM_TIMER_WAIT: 0
      MIN_TIMER_WAIT: 0
      AVG_TIMER_WAIT: 0
      MAX_TIMER_WAIT: 0

```

1.1.1.2.9.2.1.34 Performance Schema events_waits_summary_by_host_by_event_name Table

The [Performance Schema](#) `events_waits_summary_by_host_by_event_name` table contains wait events summarized by host and event name. It contains the following columns:

Column	Description
HOST	Host. Used together with <code>EVENT_NAME</code> for grouping events.
EVENT_NAME	Event name. Used together with <code>USER</code> and <code>HOST</code> for grouping events.
COUNT_STAR	Number of summarized events
SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.
MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.

AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.
MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.

The *_TIMER_WAIT columns only calculate results for timed events, as non-timed events have a NULL wait time.

Example

```

SELECT * FROM events_waits_summary_by_host_by_event_name\G
...
***** 610. row *****
      HOST: NULL
      EVENT_NAME: wait/io/socket/sql/server_unix_socket
      COUNT_STAR: 0
      SUM_TIMER_WAIT: 0
      MIN_TIMER_WAIT: 0
      AVG_TIMER_WAIT: 0
      MAX_TIMER_WAIT: 0
***** 611. row *****
      HOST: NULL
      EVENT_NAME: wait/io/socket/sql/client_connection
      COUNT_STAR: 0
      SUM_TIMER_WAIT: 0
      MIN_TIMER_WAIT: 0
      AVG_TIMER_WAIT: 0
      MAX_TIMER_WAIT: 0
***** 612. row *****
      HOST: NULL
      EVENT_NAME: idle
      COUNT_STAR: 0
      SUM_TIMER_WAIT: 0
      MIN_TIMER_WAIT: 0
      AVG_TIMER_WAIT: 0
      MAX_TIMER_WAIT: 0

```

1.1.1.2.9.2.1.35 Performance Schema events_waits_summary_by_instance Table

The [Performance Schema](#) events_waits_summary_by_instance table contains wait events summarized by instance. It contains the following columns:

Column	Description
EVENT_NAME	Event name. Used together with OBJECT_INSTANCE_BEGIN for grouping events.
OBJECT_INSTANCE_BEGIN	If an instrument creates multiple instances, each instance has a unique OBJECT_INSTANCE_BEGIN value to allow for grouping by instance.
COUNT_STAR	Number of summarized events
SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.
MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.
AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.
MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.

The *_TIMER_WAIT columns only calculate results for timed events, as non-timed events have a NULL wait time.

Example

```

SELECT * FROM events_waits_summary_by_instance\G
...
***** 202. row *****
EVENT_NAME: wait/io/file/sql/binlog
OBJECT_INSTANCE_BEGIN: 140578961969856
COUNT_STAR: 6
SUM_TIMER_WAIT: 90478331960
MIN_TIMER_WAIT: 263344
AVG_TIMER_WAIT: 15079721848
MAX_TIMER_WAIT: 67760576376
***** 203. row *****
EVENT_NAME: wait/io/file/sql/dbopt
OBJECT_INSTANCE_BEGIN: 140578961970560
COUNT_STAR: 6
SUM_TIMER_WAIT: 39891428472
MIN_TIMER_WAIT: 387168
AVG_TIMER_WAIT: 6648571412
MAX_TIMER_WAIT: 24503293304
***** 204. row *****
EVENT_NAME: wait/io/file/sql/dbopt
OBJECT_INSTANCE_BEGIN: 140578961971264
COUNT_STAR: 6
SUM_TIMER_WAIT: 39902495024
MIN_TIMER_WAIT: 177888
AVG_TIMER_WAIT: 6650415692
MAX_TIMER_WAIT: 21026400404

```

1.1.1.2.9.2.1.36 Performance Schema events_waits_summary_by_thread_by_event_name Table

The [Performance Schema](#) `events_waits_summary_by_thread_by_event_name` table contains wait events summarized by thread and event name. It contains the following columns:

Column	Description
THREAD_ID	Thread associated with the event. Together with <code>EVENT_NAME</code> uniquely identifies the row.
EVENT_NAME	Event name. Used together with <code>THREAD_ID</code> for grouping events.
COUNT_STAR	Number of summarized events
SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.
MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.
AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.
MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.

The `*_TIMER_WAIT` columns only calculate results for timed events, as non-timed events have a `NULL` wait time.

Example

```

SELECT * FROM events_waits_summary_by_thread_by_event_name\G
...
***** 6424. row *****
    THREAD_ID: 64
    EVENT_NAME: wait/io/socket/sql/server_unix_socket
    COUNT_STAR: 0
    SUM_TIMER_WAIT: 0
    MIN_TIMER_WAIT: 0
    AVG_TIMER_WAIT: 0
    MAX_TIMER_WAIT: 0
***** 6425. row *****
    THREAD_ID: 64
    EVENT_NAME: wait/io/socket/sql/client_connection
    COUNT_STAR: 0
    SUM_TIMER_WAIT: 0
    MIN_TIMER_WAIT: 0
    AVG_TIMER_WAIT: 0
    MAX_TIMER_WAIT: 0
***** 6426. row *****
    THREAD_ID: 64
    EVENT_NAME: idle
    COUNT_STAR: 73
    SUM_TIMER_WAIT: 22005252162000000
    MIN_TIMER_WAIT: 3000000
    AVG_TIMER_WAIT: 301441810000000
    MAX_TIMER_WAIT: 4912417573000000

```

1.1.1.2.9.2.1.37 Performance Schema events_waits_summary_by_user_by_event_name Table

The [Performance Schema](#) `events_waits_summary_by_user_by_event_name` table contains wait events summarized by user and event name. It contains the following columns:

Column	Description
USER	User. Used together with <code>EVENT_NAME</code> for grouping events.
EVENT_NAME	Event name. Used together with <code>USER</code> for grouping events.
COUNT_STAR	Number of summarized events
SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.
MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.
AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.
MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.

The `*_TIMER_WAIT` columns only calculate results for timed events, as non-timed events have a `NULL` wait time.

Example

```

SELECT * FROM events_waits_summary_by_user_by_event_name\G
...
***** 916. row *****
      USER: NULL
      EVENT_NAME: wait/io/socket/sql/server_unix_socket
      COUNT_STAR: 0
      SUM_TIMER_WAIT: 0
      MIN_TIMER_WAIT: 0
      AVG_TIMER_WAIT: 0
      MAX_TIMER_WAIT: 0
***** 917. row *****
      USER: NULL
      EVENT_NAME: wait/io/socket/sql/client_connection
      COUNT_STAR: 0
      SUM_TIMER_WAIT: 0
      MIN_TIMER_WAIT: 0
      AVG_TIMER_WAIT: 0
      MAX_TIMER_WAIT: 0
***** 918. row *****
      USER: NULL
      EVENT_NAME: idle
      COUNT_STAR: 0
      SUM_TIMER_WAIT: 0
      MIN_TIMER_WAIT: 0
      AVG_TIMER_WAIT: 0
      MAX_TIMER_WAIT: 0

```

1.1.1.2.9.2.1.38 Performance Schema events_waits_summary_global_by_event_name Table

The [Performance Schema](#) `events_waits_summary_global_by_event_name` table contains wait events summarized by event name. It contains the following columns:

Column	Description
<code>EVENT_NAME</code>	Event name.
<code>COUNT_STAR</code>	Number of summarized events
<code>SUM_TIMER_WAIT</code>	Total wait time of the summarized events that are timed.
<code>MIN_TIMER_WAIT</code>	Minimum wait time of the summarized events that are timed.
<code>AVG_TIMER_WAIT</code>	Average wait time of the summarized events that are timed.
<code>MAX_TIMER_WAIT</code>	Maximum wait time of the summarized events that are timed.

The `*_TIMER_WAIT` columns only calculate results for timed events, as non-timed events have a `NULL` wait time.

Example

```

SELECT * FROM events_waits_summary_global_by_event_name\G
...
***** 303. row *****
EVENT_NAME: wait/io/socket/sql/server_tcpip_socket
COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
***** 304. row *****
EVENT_NAME: wait/io/socket/sql/server_unix_socket
COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
***** 305. row *****
EVENT_NAME: wait/io/socket/sql/client_connection
COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
***** 306. row *****
EVENT_NAME: idle
COUNT_STAR: 265
SUM_TIMER_WAIT: 46861125181000000
MIN_TIMER_WAIT: 1000000
AVG_TIMER_WAIT: 176834434000000
MAX_TIMER_WAIT: 4912417573000000

```

1.1.1.2.9.2.1.39 Performance Schema file_instances Table

Description

The `file_instances` table lists instances of instruments seen by the Performance Schema when executing file I/O instrumentation, and the associated files. Only files that have been opened, and that have not been deleted, will be listed in the table.

The `performance_schema_max_file_instances` system variable specifies the maximum number of instrumented file objects.

Column	Description
FILE_NAME	File name.
EVENT_NAME	Instrument name associated with the file.
OPEN_COUNT	Open handles on the file. A value of greater than zero means that the file is currently open.

Example

```

SELECT * FROM performance_schema.file_instances WHERE OPEN_COUNT>0;
+-----+-----+
+-----+
| FILE_NAME                               | EVENT_NAME                               |
OPEN_COUNT |
+-----+-----+
+-----+
| /var/log/mysql/mariadb-bin.index        | wait/io/file/sql/binlog_index          |
1 |
| /var/lib/mysql/ibdata1                 | wait/io/file/innodb/innodb_data_file   |
2 |
| /var/lib/mysql/ib_logfile0             | wait/io/file/innodb/innodb_log_file    |
2 |
| /var/lib/mysql/ib_logfile1            | wait/io/file/innodb/innodb_log_file    |
2 |
| /var/lib/mysql/mysql/gtid_slave_pos.ibd | wait/io/file/innodb/innodb_data_file   |
3 |
| /var/lib/mysql/mysql/innodb_index_stats.ibd | wait/io/file/innodb/innodb_data_file   |
3 |
| /var/lib/mysql/mysql/innodb_table_stats.ibd | wait/io/file/innodb/innodb_data_file   |
3 |
...

```

1.1.1.2.9.2.1.40 Performance Schema file_summary_by_event_name Table

The [Performance Schema](#) `file_summary_by_event_name` table contains file events summarized by event name. It contains the following columns:

Column	Description
EVENT_NAME	Event name.
COUNT_STAR	Number of summarized events
SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.
MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.
AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.
MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.
COUNT_READ	Number of all read operations, including <code>FGETS</code> , <code>FGETC</code> , <code>FREAD</code> , and <code>READ</code> .
SUM_TIMER_READ	Total wait time of all read operations that are timed.
MIN_TIMER_READ	Minimum wait time of all read operations that are timed.
AVG_TIMER_READ	Average wait time of all read operations that are timed.
MAX_TIMER_READ	Maximum wait time of all read operations that are timed.
SUM_NUMBER_OF_BYTES_READ	Bytes read by read operations.
COUNT_WRITE	Number of all write operations, including <code>FPUTS</code> , <code>FPUTC</code> , <code>FPRINTF</code> , <code>VFPRINTF</code> , <code>FWRITE</code> , and <code>PWRITE</code> .
SUM_TIMER_WRITE	Total wait time of all write operations that are timed.
MIN_TIMER_WRITE	Minimum wait time of all write operations that are timed.
AVG_TIMER_WRITE	Average wait time of all write operations that are timed.
MAX_TIMER_WRITE	Maximum wait time of all write operations that are timed.
SUM_NUMBER_OF_BYTES_WRITE	Bytes written by write operations.
COUNT_MISC	Number of all miscellaneous operations not counted above, including <code>CREATE</code> , <code>DELETE</code> , <code>OPEN</code> , <code>CLOSE</code> , <code>STREAM_OPEN</code> , <code>STREAM_CLOSE</code> , <code>SEEK</code> , <code>TELL</code> , <code>FLUSH</code> , <code>STAT</code> , <code>FSTAT</code> , <code>CHSIZE</code> , <code>RENAME</code> , and <code>SYNC</code> .
SUM_TIMER_MISC	Total wait time of all miscellaneous operations that are timed.

MIN_TIMER_MISC	Minimum wait time of all miscellaneous operations that are timed.
AVG_TIMER_MISC	Average wait time of all miscellaneous operations that are timed.
MAX_TIMER_MISC	Maximum wait time of all miscellaneous operations that are timed.

I/O operations can be avoided by caching, in which case they will not be recorded in this table.

You can [TRUNCATE](#) the table, which will reset all counters to zero.

Example

```

SELECT * FROM file_summary_by_event_name\G
...
***** 49. row *****
      EVENT_NAME: wait/io/file/aria/MAD
      COUNT_STAR: 60
      SUM_TIMER_WAIT: 397234368
      MIN_TIMER_WAIT: 0
      AVG_TIMER_WAIT: 6620224
      MAX_TIMER_WAIT: 16808672
      COUNT_READ: 0
      SUM_TIMER_READ: 0
      MIN_TIMER_READ: 0
      AVG_TIMER_READ: 0
      MAX_TIMER_READ: 0
      SUM_NUMBER_OF_BYTES_READ: 0
      COUNT_WRITE: 0
      SUM_TIMER_WRITE: 0
      MIN_TIMER_WRITE: 0
      AVG_TIMER_WRITE: 0
      MAX_TIMER_WRITE: 0
      SUM_NUMBER_OF_BYTES_WRITE: 0
      COUNT_MISC: 60
      SUM_TIMER_MISC: 397234368
      MIN_TIMER_MISC: 0
      AVG_TIMER_MISC: 6620224
      MAX_TIMER_MISC: 16808672
***** 50. row *****
      EVENT_NAME: wait/io/file/aria/control
      COUNT_STAR: 3
      SUM_TIMER_WAIT: 24055778544
      MIN_TIMER_WAIT: 0
      AVG_TIMER_WAIT: 8018592848
      MAX_TIMER_WAIT: 24027262400
      COUNT_READ: 1
      SUM_TIMER_READ: 24027262400
      MIN_TIMER_READ: 0
      AVG_TIMER_READ: 24027262400
      MAX_TIMER_READ: 24027262400
      SUM_NUMBER_OF_BYTES_READ: 52
      COUNT_WRITE: 0
      SUM_TIMER_WRITE: 0
      MIN_TIMER_WRITE: 0
      AVG_TIMER_WRITE: 0
      MAX_TIMER_WRITE: 0
      SUM_NUMBER_OF_BYTES_WRITE: 0
      COUNT_MISC: 2
      SUM_TIMER_MISC: 28516144
      MIN_TIMER_MISC: 0
      AVG_TIMER_MISC: 14258072
      MAX_TIMER_MISC: 27262208

```

1.1.1.2.9.2.1.41 Performance Schema file_summary_by_instance Table

The [Performance Schema](#) `file_summary_by_instance` table contains file events summarized by instance. It contains the following columns:

Column	Description
FILE_NAME	File name.
EVENT_NAME	Event name.
OBJECT_INSTANCE_BEGIN	Address in memory. Together with FILE_NAME and EVENT_NAME uniquely identifies a row.
COUNT_STAR	Number of summarized events
SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.
MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.
AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.
MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.
COUNT_READ	Number of all read operations, including FGETS , FGETC , FREAD , and READ .
SUM_TIMER_READ	Total wait time of all read operations that are timed.
MIN_TIMER_READ	Minimum wait time of all read operations that are timed.
AVG_TIMER_READ	Average wait time of all read operations that are timed.
MAX_TIMER_READ	Maximum wait time of all read operations that are timed.
SUM_NUMBER_OF_BYTES_READ	Bytes read by read operations.
COUNT_WRITE	Number of all write operations, including FPUTS , FPUTC , FPRINTF , VFPRINTF , FWRITE , and PWRITE .
SUM_TIMER_WRITE	Total wait time of all write operations that are timed.
MIN_TIMER_WRITE	Minimum wait time of all write operations that are timed.
AVG_TIMER_WRITE	Average wait time of all write operations that are timed.
MAX_TIMER_WRITE	Maximum wait time of all write operations that are timed.
SUM_NUMBER_OF_BYTES_WRITE	Bytes written by write operations.
COUNT_MISC	Number of all miscellaneous operations not counted above, including CREATE , DELETE , OPEN , CLOSE , STREAM_OPEN , STREAM_CLOSE , SEEK , TELL , FLUSH , STAT , FSTAT , CHSIZE , RENAME , and SYNC .
SUM_TIMER_MISC	Total wait time of all miscellaneous operations that are timed.
MIN_TIMER_MISC	Minimum wait time of all miscellaneous operations that are timed.
AVG_TIMER_MISC	Average wait time of all miscellaneous operations that are timed.
MAX_TIMER_MISC	Maximum wait time of all miscellaneous operations that are timed.

I/O operations can be avoided by caching, in which case they will not be recorded in this table.

You can [TRUNCATE](#) the table, which will reset all counters to zero.

Example

```

SELECT * FROM file_summary_by_instance\G
...
***** 204. row *****
      FILE_NAME: /var/lib/mysql/test/db.opt
      EVENT_NAME: wait/io/file/sql/dbopt

1.1.1.2.9.2.1.42 Performance Schema global_status Table

MariaDB starting with [10.5.2](#)

The `global_status` table was added in [MariaDB 10.5.2](#).

The `global_status` table contains a list of status variables and their global values. The table only stores status variable statistics for threads which are instrumented, and does not collect statistics for `Com_XXX` variables.

The table contains the following columns:

Column	Description
<code>VARIABLE_NAME</code>	The global status variable name.

VARIABLE_VALUE	The global status variable value.
----------------	-----------------------------------

TRUNCATE TABLE resets global status variables, including thread, account, host, and user status, but not those that are never reset by the server.

1.1.1.2.9.2.1.43 Performance Schema hosts Table

Description

The `hosts` table contains a row for each host used by clients to connect to the server, containing current and total connections.

The size is determined by the `performance_schema_hosts_size` system variable, which, if set to zero, will disable connection statistics in the hosts table.

It contains the following columns:

Column	Description
HOST	Host name used by the client to connect, <code>NULL</code> for internal threads or user sessions that failed to authenticate.
CURRENT_CONNECTIONS	Current number of the host's connections.
TOTAL_CONNECTIONS	Total number of the host's connections

Example

```
SELECT * FROM hosts;
+-----+-----+-----+
| HOST      | CURRENT_CONNECTIONS | TOTAL_CONNECTIONS |
+-----+-----+-----+
| localhost |          1          |          45        |
| NULL      |          20         |          23        |
+-----+-----+-----+
```

1.1.1.2.9.2.1.44 Performance Schema host_cache Table

The `host_cache` table contains host and IP information from the `host_cache`, used for avoiding DNS lookups for new client connections.

The `host_cache` table contains the following columns:

Column	Description
IP	Client IP address.
HOST	IP's resolved DNS host name, or <code>NULL</code> if unknown.
HOST_VALIDATED	YES if the IP-to-host DNS lookup was successful, and the <code>HOST</code> column can be used to avoid DNS calls, or NO if unsuccessful, in which case DNS lookup is performed for each connect until either successful or a permanent error.
SUM_CONNECT_ERRORS	Number of connection errors. Counts only protocol handshake errors for hosts that passed validation. These errors count towards <code>max_connect_errors</code> .
COUNT_HOST_BLOCKED_ERRORS	Number of blocked connections because <code>SUM_CONNECT_ERRORS</code> exceeded the <code>max_connect_errors</code> system variable.
COUNT_NAMEINFO_TRANSIENT_ERRORS	Number of transient errors during IP-to-host DNS lookups.

COUNT_NAMEINFO_PERMANENT_ERRORS	Number of permanent errors during IP-to-host DNS lookups.
COUNT_FORMAT_ERRORS	Number of host name format errors, for example a numeric host column.
COUNT_ADDRINFO_TRANSIENT_ERRORS	Number of transient errors during host-to-IP reverse DNS lookups.
COUNT_ADDRINFO_PERMANENT_ERRORS	Number of permanent errors during host-to-IP reverse DNS lookups.
COUNT_FCRDNS_ERRORS	Number of forward-confirmed reverse DNS errors, which occur when IP-to-host DNS lookup does not match the originating IP address.
COUNT_HOST_ACL_ERRORS	Number of errors occurring because no user from the host is permitted to log in. These attempts return error code 1130 <code>ER_HOST_NOT_PRIVILEGED</code> and do not proceed to username and password authentication.
COUNT_NO_AUTH_PLUGIN_ERRORS	Number of errors due to requesting an authentication plugin that was not available. This can be due to the plugin never having been loaded, or the load attempt failing.
COUNT_AUTH_PLUGIN_ERRORS	Number of errors reported by an authentication plugin. Plugins can increment <code>COUNT_AUTHENTICATION_ERRORS</code> or <code>COUNT_HANDSHAKE_ERRORS</code> instead, but, if specified or the error is unknown, this column is incremented.
COUNT_HANDSHAKE_ERRORS	Number of errors detected at the wire protocol level.
COUNT_PROXY_USER_ERRORS	Number of errors detected when a proxy user is proxied to a user that does not exist.
COUNT_PROXY_USER_ACL_ERRORS	Number of errors detected when a proxy user is proxied to a user that exists, but the proxy user doesn't have the PROXY privilege.
COUNT_AUTHENTICATION_ERRORS	Number of errors where authentication failed.
COUNT_SSL_ERRORS	Number of errors due to TLS problems.
COUNT_MAX_USER_CONNECTIONS_ERRORS	Number of errors due to the per-user quota being exceeded.
COUNT_MAX_USER_CONNECTIONS_PER_HOUR_ERRORS	Number of errors due to the per-hour quota being exceeded.
COUNT_DEFAULT_DATABASE_ERRORS	Number of errors due to the user not having permission to access the specified default database, or it not existing.
COUNT_INIT_CONNECT_ERRORS	Number of errors due to statements in the <code>init_connect</code> system variable.
COUNT_LOCAL_ERRORS	Number of local server errors, such as out-of-memory errors, unrelated to network, authentication, or authorization.
COUNT_UNKNOWN_ERRORS	Number of unknown errors that cannot be allocated to another column.
FIRST_SEEN	Timestamp of the first connection attempt by the IP.
LAST_SEEN	Timestamp of the most recent connection attempt by the IP.
FIRST_ERROR_SEEN	Timestamp of the first error seen from the IP.
LAST_ERROR_SEEN	Timestamp of the most recent error seen from the IP.

The `host_cache` table, along with the `host_cache`, is cleared with `FLUSH HOSTS`, `TRUNCATE TABLE host_cache` or by setting the `host_cache_size` system variable at runtime.

1.1.1.2.9.2.1.45 Performance Schema memory_summary_by_account_by_event_name Table

The `memory_summary_by_account_by_event_name` table was introduced in [MariaDB 10.5.2](#).

There are five memory summary tables in the Performance Schema that share a number of fields in common. These include:

- `memory_summary_by_account_by_event_name`
- [memory_summary_by_host_by_event_name](#)
- [memory_summary_by_thread_by_event_name](#)
- [memory_summary_by_user_by_event_name](#)
- [memory_global_by_event_name](#)

The `memory_summary_by_account_by_event_name` table contains memory usage statistics aggregated by account and event.

The table contains the following columns:

Field	Type	Null	Default	Description
USER	char(32)	YES	NULL	User portion of the account.
HOST	char(60)	YES	NULL	Host portion of the account.
EVENT_NAME	varchar(128)	NO	NULL	Event name.
COUNT_ALLOC	bigint(20) unsigned	NO	NULL	Total number of allocations to memory.
COUNT_FREE	bigint(20) unsigned	NO	NULL	Total number of attempts to free the allocated memory.
SUM_NUMBER_OF_BYTES_ALLOC	bigint(20) unsigned	NO	NULL	Total number of bytes allocated.
SUM_NUMBER_OF_BYTES_FREE	bigint(20) unsigned	NO	NULL	Total number of bytes freed
LOW_COUNT_USED	bigint(20)	NO	NULL	Lowest number of allocated blocks (lowest value of <code>CURRENT_COUNT_USED</code>).
CURRENT_COUNT_USED	bigint(20)	NO	NULL	Currently allocated blocks that have not been freed (<code>COUNT_ALLOC</code> minus <code>COUNT_FREE</code>).
HIGH_COUNT_USED	bigint(20)	NO	NULL	Highest number of allocated blocks (highest value of <code>CURRENT_COUNT_USED</code>).
LOW_NUMBER_OF_BYTES_USED	bigint(20)	NO	NULL	Lowest number of bytes used.
CURRENT_NUMBER_OF_BYTES_USED	bigint(20)	NO	NULL	Current number of bytes used (total allocated minus total freed).
HIGH_NUMBER_OF_BYTES_USED	bigint(20)	NO	NULL	Highest number of bytes used.

1.1.1.2.9.2.1.46 Performance Schema `memory_summary_by_host_by_event_name` Table

MariaDB starting with [10.5.2](#)

The `memory_summary_by_host_by_event_name` table was introduced in [MariaDB 10.5.2](#).

There are five memory summary tables in the Performance Schema that share a number of fields in common. These include:

- [memory_summary_by_account_by_event_name](#)
- `memory_summary_by_host_by_event_name`
- [memory_summary_by_thread_by_event_name](#)
- [memory_summary_by_user_by_event_name](#)
- [memory_global_by_event_name](#)

The `memory_summary_by_host_by_event_name` table contains memory usage statistics aggregated by host and event.

The table contains the following columns:

Field	Type	Null	Default	Description
HOST	char(60)	YES	NULL	Host portion of the account.
EVENT_NAME	varchar(128)	NO	NULL	Event name.
COUNT_ALLOC	bigint(20) unsigned	NO	NULL	Total number of allocations to memory.
COUNT_FREE	bigint(20) unsigned	NO	NULL	Total number of attempts to free the allocated memory.
SUM_NUMBER_OF_BYTES_ALLOC	bigint(20) unsigned	NO	NULL	Total number of bytes allocated.
SUM_NUMBER_OF_BYTES_FREE	bigint(20) unsigned	NO	NULL	Total number of bytes freed
LOW_COUNT_USED	bigint(20)	NO	NULL	Lowest number of allocated blocks (lowest value of CURRENT_COUNT_USED).
CURRENT_COUNT_USED	bigint(20)	NO	NULL	Currently allocated blocks that have not been freed (COUNT_ALLOC minus COUNT_FREE).
HIGH_COUNT_USED	bigint(20)	NO	NULL	Highest number of allocated blocks (highest value of CURRENT_COUNT_USED).
LOW_NUMBER_OF_BYTES_USED	bigint(20)	NO	NULL	Lowest number of bytes used.
CURRENT_NUMBER_OF_BYTES_USED	bigint(20)	NO	NULL	Current number of bytes used (total allocated minus total freed).
HIGH_NUMBER_OF_BYTES_USED	bigint(20)	NO	NULL	Highest number of bytes used.

1.1.1.2.9.2.1.47 Performance Schema memory_summary_by_thread_by_event_name Table

MariaDB starting with [10.5.2](#)

The memory_summary_by_thread_by_event_name table was introduced in [MariaDB 10.5.2](#).

There are five memory summary tables in the Performance Schema that share a number of fields in common. These include:

- [memory_summary_by_account_by_event_name](#)
- [memory_summary_by_host_by_event_name](#)
- [memory_summary_by_thread_by_event_name](#)
- [memory_summary_by_user_by_event_name](#)
- [memory_global_by_event_name](#)

The `memory_summary_by_thread_by_event_name` table contains memory usage statistics aggregated by thread and event.

The table contains the following columns:

Field	Type	Null	Default	Description
THREAD_ID	bigint(20) unsigned	NO	NULL	Thread id.
EVENT_NAME	varchar(128)	NO	NULL	Event name.
COUNT_ALLOC	bigint(20) unsigned	NO	NULL	Total number of allocations to memory.
COUNT_FREE	bigint(20) unsigned	NO	NULL	Total number of attempts to free the allocated memory.
SUM_NUMBER_OF_BYTES_ALLOC	bigint(20) unsigned	NO	NULL	Total number of bytes allocated.

SUM_NUMBER_OF_BYTES_FREE	bigint(20) unsigned	NO	NULL	Total number of bytes freed
LOW_COUNT_USED	bigint(20)	NO	NULL	Lowest number of allocated blocks (lowest value of CURRENT_COUNT_USED).
CURRENT_COUNT_USED	bigint(20)	NO	NULL	Currently allocated blocks that have not been freed (COUNT_ALLOC minus COUNT_FREE).
HIGH_COUNT_USED	bigint(20)	NO	NULL	Highest number of allocated blocks (highest value of CURRENT_COUNT_USED).
LOW_NUMBER_OF_BYTES_USED	bigint(20)	NO	NULL	Lowest number of bytes used.
CURRENT_NUMBER_OF_BYTES_USED	bigint(20)	NO	NULL	Current number of bytes used (total allocated minus total freed).
HIGH_NUMBER_OF_BYTES_USED	bigint(20)	NO	NULL	Highest number of bytes used.

1.1.1.2.9.2.1.48 Performance Schema memory_summary_by_user_by_event_name Table

MariaDB starting with [10.5.2](#)

The memory_summary_by_user_by_event_name table was introduced in [MariaDB 10.5.2](#).

There are five memory summary tables in the Performance Schema that share a number of fields in common. These include:

- [memory_summary_by_account_by_event_name](#)
- [memory_summary_by_host_by_event_name](#)
- [memory_summary_by_thread_by_event_name](#)
- [memory_summary_by_user_by_event_name](#)
- [memory_global_by_event_name](#)

The `memory_summary_by_user_by_event_name` table contains memory usage statistics aggregated by user and event.

The table contains the following columns:

Field	Type	Null	Default	Description
USER	char(32)	YES	NULL	User portion of the account.
EVENT_NAME	varchar(128)	NO	NULL	Event name.
COUNT_ALLOC	bigint(20) unsigned	NO	NULL	Total number of allocations to memory.
COUNT_FREE	bigint(20) unsigned	NO	NULL	Total number of attempts to free the allocated memory.
SUM_NUMBER_OF_BYTES_ALLOC	bigint(20) unsigned	NO	NULL	Total number of bytes allocated.
SUM_NUMBER_OF_BYTES_FREE	bigint(20) unsigned	NO	NULL	Total number of bytes freed
LOW_COUNT_USED	bigint(20)	NO	NULL	Lowest number of allocated blocks (lowest value of CURRENT_COUNT_USED).
CURRENT_COUNT_USED	bigint(20)	NO	NULL	Currently allocated blocks that have not been freed (COUNT_ALLOC minus COUNT_FREE).
HIGH_COUNT_USED	bigint(20)	NO	NULL	Highest number of allocated blocks (highest value of CURRENT_COUNT_USED).
LOW_NUMBER_OF_BYTES_USED	bigint(20)	NO	NULL	Lowest number of bytes used.
CURRENT_NUMBER_OF_BYTES_USED	bigint(20)	NO	NULL	Current number of bytes used (total allocated minus total freed).
HIGH_NUMBER_OF_BYTES_USED	bigint(20)	NO	NULL	Highest number of bytes used.

1.1.1.2.9.2.1.49 Performance Schema memory_summary_global_by_event_name Table

MariaDB starting with [10.5.2](#)
The memory_summary_global_by_event_name table was introduced in [MariaDB 10.5.2](#).

There are five memory summary tables in the Performance Schema that share a number of fields in common. These include:

- [memory_summary_by_account_by_event_name](#)
- [memory_summary_by_host_by_event_name](#)
- [memory_summary_by_thread_by_event_name](#)
- [memory_summary_by_user_by_event_name](#)
- [memory_summary_global_by_event_name](#)

The `memory_summary_global_by_event_name` table contains memory usage statistics aggregated by event and event.

The table contains the following columns:

Field	Type	Null	Default	Description
EVENT_NAME	varchar(128)	NO	NULL	Event name.
COUNT_ALLOC	bigint(20) unsigned	NO	NULL	Total number of allocations to memory.
COUNT_FREE	bigint(20) unsigned	NO	NULL	Total number of attempts to free the allocated memory.
SUM_NUMBER_OF_BYTES_ALLOC	bigint(20) unsigned	NO	NULL	Total number of bytes allocated.
SUM_NUMBER_OF_BYTES_FREE	bigint(20) unsigned	NO	NULL	Total number of bytes freed
LOW_COUNT_USED	bigint(20)	NO	NULL	Lowest number of allocated blocks (lowest value of CURRENT_COUNT_USED).
CURRENT_COUNT_USED	bigint(20)	NO	NULL	Currently allocated blocks that have not been freed (COUNT_ALLOC minus COUNT_FREE).
HIGH_COUNT_USED	bigint(20)	NO	NULL	Highest number of allocated blocks (highest value of CURRENT_COUNT_USED).
LOW_NUMBER_OF_BYTES_USED	bigint(20)	NO	NULL	Lowest number of bytes used.
CURRENT_NUMBER_OF_BYTES_USED	bigint(20)	NO	NULL	Current number of bytes used (total allocated minus total freed).
HIGH_NUMBER_OF_BYTES_USED	bigint(20)	NO	NULL	Highest number of bytes used.

Example

Seeing what memory was most often allocated for:

```
SELECT * FROM memory_summary_global_by_event_name
ORDER BY count_alloc DESC LIMIT 1\G
***** 1. row *****
      EVENT_NAME: memory/sql/QUICK_RANGE_SELECT::alloc
      COUNT_ALLOC: 147976
      COUNT_FREE: 147976
SUM_NUMBER_OF_BYTES_ALLOC: 600190656
SUM_NUMBER_OF_BYTES_FREE: 600190656
      LOW_COUNT_USED: 0
      CURRENT_COUNT_USED: 0
      HIGH_COUNT_USED: 68
      LOW_NUMBER_OF_BYTES_USED: 0
      CURRENT_NUMBER_OF_BYTES_USED: 0
      HIGH_NUMBER_OF_BYTES_USED: 275808
```

1.1.1.2.9.2.1.50 Performance Schema metadata_locks Table

MariaDB starting with [10.5.2](#)

The metadata_locks table was introduced in [MariaDB 10.5.2](#).

The metadata_locks table contains [metadata lock](#) information.

To enable metadata lock instrumentation, at runtime:

```
UPDATE performance_schema.setup_instruments SET enabled='YES', timed='YES'
WHERE name LIKE 'wait/lock/metadata%';
```

or in the [configuration file](#):

```
performance-schema-instrument='wait/lock/metadata/sql/mdl=ON'
```

The table is by default autosized, but the size can be configured with the [performance_schema_max_metadata_locks](#) system variable.

The table is read-only, and [TRUNCATE TABLE](#) cannot be used to empty the table.

The table contains the following columns:

Field	Type	Null	Default	Description
OBJECT_TYPE	varchar(64)	NO	NULL	Object type. One of BACKUP , COMMIT , EVENT , FUNCTION , GLOBAL , LOCKING SERVICE , PROCEDURE , SCHEMA , TABLE , TABLESPACE , TRIGGER (unused) or USER LEVEL LOCK .
OBJECT_SCHEMA	varchar(64)	YES	NULL	Object schema.
OBJECT_NAME	varchar(64)	YES	NULL	Object name.
OBJECT_INSTANCE_BEGIN	bigint(20) unsigned	NO	NULL	Address in memory of the instrumented object.
LOCK_TYPE	varchar(32)	NO	NULL	Lock type. One of BACKUP_FTWRLL1 , BACKUP_START , BACKUP_TRANS_DML , EXCLUSIVE , INTENTION_EXCLUSIVE , SHARED , SHARED_HIGH_PRIO , SHARED_NO_READ_WRITE , SHARED_NO_WRITE , SHARED_READ , SHARED_UPGRADABLE or SHARED_WRITE .
LOCK_DURATION	varchar(32)	NO	NULL	Lock duration. One of EXPLICIT (locks released by explicit action, for example a global lock acquired with FLUSH TABLES WITH READ LOCK) , STATEMENT (locks implicitly released at statement end) or TRANSACTION (locks implicitly released at transaction end).
LOCK_STATUS	varchar(32)	NO	NULL	Lock status. One of GRANTED , KILLED , PENDING , POST_RELEASE_NOTIFY , PRE_ACQUIRE_NOTIFY , TIMEOUT or VICTIM .
SOURCE	varchar(64)	YES	NULL	Source file containing the instrumented code that produced the event, as well as the line number where the instrumentation occurred. This allows one to examine the source code involved.
OWNER_THREAD_ID	bigint(20) unsigned	YES	NULL	Thread that requested the lock.
OWNER_EVENT_ID	bigint(20) unsigned	YES	NULL	Event that requested the lock.

1.1.1.2.9.2.1.51 Performance Schema mutex_instances Table

Description

The `mutex_instances` table lists all mutexes that the Performance Schema seeing while the server is executing.

A mutex is a code mechanism for ensuring that threads can only access resources one at a time. A second thread attempting to access a resource will find it protected by a mutex, and will wait for it to be unlocked.

The `performance_schema_max_mutex_instances` system variable specifies the maximum number of instrumented mutex instances.

Column	Description
NAME	Instrument name associated with the mutex.
OBJECT_INSTANCE_BEGIN	Memory address of the instrumented mutex.
LOCKED_BY_THREAD_ID	The <code>THREAD_ID</code> of the locking thread if a thread has a mutex locked, otherwise <code>NULL</code> .

1.1.1.2.9.2.1.52 Performance Schema `objects_summary_global_by_type` Table

It aggregates object wait events, and contains the following columns:

Column	Description
OBJECT_TYPE	Groups records together with <code>OBJECT_SCHEMA</code> and <code>OBJECT_NAME</code> .
OBJECT_SCHEMA	Groups records together with <code>OBJECT_TYPE</code> and <code>OBJECT_NAME</code> .
OBJECT_NAME	Groups records together with <code>OBJECT_SCHEMA</code> and <code>OBJECT_TYPE</code> .
COUNT_STAR	Number of summarized events
SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.
MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.
AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.
MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.

You can `TRUNCATE` the table, which will reset all counters to zero.

Example

```
SELECT * FROM objects_summary_global_by_type\G
...
***** 101. row *****
OBJECT_TYPE: TABLE
OBJECT_SCHEMA: test
OBJECT_NAME: v
COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
***** 102. row *****
OBJECT_TYPE: TABLE
OBJECT_SCHEMA: test
OBJECT_NAME: xx2
COUNT_STAR: 2
SUM_TIMER_WAIT: 1621920
MIN_TIMER_WAIT: 481344
AVG_TIMER_WAIT: 810960
MAX_TIMER_WAIT: 1140576
```

1.1.1.2.9.2.1.53 Performance Schema

performance_timers Table

Description

The `performance_timers` table lists available event timers.

It contains the following columns:

Column	Description
<code>TIMER_NAME</code>	Time name, used in the setup_timers table.
<code>TIMER_FREQUENCY</code>	Number of timer units per second. Dependent on the processor speed.
<code>TIMER_RESOLUTION</code>	Number of timer units by which timed values increase each time.
<code>TIMER_OVERHEAD</code>	Minimum timer overhead, determined during initialization by calling the timer 20 times and selecting the smallest value. Total overhead will be at least double this, as the timer is called at the beginning and end of each timed event.

Any `NULL` values indicate that that particular timer is not available on your platform, Any timer names with a non-`NULL` value can be used in the [setup_timers](#) table.

Example

```
SELECT * FROM performance_timers;
+-----+-----+-----+-----+
| TIMER_NAME | TIMER_FREQUENCY | TIMER_RESOLUTION | TIMER_OVERHEAD |
+-----+-----+-----+-----+
| CYCLE      | 2293651741      | 1                | 28              |
| NANOSECOND | 1000000000      | 1                | 48              |
| MICROSECOND | 1000000         | 1                | 52              |
| MILLISECOND | 1000            | 1000             | 9223372036854775807 |
| TICK       | 106             | 1                | 496             |
+-----+-----+-----+-----+
```

1.1.1.2.9.2.1.54 Performance Schema prepared_statements_instances Table

MariaDB starting with [10.5.2](#)

The `prepared_statements_instances` table was introduced in [MariaDB 10.5.2](#).

The `prepared_statements_instances` table contains aggregated statistics of prepared statements.

The maximum number of rows in the table is determined by the `performance_schema_max_prepared_statement_instances` system variable, which is by default autosized on startup.

The table contains the following columns:

```
+-----+-----+-----+-----+-----+-----+
| Field | Type | Null |
+-----+-----+-----+-----+-----+-----+
| OBJECT_INSTANCE_BEGIN | bigint(20) unsigned | NO |
| STATEMENT_ID | bigint(20) unsigned | NO |
| STATEMENT_NAME | varchar(64) | YES |
| SQL_TEXT | longtext | NO |
| OWNER_THREAD_ID | bigint(20) unsigned | NO |
| OWNER_EVENT_ID | bigint(20) unsigned | NO |
| NULL |
```

OWNER_OBJECT_TYPE	enum('EVENT','FUNCTION','PROCEDURE','TABLE','TRIGGER')	YES
NULL		
OWNER_OBJECT_SCHEMA	varchar(64)	YES
NULL		
OWNER_OBJECT_NAME	varchar(64)	YES
NULL		
TIMER_PREPARE	bigint(20) unsigned	NO
NULL		
COUNT_REPREPARE	bigint(20) unsigned	NO
NULL		
COUNT_EXECUTE	bigint(20) unsigned	NO
NULL		
SUM_TIMER_EXECUTE	bigint(20) unsigned	NO
NULL		
MIN_TIMER_EXECUTE	bigint(20) unsigned	NO
NULL		
AVG_TIMER_EXECUTE	bigint(20) unsigned	NO
NULL		
MAX_TIMER_EXECUTE	bigint(20) unsigned	NO
NULL		
SUM_LOCK_TIME	bigint(20) unsigned	NO
NULL

NULL		

1.1.1.2.9.2.1.55 Performance Schema replication_applier_configuration Table

MariaDB starting with [10.5.2](#)

The `replication_applier_configuration` table, along with many other new [Performance Schema tables](#), was added in [MariaDB 10.5.2](#).

transactions.

It contains the following fields.

Field	Type	Null	Description
CHANNEL_NAME	char(64)	NO	Replication channel name.
DESIRED_DELAY	int(11)	NO	Target number of seconds the replica should be delayed to the master.

1.1.1.2.9.2.1.56 Performance Schema replication_applier_status Table

MariaDB starting with [10.5.2](#)

The `replication_applier_status` table, along with many other new [Performance Schema tables](#), was added in [MariaDB 10.5.2](#).

The [Performance Schema](#) `replication_applier_status` table contains information about the general transaction execution status on the replica.

It contains the following fields.

Field	Type	Null	Description
CHANNEL_NAME	char(64)	NO	The replication channel name.
SERVICE_STATE	enum('ON','OFF')	NO	Shows ON when the replication channel's applier threads are active or idle, OFF means that the applier threads are not active.
REMAINING_DELAY	int(10) unsigned	YES	Seconds the replica needs to wait to reach the desired delay from master.
COUNT_TRANSACTIONS_RETRIES	bigint(20) unsigned	NO	The number of retries that were made because the replication SQL thread failed to apply a transaction.

1.1.1.2.9.2.1.57 Performance Schema replication_applier_status_by_coordinator Table

MariaDB starting with [10.5.2](#)

The `replication_applier_status_by_coordinator` table was added in [MariaDB 10.5.2](#).

The [Performance Schema](#) `replication_applier_status_by_coordinator` table displays the status of the coordinator thread used in multi-threaded replicas to manage multiple worker threads.

It contains the following fields.

Column	Type	Null	Description
CHANNEL_NAME	varchar(256)	NO	Replication channel name.
THREAD_ID	bigint(20) unsigned	YES	The SQL/coordinator thread ID.
SERVICE_STATE	enum('ON','OFF')	NO	ON (thread exists and is active or idle) or OFF (thread no longer exists).
LAST_ERROR_NUMBER	int(11)	NO	Last error number that caused the SQL/coordinator thread to stop.
LAST_ERROR_MESSAGE	varchar(1024)	NO	Last error message that caused the SQL/coordinator thread to stop.
LAST_ERROR_TIMESTAMP	timestamp	NO	Timestamp that shows when the most recent SQL/coordinator error occurred.
LAST_SEEN_TRANSACTION	char(57)	NO	The transaction the worker has last seen.
LAST_TRANS_RETRY_COUNT	int(11)	NO	Total number of retries attempted by last transaction.

1.1.1.2.9.2.1.58 Performance Schema replication_applier_status_by_worker Table

MariaDB starting with [10.6.0](#)

The `replication_applier_status_by_worker` table was added in [MariaDB 10.6.0](#).

The [Performance Schema](#) `replication_applier_status_by_worker` table displays replica worker thread specific information.

It contains the following fields.

Column	Description
CHANNEL_NAME	Name of replication channel through which the transaction is received.
THREAD_ID	Thread_Id as displayed in the performance_schema.threads table for thread with name 'thread/sql/rpl_parallel_thread'. THREAD_ID will be NULL when worker threads are stopped due to error/force stop.
SERVICE_STATE	Whether or not the thread is running.
LAST_SEEN_TRANSACTION	Last GTID executed by worker
LAST_ERROR_NUMBER	Last Error that occurred on a particular worker.
LAST_ERROR_MESSAGE	Last error specific message.
LAST_ERROR_TIMESTAMP	Time stamp of last error.
WORKER_IDLE_TIME	Total idle time in seconds that the worker thread has spent waiting for work from SQL thread.
LAST_TRANS_RETRY_COUNT	Total number of retries attempted by last transaction.

1.1.1.2.9.2.1.59 Performance Schema replication_connection_configuration Table

MariaDB starting with [10.5.2](#)

The `replication_connection_configuration` table was added in [MariaDB 10.6.0](#).

The [Performance Schema](#) `replication_connection_configuration` table displays replica's configuration settings used for connecting to the primary.

It contains the following fields.

Column	Type	Null	Description
CHANNEL_NAME	varchar(256)	NO	The replication channel used.
HOST	char(60)	NO	The host name of the source that the replica is connected to.
PORT	int(11)	NO	The port used to connect to the source.
USER	char(32)	NO	The user name of the replication user account used to connect to the source.
USING_GTID	enum('NO', 'CURRENT_POS', 'SLAVE_POS')	NO	Whether replication is using GTIDs or not.
SSL_ALLOWED	enum('YES', 'NO', 'IGNORED')	NO	Whether SSL is allowed for the replica connection.
SSL_CA_FILE	varchar(512)	NO	Path to the file that contains one or more certificates for trusted Certificate Authorities (CA) to use for TLS.

SSL_CA_PATH	varchar(512)	NO	Path to a directory that contains one or more PEM files that contain X509 certificates for a trusted Certificate Authority (CA) to use for TLS.
SSL_CERTIFICATE	varchar(512)	NO	Path to the certificate used to authenticate the master.
SSL_CIPHER	varchar(512)	NO	Which cipher is used for encryption.
SSL_KEY	varchar(512)	NO	Path to the private key used for TLS.
SSL_VERIFY_SERVER_CERTIFICATE	enum('YES','NO')	NO	Whether the server certificate is verified as part of the SSL connection.
SSL_CRL_FILE	varchar(255)	NO	Path to the PEM file containing one or more revoked X.509 certificates.
SSL_CRL_PATH	varchar(255)	NO	PATH to a folder containing PEM files containing one or more revoked X.509 certificates.
CONNECTION_RETRY_INTERVAL	int(11)	NO	The number of seconds between connect retries.
CONNECTION_RETRY_COUNT	bigint(20) unsigned	NO	The number of times the replica can attempt to reconnect to the source in the event of a lost connection.
HEARTBEAT_INTERVAL	double(10,3) unsigned	NO	Number of seconds after which a heartbeat will be sent.
IGNORE_SERVER_IDS	longtext	NO	Binary log events from servers (ids) to ignore.
REPL_DO_DOMAIN_IDS	longtext	NO	Only apply binary logs from these domain ids.
REPL_IGNORE_DOMAIN_IDS	longtext	NO	Binary log events from domains to ignore.

1.1.1.2.9.2.1.60 Performance Schema `rwlock_instances` Table

The `rwlock_instances` table lists all read write lock (rwlock) instances that the Performance Schema sees while the server is executing. A read write is a mechanism for ensuring threads can either share access to common resources, or have exclusive access.

The [performance_schema_max_rwlock_instances](#) system variable specifies the maximum number of instrumented rwlock objects.

The `rwlock_instances` table contains the following columns:

Column	Description
NAME	Instrument name associated with the read write lock
OBJECT_INSTANCE_BEGIN	Address in memory of the instrumented lock
WRITE_LOCKED_BY_THREAD_ID	THREAD_ID of the locking thread if locked in write (exclusive) mode, otherwise NULL.
READ_LOCKED_BY_COUNT	Count of current read locks held

1.1.1.2.9.2.1.61 Performance Schema `session_account_connect_attrs` Table

Description

The `session_account_connect_attrs` table shows connection attributes for the current session.

Applications can pass key/value connection attributes to the server when a connection is made. The [session_connect_attrs](#) and `session_account_connect_attrs` tables provide access to this information, for all sessions and the current session respectively.

The C API functions [mysql_options\(\)](#) and [mysql_optionsv\(\)](#) are used for passing connection attributes to the server.

`session_account_connect_attrs` contains the following columns:

Column	Description
<code>PROCESSLIST_ID</code>	Session connection identifier.
<code>ATTR_NAME</code>	Attribute name.
<code>ATTR_VALUE</code>	Attribute value.
<code>ORDINAL_POSITION</code>	Order in which attribute was added to the connection attributes.

Example

```
SELECT * FROM performance_schema.session_account_connect_attrs;
```

```
+-----+-----+-----+-----+
| PROCESSLIST_ID | ATTR_NAME      | ATTR_VALUE      | ORDINAL_POSITION |
+-----+-----+-----+-----+
|          45 | _os            | debian-linux-gnu |          0 |
|          45 | _client_name   | libmysql         |          1 |
|          45 | _pid           | 7711             |          2 |
|          45 | _client_version | 10.0.5          |          3 |
|          45 | _platform      | x86_64           |          4 |
|          45 | program_name   | mysql            |          5 |
+-----+-----+-----+-----+
```

1.1.1.2.9.2.1.62 Performance Schema `session_connect_attrs` Table

Contents

- [Description](#)
- [Example](#)
- [Using Other Connectors](#)
 - [JDBC](#)
 - [Node.js](#)
 - [R2DBC](#)

Description

`session_connect_attrs` is a [Performance Schema](#) table that shows connection attributes for all sessions. The Performance Schema needs to be enabled for the table to be populated.

Applications can pass key/value connection attributes to the server when a connection is made. The `session_connect_attrs` and `session_account_connect_attrs` tables provide access to this information, for all sessions and the current session respectively.

The C API functions `mysql_options()` and `mysql_optionsv()` are used for passing connection attributes to the server.

`session_connect_attrs` contains the following columns:

Column	Description
<code>PROCESSLIST_ID</code>	Session connection identifier.
<code>ATTR_NAME</code>	Attribute name.
<code>ATTR_VALUE</code>	Attribute value.
<code>ORDINAL_POSITION</code>	Order in which attribute was added to the connection attributes.

Example

Returning the current connection's attributes:

```
SELECT * FROM performance_schema.session_connect_attrs WHERE processlist_id=CONNECTION_ID();
```

PROCESSLIST_ID	ATTR_NAME	ATTR_VALUE	ORDINAL_POSITION
45	_os	debian-linux-gnu	0
45	_client_name	libmysql	1
45	_pid	7711	2
45	_client_version	10.0.5	3
45	_platform	x86_64	4
45	program_name	mysql	5

Using Other Connectors

JDBC

Connection attributes values are set using the option [connectionAttributes](#).

Example using connection string `jdbc:mariadb://localhost/?connectionAttributes=test:test1,test2:test2Val,test3`

```
SELECT * FROM performance_schema.session_connect_attrs WHERE processlist_id=17;
```

PROCESSLIST_ID	ATTR_NAME	ATTR_VALUE	ORDINAL_POSITION
17	_client_name	MariaDB Connector/J	0
17	_client_version	3.1.3	1
17	_server_host	localhost	2
17	_os	Windows 11	3
17	_thread	1	4
17	_java_vendor	Oracle Corporation	5
17	_java_version	19.0.2	6
17	test	test1	7
17	test2	test2Val	8
17	test3	NULL	9

Node.js

Connection attributes values are set using the option [connectAttributes](#).

Example using connection

```
const conn = await mariadb.createConnection({
  host: 'localhost',
  user: 'root',
  connectAttributes: { test: 'test1', test2: 'test2Val', test3: 'f' }
});
```

```
SELECT * FROM performance_schema.session_connect_attrs WHERE processlist_id=30;
```

PROCESSLIST_ID	ATTR_NAME	ATTR_VALUE	ORDINAL_POSITION
30	_client_name	MariaDB connector/Node	0
30	_client_version	3.1.1	1
30	_server_host	:::1	2
30	_os	win32	3
30	_client_host	NOSTROMO	4
30	_node_version	18.15.0	5
30	test	test1	6
30	test2	test2Val	7
30	test3	f	8

R2DBC

Connection attributes values are set using the option [connectionAttributes](#).

Example using connection string jdbc:mariadb://localhost/?

connectionAttributes=test:test1,test2:test2Val,test3

```

    TreeMap<String, String> connectionAttributes = new TreeMap<>();
    connectionAttributes.put("entry1", "val1");
    connectionAttributes.put("entry2", "val2");

    MariadbConnectionConfiguration conf = MariadbConnectionConfiguration.builder()
        .host("localhost")
        .port(3306)
        .username("root")
        .connectionAttributes(connectionAttributes)
        .database("test")
        .build();
    MariadbConnectionFactory connFactory = new MariadbConnectionFactory(conf);
    MariadbConnection connection = connFactory.create().block();

```

```

SELECT * FROM performance_schema.session_connect_attrs WHERE processlist_id=34;
+-----+-----+-----+-----+
| PROCESSLIST_ID | ATTR_NAME      | ATTR_VALUE      | ORDINAL_POSITION |
+-----+-----+-----+-----+
| 34 | _client_name   | mariadb         | 0 |
| 34 | _client_version | 1.1.4          | 1 |
| 34 | _server_host   | localhost       | 2 |
| 34 | _os            | Windows 11     | 3 |
| 34 | _thread        | 49              | 4 |
| 34 | _java_vendor   | Oracle Corporation | 5 |
| 34 | _java_version  | 19.0.2         | 6 |
| 34 | entry1         | val1            | 7 |
| 34 | entry2         | val2            | 8 |
+-----+-----+-----+-----+

```

1.1.1.2.9.2.1.63 Performance Schema session_status Table

MariaDB starting with [10.5.2](#)
 The `session_status` table was added in [MariaDB 10.5.2](#).

The `session_status` table contains a list of status variables for the current session. The table only stores status variable statistics for threads which are instrumented, and does not collect statistics for `Com_xxx` variables.

The table contains the following columns:

Column	Description
VARIABLE_NAME	The session status variable name.
VARIABLE_VALUE	The session status variable value.

It is not possible to empty this table with a `TRUNCATE TABLE` statement.

1.1.1.2.9.2.1.64 Performance Schema setup_actors Table

The `setup_actors` table contains information for determining whether monitoring should be enabled for new client connection threads.

The default size is 100 rows, which can be changed by modifying the `performance_schema_setup_actors_size` system variable at server startup.

If a row in the table matches a new foreground thread's client and host, the matching `INSTRUMENTED` column in the `threads` table is set to either `YES` or `NO`, which allows selective application of instrumenting by host, by user, or combination thereof.

Column	Description
--------	-------------

HOST	Host name, either a literal, or the % wildcard representing any host.
USER	User name, either a literal or the % wildcard representing any name.
ROLE	Unused

Initially, any user and host is matched:

```
SELECT * FROM performance_schema.setup_actors;
+-----+-----+-----+
| HOST | USER | ROLE |
+-----+-----+-----+
| %    | %    | %    |
+-----+-----+-----+
```

1.1.1.2.9.2.1.65 Performance Schema setup_consumers Table

Lists the types of consumers for which event information is available.

The `setup_consumers` table contains the following columns:

Column	Description
NAME	Consumer name
ENABLED	YES or NO for whether or not the consumer is enabled. You can modify this column to ensure that event information is added, or is not added.

The table can be modified directly, or the server started with the option enabled, for example:

```
performance-schema-consumer-events-waits-history=ON
```

Example

```
SELECT * FROM performance_schema.setup_consumers;
+-----+-----+
| NAME                                | ENABLED |
+-----+-----+
| events_stages_current               | NO      |
| events_stages_history               | NO      |
| events_stages_history_long          | NO      |
| events_statements_current           | YES     |
| events_statements_history           | NO      |
| events_statements_history_long      | NO      |
| events_waits_current                | NO      |
| events_waits_history                | NO      |
| events_waits_history_long           | NO      |
| global_instrumentation              | YES     |
| thread_instrumentation              | YES     |
| statements_digest                   | YES     |
+-----+-----+
```

1.1.1.2.9.2.1.66 Performance Schema setup_instruments Table

The `setup_instruments` table contains a list of instrumented object classes for which it is possible to collect events.

There is one row for each instrument in the source code. When an instrument is enabled and executed, instances are created which are then stored in the [cond_instances](#), [file_instances](#), [mutex_instances](#), [rwlock_instances](#) or [socket_instance](#) tables.

It contains the following columns:

Column	Description
NAME	Instrument name
ENABLED	Whether or not the instrument is enabled. It can be disabled, and the instrument will produce no events.
TIMED	Whether or not the instrument is timed. It can be set, but if disabled, events produced by the instrument will have NULL values for the corresponding <code>TIMER_START</code> , <code>TIMER_END</code> , and <code>TIMER_WAIT</code> values.

Example

From [MariaDB 10.5.7](#), default settings with the Performance Schema enabled:

```
SELECT * FROM setup_instruments ORDER BY name;
```

NAME	ENABLED	TIME

1.1.1.2.9.2.1.67 Performance Schema setup_objects Table

Description

The `setup_objects` table determines whether objects are monitored by the performance schema or not. By default limited to 100 rows, this can be changed by setting the `performance_schema_setup_objects_size` system variable when the server starts.

It contains the following columns:

Column	Description
OBJECT_TYPE	Type of object to instrument, currently only <code>'TABLE'</code> , for base table.
OBJECT_SCHEMA	Schema containing the object, either the literal or <code>%</code> for any schema.
OBJECT_NAME	Name of the instrumented object, either the literal or <code>%</code> for any object.
ENABLED	Whether the object's events are instrumented or not. Can be disabled, in which case monitoring is not enabled for those objects.
TIMED	Whether the object's events are timed or not. Can be modified.

When the Performance Schema looks for matches in the `setup_objects`, there may be more than one row matching, with different `ENABLED` and `TIMED` values. It looks for the most specific matches first, that is, it will first look for the specific database and table name combination, then the specific database, only then falling back to a wildcard for both.

Rows can be added or removed from the table, while for existing rows, only the `TIMED` and `ENABLED` columns can be updated. By default, all tables except those in the `performance_schema`, `information_schema` and `mysql` databases are instrumented.

1.1.1.2.9.2.1.68 Performance Schema `setup_timers` Table

Description

The `setup_timers` table shows the currently selected event timers. Deprecated since 10.5, removed in 12.0

It contains the following columns:

Column	Description
<code>NAME</code>	Type of instrument the timer is used for.
<code>TIMER_NAME</code>	Timer applying to the instrument type. Can be modified.

The `TIMER_NAME` value can be changed to choose a different timer, and can be any non-NULL value in the [performance_timers.TIMER_NAME](#) column.

If you modify the table, monitoring is immediately affected, and currently monitored events would use a combination of old and new timers, which is probably undesirable. It is best to reset the Performance Schema statistics if you make changes to this table.

Example

```
SELECT * FROM setup_timers;
+-----+-----+
| NAME      | TIMER_NAME |
+-----+-----+
| idle      | MICROSECOND |
| wait      | CYCLE       |
| stage     | NANOSECOND  |
| statement | NANOSECOND  |
+-----+-----+
```

1.1.1.2.9.2.1.69 Performance Schema `socket_instances` Table

The `socket_instances` table lists active server connections, with each record being a Unix socket file or TCP/IP connection.

The `socket_instances` table contains the following columns:

Column	Description
<code>EVENT_NAME</code>	NAME from the <code>setup_instruments</code> table, and the name of the <code>wait/io/socket/*</code> instrument that produced the event.
<code>OBJECT_INSTANCE_BEGIN</code>	Memory address of the object.
<code>THREAD_ID</code>	Thread identifier that the server assigns to each socket.
<code>SOCKET_ID</code>	The socket's internal file handle.
<code>IP</code>	Client IP address. Blank for Unix socket file, otherwise an IPv4 or IPv6 address. Together with the <code>PORT</code> identifies the connection.
<code>PORT</code>	TCP/IP port number, from 0 to 65535. Together with the <code>IP</code> identifies the connection.

STATE

Socket status, either `IDLE` if waiting to receive a request from a client, or `ACTIVE`

1.1.1.2.9.2.1.70 Performance Schema `socket_summary_by_event_name` Table

It aggregates timer and byte count statistics for all socket I/O operations by socket instrument.

Column	Description
<code>EVENT_NAME</code>	Socket instrument.
<code>COUNT_STAR</code>	Number of summarized events
<code>SUM_TIMER_WAIT</code>	Total wait time of the summarized events that are timed.
<code>MIN_TIMER_WAIT</code>	Minimum wait time of the summarized events that are timed.
<code>AVG_TIMER_WAIT</code>	Average wait time of the summarized events that are timed.
<code>MAX_TIMER_WAIT</code>	Maximum wait time of the summarized events that are timed.
<code>COUNT_READ</code>	Number of all read operations, including <code>RECV</code> , <code>RECVFROM</code> , and <code>RECVMSG</code> .
<code>SUM_TIMER_READ</code>	Total wait time of all read operations that are timed.
<code>MIN_TIMER_READ</code>	Minimum wait time of all read operations that are timed.
<code>AVG_TIMER_READ</code>	Average wait time of all read operations that are timed.
<code>MAX_TIMER_READ</code>	Maximum wait time of all read operations that are timed.
<code>SUM_NUMBER_OF_BYTES_READ</code>	Bytes read by read operations.
<code>COUNT_WRITE</code>	Number of all write operations, including <code>SEND</code> , <code>SENDTO</code> , and <code>SENDMSG</code> .
<code>SUM_TIMER_WRITE</code>	Total wait time of all write operations that are timed.
<code>MIN_TIMER_WRITE</code>	Minimum wait time of all write operations that are timed.
<code>AVG_TIMER_WRITE</code>	Average wait time of all write operations that are timed.
<code>MAX_TIMER_WRITE</code>	Maximum wait time of all write operations that are timed.
<code>SUM_NUMBER_OF_BYTES_WRITE</code>	Bytes written by write operations.
<code>COUNT_MISC</code>	Number of all miscellaneous operations not counted above, including <code>CONNECT</code> , <code>LISTEN</code> , <code>ACCEPT</code> , <code>CLOSE</code> , and <code>SHUTDOWN</code> .
<code>SUM_TIMER_MISC</code>	Total wait time of all miscellaneous operations that are timed.
<code>MIN_TIMER_MISC</code>	Minimum wait time of all miscellaneous operations that are timed.
<code>AVG_TIMER_MISC</code>	Average wait time of all miscellaneous operations that are timed.
<code>MAX_TIMER_MISC</code>	Maximum wait time of all miscellaneous operations that are timed.

You can [TRUNCATE](#) the table, which will reset all counters to zero.

Example

```

SELECT * FROM socket_summary_by_event_name\G
***** 1. row *****
      EVENT_NAME: wait/io/socket/sql/server_tcpip_socket
      COUNT_STAR: 0
      SUM_TIMER_WAIT: 0
      MIN_TIMER_WAIT: 0

      COUNT_WRITE: 0
      SUM_TIMER_WRITE: 0
      MIN_TIMER_WRITE: 0
      AVG_TIMER_WRITE: 0
      MAX_TIMER_WRITE: 0
      SUM_NUMBER_OF_BYTES_WRITE: 0
      COUNT_MISC: 0
      SUM_TIMER_MISC: 0
      MIN_TIMER_MISC: 0
      AVG_TIMER_MISC: 0
      MAX_TIMER_MISC: 0
...

```

1.1.1.2.9.2.1.71 Performance Schema socket_summary_by_instance Table

It aggregates timer and byte count statistics for all socket I/O operations by socket instance.

Column	Description
EVENT_NAME	Socket instrument.
OBJECT_INSTANCE_BEGIN	Address in memory.
COUNT_STAR	Number of summarized events
SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.
MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.
AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.

MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.
COUNT_READ	Number of all read operations, including <code>RECV</code> , <code>RECVFROM</code> , and <code>RECVMSG</code> .
SUM_TIMER_READ	Total wait time of all read operations that are timed.
MIN_TIMER_READ	Minimum wait time of all read operations that are timed.
AVG_TIMER_READ	Average wait time of all read operations that are timed.
MAX_TIMER_READ	Maximum wait time of all read operations that are timed.
SUM_NUMBER_OF_BYTES_READ	Bytes read by read operations.
COUNT_WRITE	Number of all write operations, including <code>SEND</code> , <code>SENDTO</code> , and <code>SENDMSG</code> .
SUM_TIMER_WRITE	Total wait time of all write operations that are timed.
MIN_TIMER_WRITE	Minimum wait time of all write operations that are timed.
AVG_TIMER_WRITE	Average wait time of all write operations that are timed.
MAX_TIMER_WRITE	Maximum wait time of all write operations that are timed.
SUM_NUMBER_OF_BYTES_WRITE	Bytes written by write operations.
COUNT_MISC	Number of all miscellaneous operations not counted above, including <code>CONNECT</code> , <code>LISTEN</code> , <code>ACCEPT</code> , <code>CLOSE</code> , and <code>SHUTDOWN</code> .
SUM_TIMER_MISC	Total wait time of all miscellaneous operations that are timed.
MIN_TIMER_MISC	Minimum wait time of all miscellaneous operations that are timed.
AVG_TIMER_MISC	Average wait time of all miscellaneous operations that are timed.
MAX_TIMER_MISC	Maximum wait time of all miscellaneous operations that are timed.

The corresponding row in the table is deleted when a connection terminates.

You can [TRUNCATE](#) the table, which will reset all counters to zero.

1.1.1.2.9.2.1.72 Performance Schema `status_by_account` Table

MariaDB starting with [10.5.2](#)

The `status_by_account` table was added in [MariaDB 10.5.2](#).

The `status_by_account` table contains status variable information by user/host account. The table does not collect statistics for `Com_xxx` variables.

The table contains the following columns:

Column	Description
USER	User for which the status variable is reported.
HOST	Host for which the status variable is reported.
VARIABLE_NAME	Status variable name.
VARIABLE_VALUE	Aggregated status variable value

If [TRUNCATE TABLE](#) is run, will aggregate the status from terminated sessions to user and host status, then reset the account status.

If [FLUSH STATUS](#) is run, session status from all active sessions are added to the global status variables, the status of all active sessions are reset, and values aggregated from disconnected sessions are reset.

1.1.1.2.9.2.1.73 Performance Schema `status_by_host` Table

MariaDB starting with [10.5.2](#)

The `status_by_host` table was added in [MariaDB 10.5.2](#).

The `status_by_host` table contains status variable information by host. The table does not collect statistics for `Com_xxx` variables.

The table contains the following columns:

Column	Description
HOST	Host for which the status variable is reported.
VARIABLE_NAME	Status variable name.
VARIABLE_VALUE	Aggregated status variable value

If [TRUNCATE TABLE](#) is run, will reset the aggregated host status from terminated sessions.

If [FLUSH STATUS](#) is run, session status from all active sessions are added to the global status variables, the status of all active sessions are reset, and values aggregated from disconnected sessions are reset.

1.1.1.2.9.2.1.74 Performance Schema `status_by_thread` Table

MariaDB starting with [10.5.2](#)

The `session_status` table was added in [MariaDB 10.5.2](#).

The `status_by_thread` table contains status variable information about active foreground threads. The table does not collect statistics for `Com_xxx` variables.

The table contains the following columns:

Column	Description
THREAD_ID	The thread identifier of the session in which the status variable is defined.
VARIABLE_NAME	Status variable name.
VARIABLE_VALUE	Aggregated status variable value.

If [TRUNCATE TABLE](#) is run, will aggregate the status for all threads to the global status and account status, then reset the thread status. If account statistics are not collected but host and user status are, the session status is added to host and user status.

1.1.1.2.9.2.1.75 Performance Schema `status_by_user` Table

MariaDB starting with [10.5.2](#)

The `status_by_account` table was added in [MariaDB 10.5.2](#).

The `status_by_account` table contains status variable information by user. The table does not collect statistics for `Com_xxx` variables.

The table contains the following columns:

Column	Description
USER	User for which the status variable is reported.
VARIABLE_NAME	Status variable name.
VARIABLE_VALUE	Aggregated status variable value

If [TRUNCATE TABLE](#) is run, will reset the aggregated user status from terminated sessions.

If [FLUSH STATUS](#) is run, session status from all active sessions are added to the global status variables, the status of all active sessions are reset, and values aggregated from disconnected sessions are reset.

1.1.1.2.9.2.1.76 Performance Schema table_handles Table

MariaDB starting with [10.5.2](#)

The `table_handles` table was added in [MariaDB 10.5.2](#).

The `table_handles` table contains table lock information. It uses the `wait/lock/table/sql/handler` instrument, which is enabled by default.

Information includes which table handles are open, which sessions are holding the locks, and how they are locked.

The table is read-only, and `TRUNCATE TABLE` cannot be performed on the table.

The maximum number of opened table objects is determined by the `performance_schema_max_table_handles` system variable.

The table contains the following columns:

Column	Description
OBJECT_TYPE	The table opened by a table handle.
OBJECT_SCHEMA	The schema that contains the object.
OBJECT_NAME	The name of the instrumented object.
OBJECT_INSTANCE_BEGIN	The table handle address in memory.
OWNER_THREAD_ID	The thread owning the table handle.
OWNER_EVENT_ID	The event which caused the table handle to be opened.
INTERNAL_LOCK	The table lock used at the SQL level.
EXTERNAL_LOCK	The table lock used at the storage engine level.

1.1.1.2.9.2.1.77 Performance Schema table_io_waits_summary_by_index_usage Table

The `table_io_waits_summary_by_index_usage` table records table I/O waits by index.

Column	Description
OBJECT_TYPE	<code>TABLE</code> in the case of all indexes.
OBJECT_SCHEMA	Schema name.
OBJECT_NAME	Table name.
INDEX_NAME	Index name, or <code>PRIMARY</code> for the primary index, <code>NULL</code> for no index (inserts are counted in this case).
COUNT_STAR	Number of summarized events and the sum of the <code>x_READ</code> and <code>x_WRITE</code> columns.
SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.
MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.
AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.
MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.
COUNT_READ	Number of all read operations, and the sum of the equivalent <code>x_FETCH</code> columns.
SUM_TIMER_READ	Total wait time of all read operations that are timed.
MIN_TIMER_READ	Minimum wait time of all read operations that are timed.
AVG_TIMER_READ	Average wait time of all read operations that are timed.
MAX_TIMER_READ	Maximum wait time of all read operations that are timed.

COUNT_WRITE	Number of all write operations, and the sum of the equivalent x_INSERT , x_UPDATE and x_DELETE columns.
SUM_TIMER_WRITE	Total wait time of all write operations that are timed.
MIN_TIMER_WRITE	Minimum wait time of all write operations that are timed.
AVG_TIMER_WRITE	Average wait time of all write operations that are timed.
MAX_TIMER_WRITE	Maximum wait time of all write operations that are timed.
COUNT_FETCH	Number of all fetch operations.
SUM_TIMER_FETCH	Total wait time of all fetch operations that are timed.
MIN_TIMER_FETCH	Minimum wait time of all fetch operations that are timed.
AVG_TIMER_FETCH	Average wait time of all fetch operations that are timed.
MAX_TIMER_FETCH	Maximum wait time of all fetch operations that are timed.
COUNT_INSERT	Number of all insert operations.
SUM_TIMER_INSERT	Total wait time of all insert operations that are timed.
MIN_TIMER_INSERT	Minimum wait time of all insert operations that are timed.
AVG_TIMER_INSERT	Average wait time of all insert operations that are timed.
MAX_TIMER_INSERT	Maximum wait time of all insert operations that are timed.
COUNT_UPDATE	Number of all update operations.
SUM_TIMER_UPDATE	Total wait time of all update operations that are timed.
MIN_TIMER_UPDATE	Minimum wait time of all update operations that are timed.
AVG_TIMER_UPDATE	Average wait time of all update operations that are timed.
MAX_TIMER_UPDATE	Maximum wait time of all update operations that are timed.
COUNT_DELETE	Number of all delete operations.
SUM_TIMER_DELETE	Total wait time of all delete operations that are timed.
MIN_TIMER_DELETE	Minimum wait time of all delete operations that are timed.
AVG_TIMER_DELETE	Average wait time of all delete operations that are timed.
MAX_TIMER_DELETE	Maximum wait time of all delete operations that are timed.

You can [TRUNCATE](#) the table, which will reset all counters to zero. The table is also truncated if the [table_io_waits_summary_by_table](#) table is truncated.

If a table's index structure is changed, index statistics recorded in this table may also be reset.

1.1.1.2.9.2.1.78 Performance Schema table_io_waits_summary_by_table Table

The [table_io_waits_summary_by_table](#) table records table I/O waits by table.

Column	Description
OBJECT_TYPE	Since this table records waits by table, always set to TABLE .
OBJECT_SCHEMA	Schema name.
OBJECT_NAME	Table name.
COUNT_STAR	Number of summarized events and the sum of the x_READ and x_WRITE columns.
SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.
MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.
AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.
MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.

COUNT_READ	Number of all read operations, and the sum of the equivalent <code>x_FETCH</code> columns.
SUM_TIMER_READ	Total wait time of all read operations that are timed.
MIN_TIMER_READ	Minimum wait time of all read operations that are timed.
AVG_TIMER_READ	Average wait time of all read operations that are timed.
MAX_TIMER_READ	Maximum wait time of all read operations that are timed.
COUNT_WRITE	Number of all write operations, and the sum of the equivalent <code>x_INSERT</code> , <code>x_UPDATE</code> and <code>x_DELETE</code> columns.
SUM_TIMER_WRITE	Total wait time of all write operations that are timed.
MIN_TIMER_WRITE	Minimum wait time of all write operations that are timed.
AVG_TIMER_WRITE	Average wait time of all write operations that are timed.
MAX_TIMER_WRITE	Maximum wait time of all write operations that are timed.
COUNT_FETCH	Number of all fetch operations.
SUM_TIMER_FETCH	Total wait time of all fetch operations that are timed.
MIN_TIMER_FETCH	Minimum wait time of all fetch operations that are timed.
AVG_TIMER_FETCH	Average wait time of all fetch operations that are timed.
MAX_TIMER_FETCH	Maximum wait time of all fetch operations that are timed.
COUNT_INSERT	Number of all insert operations.
SUM_TIMER_INSERT	Total wait time of all insert operations that are timed.
MIN_TIMER_INSERT	Minimum wait time of all insert operations that are timed.
AVG_TIMER_INSERT	Average wait time of all insert operations that are timed.
MAX_TIMER_INSERT	Maximum wait time of all insert operations that are timed.
COUNT_UPDATE	Number of all update operations.
SUM_TIMER_UPDATE	Total wait time of all update operations that are timed.
MIN_TIMER_UPDATE	Minimum wait time of all update operations that are timed.
AVG_TIMER_UPDATE	Average wait time of all update operations that are timed.
MAX_TIMER_UPDATE	Maximum wait time of all update operations that are timed.
COUNT_DELETE	Number of all delete operations.
SUM_TIMER_DELETE	Total wait time of all delete operations that are timed.
MIN_TIMER_DELETE	Minimum wait time of all delete operations that are timed.
AVG_TIMER_DELETE	Average wait time of all delete operations that are timed.
MAX_TIMER_DELETE	Maximum wait time of all delete operations that are timed.

You can [TRUNCATE](#) the table, which will reset all counters to zero. Truncating this table will also truncate the [table_io_waits_summary_by_index_usage](#) table.

1.1.1.2.9.2.1.79 Performance Schema `table_lock_waits_summary_by_table` Table

The `table_lock_waits_summary_by_table` table records table lock waits by table.

Column	Description
OBJECT_TYPE	Since this table records waits by table, always set to <code>TABLE</code> .
OBJECT_SCHEMA	Schema name.

OBJECT_NAME	Table name.
COUNT_STAR	Number of summarized events and the sum of the x_READ and x_WRITE columns.
SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.
MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.
AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.
MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.
COUNT_READ	Number of all read operations, and the sum of the equivalent x_READ_NORMAL, x_READ_WITH_SHARED_LOCKS, x_READ_HIGH_PRIORITY and x_READ_NO_INSERT columns.
SUM_TIMER_READ	Total wait time of all read operations that are timed.
MIN_TIMER_READ	Minimum wait time of all read operations that are timed.
AVG_TIMER_READ	Average wait time of all read operations that are timed.
MAX_TIMER_READ	Maximum wait time of all read operations that are timed.
COUNT_WRITE	Number of all write operations, and the sum of the equivalent x_WRITE_ALLOW_WRITE, x_WRITE_CONCURRENT_INSERT, x_WRITE_DELAYED, x_WRITE_LOW_PRIORITY and x_WRITE_NORMAL columns.
SUM_TIMER_WRITE	Total wait time of all write operations that are timed.
MIN_TIMER_WRITE	Minimum wait time of all write operations that are timed.
AVG_TIMER_WRITE	Average wait time of all write operations that are timed.
MAX_TIMER_WRITE	Maximum wait time of all write operations that are timed.
COUNT_READ_NORMAL	Number of all internal read normal locks.
SUM_TIMER_READ_NORMAL	Total wait time of all internal read normal locks that are timed.
MIN_TIMER_READ_NORMAL	Minimum wait time of all internal read normal locks that are timed.
AVG_TIMER_READ_NORMAL	Average wait time of all internal read normal locks that are timed.
MAX_TIMER_READ_NORMAL	Maximum wait time of all internal read normal locks that are timed.
COUNT_READ_WITH_SHARED_LOCKS	Number of all internal read with shared locks.
SUM_TIMER_READ_WITH_SHARED_LOCKS	Total wait time of all internal read with shared locks that are timed.
MIN_TIMER_READ_WITH_SHARED_LOCKS	Minimum wait time of all internal read with shared locks that are timed.
AVG_TIMER_READ_WITH_SHARED_LOCKS	Average wait time of all internal read with shared locks that are timed.
MAX_TIMER_READ_WITH_SHARED_LOCKS	Maximum wait time of all internal read with shared locks that are timed.
COUNT_READ_HIGH_PRIORITY	Number of all internal read high priority locks.
SUM_TIMER_READ_HIGH_PRIORITY	Total wait time of all internal read high priority locks that are timed.
MIN_TIMER_READ_HIGH_PRIORITY	Minimum wait time of all internal read high priority locks that are timed.
AVG_TIMER_READ_HIGH_PRIORITY	Average wait time of all internal read high priority locks that are timed.
MAX_TIMER_READ_HIGH_PRIORITY	Maximum wait time of all internal read high priority locks that are timed.
COUNT_READ_NO_INSERT	Number of all internal read no insert locks.
SUM_TIMER_READ_NO_INSERT	Total wait time of all internal read no insert locks that are timed.
MIN_TIMER_READ_NO_INSERT	Minimum wait time of all internal read no insert locks that are timed.
AVG_TIMER_READ_NO_INSERT	Average wait time of all internal read no insert locks that are timed.
MAX_TIMER_READ_NO_INSERT	Maximum wait time of all internal read no insert locks that are timed.
COUNT_READ_EXTERNAL	Number of all external read locks.

SUM_TIMER_READ_EXTERNAL	Total wait time of all external read locks that are timed.
MIN_TIMER_READ_EXTERNAL	Minimum wait time of all external read locks that are timed.
AVG_TIMER_READ_EXTERNAL	Average wait time of all external read locks that are timed.
MAX_TIMER_READ_EXTERNAL	Maximum wait time of all external read locks that are timed.
COUNT_WRITE_ALLOW_WRITE	Number of all internal read normal locks.
SUM_TIMER_WRITE_ALLOW_WRITE	Total wait time of all internal write allow write locks that are timed.
MIN_TIMER_WRITE_ALLOW_WRITE	Minimum wait time of all internal write allow write locks that are timed.
AVG_TIMER_WRITE_ALLOW_WRITE	Average wait time of all internal write allow write locks that are timed.
MAX_TIMER_WRITE_ALLOW_WRITE	Maximum wait time of all internal write allow write locks that are timed.
COUNT_WRITE_CONCURRENT_INSERT	Number of all internal concurrent insert write locks.
SUM_TIMER_WRITE_CONCURRENT_INSERT	Total wait time of all internal concurrent insert write locks that are timed.
MIN_TIMER_WRITE_CONCURRENT_INSERT	Minimum wait time of all internal concurrent insert write locks that are timed.
AVG_TIMER_WRITE_CONCURRENT_INSERT	Average wait time of all internal concurrent insert write locks that are timed.
MAX_TIMER_WRITE_CONCURRENT_INSERT	Maximum wait time of all internal concurrent insert write locks that are timed.
COUNT_WRITE_DELAYED	Number of all internal write delayed locks.
SUM_TIMER_WRITE_DELAYED	Total wait time of all internal write delayed locks that are timed.
MIN_TIMER_WRITE_DELAYED	Minimum wait time of all internal write delayed locks that are timed.
AVG_TIMER_WRITE_DELAYED	Average wait time of all internal write delayed locks that are timed.
MAX_TIMER_WRITE_DELAYED	Maximum wait time of all internal write delayed locks that are timed.
COUNT_WRITE_LOW_PRIORITY	Number of all internal write low priority locks.
SUM_TIMER_WRITE_LOW_PRIORITY	Total wait time of all internal write low priority locks that are timed.
MIN_TIMER_WRITE_LOW_PRIORITY	Minimum wait time of all internal write low priority locks that are timed.
AVG_TIMER_WRITE_LOW_PRIORITY	Average wait time of all internal write low priority locks that are timed.
MAX_TIMER_WRITE_LOW_PRIORITY	Maximum wait time of all internal write low priority locks that are timed.
COUNT_WRITE_NORMAL	Number of all internal write normal locks.
SUM_TIMER_WRITE_NORMAL	Total wait time of all internal write normal locks that are timed.
MIN_TIMER_WRITE_NORMAL	Minimum wait time of all internal write normal locks that are timed.
AVG_TIMER_WRITE_NORMAL	Average wait time of all internal write normal locks that are timed.
MAX_TIMER_WRITE_NORMAL	Maximum wait time of all internal write normal locks that are timed.
COUNT_WRITE_EXTERNAL	Number of all external write locks.
SUM_TIMER_WRITE_EXTERNAL	Total wait time of all external write locks that are timed.
MIN_TIMER_WRITE_EXTERNAL	Minimum wait time of all external write locks that are timed.
AVG_TIMER_WRITE_EXTERNAL	Average wait time of all external write locks that are timed.
MAX_TIMER_WRITE_EXTERNAL	Maximum wait time of all external write locks that are timed.

You can [TRUNCATE](#) the table, which will reset all counters to zero.

1.1.1.2.9.2.1.80 Performance Schema threads Table

Each server thread is represented as a row in the `threads` table.

The `threads` table contains the following columns:

Column	Description
--------	-------------

THREAD_ID	A unique thread identifier.
NAME	Name associated with the server's thread instrumentation code, for example <code>thread/sql/main</code> for the server's <code>main()</code> function, and <code>thread/sql/one_connection</code> for a user connection.
TYPE	FOREGROUND or BACKGROUND , depending on the thread type. User connection threads are FOREGROUND , internal server threads are BACKGROUND .
PROCESSLIST_ID	The PROCESSLIST.ID value for threads displayed in the INFORMATION_SCHEMA.PROCESSLIST table, or 0 for background threads. Also corresponds with the CONNECTION_ID() return value for the thread.
PROCESSLIST_USER	Foreground thread user, or NULL for a background thread.
PROCESSLIST_HOST	Foreground thread host, or NULL for a background thread.
PROCESSLIST_DB	Thread's default database, or NULL if none exists.
PROCESSLIST_COMMAND	Type of command executed by the thread. These correspond to the the COM_XXX client/server protocol commands, and the Com_XXX status variables. See Thread Command Values .
PROCESSLIST_TIME	Time in seconds the thread has been in its current state.
PROCESSLIST_STATE	Action, event or state indicating what the thread is doing.
PROCESSLIST_INFO	Statement being executed by the thread, or NULL if a statement is not being executed. If a statement results in calling other statements, such as for a stored procedure , the innermost statement from the stored procedure is shown here.
PARENT_THREAD_ID	THREAD_ID of the parent thread, if any. Subthreads can for example be spawned as a result of INSERT DELAYED statements.
ROLE	Unused.
INSTRUMENTED	YES or NO for Whether the thread is instrumented or not. For foreground threads, the initial value is determined by whether there's a user/host match in the setup_actors table. Subthreads are again matched, while for background threads, this will be set to YES by default. To monitor events that the thread executes, INSTRUMENTED must be YES and the thread_instrumentation consumer in the setup_consumers table must also be YES .
HISTORY	YES or NO for Whether to log historical events for the thread. For foreground threads, the initial value is determined by whether there's a user/host match in the setup_actors table. Subthreads are again matched, while for background threads, this will be set to YES by default. To monitor events that the thread executes, INSTRUMENTED must be YES and the thread_instrumentation consumer in the setup_consumers table must also be YES . Added in MariaDB 10.5 .
CONNECTION_TYPE	The protocol used to establish the connection. One of TCP/IP , SSL/TLS , Socket , Named Pipe , Shared Memory , or NULL for background threads. Added in MariaDB 10.5 .
THREAD_OS_ID	The thread or task identifier as defined by the underlying operating system, if there is one. Added in MariaDB 10.5

Example

```

SELECT * FROM performance_schema.threads\G;
***** 1. row *****
      THREAD_ID: 1
        NAME: thread/sql/main
        TYPE: BACKGROUND
    PROCESSLIST_ID: NULL
    PROCESSLIST_USER: NULL
    PROCESSLIST_HOST: NULL
    PROCESSLIST_DB: NULL
    PROCESSLIST_COMMAND: NULL
    PROCESSLIST_TIME: 215859
    PROCESSLIST_STATE: Table lock
    PROCESSLIST_INFO: INTERNAL DDL LOG RECOVER IN PROGRESS
    PARENT_THREAD_ID: NULL
        ROLE: NULL
    INSTRUMENTED: YES
...
***** 21. row *****
      THREAD_ID: 64
        NAME: thread/sql/one_connection
        TYPE: FOREGROUND
    PROCESSLIST_ID: 44
    PROCESSLIST_USER: root
    PROCESSLIST_HOST: localhost
    PROCESSLIST_DB: NULL
    PROCESSLIST_COMMAND: Query
    PROCESSLIST_TIME: 0
    PROCESSLIST_STATE: Sending data
    PROCESSLIST_INFO: SELECT * FROM performance_schema.threads
    PARENT_THREAD_ID: NULL
        ROLE: NULL
    INSTRUMENTED: YES

```

1.1.1.2.9.2.1.81 Performance Schema user_variables_by_thread Table

MariaDB starting with [10.5.2](#)

The `user_variables_by_thread` table was added in [MariaDB 10.5.2](#).

The `user_variables_by_thread` table contains information about [user-defined variables](#) and the threads that defined them.

`TRUNCATE TABLE` cannot be performed on the table.

The table contains the following columns:

Column	Description
THREAD_ID	The thread identifier of the session in which the variable is defined.
VARIABLE_NAME	The variable name, without the leading @ character.
VARIABLE_VALUE	The variable value

Example

```

SET @var = 0;

SELECT * FROM user_variables_by_thread;
+-----+-----+-----+
| THREAD_ID | VARIABLE_NAME | VARIABLE_VALUE |
+-----+-----+-----+
|         11 | var           | 0              |
+-----+-----+-----+

```

1.1.1.2.9.2.1.82 Performance Schema users Table

Description

Each user that connects to the server is stored as a row in the `users` table, along with current and total connections.

The table size is determined at startup by the value of the `performance_schema_users_size` system variable. If this is set to `0`, user statistics will be disabled.

Column	Description
<code>USER</code>	The connection's client user name for the connection, or <code>NULL</code> if an internal thread.
<code>CURRENT_CONNECTIONS</code>	Current connections for the user.
<code>TOTAL_CONNECTIONS</code>	Total connections for the user.

Example

```
SELECT * FROM performance_schema.users;
```

USER	CURRENT_CONNECTIONS	TOTAL_CONNECTIONS
debian-sys-maint	0	35
NULL	20	23
root	1	2

1.1.1.2.9.2.2 Performance Schema Overview

Contents

- [1. Introduction](#)
- [2. Activating the Performance Schema](#)
- [3. Enabling the Performance Schema](#)
- [4. Listing Performance Schema Variables](#)
- [5. Column Comments](#)

The Performance Schema is a feature for monitoring server performance.

Introduction

It is implemented as a storage engine, and so will appear in the list of storage engines available.

```
SHOW ENGINES;
```

Engine	Support	Comment	Transactions	XA	Savepoi
...					
PERFORMANCE_SCHEMA	YES	Performance Schema	NO	NO	NO
...					

However, `performance_schema` is not a regular storage engine for storing data, it's a mechanism for implementing the Performance Schema feature.

The storage engine contains a database called `performance_schema`, which in turn consists of a number of tables that can be queried with regular SQL statements, returning specific performance information.

```
USE performance_schema
```

```
SHOW TABLES;
+-----+
| Tables_in_performance_schema |
+-----+
| accounts |
...
| users |
+-----+
80 rows in set (0.00 sec)
```

See [List of Performance Schema Tables](#) for a full list and links to detailed descriptions of each table. From [MariaDB 10.5](#), there are 80 Performance Schema tables, while until [MariaDB 10.4](#), there are 52.

Activating the Performance Schema

The performance schema is disabled by default for performance reasons. You can check its current status by looking at the value of the `performance_schema` system variable.

```
SHOW VARIABLES LIKE 'performance_schema';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| performance_schema | ON |
+-----+-----+
```

The performance schema cannot be activated at runtime - it must be set when the server starts by adding the following line in your `my.cnf` configuration file.

```
performance_schema=ON
```

Until [MariaDB 10.4](#), all memory used by the Performance Schema is allocated at startup. From [MariaDB 10.5](#), some memory is allocated dynamically, depending on load, number of connections, number of tables open etc.

Enabling the Performance Schema

You need to set up all consumers (starting collection of data) and instrumentations (what to collect):

```
UPDATE performance_schema.setup_consumers SET ENABLED = 'YES';
UPDATE performance_schema.setup_instruments SET ENABLED = 'YES', TIMED = 'YES';
```

You can decide what to enable/disable with `WHERE NAME like "%what_to_enable"`; You can disable instrumentations by setting `ENABLED` to `"NO"`.

You can also do this in your `my.cnf` file. The following enables all instrumentation of all stages (computation units) in MariaDB:

```
[mysqld]
performance_schema=ON
performance-schema-instrument='stage/%=ON'
performance-schema-consumer-events-stages-current=ON
performance-schema-consumer-events-stages-history=ON
performance-schema-consumer-events-stages-history-long=ON
```

Listing Performance Schema Variables

```
SHOW VARIABLES LIKE "perf%";
+-----+-----+
| Variable_name | Value |
+-----+-----+
| performance_schema | ON |
...
| performance_schema_users_size | 100 |
+-----+-----+
```

See [Performance Schema System Variables](#) for a full list of available system variables.

Note that the "consumer" events are not shown on this list, as they are only available as options, not as system variables, and they can only be enabled at [startup](#).

Column Comments

MariaDB starting with [10.7.1](#)

From [MariaDB 10.7.1](#), comments have been added to table columns in the Performance Schema. These can be viewed with, for example:

```
SELECT column_name, column_comment FROM information_schema.columns
  WHERE table_schema='performance_schema' AND table_name='file_instances';
...
***** 2. row *****
  column_name: EVENT_NAME
  column_comment: Instrument name associated with the file.
***** 3. row *****
  column_name: OPEN_COUNT
  column_comment: Open handles on the file. A value of greater than zero means
                  that the file is currently open.
...

```

This page documents status variables related to the [Performance Schema](#). See [Server Status Variables](#) for a complete list of status variables that can be viewed with [SHOW STATUS](#).

See also the [Full list of MariaDB options, system and status variables](#).

`Performance_schema_accounts_lost`

- **Description:** Number of times a row could not be added to the performance schema accounts table due to it being full. The global value can be flushed by [FLUSH STATUS](#).
- **Scope:** Global, Session
- **Data Type:** `numeric`

Performance_schema_cond_classes_lost

- **Description:** Number of condition instruments that could not be loaded.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Performance_schema_cond_instances_lost

- **Description:** Number of instances a condition object could not be created. The global value can be flushed by [FLUSH STATUS](#).
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Performance_schema_digest_lost

- **Description:** The global value can be flushed by [FLUSH STATUS](#).
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Performance_schema_file_classes_lost

- **Description:** Number of file instruments that could not be loaded.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Performance_schema_file_handles_lost

- **Description:** Number of instances a file object could not be opened. The global value can be flushed by [FLUSH STATUS](#).
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Performance_schema_file_instances_lost

- **Description:** Number of instances a file object could not be created. The global value can be flushed by [FLUSH STATUS](#).
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Performance_schema_hosts_lost

- **Description:** Number of times a row could not be added to the performance schema hosts table due to it being full. The global value can be flushed by [FLUSH STATUS](#).
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Performance_schema_index_stat_lost

- **Description:**
 - **Scope:** Global, Session
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 10.5.2](#)
-

Performance_schema_locker_lost

- **Description:** Number of events not recorded, due to either being recursive, or having a deeper nested events stack than the implementation limit. The global value can be flushed by [FLUSH STATUS](#).

- **Scope:** Global, Session
 - **Data Type:** numeric
-

Performance_schema_memory_classes_lost

- **Description:**
 - **Scope:** Global, Session
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 10.5.2](#)
-

Performance_schema_metadata_lock_lost

- **Description:**
 - **Scope:** Global, Session
 - **Data Type:** numeric

-

Performance_schema_mutex_classes_lost

- **Description:** Number of mutual exclusion instruments that could not be loaded.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Performance_schema_mutex_instances_lost

- **Description:** Number of instances a mutual exclusion object could not be created. The global value can be flushed by [FLUSH STATUS](#).
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Performance_schema_nested_statement_lost

- **Description:**
 - **Scope:** Global, Session
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 10.5.2](#)
-

Performance_schema_prepared_statements_lost

- **Description:**
 - **Scope:** Global, Session
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 10.5.2](#)
-

Performance_schema_program_lost

- **Description:**
 - **Scope:** Global, Session
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 10.5.2](#)
-

Performance_schema_rwlock_classes_lost

- **Description:** Number of read/write lock instruments that could not be loaded.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Performance_schema_rwlock_instances_lost

- **Description:** Number of instances a read/write lock object could not be created. The global value can be flushed by [FLUSH STATUS](#).
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Performance_schema_session_connect_attrs_lost

- **Description:** Number of connections for which connection attribute truncation has occurred. The global value can be flushed by [FLUSH STATUS](#).
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Performance_schema_socket_classes_lost

- **Description:**
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Performance_schema_socket_instances_lost

- **Description:** Number of instances a socket object could not be created. The global value can be flushed by [FLUSH STATUS](#).
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Performance_schema_stage_classes_lost

- **Description:** Number of stage event instruments that could not be loaded. The global value can be flushed by [FLUSH STATUS](#).
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Performance_schema_statement_classes_lost

- **Description:** Number of statement instruments that could not be loaded. The global value can be flushed by [FLUSH STATUS](#).
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Performance_schema_table_handles_lost

- **Description:** Number of instances a table object could not be opened. The global value can be flushed by [FLUSH STATUS](#).
 - **Scope:** Global, Session
 - **Data Type:** numeric

The following variables are used with MariaDB's [Performance Schema](#). See [Performance Schema Options](#) for Performance Schema options that are not system variables. See [Server System Variables](#) for a complete list of system variables and instructions on setting them.

See also the [Full list of MariaDB options, system and status variables](#).

performance_schema

- **Description:** If set to 1 (0 is default), enables the Performance Schema
 - **Commandline:** `--performance-schema=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** boolean
 - **Default Value:** OFF
-

performance_schema_accounts_size

- **Description:** Maximum number of rows in the [performance_schema.accounts](#) table. If set to 0, the [Performance Schema](#) will not store statistics in the accounts table. Use -1 (the default) for automated sizing.
 - **Commandline:** `--performance-schema-accounts-size=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** numeric
 - **Default Value:** -1
 - **Range:** -1 to 1048576
-

performance_schema_digests_size

- **Description:** Maximum number of rows that can be stored in the [events_statements_summary_by_digest](#) table. 0 for disabling, -1 (the default) for automated sizing.
 - **Commandline:** `--performance-schema-digests-size=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** numeric
 - **Default Value:** -1
 - **Range:** -1 to 1048576
-

performance_schema_events_stages_history_long_size

- **Description:** Number of rows in the [events_stages_history_long](#) table. 0 for disabling, -1 (the default) for automated sizing.
 - **Commandline:** `--performance-schema-events-stages-history-long-size=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** numeric
 - **Default Value:** -1
 - **Range:** -1 to 1048576
-

performance_schema_events_stages_history_size

- **Description:** Number of rows per thread in the [events_stages_history](#) table. 0 for disabling, -1 (the default) for automated sizing.
 - **Commandline:** `--performance-schema-events-stages-history-size=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** numeric
 - **Default Value:** -1
 - **Range:** -1 to 1024
-

performance_schema_events_statements_history_long_size

- **Description:** Number of rows in the [events_statements_history_long](#) table. 0 for disabling, -1 (the default) for automated sizing.
 - **Commandline:** `--performance-schema-events-statements-history-long-size=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:** -1
 - **Range:** -1 to 1048576
-

`performance_schema_events_statements_history_size`

- **Description:** Number of rows per thread in the [events_statements_history](#) table. 0 for disabling, -1 (the default) for automated sizing.
 - **Commandline:** `--performance-schema-events-statements-history-size=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:** -1
 - **Range:** -1 to 1024
-

`performance_schema_events_transactions_history_long_size`

- **Description:** Number of rows in [events_transactions_history_long](#) table. Use 0 to disable, -1 for automated sizing.
 - **Commandline:** `--performance-schema-events-transactions-history-long-size=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:** -1
 - **Range:** -1 to 1048576
 - **Introduced:** [MariaDB 10.5.2](#)
-

`performance_schema_events_transactions_history_size`

- **Description:** Number of rows per thread in [events_transactions_history](#). Use 0 to disable, -1 for automated sizing.
 - **Commandline:** `--performance-schema-events-transactions-history-size=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:** -1
 - **Range:** -1 to 1024
 - **Introduced:** [MariaDB 10.5.2](#)
-

`performance_schema_events_waits_history_long_size`

- **Description:** Number of rows contained in the [events_waits_history_long](#) table. 0 for disabling, -1 (the default) for automated sizing.
 - **Commandline:** `--performance-schema-events-waits-history-long-size=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:** -1
 - **Range:** -1 to 1048576
-

`performance_schema_events_waits_history_size`

- **Description:** Number of rows per thread contained in the [events_waits_history](#) table. 0 for disabling, -1 (the default) for automated sizing.
- **Commandline:** `--performance-schema-events-waits-history-size=#`
- **Scope:** Global

- **Dynamic:** No
 - **Data Type:** numeric
 - **Default Value:** -1
 - **Range:** -1 to 1024
-

performance_schema_hosts_size

- **Description:** Number of rows stored in the [hosts](#) table. If set to zero, no connection statistics are kept for the hosts table. -1 (the default) for automated sizing.
 - **Commandline:** --performance-schema-hosts-size=#
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** numeric
 - **Default Value:** -1
 - **Range:** -1 to 1048576
-

performance_schema_max_cond_classes

- **Description:** Specifies the maximum number of condition instruments.
 - **Commandline:** --performance-schema-max-cond-classes=#
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** numeric
 - **Default Value:** 90 (\geq [MariaDB 10.5.1](#)), 80 (\leq [MariaDB 10.5.0](#))
 - **Range:** 0 to 256
-

performance_schema_max_cond_instances

- **Description:** Specifies the maximum number of instrumented condition objects. 0 for disabling, -1 (the default) for automated sizing.
 - **Commandline:** --performance-schema-max-cond-instances=#
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** numeric
 - **Default Value:** -1
 - **Range:** -1 to 1048576
-

performance_schema_max_digest_length

- **Description:** Maximum length considered for digest text, when stored in performance_schema tables.
 - **Commandline:** --performance-schema-max-digest-length=#
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** numeric
 - **Default Value:** 1024
 - **Range:** 0 to 1048576
-

performance_schema_max_file_classes

- **Description:** Specifies the maximum number of file instruments.
 - **Commandline:** --performance-schema-max-file-classes=#
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** numeric
 - **Default Value:** 80 (\geq [MariaDB 10.5.2](#)), 50 (\leq [MariaDB 10.5.1](#))
 - **Range:** 0 to 256
-

performance_schema_max_file_handles

- **Description:** Specifies the maximum number of opened file objects. Should always be higher than [open_files_limit](#).
 - **Commandline:** `--performance-schema-max-file-handles=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:** `32768`
 - **Range:** `-1 to 32768`
-

`performance_schema_max_file_instances`

- **Description:** Specifies the maximum number of instrumented file objects. `0` for disabling, `-1` (the default) for automated sizing.
 - **Commandline:** `--performance-schema-max-file-instances=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:** `-1`
 - **Range:** `-1 to 1048576`
-

`performance_schema_max_index_stat`

- **Description:** Maximum number of index statistics for instrumented tables. Use `0` to disable, `-1` for automated scaling.
 - **Commandline:** `--performance-schema-max-index-stat=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:** `-1`
 - **Range:** `-1 to 1048576`
 - **Introduced:** [MariaDB 10.5.2](#)
-

`performance_schema_max_memory_classes`

- **Description:** Maximum number of memory pool instruments.
 - **Commandline:** `--performance-schema-max-memory-classes=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:** `320`
 - **Range:** `0 to 1024`
 - **Introduced:** [MariaDB 10.5.2](#)
-

`performance_schema_max_metadata_locks`

- **Description:** Maximum number of [Performance Schema metadata locks](#). Use `0` to disable, `-1` for automated scaling.
 - **Commandline:** `--performance-schema-max-metadata-locks=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:** `-1`
 - **Range:** `-1 to 104857600`
 - **Introduced:** [MariaDB 10.5.2](#)
-

`performance_schema_max_mutex_classes`

- **Description:** Specifies the maximum number of mutex instruments.
- **Commandline:** `--performance-schema-max-mutex-classes=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `210` (\geq [MariaDB 10.5.2](#)), `200` (\leq [MariaDB 10.5.1](#))

- **Range:** 0 to 256
-

performance_schema_max_mutex_instances

- **Description:** Specifies the maximum number of instrumented mutex instances. 0 for disabling, -1 (the default) for automated sizing.
 - **Commandline:** `--performance-schema-max-mutex-instances=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** numeric
 - **Default Value:** -1
 - **Range:** -1 to 104857600
-

performance_schema_max_prepared_statement_instances

- **Description:** Maximum number of instrumented prepared statements. Use 0 to disable, -1 for automated scaling.
 - **Commandline:** `--performance-schema-max-prepared-statement-instances=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** numeric
 - **Default Value:** -1
 - **Range:** -1 to 1048576
 - **Introduced:** [MariaDB 10.5.2](#)
-

performance_schema_max_program_instances

- **Description:** Maximum number of instrumented programs. Use 0 to disable, -1 for automated scaling.
 - **Commandline:** `--performance-schema-max-program-instances=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** numeric
 - **Default Value:** -1
 - **Range:** -1 to 1048576
 - **Introduced:** [MariaDB 10.5.2](#)
-

performance_schema_max_rwlock_classes

- **Description:** Specifies the maximum number of rwlock instruments.
 - **Commandline:** `--performance-schema-max-rwlock-classes=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** numeric
 - **Default Value:** 50 (\geq [MariaDB 10.5.2](#)), 40 (\leq [MariaDB 10.5.1](#))
 - **Range:** 0 to 256
-

performance_schema_max_rwlock_instances

- **Description:** Specifies the maximum number of instrumented rwlock objects. 0 for disabling, -1 (the default) for automated sizing.
 - **Commandline:** `--performance-schema-max-rwlock-instances=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** numeric
 - **Default Value:** -1
 - **Range:** -1 to 104857600
-

performance_schema_max_socket_classes

- **Description:** Specifies the maximum number of socket instruments.

- **Commandline:** `--performance-schema-max-socket-classes=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:** 10
 - **Range:** 0 to 256
-

`performance_schema_max_socket_instances`

- **Description:** Specifies the maximum number of instrumented socket objects. 0 for disabling, -1 (the default) for automated sizing.
 - **Commandline:** `--performance-schema-max-socket-instances=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:** -1
 - **Range:** -1 to 1048576
-

`performance_schema_max_sql_text_length`

- **Description:** Maximum length of displayed sql text.
 - **Commandline:** `--performance-schema-max-sql-text-length=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:** 1024
 - **Range:** 0 to 1048576
 - **Introduced:** [MariaDB 10.5.2](#)
-

`performance_schema_max_stage_classes`

- **Description:** Specifies the maximum number of stage instruments.
 - **Commandline:** `--performance-schema-max-stage-classes=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:** 160
 - **Range:** 0 to 256
-

`performance_schema_max_statement_classes`

- **Description:** Specifies the maximum number of statement instruments. Automatically calculated at server build based on the number of available statements. Should be left as either autosized or disabled, as changing to any positive value has no benefit and will most likely allocate unnecessary memory. Setting to zero disables all statement instrumentation, and no memory will be allocated for this purpose.
 - **Commandline:** `--performance-schema-max-statement-classes=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:** Autosized (see description)
 - **Range:** 0 to 256
-

`performance_schema_max_statement_stack`

- **Description:** Number of rows per thread in `EVENTS_STATEMENTS_CURRENT`.
 - **Commandline:** `--performance-schema-max-statement-stack=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:** 10
-

- **Range:** 1 to 256
 - **Introduced:** [MariaDB 10.5.2](#)
-

performance_schema_max_table_handles

- **Description:** Specifies the maximum number of opened table objects. 0 for disabling, -1 (the default) for automated sizing. See also the [Performance Schema table_handles table](#).
 - **Commandline:** --performance-schema-max-table-handles=#
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** numeric
 - **Default Value:** -1
 - **Range:** -1 to 1048576
-

performance_schema_max_table_instances

- **Description:** Specifies the maximum number of instrumented table objects. 0 for disabling, -1 (the default) for automated sizing.
 - **Commandline:** --performance-schema-max-table-instances=#
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** numeric
 - **Default Value:** -1
 - **Range:** -1 to 1048576
-

performance_schema_max_table_lock_stat

- **Description:** Maximum number of lock statistics for instrumented tables. Use 0 to disable, -1 for automated scaling.
 - **Commandline:** --performance-schema-max-table-lock-stat=#
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** numeric
 - **Default Value:** -1
 - **Range:** -1 to 1048576
 - **Introduced:** [MariaDB 10.5.2](#)
-

performance_schema_max_thread_classes

- **Description:** Specifies the maximum number of thread instruments.
 - **Commandline:** --performance-schema-max-thread-classes=#
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** numeric
 - **Default Value:** 50
 - **Range:** 0 to 256
-

performance_schema_max_thread_instances

- **Description:** Specifies how many of the running server threads (see [max_connections](#) and [max_delayed_threads](#)) can be instrumented. Should be greater than the sum of `max_connections` and `max_delayed_threads`. 0 for disabling, -1 (the default) for automated sizing.
 - **Commandline:** --performance-schema-max-thread-instances=#
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** numeric
 - **Default Value:** -1
 - **Range:** -1 to 1048576
-

performance_schema_session_connect_attrs_size

- **Description:** Per thread preallocated memory for holding connection attribute strings. Incremented if the strings are larger than the reserved space. 0 for disabling, -1 (the default) for automated sizing.
 - **Commandline:** --performance-schema-session-connect-attrs-size=#
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** numeric
 - **Default Value:** -1
 - **Range:** -1 to 1048576
-

performance_schema_setup_actors_size

- **Description:** The maximum number of rows to store in the performance schema [setup_actors](#) table. -1 (from [MariaDB 10.5.2](#)) denotes automated sizing.
 - **Commandline:** --performance-schema-setup-actors-size=#
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** numeric
 - **Default Value:** -1 ([>= MariaDB 10.5.2](#)), 100 ([<= MariaDB 10.5.1](#))
 - **Range:** -1 to 1024 ([>= MariaDB 10.5.2](#)), 0 to 1024 ([<= MariaDB 10.5.1](#))
-

performance_schema_setup_objects_size

- **Description:** The maximum number of rows that can be stored in the performance schema [setup_objects](#) table. -1 (from [MariaDB 10.5.2](#)) denotes automated sizing.
 - **Commandline:** --performance-schema-setup-objects-size=#
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** numeric
 - **Default Value:** -1 ([>= MariaDB 10.5.2](#)), 100 ([<= MariaDB 10.5.1](#))
 - **Range:** -1 to 1048576 ([>= MariaDB 10.5.2](#)), 0 to 1048576 ([<= MariaDB 10.5.1](#))
-

performance_schema_users_size

- **Description:** Number of rows in the [performance_schema.users](#) table. If set to 0, the [Performance Schema](#) will not store connection statistics in the users table. -1 (the default) for automated sizing.
 - **Commandline:** --performance-schema-users-size=#
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** numeric
 - **Default Value:** -1
 - **Range:** -1 to 1048576
-

1.1.1.2.9.2.5 Performance Schema Digests

The Performance Schema digest is a normalized form of a statement, with the specific data values removed. It allows statistics to be gathered for similar kinds of statements.

For example:

```
SELECT * FROM customer WHERE age < 20
SELECT * FROM customer WHERE age < 30
```

With the data values removed, both of these statements normalize to:

```
SELECT * FROM customer WHERE age < ?
```

which is the digest text. The digest text is used to compute a digest. For example:

```
DIGEST_TEXT: SELECT * FROM `performance_schema`.`users`
DIGEST: 0f70cec4015f2a346df4ac0e9475d9f1
```

By contrast, the following two statements would not have the same digest as, while the data values are the same, they call upon different tables.

```
SELECT * FROM customer1 WHERE age < 20
SELECT * FROM customer2 WHERE age < 20
```

The digest text is limited to 1024 bytes. Queries exceeding this limit are truncated with '...', meaning that long queries that would otherwise have different digests may share the same digest.

Digest information is used in a number of performance scheme tables. These include

- [events_statements_current](#)
- [events_statements_history](#)
- [events_statements_history_long](#)
- [events_statements_summary_by_digest](#) (a summary table by schema and digest)

1.1.1.2.9.2.6 PERFORMANCE_SCHEMA Storage Engine

If you run [SHOW ENGINES](#), you'll see the following storage engine listed.

```
SHOW ENGINES\G
...
  Engine: PERFORMANCE_SCHEMA
  Support: YES
  Comment: Performance Schema
  Transactions: NO
    XA: NO
  Savepoints: NO
...
```

The PERFORMANCE_SCHEMA is not a regular storage engine for storing data, it's a mechanism for implementing the [Performance Schema](#) feature.

The [SHOW ENGINE PERFORMANCE_SCHEMA STATUS](#) statement is also available, which shows how much memory is used by the tables and internal buffers.

See [Performance Schema](#) for more details.

1.1.1.2.9.3 The mysql Database Tables

MariaDB comes pre-installed with a system database called `mysql` containing many important tables storing, in particular, [grant and privilege](#) information. Before [MariaDB 10.4](#), system tables used the [MyISAM](#) storage engine. From [MariaDB 10.4](#), they use [Aria](#).

mysql.column_stats Table

Column stats for engine-independent statistics.

mysql.columns_priv Table

Column-level privileges

mysql.db Table

Database-level access and privileges. [↗](#)

mysql.event Table

Information about MariaDB events.

mysql.func Table

User-defined function information

mysql.general_log Table

Contents of the general query log if written to table

mysql.global_priv Table

Global privileges. [↗](#)

mysql.gtid_slave_pos Table

For replicas to keep track of the GTID.

mysql.help_category Table

Help categories. [↗](#)

mysql.help_keyword Table

Help keywords. [↗](#)

mysql.help_relation Table

HELP command relations [↗](#)

mysql.help_topic Table

Help topics. [↗](#)

mysql.index_stats Table

Index stats for engine-independent statistics.

mysql.innodb_index_stats

Data related to particular persistent index statistics, multiple rows for each index.

mysql.innodb_table_stats

Data related to persistent indexes, one row per table.

mysql.password_reuse_check_history Table

Contains old passwords for purposes of preventing password reuse.

mysql.plugin Table

Plugins loaded with INSTALL SONAME, INSTALL PLUGIN or the mariadb-plugin utility.

mysql.proc Table

Information about stored routines.

mysql.procs_priv Table

Stored procedure and stored function privileges

mysql.proxies_priv Table

Proxy privileges. [↗](#)

mysql.roles_mapping Table

MariaDB roles information.

mysql.servers Table

MariaDB servers. [↗](#)

mysql.slow_log Table

Contents of the slow query log if written to table.

mysql.tables_priv Table

Table-level privileges

mysql.table_stats Table

Table stats for engine-independent statistics.

mysql.time_zone Table

Time zone table in the mysql database. [↗](#)

mysql.time_zone_leap_second Table

Time zone leap second. [↗](#)

mysql.time_zone_name Table

[Time zone name.](#)

mysql.time_zone_transition Table

[Time zone transition table.](#)

mysql.time_zone_transition_type Table

[Time zone transition type table.](#)

mysql.transaction_registry Table

[Used for transaction-precise versioning.](#)

mysql.user Table

[User access and global privileges.](#)

Obsolete mysql Database Tables

[Tables no longer present in the mysql system database.](#)

Spider mysql Database Tables

[System tables related to the Spider storage engine.](#)

There are [2 related questions](#).

1.1.1.2.9.3.1 mysql.column_stats Table

The `mysql.column_stats` table is one of three tables storing data used for [Engine-independent table statistics](#). The others are `mysql.table_stats` and `mysql.index_stats`.

Note that statistics for blob and text columns are not collected. If explicitly specified, a warning is returned.

MariaDB starting with [10.4](#)

In [MariaDB 10.4](#) and later, this table uses the [Aria](#) storage engine.

MariaDB until [10.3](#)

In [MariaDB 10.3](#) and before, this table uses the [MyISAM](#) storage engine.

The `mysql.column_stats` table contains the following fields:

Field	Type	Null	Key	Default	Description
<code>db_name</code>	<code>varchar(64)</code>	NO	PRI	NULL	Database the table is in.
<code>table_name</code>	<code>varchar(64)</code>	NO	PRI	NULL	Table name.
<code>column_name</code>	<code>varchar(64)</code>	NO	PRI	NULL	Name of the column.
<code>min_value</code>	<code>varchar(255)</code>	YES		NULL	Minimum value in the table (in text form).
<code>max_value</code>	<code>varchar(255)</code>	YES		NULL	Maximum value in the table (in text form).
<code>nulls_ratio</code>	<code>decimal(12,4)</code>	YES		NULL	Fraction of <code>NULL</code> values (0- no <code>NULL</code> s, 0.5 - half values are <code>NULL</code> s, 1 - all values are <code>NULL</code> s).
<code>avg_length</code>	<code>decimal(12,4)</code>	YES		NULL	Average length of column value, in bytes. Counted as if one ran <code>SELECT AVG(LENGTH(col))</code> . This doesn't count <code>NULL</code> bytes, assumes endspace removal for <code>CHAR(n)</code> , etc.
<code>avg_frequency</code>	<code>decimal(12,4)</code>	YES		NULL	Average number of records with the same value

hist_size	tinyint(3) unsigned	YES		NULL	Histogram size in bytes, from 0-255, or, from MariaDB 10.7 , number of buckets if the histogram type is <code>JSON_HB</code> .
hist_type	enum('SINGLE_PREC_HB', 'DOUBLE_PREC_HB') (>= MariaDB 10.7) enum('SINGLE_PREC_HB', 'DOUBLE_PREC_HB', 'JSON_HB') (<= MariaDB 10.6)	YES		NULL	Histogram type. See the histogram_type system variable.
histogram	blob (>= MariaDB 10.7) varbinary(255) (<= MariaDB 10.6)	YES		NULL	

It is possible to manually update the table. See [Manual updates to statistics tables](#) for details.

1.1.1.2.9.3.2 mysql.columns_priv Table

The `mysql.columns_priv` table contains information about column-level privileges. The table can be queried and although it is possible to directly update it, it is best to use [GRANT](#) for setting privileges.

Note that the MariaDB privileges occur at many levels. A user may be granted a privilege at the column level, but may still not have permission on a table level, for example. See [privileges](#) for a more complete view of the MariaDB privilege system.

The `INFORMATION_SCHEMA.COLUMN_PRIVILEGES` table derives its contents from `mysql.columns_priv`.

MariaDB starting with [10.4](#)

In [MariaDB 10.4](#) and later, this table uses the [Aria](#) storage engine.

MariaDB until [10.3](#)

In [MariaDB 10.3](#) and before, this table uses the [MyISAM](#) storage engine.

The `mysql.columns_priv` table contains the following fields:

Field	Type	Null	Key	Default	Description
Host	char(60)	NO	PRI		Host (together with <code>User</code> , <code>Db</code> , <code>Table_name</code> and <code>Column_name</code> makes up the unique identifier for this record.
Db	char(64)	NO	PRI		Database name (together with <code>User</code> , <code>Host</code> , <code>Table_name</code> and <code>Column_name</code> makes up the unique identifier for this record.
User	char(80)	NO	PRI		User (together with <code>Host</code> , <code>Db</code> , <code>Table_name</code> and <code>Column_name</code> makes up the unique identifier for this record.
Table_name	char(64)	NO	PRI		Table name (together with <code>User</code> , <code>Db</code> , <code>Host</code> and <code>Column_name</code> makes up the unique identifier for this record.
Column_name	char(64)	NO	PRI		Column name (together with <code>User</code> , <code>Db</code> , <code>Table_name</code> and <code>Host</code> makes up the unique identifier for this record.
Timestamp	timestamp	NO		CURRENT_TIMESTAMP	
Column_priv	set('Select', 'Insert', 'Update', 'References')	NO			The privilege type. See Column Privileges for details.

The `Acl_column_grants` status variable, added in [MariaDB 10.1.4](#), indicates how many rows the `mysql.columns_priv` table contains.

1.1.1.2.9.3.3 mysql.db Table

The `mysql.db` table contains information about database-level privileges. The table can be queried and although it is possible to directly update it, it is best to use [GRANT](#) for setting privileges.

Note that the MariaDB privileges occur at many levels. A user may not be granted a privilege at the database level, but may still have permission on a table level, for example. See [privileges](#) for a more complete view of the MariaDB privilege system.

This table uses the [Aria](#) storage engine.

The `mysql.db` table contains the following fields:

Field	Type	Null	Key	Default	Description	Introduced
Host	char(60)	NO	PRI		Host (together with <code>User</code> and <code>Db</code> makes up the unique identifier for this record. Until MariaDB 5.5 , if the host field was blank, the corresponding record in the mysql.host table would be examined. From MariaDB 10.0 , a blank host field is the same as the <code>%</code> wildcard.	
Db	char(64)	NO	PRI		Database (together with <code>User</code> and <code>Host</code> makes up the unique identifier for this record.	
User	char(80)	NO	PRI		User (together with <code>Host</code> and <code>Db</code> makes up the unique identifier for this record.	
Select_priv	enum('N','Y')	NO		N	Can perform SELECT statements.	
Insert_priv	enum('N','Y')	NO		N	Can perform INSERT statements.	
Update_priv	enum('N','Y')	NO		N	Can perform UPDATE statements.	
Delete_priv	enum('N','Y')	NO		N	Can perform DELETE statements.	
Create_priv	enum('N','Y')	NO		N	Can CREATE TABLE 's.	
Drop_priv	enum('N','Y')	NO		N	Can DROP DATABASE 's or DROP TABLE 's.	
Grant_priv	enum('N','Y')	NO		N	User can grant privileges they possess.	
References_priv	enum('N','Y')	NO		N	Unused	
Index_priv	enum('N','Y')	NO		N	Can create an index on a table using the CREATE INDEX statement. Without the <code>INDEX</code> privilege, user can still create indexes when creating a table using the CREATE TABLE statement if the user has have the <code>CREATE</code> privilege, and user can create indexes using the ALTER TABLE statement if they have the <code>ALTER</code> privilege.	
Alter_priv	enum('N','Y')	NO		N	Can perform ALTER TABLE statements.	
Create_tmp_table_priv	enum('N','Y')	NO		N	Can create temporary tables with the CREATE TEMPORARY TABLE statement.	
Lock_tables_priv	enum('N','Y')	NO		N	Acquire explicit locks using the LOCK TABLES statement; user also needs to have the <code>SELECT</code> privilege on a table in order to lock it.	
Create_view_priv	enum('N','Y')	NO		N	Can create a view using the CREATE_VIEW statement.	

Show_view_priv	enum('N','Y')	NO		N	Can show the CREATE VIEW statement to create a view using the SHOW CREATE VIEW statement.	
Create_routine_priv	enum('N','Y')	NO		N	Can create stored programs using the CREATE PROCEDURE and CREATE FUNCTION statements.	
Alter_routine_priv	enum('N','Y')	NO		N	Can change the characteristics of a stored function using the ALTER FUNCTION statement.	
Execute_priv	enum('N','Y')	NO		N	Can execute stored procedure or functions.	
Event_priv	enum('N','Y')	NO		N	Create, drop and alter events .	
Trigger_priv	enum('N','Y')	NO		N	Can execute triggers associated with tables the user updates, execute the CREATE TRIGGER and DROP TRIGGER statements.	
Delete_history_priv	enum('N','Y')	NO		N	Can delete rows created through system versioning .	MariaDB 10.3.5

The [Acl_database_grants](#) status variable, added in [MariaDB 10.1.4](#) , indicates how many rows the `mysql.db` table contains.

1.1.1.2.9.3.4 mysql.event Table

The `mysql.event` table contains information about MariaDB [events](#). Similar information can be obtained by viewing the [INFORMATION_SCHEMA.EVENTS](#) table, or with the [SHOW EVENTS](#) and [SHOW CREATE EVENT](#) statements.

The table is upgraded live, and there is no need to restart the server if the table has changed.

MariaDB starting with [10.4](#)

In [MariaDB 10.4](#) and later, this table uses the [Aria](#) storage engine.

MariaDB until [10.3](#)

In [MariaDB 10.3](#) and before, this table uses the [MyISAM](#) storage engine.

The `mysql.event` table contains the following fields:

Field	Type	Null	Key	Default	Description
db	char(64)	NO	PRI		
name	char(64)	NO	PRI		
body	longblob	NO		NULL	
definer	char(141)	NO			
execute_at	datetime	YES		NULL	
interval_value	int(11)	YES		NULL	
interval_field	enum('YEAR', 'QUARTER', 'MONTH', 'DAY', 'HOUR', 'MINUTE', 'WEEK', 'SECOND', 'MICROSECOND', 'YEAR_MONTH', 'DAY_HOUR', 'DAY_MINUTE', 'DAY_SECOND', 'HOUR_MINUTE', 'HOUR_SECOND', 'MINUTE_SECOND', 'DAY_MICROSECOND', 'HOUR_MICROSECOND', 'MINUTE_MICROSECOND', 'SECOND_MICROSECOND')	YES		NULL	
created	timestamp	NO		CURRENT_TIMESTAMP	

modified	timestamp	NO		0000-00-00 00:00:00	
last_executed	datetime	YES		NULL	
starts	datetime	YES		NULL	
ends	datetime	YES		NULL	
status	enum('ENABLED', 'DISABLED', 'SLAVESIDE_DISABLED')	NO		ENABLED	Current status of the event, one of enabled, disabled, or disabled on the slaveside.
on_completion	enum('DROP', 'PRESERVE')	NO		DROP	
sql_mode	set('REAL_AS_FLOAT', 'PIPES_AS_CONCAT', 'ANSI_QUOTES', 'IGNORE_SPACE', 'IGNORE_BAD_TABLE_OPTIONS', 'ONLY_FULL_GROUP_BY', 'NO_UNSIGNED_SUBTRACTION', 'NO_DIR_IN_CREATE', 'POSTGRESQL', 'ORACLE', 'MSSQL', 'DB2', 'MAXDB', 'NO_KEY_OPTIONS', 'NO_TABLE_OPTIONS', 'NO_FIELD_OPTIONS', 'MYSQL323', 'MYSQL40', 'ANSI', 'NO_AUTO_VALUE_ON_ZERO', 'NO_BACKSLASH_ESCAPES', 'STRICT_TRANS_TABLES', 'STRICT_ALL_TABLES', 'NO_ZERO_IN_DATE', 'NO_ZERO_DATE', 'INVALID_DATES', 'ERROR_FOR_DIVISION_BY_ZERO', 'TRADITIONAL', 'NO_AUTO_CREATE_USER', 'HIGH_NOT_PRECEDENCE', 'NO_ENGINE_SUBSTITUTION', 'PAD_CHAR_TO_FULL_LENGTH')	NO			The SQL_MODE at the time the event was created.
comment	char(64)	NO			
originator	int(10) unsigned	NO		NULL	
time_zone	char(64)	NO		SYSTEM	
character_set_client	char(32)	YES		NULL	
collation_connection	char(32)	YES		NULL	
db_collation	char(32)	YES		NULL	
body_utf8	longblob	YES		NULL	

1.1.1.2.9.3.5 mysql.func Table

The `mysql.func` table stores information about [user-defined functions](#) (UDFs) created with the [CREATE FUNCTION UDF](#) statement.

MariaDB starting with [10.4](#)

In [MariaDB 10.4](#) and later, this table uses the [Aria](#) storage engine.

MariaDB until [10.3](#)

In [MariaDB 10.3](#) and before, this table uses the [MyISAM](#) storage engine.

The `mysql.func` table contains the following fields:

Field	Type	Null	Key	Default	Description
<code>name</code>	<code>char(64)</code>	NO	PRI		UDF name
<code>ret</code>	<code>tinyint(1)</code>	NO		0	
<code>dl</code>	<code>char(128)</code>	NO			Shared library name
<code>type</code>	<code>enum('function','aggregate')</code>	NO		NULL	Type, either <code>function</code> or <code>aggregate</code> . Aggregate functions are summary functions such as <code>SUM()</code> and <code>AVG()</code> .

Example

```
SELECT * FROM mysql.func;
+-----+-----+-----+-----+
| name          | ret | dl          | type          |
+-----+-----+-----+-----+
| spider_direct_sql      | 2  | ha_spider.so | function      |
| spider_bg_direct_sql   | 2  | ha_spider.so | aggregate     |
| spider_ping_table     | 2  | ha_spider.so | function      |
| spider_copy_tables    | 2  | ha_spider.so | function      |
| spider_flush_table_mon_cache | 2  | ha_spider.so | function      |
+-----+-----+-----+-----+
```

1.1.1.2.9.3.6 mysql.general_log Table

The `mysql.general_log` table stores the contents of the [General Query Log](#) if general logging is active and the output is being written to table (see [Writing logs into tables](#)).

It contains the following fields:

Field	Type	Null	Key	Default	Description
<code>event_time</code>	<code>timestamp(6)</code>	NO		<code>CURRENT_TIMESTAMP(6)</code>	Time the query was executed.
<code>user_host</code>	<code>mediumtext</code>	NO		NULL	User and host combination.
<code>thread_id</code>	<code>int(11)</code>	NO		NULL	Thread id.
<code>server_id</code>	<code>int(10) unsigned</code>	NO		NULL	Server id.
<code>command_type</code>	<code>varchar(64)</code>	NO		NULL	Type of command.
<code>argument</code>	<code>mediumtext</code>	NO		NULL	Full query.

Example

```
SELECT * FROM mysql.general_log\G
***** 1. row *****
  event_time: 2014-11-11 08:40:04.117177
  user_host: root[root] @ localhost []
  thread_id: 74
  server_id: 1
command_type: Query
  argument: SELECT * FROM test.s
***** 2. row *****
  event_time: 2014-11-11 08:40:10.501131
  user_host: root[root] @ localhost []
  thread_id: 74
  server_id: 1
command_type: Query
  argument: SELECT * FROM mysql.general_log
...

```

1.1.1.2.9.3.7 mysql.global_priv Table

The `mysql.global_priv` table contains information about users that have permission to access the MariaDB server, and their global privileges. It was introduced in [MariaDB 10.4.1](#) to replace the `mysql.user` table in earlier versions.

Note that the MariaDB privileges occur at many levels. A user may not be granted `create` privilege at the user level, but may still have `create` permission on certain tables or databases, for example. See [privileges](#) for a more complete view of the MariaDB privilege system.

The `mysql.global_priv` table contains the following fields:

Field	Type	Null	Key	Default	Description
Host	char(60)	NO	PRI		Host (together with <code>User</code> makes up the unique identifier for this account).
User	char(80)	NO	PRI		User (together with <code>Host</code> makes up the unique identifier for this account).
Priv	longtext	NO			Global privileges, granted to the account and other account properties

From [MariaDB 10.5.2](#), in order to help the server understand which version a privilege record was written by, the `priv` field contains a new JSON field, `version_id` ([MDEV-21704](#)).

Examples

```
select * from mysql.global_priv;
+-----+-----+-----+-----+-----+-----+
| Host      | User      | Priv      |
+-----+-----+-----+-----+
| localhost | root      | {"access":
18446744073709551615,"plugin":"mysql_native_password","authentication_string":"*6C387FC3893DBA1
E3BA155E74754DA6682D04747"} |
| 127.%    | msandbox | {"access":1073740799,"plugin":"mysql_native_password","authentication_string":"*6C387FC3893DBA1
E3BA155E74754DA6682D04747"} |
| localhost | msandbox | {"access":1073740799,"plugin":"mysql_native_password","authentication_string":"*6C387FC3893DBA1
E3BA155E74754DA6682D04747"} |
| localhost | msandbox_rw | {"access":487487,"plugin":"mysql_native_password","authentication_string":"*6C387FC3893DBA1E3BA
155E74754DA6682D04747"} |
| 127.%    | msandbox_rw | {"access":487487,"plugin":"mysql_native_password","authentication_string":"*6C387FC3893DBA1E3BA
155E74754DA6682D04747"} |
| 127.%    | msandbox_ro | {"access":262145,"plugin":"mysql_native_password","authentication_string":"*6C387FC3893DBA1E3BA
155E74754DA6682D04747"} |
| localhost | msandbox_ro | {"access":262145,"plugin":"mysql_native_password","authentication_string":"*6C387FC3893DBA1E3BA
155E74754DA6682D04747"} |
| 127.%    | rsandbox | {"access":524288,"plugin":"mysql_native_password","authentication_string":"*B07EB15A2E7BD9620DA
E47B194D5B9DBA14377AD"} |
+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+
```

Readable format:

```
SELECT CONCAT(user, '@', host, ' => ', JSON_DETAILED(priv)) FROM mysql.global_priv;

+-----+
| CONCAT(user, '@', host, ' => ', JSON_DETAILED(priv)) |
+-----+
| root@localhost => {
  "access": 18446744073709551615,
  "plugin": "mysql_native_password",
  "authentication_string": "*6C387FC3893DBA1E3BA155E74754DA6682D04747"
} |
| msandbox@127.% => {
  "access": 1073740799,
  "plugin": "mysql_native_password",
  "authentication_string": "*6C387FC3893DBA1E3BA155E74754DA6682D04747"
} |
+-----+
```

A particular user:

```
SELECT CONCAT(user, '@', host, ' => ', JSON_DETAILED(priv)) FROM mysql.global_priv
WHERE user='marijn';

+-----+
| CONCAT(user, '@', host, ' => ', JSON_DETAILED(priv)) |
+-----+
| marijn@localhost => {
  "access": 0,
  "plugin": "mysql_native_password",
  "authentication_string": "",
  "account_locked": true,
  "password_last_changed": 1558017158
} |
+-----+
```

From [MariaDB 10.5.2](#):

```
GRANT FILE ON *.* TO user1@localhost;
SELECT Host, User, JSON_DETAILED(Priv) FROM mysql.global_priv WHERE user='user1'\G

***** 1. row *****
      Host: localhost
      User: user1
JSON_DETAILED(Priv): {
  "access": 512,
  "plugin": "mysql_native_password",
  "authentication_string": "",
  "password_last_changed": 1581070979,
  "version_id": 100502
}
```

Mapping the access Field Values to Grants

The `access` field contains the grants of the user which can be mapped to individual grants with the following table. The most up-to-date information can be found in the `sql/privilege.h` file in the source code.

Grant	Bit
SELECT	(1UL << 0)
INSERT	(1UL << 1)
UPDATE	(1UL << 2)
DELETE	(1UL << 3)
CREATE	(1UL << 4)
DROP	(1UL << 5)
RELOAD	(1UL << 6)
SHUTDOWN	(1UL << 7)

PROCESS	(1UL << 8)
FILE	(1UL << 9)
GRANT	(1UL << 10)
REFERENCES	(1UL << 11)
INDEX	(1UL << 12)
ALTER	(1UL << 13)
SHOW_DB	(1UL << 14)
SUPER	(1UL << 15)
CREATE_TMP	(1UL << 16)
LOCK_TABLES	(1UL << 17)
EXECUTE	(1UL << 18)
REPL_SLAVE	(1UL << 19)
BINLOG_MONITOR	(1UL << 20)
CREATE_VIEW	(1UL << 21)
SHOW_VIEW	(1UL << 22)
CREATE_PROC	(1UL << 23)
ALTER_PROC	(1UL << 24)
CREATE_USER	(1UL << 25)
EVENT	(1UL << 26)
TRIGGER	(1UL << 27)
CREATE_TABLESPACE	(1UL << 28)
DELETE_HISTORY	(1UL << 29)
SET_USER	(1UL << 30)
FEDERATED_ADMIN	(1UL << 31)
CONNECTION_ADMIN	(1ULL << 32)
READ_ONLY_ADMIN	(1ULL << 33)
REPL_SLAVE_ADMIN	(1ULL << 34)
REPL_MASTER_ADMIN	(1ULL << 35)
BINLOG_ADMIN	(1ULL << 36)
BINLOG_REPLAY	(1ULL << 37)
SLAVE_MONITOR	(1ULL << 38)
SHOW_CREATE_ROUTINE	(1ULL << 39)

1.1.1.2.9.3.8 mysql.gtid_slave_pos Table

The `mysql.gtid_slave_pos` table is used in [replication](#) by replica servers to keep track of their current position (the [global transaction ID](#) of the last transaction applied). Using the table allows the replica to maintain a consistent value for the `gtid_slave_pos` system variable across server restarts. See [Global Transaction ID](#).

You should never attempt to modify the table directly. If you do need to change the global `gtid_slave_pos` value, use `SET GLOBAL gtid_slave_pos = ...` instead.

The table is updated with the new position as part of each transaction committed during replication. This makes it preferable that the table is using the same storage engine as the tables otherwise being modified in the transaction, since otherwise a multi-engine transaction is needed that can reduce performance.

Starting from [MariaDB 10.3.1](#), multiple versions of this table are supported, each using a different storage engine. This is selected with the `gtid_pos_auto_engines` option, by giving a comma-separated list of engine names. The server will then on-demand create an extra version of the table using the appropriate storage engine, and select the table version using the

same engine as the rest of the transaction, avoiding multi-engine transactions.

For example, when `gtid_pos_auto_engines=innodb,rocksdb`, tables `mysql.gtid_slave_pos_InnoDB` and `mysql.gtid_slave_pos_RocksDB` will be created and used, if needed. If there is no match to the storage engine, the default `mysql.gtid_slave_pos` table will be used; this also happens if non-transactional updates (like MyISAM) are replicated, since there is then no active transaction at the time of the `mysql.gtid_slave_pos` table update.

Prior to [MariaDB 10.3.1](#), only the default `mysql.gtid_slave_pos` table is available. In these versions, the table should preferably be using the storage engine that is used for most replicated transactions.

The default `mysql.gtid_slave_pos` table will be initially created using the default storage engine set for the server (which itself defaults to InnoDB). If the application load is primarily non-transactional MyISAM or Aria tables, it can be beneficial to change the storage engine to avoid including an InnoDB update with every operation:

```
ALTER TABLE mysql.gtid_slave_pos ENGINE=MyISAM;
```

The `mysql.gtid_slave_pos` table should not be changed manually in any other way. From [MariaDB 10.3.1](#), it is preferable to use the `gtid_pos_auto_engines` server variable to get the GTID position updates to use the TokuDB or RocksDB storage engine.

Note that for scalability reasons, the automatic creation of a new `mysql.gtid_slave_posXXX` table happens asynchronously when the first transaction with the new storage engine is committed. So the very first few transactions will update the old version of the table, until the new version is created and available.

The table `mysql.gtid_slave_pos` contains the following fields

Field	Type	Null	Key	Default	Description
<code>domain_id</code>	<code>int(10) unsigned</code>	NO	PRI	NULL	Domain id (see Global Transaction ID domain ID).
<code>sub_id</code>	<code>bigint(20) unsigned</code>	NO	PRI	NULL	This field enables multiple parallel transactions within same <code>domain_id</code> to update this table without contention. At any instant, the replication state corresponds to records with largest <code>sub_id</code> for each <code>domain_id</code> .
<code>server_id</code>	<code>int(10) unsigned</code>	NO		NULL	Server id .
<code>seq_no</code>	<code>bigint(20) unsigned</code>	NO		NULL	Sequence number, an integer that is monotonically increasing for each new event group logged into the binlog.

From [MariaDB 10.3.1](#), some status variables are available to monitor the use of the different `gtid_slave_pos` table versions:

[Transactions_gtid_foreign_engine](#)

Number of replicated transactions where the update of the `gtid_slave_pos` table had to choose a storage engine that did not otherwise participate in the transaction. This can indicate that setting `gtid_pos_auto_engines` might be useful.

[Rpl_transactions_multi_engine](#)

Number of replicated transactions that involved changes in multiple (transactional) storage engines, before considering the update of `gtid_slave_pos`. These are transactions that were already cross-engine, independent of the GTID position update introduced by replication

[Transactions_multi_engine](#)

Number of transactions that changed data in multiple (transactional) storage engines. If this is significantly larger than `Rpl_transactions_multi_engine`, it indicates that setting `gtid_pos_auto_engines` could reduce the need for cross-engine transactions.

1.1.1.2.9.3.9 mysql.help_category Table

`mysql.help_category` is one of the four tables used by the [HELP command](#). It is populated when the server is installed by the `fill_help_tables.sql` script. The other help tables are [help_relation](#), [help_topic](#) and [help_keyword](#).

This table uses the [Aria](#) storage engine. Prior to [MariaDB 10.4](#) it used the [MyISAM](#) engine.

The `mysql.help_category` table contains the following fields:

Field	Type	Null	Key	Default	Description
-------	------	------	-----	---------	-------------

help_category_id	smallint(5) unsigned	NO	PRI	NULL	
name	char(64)	NO	UNI	NULL	
parent_category_id	smallint(5) unsigned	YES		NULL	
url	char(128)	NO		NULL	

Example

```
SELECT * FROM help_category;
```

```

+-----+-----+-----+-----+
| help_category_id | name | parent_category_id | url |
+-----+-----+-----+-----+
| 1 | Geographic | 0 | |
| 2 | Polygon properties | 34 | |
| 3 | WKT | 34 | |
| 4 | Numeric Functions | 38 | |
| 5 | Plugins | 35 | |
| 6 | MBR | 34 | |
| 7 | Control flow functions | 38 | |
| 8 | Transactions | 35 | |
| 9 | Help Metadata | 35 | |
| 10 | Account Management | 35 | |
| 11 | Point properties | 34 | |
| 12 | Encryption Functions | 38 | |
| 13 | LineString properties | 34 | |
| 14 | Miscellaneous Functions | 38 | |
| 15 | Logical operators | 38 | |
| 16 | Functions and Modifiers for Use with GROUP BY | 35 | |
| 17 | Information Functions | 38 | |
| 18 | Comparison operators | 38 | |
| 19 | Bit Functions | 38 | |
| 20 | Table Maintenance | 35 | |
| 21 | User-Defined Functions | 35 | |
| 22 | Data Types | 35 | |
| 23 | Compound Statements | 35 | |
| 24 | Geometry constructors | 34 | |
| 25 | GeometryCollection properties | 1 | |
| 26 | Administration | 35 | |
| 27 | Data Manipulation | 35 | |
| 28 | Utility | 35 | |
| 29 | Language Structure | 35 | |
| 30 | Geometry relations | 34 | |
| 31 | Date and Time Functions | 38 | |
| 32 | WKB | 34 | |
| 33 | Procedures | 35 | |
| 34 | Geographic Features | 35 | |
| 35 | Contents | 0 | |
| 36 | Geometry properties | 34 | |
| 37 | String Functions | 38 | |
| 38 | Functions | 35 | |
| 39 | Data Definition | 35 | |
+-----+-----+-----+-----+

```

1.1.1.2.9.3.10 mysql.help_keyword Table

`mysql.help_keyword` is one of the four tables used by the [HELP command](#). It is populated when the server is installed by the `fill_help_tables.sql` script. The other help tables are [help_relation](#), [help_category](#) and [help_topic](#).

This table uses the [Aria](#) storage engine. Prior to [MariaDB 10.4](#) it used the [MyISAM](#) engine.

The `mysql.help_keyword` table contains the following fields:

Field	Type	Null	Key	Default	Description
help_keyword_id	int(10) unsigned	NO	PRI	NULL	
name	char(64)	NO	UNI	NULL	

Example

```
SELECT * FROM help_keyword;
+-----+-----+
| help_keyword_id | name          |
+-----+-----+
| 0 | JOIN         |
| 1 | HOST         |
| 2 | REPEAT       |
| 3 | SERIALIZABLE |
| 4 | REPLACE      |
| 5 | AT           |
| 6 | SCHEDULE     |
| 7 | RETURNS      |
| 8 | STARTS       |
| 9 | MASTER_SSL_CA |
| 10 | NCHAR        |
| 11 | COLUMNS     |
| 12 | COMPLETION   |
| ...         |
```

1.1.1.2.9.3.11 mysql.help_relation Table

mysql.help_relation is one of the four tables used by the [HELP command](#). It is populated when the server is installed by the `fill_help_tables.sql` script. The other help tables are [help_topic](#), [help_category](#) and [help_keyword](#).

This table uses the [Aria](#) storage engine. Prior to [MariaDB 10.4](#) it used the [MyISAM](#) engine.

The `mysql.help_relation` table contains the following fields:

Field	Type	Null	Key	Default	Description
help_topic_id	int(10) unsigned	NO	PRI	NULL	
help_keyword_id	int(10) unsigned	NO	PRI	NULL	

Example

```
...
| 106 | 456 |
| 463 | 456 |
| 468 | 456 |
| 463 | 457 |
| 194 | 458 |
| 478 | 458 |
| 374 | 459 |
| 459 | 459 |
| 39 | 460 |
| 58 | 460 |
| 185 | 460 |
| 264 | 460 |
| 269 | 460 |
| 209 | 461 |
| 468 | 461 |
| 201 | 462 |
| 468 | 463 |
+-----+-----+
```

1.1.1.2.9.3.12 mysql.help_topic Table

mysql.help_topic is one of the four tables used by the [HELP command](#). It is populated when the server is installed by the `fill_help_tables.sql` script. The other help tables are [help_relation](#), [help_category](#) and [help_keyword](#).

This table uses the [Aria](#) storage engine. Prior to [MariaDB 10.4](#) it used the [MyISAM](#) engine.

The `mysql.help_topic` table contains the following fields:

Field	Type	Null	Key	Default	Description
help_topic_id	int(10) unsigned	NO	PRI	NULL	
name	char(64)	NO	UNI	NULL	
help_category_id	smallint(5) unsigned	NO		NULL	
description	text	NO		NULL	
example	text	NO		NULL	
url	char(128)	NO		NULL	

Example

```
SELECT * FROM help_topic\G;
...
***** 704. row *****
  help_topic_id: 692
        name: JSON_DEPTH
help_category_id: 41
  description: JSON functions were added in MariaDB 10.2.3.
```

Syntax

```
-----
JSON_DEPTH(json_doc)
```

Description

```
-----
Returns the maximum depth of the given JSON document, or
NULL if the argument is null. An error will occur if the
argument is an invalid JSON document.
Scalar values or empty arrays or objects have a depth of 1.
Arrays or objects that are not empty but contain only
elements or member values of depth 1 will have a depth of 2.
In other cases, the depth will be greater than 2.
```

Examples

```
-----
SELECT JSON_DEPTH('[]'), JSON_DEPTH('true'),
JSON_DEPTH('{}');
+-----+-----+-----+
| JSON_DEPTH('[]') | JSON_DEPTH('true') |
JSON_DEPTH('{}') |
+-----+-----+-----+
| 1 | 1 | 1 |
+-----+-----+-----+
```

```
SELECT JSON_DEPTH('[1, 2, 3]'), JSON_DEPTH('[[], {},
[]]');
+-----+-----+-----+
| JSON_DEPTH('[1, 2, 3]') | JSON_DEPTH('[[], {}, []]') |
+-----+-----+-----+
| 2 | 2 |
+-----+-----+-----+
```

```
SELECT JSON_DEPTH('[1, 2, [3, 4, 5, 6], 7]');
+-----+
| JSON_DEPTH('[1, 2, [3, 4, 5, 6], 7]') |
+-----+
| 3 |
+-----+
```

```
URL: https://mariadb.com/kb/en/json\_depth/
example:
url: https://mariadb.com/kb/en/json\_depth/
```

1.1.1.2.9.3.13 mysql.index_stats Table

The `mysql.index_stats` table is one of three tables storing data used for [Engine-independent table statistics](#). The others are [mysql.column_stats](#) and [mysql.table_stats](#).

MariaDB starting with 10.4

In [MariaDB 10.4](#) and later, this table uses the [Aria](#) storage engine.

MariaDB until 10.3

In [MariaDB 10.3](#) and before, this table uses the [MyISAM](#) storage engine.

The `mysql.index_stats` table contains the following fields:

Field	Type	Null	Key	Default	Description
<code>db_name</code>	<code>varchar(64)</code>	NO	PRI	NULL	Database the table is in.
<code>table_name</code>	<code>varchar(64)</code>	NO	PRI	NULL	Table name
<code>index_name</code>	<code>varchar(64)</code>	NO	PRI	NULL	Name of the index
<code>prefix_arity</code>	<code>int(11)</code> unsigned	NO	PRI	NULL	Index prefix length. 1 for the first keypart, 2 for the first two, and so on. InnoDB's extended keys are supported.
<code>avg_frequency</code>	<code>decimal(12,4)</code>	YES		NULL	Average number of records one will find for given values of (keypart1, keypart2, ..), provided the values will be found in the table.

It is possible to manually update the table. See [Manual updates to statistics tables](#) for details.

1.1.1.2.9.3.14 mysql.innodb_index_stats

Contents

- [Example](#)

The `mysql.innodb_index_stats` table stores data related to particular [InnoDB Persistent Statistics](#), and contains multiple rows for each index.

This table, along with the related [mysql.innodb_table_stats](#) table, can be manually updated in order to force or test differing query optimization plans. After updating, `FLUSH TABLE innodb_index_stats` is required to load the changes.

`mysql.innodb_index_stats` is not replicated, although any [ANALYZE TABLE](#) statements on the table will be by default..

It contains the following fields:

Field	Type	Null	Key	Default	Description
<code>database_name</code>	<code>varchar(64)</code>	NO	PRI	NULL	Database name.
<code>table_name</code>	<code>varchar(64)</code>	NO	PRI	NULL	Table, partition or subpartition name.
<code>index_name</code>	<code>varchar(64)</code>	NO	PRI	NULL	Index name.
<code>last_update</code>	<code>timestamp</code>	NO		<code>current_timestamp()</code>	Time that this row was last updated.
<code>stat_name</code>	<code>varchar(64)</code>	NO	PRI	NULL	Statistic name.
<code>stat_value</code>	<code>bigint(20)</code> unsigned	NO		NULL	Estimated statistic value.
<code>sample_size</code>	<code>bigint(20)</code> unsigned	YES		NULL	Number of pages sampled for the estimated statistic value.
<code>stat_description</code>	<code>varchar(1024)</code>	NO		NULL	Statistic description.

Example

```

SELECT * FROM mysql.innodb_index_stats\G
***** 1. row *****
  database_name: mysql
    table_name: gtid_slave_pos
    index_name: PRIMARY
  last_update: 2017-08-19 20:38:34
    stat_name: n_diff_pfx01
    stat_value: 0
    sample_size: 1
stat_description: domain_id
***** 2. row *****
  database_name: mysql
    table_name: gtid_slave_pos
    index_name: PRIMARY
  last_update: 2017-08-19 20:38:34
    stat_name: n_diff_pfx02
    stat_value: 0
    sample_size: 1
stat_description: domain_id,sub_id
***** 3. row *****
  database_name: mysql
    table_name: gtid_slave_pos
    index_name: PRIMARY
  last_update: 2017-08-19 20:38:34
    stat_name: n_leaf_pages
    stat_value: 1
    sample_size: NULL
stat_description: Number of leaf pages in the index
***** 4. row *****
  database_name: mysql
    table_name: gtid_slave_pos
    index_name: PRIMARY
  last_update: 2017-08-19 20:38:34
    stat_name: size
    stat_value: 1
    sample_size: NULL
stat_description: Number of pages in the index
***** 5. row *****
  database_name: test
    table_name: ft
    index_name: FTS_DOC_ID_INDEX
  last_update: 2017-09-15 12:58:39
    stat_name: n_diff_pfx01
    stat_value: 0
    sample_size: 1
stat_description: FTS_DOC_ID
***** 6. row *****
  database_name: test
    table_name: ft
    index_name: FTS_DOC_ID_INDEX
  last_update: 2017-09-15 12:58:39
    stat_name: n_leaf_pages
    stat_value: 1
    sample_size: NULL
stat_description: Number of leaf pages in the index
...

```

1.1.1.2.9.3.15 mysql.innodb_table_stats

Contents

1. Example

The `mysql.innodb_table_stats` table stores data related to [InnoDB Persistent Statistics](#), and contains one row per table.

This table, along with the related [mysql.innodb_index_stats](#) table, can be manually updated in order to force or test differing query optimization plans. After updating, `FLUSH TABLE innodb_table_stats` is required to load the changes.

`mysql.innodb_table_stats` is not replicated, although any [ANALYZE TABLE](#) statements on the table will be by default.

It contains the following fields:

Field	Type	Null	Key	Default	Description
database_name	varchar(64)	NO	PRI	NULL	Database name.
table_name	varchar(64)	NO	PRI	NULL	Table, partition or subpartition name.
last_update	timestamp	NO		current_timestamp()	Time that this row was last updated.
n_rows	bigint(20) unsigned	NO		NULL	Number of rows in the table.
clustered_index_size	bigint(20) unsigned	NO		NULL	Size, in pages, of the primary index.
sum_of_other_index_sizes	bigint(20) unsigned	NO		NULL	Size, in pages, of non-primary indexes.

Example

```

SELECT * FROM mysql.innodb_table_stats\G
***** 1. row *****
      database_name: mysql
            table_name: gtid_slave_pos
            last_update: 2017-08-19 20:38:34
              n_rows: 0
            clustered_index_size: 1
sum_of_other_index_sizes: 0
***** 2. row *****
      database_name: test
            table_name: ft
            last_update: 2017-09-15 12:58:39
              n_rows: 0
            clustered_index_size: 1
sum_of_other_index_sizes: 2
...

```

1.1.1.2.9.3.16

mysql.password_reuse_check_history Table

MariaDB starting with [10.7.0](#)

The `mysql.password_reuse_check_history` Table is installed as part of the `password_reuse_check` plugin, available from [MariaDB 10.7.0](#).

The `mysql.password_reuse_check_history` table stores old passwords, so that when a user sets a new password, it can be checked for purposes of preventing password reuse.

It contains the following fields:

Field	Type	Null	Key	Default	Description
hash	binary(64)	NO	PRI	NULL	
time	timestamp	NO	MUL	current_timestamp()	

1.1.1.2.9.3.17 mysql.plugin Table

System tables should not normally be edited directly. Use the related SQL statements instead.

The `mysql.plugin` table can be queried to get information about installed `plugins`.

This table only contains information about `plugins` that have been installed via the following methods:

- The `INSTALL SONAME` statement.

- The [INSTALL PLUGIN](#) statement.
- The [mariadb-plugin](#) utility.

This table does not contain information about:

- Built-in plugins.
- Plugins loaded with the [--plugin-load-add](#) option.
- Plugins loaded with the [--plugin-load](#) option.

This table only contains enough information to reload the plugin when the server is restarted, which means it only contains the plugin name and the plugin library.

This table uses the [Aria](#) storage engine.

The `mysql.plugin` table contains the following fields:

Field	Type	Null	Key	Default	Description
<code>name</code>	<code>varchar(64)</code>	NO	PRI		Plugin name.
<code>dl</code>	<code>varchar(128)</code>	NO			Name of the plugin library.

Example

```
SELECT * FROM mysql.plugin;
+-----+-----+-----+-----+
| name          | dl          |
+-----+-----+
| spider        | ha_spider.so |
| spider_alloc_mem | ha_spider.so |
| METADATA_LOCK_INFO | metadata_lock_info.so |
| OQGRAPH       | ha_oqgraph.so |
| cassandra     | ha_cassandra.so |
| QUERY_RESPONSE_TIME | query_response_time.so |
| QUERY_RESPONSE_TIME_AUDIT | query_response_time.so |
| LOCALES       | locales.so |
| sequence      | ha_sequence.so |
+-----+-----+
```

1.1.1.2.9.3.18 mysql.proc Table

The `mysql.proc` table contains information about [stored procedures](#) and [stored functions](#). It contains similar information to that stored in the [INFORMATION_SCHEMA.ROUTINES](#) table.

MariaDB starting with [10.4](#)

In [MariaDB 10.4](#) and later, this table uses the [Aria](#) storage engine.

MariaDB until [10.3](#)

In [MariaDB 10.3](#) and before, this table uses the [MyISAM](#) storage engine.

The `mysql.proc` table contains the following fields:

Field	Type	Null	Key	Default	Description
<code>db</code>	<code>char(64)</code>	NO	PRI		Database name.
<code>name</code>	<code>char(64)</code>	NO	PRI		Routine name.
<code>type</code>	<code>enum('FUNCTION', 'PROCEDURE', 'PACKAGE', 'PACKAGE BODY')</code>	NO	PRI	NULL	Whether stored procedure , stored function or, from MariaDB 10.3.5 ↗ , a package or package body .
<code>specific_name</code>	<code>char(64)</code>	NO			
<code>language</code>	<code>enum('SQL')</code>	NO		SQL	Always <code>SQL</code> .
<code>sql_data_access</code>	<code>enum('CONTAINS_SQL', 'NO_SQL', 'READS_SQL_DATA', 'MODIFIES_SQL_DATA')</code>	NO		CONTAINS_SQL	

is_deterministic	enum('YES','NO')	NO		NO	Whether the routine is deterministic (can produce only one result for a given list of parameters) or not.
security_type	enum('INVOKER','DEFINER')	NO		DEFINER	INVOKER or DEFINER . Indicates which user's privileges apply to this routine.
param_list	blob	NO		NULL	List of parameters.
returns	longblob	NO		NULL	What the routine returns.
body	longblob	NO		NULL	Definition of the routine.
definer	char(141)	NO			If the security_type is DEFINER , this value indicates which user defined this routine.
created	timestamp	NO		CURRENT_TIMESTAMP	Date and time the routine was created.
modified	timestamp	NO		0000-00-00 00:00:00	Date and time the routine was modified.
sql_mode	set('REAL_AS_FLOAT', 'PIPES_AS_CONCAT', 'ANSI_QUOTES', 'IGNORE_SPACE', 'IGNORE_BAD_TABLE_OPTIONS', 'ONLY_FULL_GROUP_BY', 'NO_UNSIGNED_SUBTRACTION', 'NO_DIR_IN_CREATE', 'POSTGRESQL', 'ORACLE', 'MSSQL', 'DB2', 'MAXDB', 'NO_KEY_OPTIONS', 'NO_TABLE_OPTIONS', 'NO_FIELD_OPTIONS', 'MYSQL323', 'MYSQL40', 'ANSI', 'NO_AUTO_VALUE_ON_ZERO', 'NO_BACKSLASH_ESCAPES', 'STRICT_TRANS_TABLES', 'STRICT_ALL_TABLES', 'NO_ZERO_IN_DATE', 'NO_ZERO_DATE', 'INVALID_DATES', 'ERROR_FOR_DIVISION_BY_ZERO', 'TRADITIONAL', 'NO_AUTO_CREATE_USER', 'HIGH_NOT_PRECEDENCE', 'NO_ENGINE_SUBSTITUTION', 'PAD_CHAR_TO_FULL_LENGTH', 'EMPTY_STRING_IS_NULL', 'SIMULTANEOUS_ASSIGNMENT')	NO			The SQL_MODE at the time the routine was created.
comment	text	NO		NULL	Comment associated with the routine.
character_set_client	char(32)	YES		NULL	The character set used by the client that created the routine.
collation_connection	char(32)	YES		NULL	The collation (and character set) used by the connection that created the routine.
db_collation	char(32)	YES		NULL	The default collation (and character set) for the database, at the time the routine was created.
body_utf8	longblob	YES		NULL	Definition of the routine in utf8.
aggregate	enum('NONE', 'GROUP')	NO		NONE	From MariaDB 10.3.3 ↗
Field	Type	Null	Key	Default	Description

1.1.1.2.9.3.19 mysql.procs_priv Table

The `mysql.procs_priv` table contains information about [stored procedure](#) and [stored function](#) privileges. See [CREATE PROCEDURE](#) and [CREATE FUNCTION](#) on creating these.

The `INFORMATION_SCHEMA.ROUTINES` table derives its contents from `mysql.procs_priv`.

MariaDB starting with 10.4

In [MariaDB 10.4](#) and later, this table uses the [Aria](#) storage engine.

MariaDB until 10.3

In [MariaDB 10.3](#) and before, this table uses the [MyISAM](#) storage engine.

The `mysql.procs_priv` table contains the following fields:

Field	Type	Null	Key	Default	Description
Host	char(60)	NO	PRI		Host (together with Db, User, Routine_name and Routine_type makes up the unique identifier for this record).
Db	char(64)	NO	PRI		Database (together with Host, User, Routine_name and Routine_type makes up the unique identifier for this record).
User	char(80)	NO	PRI		User (together with Host, Db, Routine_name and Routine_type makes up the unique identifier for this record).
Routine_name	char(64)	NO	PRI		Routine_name (together with Host, Db User and Routine_type makes up the unique identifier for this record).
Routine_type	enum('FUNCTION', 'PROCEDURE', 'PACKAGE', 'PACKAGE BODY')	NO	PRI	NULL	Whether the routine is a stored procedure , stored function , or, from MariaDB 10.3.5 , a package or package body .
Grantor	char(141)	NO	MUL		
Proc_priv	set('Execute', 'Alter Routine', 'Grant')	NO			The routine privilege. See Function Privileges and Procedure Privileges for details.
Timestamp	timestamp	NO		CURRENT_TIMESTAMP	

The `Acl_function_grants` status variable, added in [MariaDB 10.1.4](#), indicates how many rows the `mysql.columns_priv` table contains with the `FUNCTION` routine type.

The `Acl_procedure_grants` status variable, added in [MariaDB 10.1.4](#), indicates how many rows the `mysql.columns_priv` table contains with the `PROCEDURE` routine type.

1.1.1.2.9.3.20 mysql.roles_mapping Table

The `mysql.roles_mapping` table contains information about [mariaDB roles](#).

MariaDB starting with 10.4

In [MariaDB 10.4](#) and later, this table uses the [Aria](#) storage engine.

MariaDB until 10.3

In [MariaDB 10.3](#) and before, this table uses the [MyISAM](#) storage engine.

The `mysql.roles_mapping` table contains the following fields:

Field	Type	Null	Key	Default	Description
Host	char(60)	NO	PRI		Host (together with <code>User</code> and <code>Role</code> makes up the unique identifier for this record.
User	char(80)	NO	PRI		User (together with <code>Host</code> and <code>Role</code> makes up the unique identifier for this record.
Role	char(80)	NO	PRI		Role (together with <code>Host</code> and <code>User</code> makes up the unique identifier for this record.
Admin_option	enum('N','Y')	NO		N	Whether the role can be granted (see the CREATE ROLE WITH ADMIN clause).

The `Acl_role_grants` status variable, added in [MariaDB 10.1.4](#), indicates how many rows the `mysql.roles_mapping` table contains.

1.1.1.2.9.3.21 mysql.servers Table

System tables should not normally be edited directly. Use the related SQL statements instead.

The `mysql.servers` table contains information about servers as used by the [Spider](#), [FEDERATED](#) or [FederatedX](#), [Connect](#) storage engines.

The contents are modified by the [CREATE SERVER](#), [ALTER SERVER](#) and [DROP SERVER](#) statements.

This table uses the [Aria](#) storage engine.

The `mysql.servers` table contains the following fields:

Field	Type	Null	Key	Default	Description
Server_name	char(64)	NO	PRI		
Host	char(64)	NO			
Db	char(64)	NO			
Username	char(80)	NO			
Password	char(64)	NO			
Port	int(4)	NO		0	
Socket	char(64)	NO			
Wrapper	char(64)	NO			mysql or mariadb
Owner	char(64)	NO			

Example

```
SELECT * FROM mysql.servers\G
***** 1. row *****
Server_name: s
  Host: 192.168.1.106
  Db: test
  Username: Remote
  Password:
  Port: 0
  Socket:
  Wrapper: mariadb
  Owner:
```

1.1.1.2.9.3.22 mysql.slow_log Table

The `mysql.slow_log` table stores the contents of the [Slow Query Log](#) if slow logging is active and the output is being

written to table (see [Writing logs into tables](#)).

It contains the following fields:

Field	Type	Null	Key	Default	Description
start_time	timestamp(6)	NO		CURRENT_TIMESTAMP(6)	Time the query began.
user_host	mediumtext	NO		NULL	User and host combination.
query_time	time(6)	NO		NULL	Total time the query took to execute.
lock_time	time(6)	NO		NULL	Total time the query was locked.
rows_sent	int(11)	NO		NULL	Number of rows sent.
rows_examined	int(11)	NO		NULL	Number of rows examined.
db	varchar(512)	NO		NULL	Default database.
last_insert_id	int(11)	NO		NULL	last_insert_id .
insert_id	int(11)	NO		NULL	Insert id.
server_id	int(10) unsigned	NO		NULL	The server's id.
sql_text	mediumtext	NO		NULL	Full query.
thread_id	bigint(21) unsigned	NO		NULL	Thread id.
rows_affected	int(11)	NO		NULL	Number of rows affected by an UPDATE or DELETE (from MariaDB 10.1.2)

Example

```

SELECT * FROM mysql.slow_log\G
...
***** 2. row *****
start_time: 2014-11-11 07:56:28.721519
user_host: root[root] @ localhost []
query_time: 00:00:12.000215
lock_time: 00:00:00.000000
rows_sent: 1
rows_examined: 0
db: test
last_insert_id: 0
insert_id: 0
server_id: 1
sql_text: SELECT SLEEP(12)
thread_id: 74
...

```

1.1.1.2.9.3.23 mysql.tables_priv Table

The `mysql.tables_priv` table contains information about table-level privileges. The table can be queried and although it is possible to directly update it, it is best to use [GRANT](#) for setting privileges.

Note that the MariaDB privileges occur at many levels. A user may be granted a privilege at the table level, but may still not have permission on a database level, for example. See [privileges](#) for a more complete view of the MariaDB privilege system.

The [INFORMATION_SCHEMA.TABLE_PRIVILEGES](#) table derives its contents from `mysql.tables_priv`.

MariaDB starting with 10.4
In [MariaDB 10.4](#) and later, this table uses the [Aria](#) storage engine.

MariaDB until 10.3
In [MariaDB 10.3](#) and before, this table uses the [MyISAM](#) storage engine.

The `mysql.tables_priv` table contains the following fields:

Field	Type	Null	Key	Default	Description
Host	char(60)	NO	PRI		Host (together with User, Db and Table_name makes up the unique identifier for this record.
Db	char(64)	NO	PRI		Database (together with User, Host and Table_name makes up the unique identifier for this record.
User	char(80)	NO	PRI		User (together with Host, Db and Table_name makes up the unique identifier for this record.
Table_name	char(64)	NO	PRI		Table name (together with User, Db and Table makes up the unique identifier for this record.
Grantor	char(141)	NO	MUL		
Timestamp	timestamp	NO		CURRENT_TIMESTAMP	
Table_priv	set('Select', 'Insert', 'Update', 'Delete', 'Create', 'Drop', 'Grant', 'References', 'Index', 'Alter', 'Create View', 'Show view', 'Trigger', 'Delete versioning rows')	NO			The table privilege type. See Table Privileges for details.
Column_priv	set('Select', 'Insert', 'Update', 'References')	NO			The column privilege type. See Column Privileges for details.

The `Acl_table_grants` status variable, added in [MariaDB 10.1.4](#), indicates how many rows the `mysql.tables_priv` table contains.

1.1.1.2.9.3.24 mysql.table_stats Table

The `mysql.table_stats` table is one of three tables storing data used for [Engine-independent table statistics](#). The others are `mysql.column_stats` and `mysql.index_stats`.

MariaDB starting with [10.4](#)

In [MariaDB 10.4](#) and later, this table uses the [Aria](#) storage engine.

MariaDB until [10.3](#)

In [MariaDB 10.3](#) and before, this table uses the [MyISAM](#) storage engine.

The `mysql.table_stats` table contains the following fields:

Field	Type	Null	Key	Default	Description
-------	------	------	-----	---------	-------------

db_name	varchar(64)	NO	PRI	NULL	Database the table is in .
table_name	varchar(64)	NO	PRI	NULL	Table name.
cardinality	bigint(21) unsigned	YES		NULL	Number of records in the table.

It is possible to manually update the table. See [Manual updates to statistics tables](#) for details.

1.1.1.2.9.3.25 mysql.time_zone Table

The `mysql.time_zone` table is one of the mysql system tables that can contain [time zone](#) information. It is usually preferable for the system to handle the time zone, in which case the table will be empty (the default), but you can populate the mysql time zone tables using the [mariadb-tzinfo-to-sql](#) utility. See [Time Zones](#) for details.

This table uses the [Aria](#) storage engine.

The `mysql.time_zone` table contains the following fields:

Field	Type	Null	Key	Default	Description
Time_zone_id	int(10) unsigned	NO	PRI	NULL	ID field, auto_increments.
Use_leap_seconds	enum('Y', 'N')	NO		N	Whether or not leap seconds are used.

Example

```
SELECT * FROM mysql.time_zone;
+-----+-----+
| Time_zone_id | Use_leap_seconds |
+-----+-----+
|          1 | N                |
|          2 | N                |
|          3 | N                |
|          4 | N                |
|          5 | N                |
|          6 | N                |
|          7 | N                |
|          8 | N                |

```

1.1.1.2.9.3.26 mysql.time_zone_leap_second Table

System tables should not normally be edited directly. Use the related SQL statements instead.

The `mysql.time_zone_leap_second` table is one of the mysql system tables that can contain [time zone](#) information. It is usually preferable for the system to handle the time zone, in which case the table will be empty (the default), but you can populate the mysql time zone tables using the [mariadb-tzinfo-to-sql](#) utility. See [Time Zones](#) for details.

This table uses the [Aria](#) storage engine.

The `mysql.time_zone_leap_second` table contains the following fields:

Field	Type	Null	Key	Default	Description
Transition_time	bigint(20)	NO	PRI	NULL	
Correction	int(11)	NO		NULL	

1.1.1.2.9.3.27 mysql.time_zone_name Table

System tables should not normally be edited directly. Use the related SQL statements instead.

The `mysql.time_zone_name` table is one of the `mysql` system tables that can contain [time zone](#) information. It is usually preferable for the system to handle the time zone, in which case the table will be empty (the default), but you can populate the `mysql` time zone tables using the [mariadb-tzinfo-to-sql](#) utility. See [Time Zones](#) for details.

This table uses the [Aria](#) storage engine.

The `mysql.time_zone_name` table contains the following fields:

Field	Type	Null	Key	Default	Description
Name	char(64)	NO	PRI	NULL	Name of the time zone.
Time_zone_id	int(10) unsigned	NO	PRI	NULL	ID field, auto_increments.

Example

```
SELECT * FROM mysql.time_zone_name;
+-----+-----+
| Name          | Time_zone_id |
+-----+-----+
| Africa/Abidjan |             1 |
| Africa/Accra  |             2 |
| Africa/Addis_Ababa |           3 |
| Africa/Algiers |             4 |
| Africa/Asmara |             5 |
| Africa/Asmera |             6 |
| Africa/Bamako |             7 |
| Africa/Bangui |             8 |
| Africa/Banjul |             9 |
| Africa/Bissau |            10 |
...
+-----+-----+
```

1.1.1.2.9.3.28 mysql.time_zone_transition Table

System tables should not normally be edited directly. Use the related SQL statements instead.

The `mysql.time_zone_transition` table is one of the `mysql` system tables that can contain [time zone](#) information. It is usually preferable for the system to handle the time zone, in which case the table will be empty (the default), but you can populate the `mysql` time zone tables using the [mariadb-tzinfo-to-sql](#) utility. See [Time Zones](#) for details.

This table uses the [Aria](#) storage engine.

The `mysql.time_zone_transition` table contains the following fields:

Field	Type	Null	Key	Default	Description
Time_zone_id	int(10) unsigned	NO	PRI	NULL	
Transition_time	bigint(20)	NO	PRI	NULL	
Transition_type_id	int(10) unsigned	NO		NULL	

Example

```

SELECT * FROM mysql.time_zone_transition;
+-----+-----+-----+
| Time_zone_id | Transition_time | Transition_type_id |
+-----+-----+-----+
|          1 |    -1830383032 |                1 |
|          2 |    -1640995148 |                2 |
|          2 |    -1556841600 |                1 |
|          2 |    -1546388400 |                2 |
|          2 |    -1525305600 |                1 |
|          2 |    -1514852400 |                2 |
|          2 |    -1493769600 |                1 |
|          2 |    -1483316400 |                2 |
|          2 |    -1462233600 |                1 |
|          2 |    -1451780400 |                2 |
|          ...
+-----+-----+-----+

```

1.1.1.2.9.3.29 mysql.time_zone_transition_type Table

System tables should not normally be edited directly. Use the related SQL statements instead.

The `mysql.time_zone_transition_type` table is one of the `mysql` system tables that can contain [time zone](#) information. It is usually preferable for the system to handle the time zone, in which case the table will be empty (the default), but you can populate the `mysql` time zone tables using the [mariadb-tzinfo-to-sql](#) utility. See [Time Zones](#) for details.

This table uses the [Aria](#) storage engine.

The `mysql.time_zone_transition_type` table contains the following fields:

Field	Type	Null	Key	Default	Description
Time_zone_id	int(10) unsigned	NO	PRI	NULL	
Transition_type_id	int(10) unsigned	NO	PRI	NULL	
Offset	int(11)	NO		0	
Is_DST	tinyint(3) unsigned	NO		0	
Abbreviation	char(8)	NO			

Example

```

SELECT * FROM mysql.time_zone_transition_type;
+-----+-----+-----+-----+-----+
| Time_zone_id | Transition_type_id | Offset | Is_DST | Abbreviation |
+-----+-----+-----+-----+-----+
|          1 |          0 |    -968 |      0 | LMT          |
|          1 |          1 |      0 |      0 | GMT          |
|          2 |          0 |    -52 |      0 | LMT          |
|          2 |          1 |   1200 |      1 | GHST         |
|          2 |          2 |      0 |      0 | GMT          |
|          3 |          0 |   8836 |      0 | LMT          |
|          3 |          1 |  10800 |      0 | EAT          |
|          3 |          2 |   9000 |      0 | BEAT         |
|          3 |          3 |   9900 |      0 | BEAUT        |
|          3 |          4 |  10800 |      0 | EAT          |
|          ...
+-----+-----+-----+-----+-----+

```

1.1.1.2.9.3.30 mysql.transaction_registry Table

System tables should not normally be edited directly. Use the related SQL statements instead.

The `mysql.transaction_registry` table was introduced in [MariaDB 10.3.4](#) as part of [system-versioned tables](#). It is used for [transaction-precise versioning](#), and contains the following fields:

Field	Type	Null	Key	Default	Description
<code>transaction_id</code>	<code>bigint(20) unsigned</code>	NO	Primary	NULL	
<code>commit_id</code>	<code>bigint(20) unsigned</code>	NO	Unique	NULL	
<code>begin_timestamp</code>	<code>timestamp(6)</code>	NO	Multiple	0000-00-00 00:00:00.000000	Timestamp when the transaction began (BEGIN statement), however see MDEV-16024 .
<code>commit</code>	<code>timestamp(6)</code>	NO	Multiple	0000-00-00 00:00:00.000000	Timestamp when the transaction was committed.
<code>isolation_level</code>	<code>enum('READ-UNCOMMITTED','READ-COMMITTED','REPEATABLE-READ','SERIALIZABLE')</code>	NO		NULL	Transaction isolation level .

1.1.1.2.9.3.31 mysql.user Table

System tables should not normally be edited directly. Use the related SQL statements instead.

MariaDB starting with [10.4](#)

In [MariaDB 10.4](#) and later, the `mysql.global_priv` table has replaced the `mysql.user` table, and `mysql.user` should be considered obsolete. It is now a [view](#) into `mysql.global_priv` created for compatibility with older applications and monitoring scripts. New tools are supposed to use `INFORMATION_SCHEMA` tables. From [MariaDB 10.4.13](#), the dedicated `mariadb.sys` user is created as the definer of the view. Previously, `root` was the definer, which resulted in privilege problems when this username was changed ([MDEV-19650](#)).

The `mysql.user` table contains information about users that have permission to access the MariaDB server, and their global privileges. The table can be queried and although it is possible to directly update it, it is best to use [GRANT](#) and [CREATE USER](#) for adding users and privileges.

Note that the MariaDB privileges occur at many levels. A user may not be granted `create` privilege at the user level, but may still have `create` permission on certain tables or databases, for example. See [privileges](#) for a more complete view of the MariaDB privilege system.

The `mysql.user` table contains the following fields:

Field	Type	Null	Key	Default	Description
<code>Host</code>	<code>char(60)</code>	NO	PRI		Host (together with <code>User</code> makes up the unique identifier for this account.
<code>User</code>	<code>char(80)</code>	NO	PRI		User (together with <code>Host</code> makes up the unique identifier for this account.
<code>Password</code>	<code>longtext (>= MariaDB 10.4.1), <code>char(41)</code> (<= MariaDB 10.4.0)</code>	NO			Hashed password, generated by the <code>PASSWORD()</code> function.
<code>Select_priv</code>	<code>enum('N','Y')</code>	NO		N	Can perform SELECT statements.
<code>Insert_priv</code>	<code>enum('N','Y')</code>	NO		N	Can perform INSERT statements.
<code>Update_priv</code>	<code>enum('N','Y')</code>	NO		N	Can perform UPDATE statements.
<code>Delete_priv</code>	<code>enum('N','Y')</code>	NO		N	Can perform DELETE statements.

Create_priv	enum('N','Y')	NO		N	Can CREATE DATABASE's or CREATE TABLE's .
Drop_priv	enum('N','Y')	NO		N	Can DROP DATABASE's or DROP TABLE's .
Reload_priv	enum('N','Y')	NO		N	Can execute FLUSH statements or equivalent mariadb-admin commands.
Shutdown_priv	enum('N','Y')	NO		N	Can shut down the server with SHUTDOWN or mariadb-admin shutdown .
Process_priv	enum('N','Y')	NO		N	Can show information about active processes, via SHOW PROCESSLIST or mariadb-admin processlist .
File_priv	enum('N','Y')	NO		N	Read and write files on the server, using statements like LOAD DATA INFILE or functions like LOAD_FILE() . Also needed to create CONNECT outward tables. MariaDB server must have permission to access those files.
Grant_priv	enum('N','Y')	NO		N	User can grant privileges they possess.
References_priv	enum('N','Y')	NO		N	Unused
Index_priv	enum('N','Y')	NO		N	Can create an index on a table using the CREATE INDEX statement. Without the <code>INDEX</code> privilege, user can still create indexes when creating a table using the CREATE TABLE statement if the user has have the <code>CREATE</code> privilege, and user can create indexes using the ALTER TABLE statement if they have the <code>ALTER</code> privilege.
Alter_priv	enum('N','Y')	NO		N	Can perform ALTER TABLE statements.
Show_db_priv	enum('N','Y')	NO		N	Can list all databases using the SHOW DATABASES statement. Without the <code>SHOW DATABASES</code> privilege, user can still issue the <code>SHOW DATABASES</code> statement, but it will only list databases containing tables on which they have privileges.
Super_priv	enum('N','Y')	NO		N	Can execute superuser statements: CHANGE MASTER TO , KILL (users who do not have this privilege can only <code>KILL</code> their own threads), PURGE LOGS  , SET global system variables , or the mariadb-admin debug command. Also, this permission allows the user to write data even if the <code>read_only</code> startup option is set, enable or disable logging, enable or disable replication on slaves, specify a <code>DEFINER</code> for statements that support that clause, connect once after reaching the <code>MAX_CONNECTIONS</code> . If a statement has been specified for the <code>init-connect</code> <code>mysqld</code> option, that command will not be executed when a user with <code>SUPER</code> privileges connects to the server.
Create_tmp_table_priv	enum('N','Y')	NO		N	Can create temporary tables with the CREATE TEMPORARY TABLE statement.
Lock_tables_priv	enum('N','Y')	NO		N	Acquire explicit locks using the LOCK TABLES statement; user also needs to have the <code>SELECT</code> privilege on a table in order to lock it.
Execute_priv	enum('N','Y')	NO		N	Can execute stored procedure or functions.
Repl_slave_priv	enum('N','Y')	NO		N	Accounts used by slave servers on the master need this privilege. This is needed to get the updates made on the master.

Repl_client_priv	enum('N','Y')	NO		N	Can execute SHOW MASTER STATUS and SHOW SLAVE STATUS statements.
Create_view_priv	enum('N','Y')	NO		N	Can create a view using the CREATE VIEW statement.
Show_view_priv	enum('N','Y')	NO		N	Can show the CREATE VIEW statement to create a view using the SHOW CREATE VIEW statement.
Create_routine_priv	enum('N','Y')	NO		N	Can create stored programs using the CREATE PROCEDURE and CREATE FUNCTION statements.
Alter_routine_priv	enum('N','Y')	NO		N	Can change the characteristics of a stored function using the ALTER FUNCTION statement.
Create_user_priv	enum('N','Y')	NO		N	Can create a user using the CREATE USER statement, or implicitly create a user with the GRANT statement.
Event_priv	enum('N','Y')	NO		N	Create, drop and alter events .
Trigger_priv	enum('N','Y')	NO		N	Can execute triggers associated with tables the user updates, execute the CREATE TRIGGER and DROP TRIGGER statements.
Create_tablespace_priv	enum('N','Y')	NO		N	
Delete_history_priv	enum('N','Y')	NO		N	Can delete rows created through system versioning .
ssl_type	enum('', 'ANY', 'X509', 'SPECIFIED')	NO			TLS type - see TLS options .
ssl_cipher	blob	NO		NULL	TLS cipher - see TLS options .
x509_issuer	blob	NO		NULL	X509 cipher - see TLS options .
x509_subject	blob	NO		NULL	SSL subject - see TLS options .
max_questions	int(11) unsigned	NO		0	Number of queries the user can perform per hour. Zero is unlimited. See per-account resource limits .
max_updates	int(11) unsigned	NO		0	Number of updates the user can perform per hour. Zero is unlimited. See per-account resource limits .
max_connections	int(11) unsigned	NO		0	Number of connections the account can start per hour. Zero is unlimited. See per-account resource limits .
max_user_connections	int(11)	NO		0	Number of simultaneous connections the account can have. Zero is unlimited. See per-account resource limits .
plugin	char(64)	NO			Authentication plugin used on connection. If empty, uses the default .
authentication_string	text	NO		NULL	Authentication string for the authentication plugin.
password_expired	enum('N','Y')	NO		N	MySQL-compatibility option, not implemented in MariaDB.
is_role	enum('N','Y')	NO		N	Whether the user is a role .
default_role	char(80)	NO		N	Role which will be enabled on user login automatically.
max_statement_time	decimal(12,6)	NO		0.000000	If non-zero, how long queries can run before being killed automatically.
Field	Type	Null	Key	Default	Description

The `Acl_roles` status variable indicates how many rows the `mysql.user` table contains where `is_role='Y'`.

The `Acl_users` status variable, indicates how many rows the `mysql.user` table contains where `is_role='N'`.

Authentication Plugin

When the `plugin` column is empty, MariaDB defaults to authenticating accounts with either the `mysql_native_password` or the `mysql_old_password` plugins. It decides which based on the hash used in the value for the `Password` column. When there's no password set or when the 4.1 password hash is used, (which is 41 characters long), MariaDB uses the `mysql_native_password` plugin. The `mysql_old_password` plugin is used with pre-4.1 password hashes, (which are 16 characters long).

MariaDB also supports the use of alternative [authentication plugins](#). When the `plugin` column is not empty for the given account, MariaDB uses it to authenticate connection attempts. The specific plugin then uses the value of either the `Password` column or the `authentication_string` column to authenticate the user.

A specific authentication plugin can be used for an account by providing the `IDENTIFIED VIA authentication_plugin` clause with the [CREATE USER](#), [ALTER USER](#), or [GRANT](#) statements.

For example, the following statement would create an account that authenticates with the [PAM authentication plugin](#):

```
CREATE USER foo2@test IDENTIFIED VIA pam;
```

If the specific authentication plugin uses the `authentication_string` column, then this value for the account can be specified after a `USING` or `AS` keyword. For example, the [PAM authentication plugin](#) accepts a [service name](#) that would go into the `authentication_string` column for the account:

```
CREATE USER foo2@test IDENTIFIED VIA pam USING 'mariadb';
```

1.1.1.2.9.3.32 Spider mysql Database Tables

The [Spider storage engine](#) installs the following system tables in the `mysql` database.

mysql.spider_link_failed_log Table

The `mysql.spider_link_failed_log` table.

mysql.spider_link_mon_servers Table

The `mysql.spider_link_mon_servers` table.

mysql.spider_tables Table

The `mysql.spider_tables` table.

mysql.spider_table_crd Table

The `mysql.spider_table_crd` table.

mysql.spider_table_position_for_recovery Table

The `mysql.spider_table_position_for_recovery` table.

mysql.spider_table_sts Table

The `mysql.spider_table_sts` table.

mysql.spider_xa Table

The `mysql.spider_xa` table.

mysql.spider_xa_failed_log Table

The `mysql.spider_xa_failed_log` table.

mysql.spider_xa_member Table

The `mysql.spider_xa_member` table.

1.1.1.2.9.3.32.1 mysql.spider_link_failed_log

Table

The `mysql.spider_link_failed_log` table is installed by the [Spider storage engine](#).

MariaDB starting with [10.4](#)

In [MariaDB 10.4](#) and later, this table uses the [Aria](#) storage engine.

MariaDB until [10.3](#)

In [MariaDB 10.3](#) and before, this table uses the [MyISAM](#) storage engine.

It contains the following fields:

Field	Type	Null	Key	Default	Description
<code>db_name</code>	<code>char(64)</code>	NO			
<code>table_name</code>	<code>char(199)</code>	NO			
<code>link_id</code>	<code>char(64)</code>	NO			
<code>failed_time</code>	<code>timestamp</code>	NO		<code>current_timestamp()</code>	

1.1.1.2.9.3.32.2 mysql.spider_link_mon_servers Table

The `mysql.spider_link_mon_servers` table is installed by the [Spider storage engine](#).

MariaDB starting with [10.4](#)

In [MariaDB 10.4](#) and later, this table uses the [Aria](#) storage engine.

MariaDB until [10.3](#)

In [MariaDB 10.3](#) and before, this table uses the [MyISAM](#) storage engine.

It contains the following fields:

Field	Type	Null	Key	Default	Description
<code>db_name</code>	<code>char(64)</code>	NO	PRI		
<code>table_name</code>	<code>char(199)</code>	NO	PRI		
<code>link_id</code>	<code>char(64)</code>	NO	PRI		
<code>sid</code>	<code>int(10) unsigned</code>	NO	PRI	0	
<code>server</code>	<code>char(64)</code>	YES		NULL	
<code>scheme</code>	<code>char(64)</code>	YES		NULL	
<code>host</code>	<code>char(64)</code>	YES		NULL	
<code>port</code>	<code>char(5)</code>	YES		NULL	
<code>socket</code>	<code>text</code>	YES		NULL	
<code>username</code>	<code>char(64)</code>	YES		NULL	
<code>password</code>	<code>char(64)</code>	YES		NULL	
<code>ssl_ca</code>	<code>text</code>	YES		NULL	
<code>ssl_capath</code>	<code>text</code>	YES		NULL	
<code>ssl_cert</code>	<code>text</code>	YES		NULL	
<code>ssl_cipher</code>	<code>char(64)</code>	YES		NULL	
<code>ssl_key</code>	<code>text</code>	YES		NULL	
<code>ssl_verify_server_cert</code>	<code>tinyint(4)</code>	NO		0	
<code>default_file</code>	<code>text</code>	YES		NULL	

default_group	char(64)	YES		NULL	
dsn	char(64)	YES		NULL	
filedsn	text	YES		NULL	
driver	char(64)	YES		NULL	

1.1.1.2.9.3.32.3 mysql.spider_tables Table

The `mysql.spider_tables` table is installed by the [Spider storage engine](#).

MariaDB starting with [10.4](#)

In [MariaDB 10.4](#) and later, this table uses the [Aria](#) storage engine.

MariaDB until [10.3](#)

In [MariaDB 10.3](#) and before, this table uses the [MyISAM](#) storage engine.

It contains the following fields:

Field	Type	Null	Key	Default	Description
db_name	char(64)	NO	PRI		
table_name	char(199)	NO	PRI		
link_id	int(11)	NO	PRI	0	
priority	bigint(20)	NO	MUL	0	
server	char(64)	YES		NULL	
scheme	char(64)	YES		NULL	
host	char(64)	YES		NULL	
port	char(5)	YES		NULL	
socket	text	YES		NULL	
username	char(64)	YES		NULL	
password	char(64)	YES		NULL	
ssl_ca	text	YES		NULL	
ssl_capath	text	YES		NULL	
ssl_cert	text	YES		NULL	
ssl_cipher	char(64)	YES		NULL	
ssl_key	text	YES		NULL	
ssl_verify_server_cert	tinyint(4)	NO		0	
monitoring_binlog_pos_at_failing	tinyint(4)	NO		0	
default_file	text	YES		NULL	
default_group	char(64)	YES		NULL	
dsn	char(64)	YES		NULL	
filedsn	text	YES		NULL	
driver	char(64)	YES		NULL	
tgt_db_name	char(64)	YES		NULL	
tgt_table_name	char(64)	YES		NULL	
link_status	tinyint(4)	NO		1	
block_status	tinyint(4)	NO		0	
static_link_id	char(64)	YES		NULL	

1.1.1.2.9.3.32.4 mysql.spider_table_crd Table

The `mysql.spider_table_crd` table is installed by the [Spider storage engine](#).

MariaDB starting with [10.4](#)

In [MariaDB 10.4](#) and later, this table uses the [Aria](#) storage engine.

MariaDB until [10.3](#)

In [MariaDB 10.3](#) and before, this table uses the [MyISAM](#) storage engine.

It contains the following fields:

Field	Type	Null	Key	Default	Description
db_name	char(64)	NO	PRI		
table_name	char(199)	NO	PRI		
key_seq	int(10) unsigned	NO	PRI	0	
cardinality	bigint(20)	NO		0	

1.1.1.2.9.3.32.5

mysql.spider_table_position_for_recovery Table

The `mysql.spider_table_position_for_recovery` table is installed by the [Spider storage engine](#).

MariaDB starting with [10.4](#)

In [MariaDB 10.4](#) and later, this table uses the [Aria](#) storage engine.

MariaDB until [10.3](#)

In [MariaDB 10.3](#) and before, this table uses the [MyISAM](#) storage engine.

It contains the following fields:

Field	Type	Null	Key	Default	Description
db_name	char(64)	NO	PRI		
table_name	char(199)	NO	PRI		
failed_link_id	int(11)	NO	PRI	0	
source_link_id	int(11)	NO	PRI	0	
file	text	YES		NULL	
position	text	YES		NULL	
gtid	text	YES		NULL	

1.1.1.2.9.3.32.6 mysql.spider_table_sts Table

The `mysql.spider_table_sts` table is installed by the [Spider storage engine](#).

MariaDB starting with [10.4](#)

In [MariaDB 10.4](#) and later, this table uses the [Aria](#) storage engine.

MariaDB until [10.3](#)

In [MariaDB 10.3](#) and before, this table uses the [MyISAM](#) storage engine.

It contains the following fields:

Field	Type	Null	Key	Default	Description
db_name	char(64)	NO	PRI		

table_name	char(199)	NO	PRI		
data_file_length	bigint(20) unsigned	NO		0	
max_data_file_length	bigint(20) unsigned	NO		0	
index_file_length	bigint(20) unsigned	NO		0	
records	bigint(20) unsigned	NO		0	
mean_rec_length	bigint(20) unsigned	NO		0	
check_time	datetime	NO		0000-00-00 00:00:00	
create_time	datetime	NO		0000-00-00 00:00:00	
update_time	datetime	NO		0000-00-00 00:00:00	
checksum	bigint(20) unsigned	YES		NULL	

1.1.1.2.9.3.32.7 mysql.spider_xa Table

The `mysql.spider_xa` table is installed by the [Spider storage engine](#).

MariaDB starting with [10.4](#)

In [MariaDB 10.4](#) and later, this table uses the [Aria](#) storage engine.

MariaDB until [10.3](#)

In [MariaDB 10.3](#) and before, this table uses the [MyISAM](#) storage engine.

It contains the following fields:

Field	Type	Null	Key	Default	Description
format_id	int(11)	NO	PRI	0	
gtrid_length	int(11)	NO	PRI	0	
bqual_length	int(11)	NO		0	
data	binary(128)	NO	PRI		
status	char(8)	NO	MUL		

1.1.1.2.9.3.32.8 mysql.spider_xa_failed_log Table

The `mysql.spider_xa_failed_log` table is installed by the [Spider storage engine](#).

MariaDB starting with [10.4](#)

In [MariaDB 10.4](#) and later, this table uses the [Aria](#) storage engine.

MariaDB until [10.3](#)

In [MariaDB 10.3](#) and before, this table uses the [MyISAM](#) storage engine.

It contains the following fields:

Field	Type	Null	Key	Default	Description
format_id	int(11)	NO		0	
gtrid_length	int(11)	NO		0	
bqual_length	int(11)	NO		0	
data	binary(128)	NO	MUL		
scheme	char(64)	NO			
host	char(64)	NO			

port	char(5)	NO			
socket	text	NO		NULL	
username	char(64)	NO			
password	char(64)	NO			
ssl_ca	text	YES		NULL	
ssl_capath	text	YES		NULL	
ssl_cert	text	YES		NULL	
ssl_cipher	char(64)	YES		NULL	
ssl_key	text	YES		NULL	
ssl_verify_server_cert	tinyint(4)	NO		0	
default_file	text	YES		NULL	
default_group	char(64)	YES		NULL	
dsn	char(64)	YES		NULL	
filedsn	text	YES		NULL	
driver	char(64)	YES		NULL	
thread_id	int(11)	YES		NULL	
status	char(8)	NO			
failed_time	timestamp	NO		current_timestamp()	

1.1.1.2.9.3.32.9 mysql.spider_xa_member Table

The `mysql.spider_xa_member` table is installed by the [Spider storage engine](#).

MariaDB starting with [10.4](#)

In [MariaDB 10.4](#) and later, this table uses the [Aria](#) storage engine.

MariaDB until [10.3](#)

In [MariaDB 10.3](#) and before, this table uses the [MyISAM](#) storage engine.

It contains the following fields:

Field	Type	Null	Key	Default	Description
format_id	int(11)	NO		0	
gtrid_length	int(11)	NO		0	
bqual_length	int(11)	NO		0	
data	binary(128)	NO	MUL		
scheme	char(64)	NO			
host	char(64)	NO			
port	char(5)	NO			
socket	text	NO		NULL	
username	char(64)	NO			
password	char(64)	NO			
ssl_ca	text	YES		NULL	
ssl_capath	text	YES		NULL	
ssl_cert	text	YES		NULL	
ssl_cipher	char(64)	YES		NULL	

ssl_key	text	YES		NULL	
ssl_verify_server_cert	tinyint(4)	NO		0	
default_file	text	YES		NULL	
default_group	char(64)	YES		NULL	
dsn	char(64)	YES		NULL	
filedsn	text	YES		NULL	
driver	char(64)	YES		NULL	

1.1.1.2.9.4 Sys Schema

MariaDB starting with [10.6.0](#)

The sys_schema is a collection of views, functions and procedures to help administrators get insight into database usage.

The [Performance Schema](#) is required to be enabled in order to make use of the Sys Schema.

This article is currently incomplete.

Sys Schema sys_config Table

[Configuration options for the Sys Schema.](#)

Sys Schema Stored Functions

[Stored functions available in the Sys Schema.](#)

Sys Schema Stored Procedures

[Stored procedures available in the Sys Schema.](#)

Sys Schema Views

[Views available in the Sys Schema.](#)

1.1.1.2.9.4.1 Sys Schema sys_config Table

MariaDB starting with [10.6.0](#)

The Sys Schema sys_config table was added in [MariaDB 10.6.0](#). The sys_config table is also backported to [MariaDB-10.5-enterprise](#).

The sys.sys_config table holds configuration options for the [Sys Schema](#).

This is a persistent table (using the [Aria](#) storage engine), with the configuration persisting across upgrades (new options are added with [INSERT IGNORE](#)).

The table also has two related triggers, which maintain the user that INSERTs or UPDATEs the configuration - sys_config_insert_set_user and sys_config_update_set_user respectively.

Its structure is as follows:

```

+-----+-----+-----+-----+-----+-----+
| Field | Type          | Null | Key | Default          | Extra          |
+-----+-----+-----+-----+-----+-----+
| variable | varchar(128) | NO   | PRI | NULL             |               |
| value    | varchar(128) | YES  |     | NULL             |               |
| set_time | timestamp     | NO   |     | CURRENT_TIMESTAMP | on update CURRENT_TIMESTAMP |
| set_by   | varchar(128) | YES  |     | NULL             |               |
+-----+-----+-----+-----+-----+-----+

```

Note, when functions check for configuration options, they first check whether a similar named user variable exists with a value, and if this is not set then pull the configuration option from this table in to that named user variable. This is done for performance reasons (to not continually SELECT from the table), however this comes with the side effect that once initied, the values last with the session, somewhat like how session variables are initied from global variables. If the values within this table are changed, they will not take effect until the user logs in again.

Options Included

Variable	Default Value	Description
statement_truncate_len	64	Sets the size to truncate statements to, for the <code>format_statement</code> function.
statement_performance_analyzer.limit	100	The maximum number of rows to include for the views that does not have a built-in limit (e.g. the 95th percentile view). If not set the limit is 100.
statement_performance_analyzer.view	NULL	Used together with the 'custom' view. If the value contains a space, it is considered a query, otherwise it must be an existing view querying the <code>performance_schema.events_statements_summary_by_digest</code> table.
diagnostics.allow_i_s_tables	OFF	Specifies whether it is allowed to do table scan queries on <code>information_schema.TABLES</code> for the diagnostics procedure.
diagnostics.include_raw	OFF	Set to 'ON' to include the raw data (e.g. the original output of "SELECT * FROM sys.metrics") for the diagnostics procedure.
ps_thread_trx_info.max_length	65535	Sets the maximum output length for JSON object output by the <code>ps_thread_trx_info()</code> function.

Notes

Some early versions of `sys_config` were stored in [InnoDB](#) format.

1.1.1.2.9.4.2 Sys Schema Stored Functions

The following [stored functions](#) are available in the [Sys Schema](#).

extract_schema_from_file_name

Returns the schema (database) name.

extract_table_from_file_name

Returns the table name from the provided path.

format_bytes

Returns a string consisting of a value and the units in a human-readable format. [↗](#)

format_path

Returns a modified path, replacing subpaths matching the values of various system variables.

format_statement

Returns a reduced length string.

format_time

Given a time in picoseconds, returns a human-readable time and unit.

list_add

Takes a list to be modified and a value to be added to the list, returning the resulting value.

list_drop

Takes a list to be modified and a value to be dropped, returning the resulting value.

ps_is_account_enabled

Whether or not Performance Schema instrumentation for a given account is enabled.

ps_is_consumer_enabled

Whether or not Performance Schema instrumentation for a given consumer is enabled.

ps_is_instrument_default_enabled

Whether or not a Performance Schema instrument is enabled by default.

ps_is_instrument_default_timed

Whether or not a Performance Schema instrument is timed by default.

ps_is_thread_instrumented

Whether or not instrumentation for a given connection_id is enabled.

ps_thread_account

Returns the account associated with the given thread_id.

ps_thread_id

Returns the thread_id associated with the given connection_id.

ps_thread_stack

Returns statements, stages, events within the Performance Schema for a given thread_id.

ps_thread_trx_info

Returns a JSON object with information about the thread specified by the given thread_id.

quote_identifier

Returns quoted, properly escaped identifier.

sys_get_config

Returns a configuration option value from the sys_config table.

version_major

Returns the MariaDB Server major release version.

version_minor

Returns the MariaDB Server minor release version.

version_patch

MariaDB Server patch release version.

1.1.1.2.9.4.2.1 extract_schema_from_file_name

Syntax

```
sys.extract_schema_from_file_name (path)
```

Description

`extract_schema_from_file_name` is a [stored function](#) available with the [Sys Schema](#).

Given a file path, it returns the schema (database) name. The file name is assumed to be within the schema directory, and therefore the function will not return the expected result with partitions, or when tables are defined using the `DATA_DIRECTORY` table option.

The function does not examine anything on disk. The return value, a `VARCHAR(64)`, is determined solely from the provided path.

Examples

```
SELECT sys.extract_schema_from_file_name('/usr/local/mysql/data/db/t1.ibd');
+-----+
| sys.extract_schema_from_file_name('/usr/local/mysql/data/db/t1.ibd') |
+-----+
| db |
+-----+
```

1.1.1.2.9.4.2.2 extract_table_from_file_name

Syntax

```
sys.extract_table_from_file_name(path)
```

Description

`extract_table_from_file_name` is a [stored function](#) available with the [Sys Schema](#).

Given a file path, it returns the table name.

The function does not examine anything on disk. The return value, a VARCHAR(64), is determined solely from the provided path.

Examples

```
SELECT sys.extract_table_from_file_name('/usr/local/mysql/data/db/t1.ibd');
+-----+
| sys.extract_table_from_file_name('/usr/local/mysql/data/db/t1.ibd') |
+-----+
| t1 |
+-----+
```

1.1.1.2.9.4.2.3 format_bytes

Syntax

```
sys.format_bytes(double)
```

Description

`format_bytes` is a [stored function](#) available with the [Sys Schema](#).

Given a byte count, returns a string consisting of a value and the units in a human-readable format. The units will be in bytes, KiB (kibibytes), MiB (mebibytes), GiB (gibibytes), TiB (tebibytes), or PiB (pebibytes).

The binary prefixes (kibi, mebi, gibi, tebi and pebi) were created in December 1998 by the International Electrotechnical Commission to avoid possible ambiguity, as the widely-used prefixes kilo, mega, giga, tera and peta can be used to refer to both the power-of-10 decimal system multipliers and the power-of-two binary system multipliers.

From [MariaDB 11.8](#), the built-in [FORMAT_BYTES](#) function can instead be used. The functions are similar, except that `FORMAT_BYTES` also displays exbibytes.

Examples

```

SELECT sys.format_bytes(1000),sys.format_bytes(1024);
+-----+-----+
| sys.format_bytes(1000) | sys.format_bytes(1024) |
+-----+-----+
| 1000 bytes           | 1.00 KiB              |
+-----+-----+

SELECT sys.format_bytes(1000000),sys.format_bytes(1048576);
+-----+-----+
| sys.format_bytes(1000000) | sys.format_bytes(1048576) |
+-----+-----+
| 976.56 KiB             | 1.00 MiB              |
+-----+-----+

SELECT sys.format_bytes(1000000000),sys.format_bytes(1073741874);
+-----+-----+
| sys.format_bytes(1000000000) | sys.format_bytes(1073741874) |
+-----+-----+
| 953.67 MiB             | 1.00 GiB              |
+-----+-----+

SELECT sys.format_bytes(1000000000000),sys.format_bytes(1099511627776);
+-----+-----+
| sys.format_bytes(1000000000000) | sys.format_bytes(1099511627776) |
+-----+-----+
| 931.32 GiB            | 1.00 TiB              |
+-----+-----+

SELECT sys.format_bytes(1000000000000000),sys.format_bytes(1125899906842624);
+-----+-----+
| sys.format_bytes(1000000000000000) | sys.format_bytes(1125899906842624) |
+-----+-----+
| 909.49 TiB           | 1.00 PiB              |
+-----+-----+

```

1.1.1.2.9.4.2.4 format_path

Syntax

```
sys.format_path(path)
```

Description

`format_path` is a [stored function](#) available with the [Sys Schema](#) that, given a path, returns a modified path after replacing subpaths matching the values of various system variables with the variable name.

The system variables that are matched are, in order:

- [datadir](#)
- [tmpdir](#)
- [slave_load_tmpdir](#)
- [innodb_data_home_dir](#)
- [innodb_log_group_home_dir](#)
- [innodb_undo_directory](#)
- [basedir](#)

Examples

```

SELECT @@tmpdir;
+-----+
| @@tmpdir |
+-----+
| /home/ian/sandboxes/msb_10_8_2/tmp |
+-----+

SELECT sys.format_path('/home/ian/sandboxes/msb_10_8_2/tmp/testdb.ibd');
+-----+
| sys.format_path('/home/ian/sandboxes/msb_10_8_2/tmp/testdb.ibd') |
+-----+
| @@tmpdir/testdb.ibd |
+-----+

```

1.1.1.2.9.4.2.5 format_statement

Syntax

```
sys.format_statement(statement)
```

Description

Returns a reduced length string. The length is specified by the [statement_truncate_len configuration option](#) (default 64), and the removed part of the string (if any) is replaced with an ellipsis (three dots).

The function is intended for use in formatting lengthy SQL statements to a fixed length.

Examples

Default truncation length 64:

```

SELECT sys.format_statement(
  'SELECT field1, field2, field3, field4, field5, field6 FROM table1'
) AS formatted_statement;
+-----+
| formatted_statement |
+-----+
| SELECT field1, field2, field3, ... d4, field5, field6 FROM table1 |
+-----+

```

Reducing the truncation length to 48:

```

SET @sys.statement_truncate_len = 48;

SELECT sys.format_statement(
  'SELECT field1, field2, field3, field4, field5, field6 FROM table1'
) AS formatted_statement;
+-----+
| formatted_statement |
+-----+
| SELECT field1, field2, ... d5, field6 FROM table1 |
+-----+

```

1.1.1.2.9.4.2.6 format_time

Syntax

```
sys.format_time(picoseconds)
```

Description

`format_time` is a [stored function](#) available with the [Sys Schema](#). Given a time in picoseconds, returns a human-readable time value and unit indicator. Unit can be:

- ps - picoseconds
- ns - nanoseconds
- us - microseconds
- ms - milliseconds
- s - seconds
- m - minutes
- h - hours
- d - days
- w - weeks

This function is very similar to the [FORMAT_PICO_TIME](#) function introduced in [MariaDB 11.0.2](#), but with the following differences:

- Represents minutes as `m` rather than `min`.
- Represent weeks.

Examples

```
SELECT
  sys.format_time(43) AS ps,
  sys.format_time(4321) AS ns,
  sys.format_time(43211234) AS us,
  sys.format_time(432112344321) AS ms,
  sys.format_time(43211234432123) AS s,
  sys.format_time(432112344321234) AS m,
  sys.format_time(4321123443212345) AS h,
  sys.format_time(432112344321234545) AS d,
  sys.format_time(43211234432123444543) AS w;
```

ps	ns	us	ms	s	m	h	d	w
43 ps	4.32 ns	43.21 us	432.11 ms	43.21 s	7.20 m	1.20 h	5.00 d	71.45 w

1.1.1.2.9.4.2.7 list_add

Syntax

```
sys.list_add(list,value)
```

Description

`list_add` is a [stored function](#) available with the [Sys Schema](#).

It takes a *list* to be modified and a *value* to be added to the list, returning the resulting value. This can be used, for example, to add a value to a system variable taking a comma-delimited list of options, such as [sql_mode](#).

The related function [list_drop](#) can be used to drop a value from a list.

Examples

```

SELECT @@sql_mode;
+-----+
| @@sql_mode |
+-----+
| STRICT_TRANS_TABLES,ERROR_FOR_DIVISION_BY_ZERO,
NO_AUTO_CREATE_USER,NO_ENGINE_SUBSTITUTION |
+-----+

SET @@sql_mode = sys.list_add(@@sql_mode, 'NO_ZERO_DATE');

SELECT @@sql_mode;
+-----+
| @@sql_mode |
+-----+
| STRICT_TRANS_TABLES,NO_ZERO_DATE,ERROR_FOR_DIVISION_BY_ZERO,
NO_AUTO_CREATE_USER,NO_ENGINE_SUBSTITUTION |
+-----+

```

1.1.1.2.9.4.2.8 list_drop

Syntax

```
sys.list_drop(list,value)
```

Description

`list_drop` is a [stored function](#) available with the [Sys Schema](#).

It takes a *list* to be modified and a *value* to be dropped from the list, returning the resulting value. This can be used, for example, to remove a value from a system variable taking a comma-delimited list of options, such as [sql_mode](#).

The related function [list_add](#) can be used to add a value to a list.

Examples

```

SELECT @@sql_mode;
+-----+
| @@sql_mode |
+-----+
| STRICT_TRANS_TABLES,ERROR_FOR_DIVISION_BY_ZERO,
NO_AUTO_CREATE_USER,NO_ENGINE_SUBSTITUTION |
+-----+

SET @@sql_mode = sys.list_drop(@@sql_mode, 'NO_ENGINE_SUBSTITUTION');

SELECT @@sql_mode;
+-----+
| @@sql_mode |
+-----+
| STRICT_TRANS_TABLES,ERROR_FOR_DIVISION_BY_ZERO,
NO_AUTO_CREATE_USER |
+-----+

```

1.1.1.2.9.4.2.9 ps_is_account_enabled

Syntax

```
sys.ps_is_account_enabled(host,user)
```

Description

`ps_is_account_enabled` is a [stored function](#) available with the [Sys Schema](#).

It takes *host* and *user* arguments, and returns an ENUM('YES','NO') depending on whether Performance Schema instrumentation for the given account is enabled.

Examples

```
SELECT sys.ps_is_account_enabled('localhost', 'root');
+-----+
| sys.ps_is_account_enabled('localhost', 'root') |
+-----+
| YES                                             |
+-----+
```

1.1.1.2.9.4.2.10 ps_is_consumer_enabled

Syntax

```
sys.ps_is_consumer_enabled(consumer)
```

Description

`ps_is_consumer_enabled` is a [stored function](#) available with the [Sys Schema](#).

It returns an ENUM('YES','NO') depending on whether Performance Schema instrumentation for the given consumer is enabled, and NULL if not given a valid consumer name.

Examples

```
SELECT sys.ps_is_consumer_enabled('global_instrumentation');
+-----+
| sys.ps_is_consumer_enabled('global_instrumentation') |
+-----+
| YES                                             |
+-----+

SELECT sys.ps_is_consumer_enabled('events_stages_current');
+-----+
| sys.ps_is_consumer_enabled('events_stages_current') |
+-----+
| NO                                             |
+-----+

SELECT sys.ps_is_consumer_enabled('nonexistent_consumer');
+-----+
| sys.ps_is_consumer_enabled('nonexistent_consumer') |
+-----+
| NULL                                           |
+-----+
```

1.1.1.2.9.4.2.11 ps_is_instrument_default_enabled

Syntax

```
sys.ps_is_instrument_default_enabled(instrument)
```

Description

`ps_is_instrument_default_enabled` is a [stored function](#) available with the [Sys Schema](#).

It returns `YES` if the given Performance Schema *instrument* is enabled by default, and `NO` if it is not, does not exist, or is a `NULL` value.

Examples

```
SELECT sys.ps_is_instrument_default_enabled('statement/sql/select');
+-----+
| sys.ps_is_instrument_default_enabled('statement/sql/select') |
+-----+
| YES |
+-----+

SELECT sys.ps_is_instrument_default_enabled('memory/sql/udf_mem');
+-----+
| sys.ps_is_instrument_default_enabled('memory/sql/udf_mem') |
+-----+
| NO |
+-----+

SELECT sys.ps_is_instrument_default_enabled('memory/sql/nonexistent');
+-----+
| sys.ps_is_instrument_default_enabled('memory/sql/nonexistent') |
+-----+
| NO |
+-----+

SELECT sys.ps_is_instrument_default_enabled(NULL);
+-----+
| sys.ps_is_instrument_default_enabled(NULL) |
+-----+
| NO |
+-----+
```

1.1.1.2.9.4.2.12 ps_is_instrument_default_timed

Syntax

```
sys.ps_is_instrument_default_timed(instrument)
```

Description

`ps_is_instrument_default_timed` is a [stored function](#) available with the [Sys Schema](#).

It returns `YES` if the given Performance Schema *instrument* is timed by default, and `NO` if it is not, does not exist, or is a `NULL` value.

Examples

```

SELECT sys.ps_is_instrument_default_timed('statement/sql/select');
+-----+
| sys.ps_is_instrument_default_timed('statement/sql/select') |
+-----+
| YES                                                         |
+-----+

SELECT sys.ps_is_instrument_default_timed('memory/sql/udf_mem');
+-----+
| sys.ps_is_instrument_default_timed('memory/sql/udf_mem') |
+-----+
| NO                                                         |
+-----+

SELECT sys.ps_is_instrument_default_timed('memory/sql/nonexistent');
+-----+
| sys.ps_is_instrument_default_timed('memory/sql/udf_memsds') |
+-----+
| NO                                                         |
+-----+

SELECT sys.ps_is_instrument_default_timed(NULL);
+-----+
| sys.ps_is_instrument_default_timed(NULL) |
+-----+
| NO                                                         |
+-----+

```

1.1.1.2.9.4.2.13 ps_is_thread_instrumented

Syntax

```
sys.ps_is_thread_instrumented(connection_id)
```

Description

`ps_is_thread_instrumented` is a [stored function](#) available with the [Sys Schema](#) that returns whether or not Performance Schema instrumentation for the given *connection_id* is enabled.

- YES - instrumentation is enabled
- NO - instrumentation is not enabled
- UNKNOWN - the connection ID is unknown
- NULL - NULL value

Examples

```

SELECT sys.ps_is_thread_instrumented(CONNECTION_ID());
+-----+
| sys.ps_is_thread_instrumented(CONNECTION_ID()) |
+-----+
| YES |
+-----+

SELECT sys.ps_is_thread_instrumented(2042);
+-----+
| sys.ps_is_thread_instrumented(2042) |
+-----+
| UNKNOWN |
+-----+

SELECT sys.ps_is_thread_instrumented(NULL);
+-----+
| sys.ps_is_thread_instrumented(NULL) |
+-----+
| NULL |
+-----+

```

1.1.1.2.9.4.2.14 ps_thread_account

Syntax

```
sys.ps_thread_account(thread_id)
```

Description

`ps_thread_account` is a [stored function](#) available with the [Sys Schema](#) that returns the account (username@hostname) associated with the given `thread_id`.

Returns `NULL` if the `thread_id` is not found.

Examples

```

SELECT sys.ps_thread_account(sys.ps_thread_id(CONNECTION_ID()));
+-----+
| sys.ps_thread_account(sys.ps_thread_id(CONNECTION_ID())) |
+-----+
| msandbox@localhost |
+-----+

SELECT sys.ps_thread_account(sys.ps_thread_id(2042));
+-----+
| sys.ps_thread_account(sys.ps_thread_id(2042)) |
+-----+
| NULL |
+-----+

SELECT sys.ps_thread_account(sys.ps_thread_id(NULL));
+-----+
| sys.ps_thread_account(sys.ps_thread_id(NULL)) |
+-----+
| msandbox@localhost |
+-----+

```

1.1.1.2.9.4.2.15 ps_thread_id

Syntax

```
sys.ps_thread_id(connection_id)
```

Description

`ps_thread_id` is a [stored function](#) available with the [Sys Schema](#) that returns the `thread_id` associated with the given `connection_id`. If the `connection_id` is NULL, returns the `thread_id` for the current connection.

Examples

```
SELECT * FROM performance_schema.threads\G
***** 13. row *****
      THREAD_ID: 13
      NAME: thread/sql/one_connection
      TYPE: FOREGROUND
      PROCESSLIST_ID: 3
      PROCESSLIST_USER: msandbox
      PROCESSLIST_HOST: localhost
      PROCESSLIST_DB: test
      PROCESSLIST_COMMAND: Query
      PROCESSLIST_TIME: 0
      PROCESSLIST_STATE: Sending data
      PROCESSLIST_INFO: SELECT * FROM performance_schema.threads
      PARENT_THREAD_ID: 1
      ROLE: NULL
      INSTRUMENTED: YES
      HISTORY: YES
      CONNECTION_TYPE: Socket
      THREAD_OS_ID: 24379
```

```
SELECT sys.ps_thread_id(3);
+-----+
| sys.ps_thread_id(3) |
+-----+
|           13 |
+-----+
```

```
SELECT sys.ps_thread_id(NULL);
+-----+
| sys.ps_thread_id(NULL) |
+-----+
|           13 |
+-----+
```

1.1.1.2.9.4.2.16 ps_thread_stack

Syntax

```
sys.ps_thread_stack(thread_id, verbose)
```

Description

`ps_thread_stack` is a [stored function](#) available with the [Sys Schema](#) that, for a given `thread_id`, returns all statements, stages, and events within the Performance Schema, as a JSON formatted stack.

The boolean `verbose` argument specifies whether or not to include `file:lineno` information in the events.

Examples

```
SELECT sys.ps_thread_stack(13, FALSE) AS thread_stack\G
***** 1. row *****
thread_stack: {"rankdir": "LR", "nodesep": "0.10",
"stack_created": "2022-03-28 16:01:06",
"mysql_version": "10.8.2-MariaDB",
"mysql_user": "msandbox@localhost",
"events": []}
```

1.1.1.2.9.4.2.17 ps_thread_trx_info

Syntax

```
sys.ps_thread_trx_info(thread_id)
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

Description

`ps_thread_trx_info` is a [stored function](#) available with the [Sys Schema](#).

It returns a JSON object with information about the thread specified by the given *thread_id*. This information includes:

- the current transaction
- executed statements (derived from the [Performance Schema events_transactions_current Table](#) and the [Performance Schema events_statements_history Table](#) (full data will only returned if the consumers for those tables are enabled)).

The maximum length of the returned JSON object is determined by the value of the [ps_thread_trx_info.max_length sys_config option](#) (by default 65535). If the returned value exceeds this length, a JSON object error is returned.

Examples

1.1.1.2.9.4.2.18 quote_identifier

Syntax

```
sys.quote_identifier(str)
```

Description

`quote_identifier` is a [stored function](#) available with the [Sys Schema](#).

It quotes a string to produce a result that can be used as an identifier in an SQL statement. The string is returned enclosed by backticks (" ` ") and with each instance of backtick (" ` ") doubled. If the argument is `NULL`, the return value is the word " NULL " without enclosing backticks.

Examples

```

SELECT sys.quote_identifier("Identifier with spaces");
+-----+
| sys.quote_identifier("Identifier with spaces") |
+-----+
| `Identifier with spaces`                       |
+-----+

SELECT sys.quote_identifier("Identifier` containing `backticks");
+-----+
| sys.quote_identifier("Identifier` containing `backticks") |
+-----+
| `Identifier`` containing ``backticks`                 |
+-----+

```

1.1.1.2.9.4.2.19 sys_get_config

Syntax

```
sys.sys_get_config(name, default)
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

Description

`sys_get_config` is a [stored function](#) available with the [Sys Schema](#).

The function returns a configuration option value from the [sys_config table](#). It takes two arguments; *name*, a configuration option name, and *default*, which is returned if the given option does not exist in the table.

Both arguments are VARCHAR(128) and can be NULL. Returns NULL if *name* is NULL, or if the given option is not found and *default* is NULL.

Examples

```

SELECT sys.sys_get_config('ps_thread_trx_info.max_length', NULL);
+-----+
| sys.sys_get_config('ps_thread_trx_info.max_length', NULL) |
+-----+
| 65535                                                       |
+-----+

```

1.1.1.2.9.4.2.20 version_major

Syntax

```
sys.version_major()
```

Description

`version_major` is a [stored function](#) available with the [Sys Schema](#).

It returns the MariaDB Server major release version.

Examples

```

SELECT VERSION(),
sys.version_major() AS major,
sys.version_minor() AS minor,
sys.version_patch() AS patch;
+-----+-----+-----+
| VERSION() | major | minor | patch |
+-----+-----+-----+
| 10.8.2-MariaDB | 10 | 8 | 2 |
+-----+-----+-----+

```

1.1.1.2.9.4.2.21 version_minor

Syntax

```
sys.version_minor()
```

Description

`version_minor` is a [stored function](#) available with the [Sys Schema](#).

It returns the MariaDB Server minor release version.

Examples

```

SELECT VERSION(),
sys.version_major() AS major,
sys.version_minor() AS minor,
sys.version_patch() AS patch;
+-----+-----+-----+
| VERSION() | major | minor | patch |
+-----+-----+-----+
| 10.8.2-MariaDB | 10 | 8 | 2 |
+-----+-----+-----+

```

1.1.1.2.9.4.2.22 version_patch

Syntax

```
sys.version_patch()
```

Description

`version_patch` is a [stored function](#) available with the [Sys Schema](#).

It returns the MariaDB Server patch release version.

Examples

```

SELECT VERSION(),
sys.version_major() AS major,
sys.version_minor() AS minor,
sys.version_patch() AS patch;
+-----+-----+-----+
| VERSION() | major | minor | patch |
+-----+-----+-----+
| 10.8.2-MariaDB | 10 | 8 | 2 |
+-----+-----+-----+

```

1.1.1.2.9.4.3 Sys Schema Stored Procedures

This article is currently incomplete.

The following [stored procedures](#) are available in the [Sys Schema](#).

create_synonym_db

Takes a source db and create a synonym db with views that point to all of t...

optimizer_switch Helper Functions

Quickly see which optimizer_switch options are on or off

ps_trace_statement_digest

Traces all Performance Schema instrumentation for a specific statement digest.

ps_trace_thread

Dumps all Performance Schema data for an instrumented thread to a .dot formatted graph file.

ps_truncate_all_tables

Resets all aggregated instrumentation.

statement_performance_analyzer

Returns a report on running statements.

table_exists

Given a database and table name, returns the table type.

1.1.1.2.9.4.3.1 create_synonym_db

Syntax

```
create_synonym_db (db_name, synonym)

# db_name (VARCHAR(64))
# synonym (VARCHAR(64))
```

Description

`create_synonym_db` is a [stored procedure](#) available with the [Sys Schema](#).

Takes a source database name `db_name` and `synonym` name and creates a synonym database with views that point to all of the tables within the source database. Useful for example for creating a synonym for the [performance_schema](#) or [information_schema](#) databases.

Returns an error if the source database doesn't exist, or the synonym already exists.

Example

```

SHOW DATABASES;
+-----+
| Database |
+-----+
| information_schema |
| mysql |
| performance_schema |
| sys |
| test |
+-----+

CALL sys.create_synonym_db('performance_schema', 'perf');
+-----+
| summary |
+-----+
| Created 81 views in the `perf` database |
+-----+

SHOW DATABASES;
+-----+
| Database |
+-----+
| information_schema |
| mysql |
| perf |
| performance_schema |
| sys |
| test |
+-----+

SHOW FULL TABLES FROM perf;
+-----+-----+
| Tables_in_perf | Table_type |
+-----+-----+
| accounts | VIEW |
| cond_instances | VIEW |
| events_stages_current | VIEW |
| events_stages_history | VIEW |
| events_stages_history_long | VIEW |
...

```

1.1.1.2.9.4.3.2 optimizer_switch Helper Functions

Syntax

```

optimizer_switch_on()
optimizer_switch_off()
optimizer_switch_choice("on" | "off")

```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Example](#)
4. [Notes](#)

Description

The above procedures can be used to check which `optimizer_switch` options are `on` or `off`. The result set is sorted according to `optimizer_switch` option name.

Example

```

select @@optimizer_switch
***** 1. row *****
index_merge=on,index_merge_union=on,index_merge_sort_union=on,index_merge_intersection=on,
index_merge_sort_intersection=off,engine_condition_pushdown=off,index_condition_pushdown=on,
derived_merge=on,derived_with_keys=on,firstmatch=on,loosescan=on,materialization=on,
in_to_exists=on,semijoin=on,partial_match_rowid_merge=on,partial_match_table_scan=on,
subquery_cache=on,mrr=off,mrr_cost_based=off,mrr_sort_keys=off,outer_join_with_cache=on,
semijoin_with_cache=on,join_cache_incremental=on,join_cache_hashed=on,join_cache_bka=on,
optimize_join_buffer_size=on,table_elimination=on,extended_keys=on,exists_to_in=on,
orderby_uses_equalities=on,condition_pushdown_for_derived=on,split_materialized=on,
condition_pushdown_for_subquery=on,rowid_filter=on,condition_pushdown_from_having=on,
not_null_range_scan=off

```

```
call sys.optimizer_switch_on();
```

```

+-----+-----+
| option                                | opt |
+-----+-----+
| condition_pushdown_for_derived        | on  |
| condition_pushdown_for_subquery       | on  |
| condition_pushdown_from_having        | on  |
| derived_merge                          | on  |
| derived_with_keys                      | on  |
| exists_to_in                           | on  |
| extended_keys                          | on  |
| firstmatch                             | on  |
| index_condition_pushdown              | on  |
| index_merge                            | on  |
| index_merge_intersection                | on  |
| index_merge_sort_union                 | on  |
| index_merge_union                      | on  |
| in_to_exists                           | on  |
| join_cache_bka                         | on  |
| join_cache_hashed                     | on  |
| join_cache_incremental                 | on  |
| loosescan                              | on  |
| materialization                        | on  |
| optimize_join_buffer_size              | on  |
| orderby_uses_equalities                 | on  |
| outer_join_with_cache                  | on  |
| partial_match_rowid_merge              | on  |
| partial_match_table_scan               | on  |
| rowid_filter                           | on  |
| semijoin                               | on  |
| semijoin_with_cache                    | on  |
| split_materialized                     | on  |
| subquery_cache                         | on  |
| table_elimination                      | on  |
+-----+-----+

```

```
call sys.optimizer_switch_off();
```

```

+-----+-----+
| option                                | opt |
+-----+-----+
| engine_condition_pushdown              | off |
| index_merge_sort_intersection           | off |
| mrr                                     | off |
| mrr_cost_based                         | off |
| mrr_sort_keys                          | off |
| not_null_range_scan                    | off |
+-----+-----+

```

Notes

sys.optimizer_switch_on() is a shortcut for sys.optimizer_switch_choice("on");

sys.optimizer_switch_off() is a shortcut for sys.optimizer_switch_choice("off");

1.1.1.2.9.4.3.3 ps_trace_statement_digest

Syntax

```
ps_trace_statement_digest(in_digest, in_runtime, in_interval, in_start_fresh, in_auto_enable)
```

Description

`ps_trace_statement_digest` is a [stored procedure](#) available with the [Sys Schema](#).

Parameters:

- `in_digest` VARCHAR(32): The statement digest identifier to analyze.
- `in_runtime` INT: Specifies the duration to run the analysis in seconds.
- `in_interval` DECIMAL(2,2): The analysis interval measured in seconds (including fraction values), at which snapshots are taken.
- `in_start_fresh` BOOLEAN: Determines whether to truncate the Performance Schema `events_statements_history_long` and `events_stages_history_long` tables before starting.
- `in_auto_enable` BOOLEAN: Determines whether to automatically enable required consumers.

Examples

```
CALL sys.ps_trace_statement_digest('891ec6860f98ba46d89dd20b0c03652c', 5, 0.5, TRUE, TRUE);
```

1.1.1.2.9.4.3.4 ps_trace_thread

Syntax

```
ps_trace_thread(thread_id, outfile, max_runtime, interval, start_fresh, auto_setup, debug)
```

Description

`ps_trace_thread` is a [stored procedure](#) available with the [Sys Schema](#).

Parameters:

- `thread_id` INT: The thread to trace.
- `outfile` VARCHAR(255): Name of the .dot file to be create.
- `max_runtime` DECIMAL(20,2): Maximum time in seconds to collect data. Fractional seconds can be used, and NULL results in data being collected for the default sixty seconds.
- `interval` DECIMAL(20,2): Time in seconds to sleep between data collection. Fractional seconds can be used, and NULL results in the sleep being the default one second.
- `start_fresh` BOOLEAN: Whether to reset all Performance Schema data before tracing.
- `auto_setup` BOOLEAN: Whether to disable all other threads, enable all instruments and consumers, and reset the settings at the end of the run.
- `debug` BOOLEAN: Whether to include file:lineno information in the graph.

Dumps all Performance Schema data for an instrumented thread to a .dot formatted graph file (for use with the [DOT graph description language](#)). All returned result sets should be used for a complete graph.

Session [binary logging](#) is disabled during execution, by adjusting the `sql_log_bin` session value (note the permissions required).

Examples

```
CALL sys.ps_trace_thread(25, CONCAT('/tmp/stack-', REPLACE(NOW(), ' ', '-'), '.dot'),
    NULL, NULL, TRUE, TRUE, TRUE);
```

```
-----+
| summary          |
+-----+
| Disabled 0 threads |
+-----+

+-----+
| Info              |
+-----+
| Data collection starting for THREAD_ID = 25 |

+-----+
```

1.1.1.2.9.4.3.5 ps_truncate_all_tables

Syntax

```
ps_truncate_all_tables(bool display)
```

Description

`ps_truncate_all_tables` is a [stored procedure](#) available with the [Sys Schema](#).

The procedure resets all aggregated instrumentation as a snapshot, producing a result set indicating the number of truncated tables. The boolean parameter *display* specifies whether to display each [TRUNCATE TABLE](#) statement before execution.

Examples

```
CALL sys.ps_truncate_all_tables(false);
-----+
| summary          |
+-----+
| Truncated 44 tables |
+-----+
```

```

CALL sys.ps_truncate_all_tables(true);
+-----+
| status |
+-----+
| Running: TRUNCATE TABLE performance_schema.events_stages_history |
+-----+

...

+-----+
| status |
+-----+
| Running: TRUNCATE TABLE performance_schema.table_lock_waits_summary_by_table |
+-----+

+-----+
| summary |
+-----+
| Truncated 44 tables |
+-----+

```

1.1.1.2.9.4.3.6 statement_performance_analyzer

Syntax

```

statement_performance_analyzer(in_action,in_table, in_views)

# in_action ENUM('snapshot', 'overall', 'delta', 'create_tmp',
                'create_table', 'save', 'cleanup')
# in_table VARCHAR(129)
# in_views SET ('with_runtimes_in_95th_percentile', 'analysis',
              'with_errors_or_warnings', 'with_full_table_scans',
              'with_sorting', 'with_temp_tables', 'custom')

```

Description

`statement_performance_analyzer` is a [stored procedure](#) available with the [Sys Schema](#) which returns a report on running statements.

The following options from the [sys_config](#) table impact the output:

- `statement_performance_analyzer.limit` - maximum number of rows (default 100) returned for views that have no built-in limit.
- `statement_performance_analyzer.view` - custom query/view to be used (default NULL). If the `statement_performance_analyzer.limit` configuration option is greater than 0, there can't be a LIMIT clause in the query/view definition

If the debug option is set (default OFF), the procedure will also produce debugging output.

1.1.1.2.9.4.3.7 table_exists

Syntax

```

table_exists(in_db_name,in_table_name, out_table_type)

# in_db_name VARCHAR(64)
# in_table_name VARCHAR(64)
# out_table_type ENUM('', 'BASE TABLE', 'VIEW', 'TEMPORARY')

```

Description

`table_exists` is a [stored procedure](#) available with the [Sys Schema](#).

Given a database `in_db_name` and table name `in_table_name`, returns the table type in the OUT parameter `out_table_type`. The return value is an ENUM field containing one of:

- '' - the table does not exist
- 'BASE TABLE' - a regular table
- 'VIEW' - a view
- 'TEMPORARY' - a temporary table

Examples

```
CALL sys.table_exists('mysql', 'time_zone', @table_type); SELECT @table_type;
+-----+
| @table_type |
+-----+
| BASE TABLE |
+-----+

CALL sys.table_exists('mysql', 'user', @table_type); SELECT @table_type;
+-----+
| @table_type |
+-----+
| VIEW        |
+-----+
```

1.1.1.2.9.4.4 Sys Schema Views

This article is currently incomplete.

host_summary and x\$host_summary Sys Schema Views

Host activity information.

host_summary_by_file_io and x\$host_summary_by_file_io Sys Schema Views

Summarize file I/O, grouped by host, sorted by descending total file I/O latency by default.

host_summary_by_file_io_type and x\$host_summary_by_file_io_type Sys Schema Views

Summary of file I/O, grouped by host and event type.

host_summary_by_stages and x\$host_summary_by_stages Sys Schema Views

Statement stages summary, grouped by host.

host_summary_by_statement_latency and x\$host_summary_by_statement_latency Sys Schema Views

Summary of statement statistics, grouped by host, rows sorted by descending...

host_summary_by_statement_type and x\$host_summary_by_statement_type Sys Schema Views

Summary of executed statement information, grouped by host and statement type.

innodb_buffer_stats_by_schema and x\$innodb_buffer_stats_by_schema Sys Schema Views

Information Schema INNODB_BUFFER_PAGE summary information, grouped by schema.

innodb_buffer_stats_by_table and x\$innodb_buffer_stats_by_table Sys Schema Views

Summary of Information Schema INNODB_BUFFER_PAGE information, grouped by schema and table.

innodb_lock_waits and x\$innodb_lock_waits Sys Schema Views

Summary of InnoDB locks that transactions are waiting upon, by default sort...

io_by_thread_by_latency and x\$io_by_thread_by_latency Sys Schema Views

Summary of I/O consumers to display time waiting for I/O, grouped by thread.

io_global_by_file_by_bytes and x\$io_global_by_file_by_bytes Sys Schema Views

Summary of global I/O consumers showing I/O in bytes grouped by file.

io_global_by_file_by_latency and x\$io_global_by_file_by_latency Sys Schema Views

Summary of global I/O consumers to display time waiting for I/O, grouped by file.

io_global_by_wait_by_bytes and x\$io_global_by_wait_by_bytes Sys Schema Views

Summary of global I/O consumers, displaying amount of I/O and time waiting ...

io_global_by_wait_by_latency and x\$io_global_by_wait_by_latency Sys Schema Views

Summary of global I/O consumers, displaying I/O and time waiting for I/O, grouped by event.

latest_file_io and x\$latest_file_io Sys Schema Views

Summary of file I/O activity, grouped by file and thread.

memory_by_host_by_current_bytes and x\$memory_by_host_by_current_bytes Views

Summarize memory use grouped by host.

metrics Sys Schema View

Global status variables, InnoDB metrics, memory allocation and the current time.

privileges_by_table_by_level Sys Schema View

Granted privileges broken down by table, level on which they were granted.

schema_auto_increment_columns Sys Schema View

AUTO_INCREMENT info, sorted by descending usage ratio and maximum column value.

schema_object_overview Sys Schema View

A count of the number of objects within each schema, sorted by schema and object.

1.1.1.2.9.4.4.1 host_summary and x\$host_summary Sys Schema Views

MariaDB starting with [10.6](#)

These [Sys Schema](#) views were introduced in [MariaDB 10.6](#)

Description

The `host_summary` and `x$host_summary` views contain host activity information, grouped by host. The `host_summary` view is intended to be easier for human reading, while the `x$host_summary` view provides the data in raw form, intended for tools that process the data.

They contain the following columns:

Column	Description
host	Host that the client connected from, or <code>background</code> for background threads (where the <code>HOST</code> column in the underlying Performance Schema table is <code>NULL</code>).
statements	Total number of statements for the host.
statement_latency	Total wait time of timed statements for the host.
statement_avg_latency	Average wait time per timed statement for the host.
table_scans	Total table scans for the host.
file_ios	Total file I/O events for the host.
file_io_latency	Total wait time of timed file I/O events for the host.
current_connections	Current connections for the host.

total_connections	Total connections for the host.
unique_users	Number of distinct users for the host.
current_memory	Current allocated memory for the host.
total_memory_allocated	Total allocated memory for the host.

Example

```

SELECT * FROM sys.host_summary\G
***** 1. row *****
      host: localhost
      statements: 59
      statement_latency: 148.11 ms
      statement_avg_latency: 2.51 ms
      table_scans: 11
      file_ios: 2065
      file_io_latency: 79.57 ms
      current_connections: 1
      total_connections: 3
      unique_users: 1
      current_memory: -2672 bytes

1.1.1.2.9.4.4.2 host_summary_by_file_io and x\$host_summary_by_file_io Sys Schema Views

MariaDB starting with [10.6](#)
 These [Sys Schema](#) views were introduced in [MariaDB 10.6](#)

Description

The `host_summary_by_file_io` and `x$host_summary_by_file_io` views summarize file I/O, grouped by host. Rows are sorted by descending total file I/O latency by default.

The `host_summary_by_file_io` view is intended to be easier for human reading, while the `x$host_summary_by_file_io` view provides the data in raw form, intended for tools that process the data.

They contain the following columns:

Column	Description
host	Host that the client connected from, or <code>background</code> for background threads (where the <code>HOST</code> column in the underlying Performance Schema table is <code>NULL</code>).
ios	Total file I/O events for the host.
ios_latency	Total wait time of timed file I/O events for the host.

Example

```
SELECT * FROM sys.host_summary_by_file_io\G
***** 1. row *****
      host: localhost
      ios: 6526
io_latency: 490.28 ms
***** 2. row *****
      host: background
      ios: 457
io_latency: 151.39 ms

SELECT * FROM sys.x$host_summary_by_file_io\G
***** 1. row *****
      host: localhost
      ios: 6532
io_latency: 490447878974
***** 2. row *****
      host: background
      ios: 457
io_latency: 151388125856
```

1.1.1.2.9.4.4.3 host_summary_by_stages and x\$host_summary_by_stages Sys Schema Views

MariaDB starting with [10.6](#)
These [Sys Schema](#) views were introduced in [MariaDB 10.6](#).

Description

The `host_summary_by_stages` and `x$host_summary_by_stages` views summarize statement stages, grouped by host. Rows are sorted by host and descending total latency by default. The `host_summary_by_stages` view is intended to be easier for human reading, while the `x$host_summary_by_stages` view provides the data in raw form, intended for tools that process the data.

They contain the following columns:

Column	Description
host	Host that the client connected from, or <code>background</code> for background threads (where the <code>HOST</code> column in the underlying Performance Schema table is <code>NULL</code>).
event_name	Stage event name.
total	Total number of occurrences of the file stage event for the host.
total_latency	Total wait time of timed occurrences of the stage event for the host.
avg_latency	Average wait time per timed occurrence of the stage event for the host.

Example

```

SELECT * FROM sys.host_summary_by_stages\G
***** 1. row *****
      host: background
      event_name: stage/innodb/buffer pool load
      total: 1
total_latency: 3.75 ms
  avg_latency: 3.75 ms

SELECT * FROM sys.x$host_summary_by_stages\G
***** 1. row *****
      host: background
      event_name: stage/innodb/buffer pool load
      total: 1
total_latency: 3747098000
  avg_latency: 3747098000

```

1.1.1.2.9.4.4.4 host_summary_by_file_io_type and x\$host_summary_by_file_io_type Sys Schema Views

MariaDB starting with [10.6](#)

These [Sys Schema](#) views were introduced in [MariaDB 10.6](#)

Description

The `host_summary_by_file_io_type` and `x$host_summary_by_file_io_type` views summarize file I/O, grouped by host and event type. Rows are sorted by host and descending total I/O latency by default. The `host_summary_by_file_io_type` view is intended to be easier for human reading, while the `x$host_summary_by_file_io_type` view provides the data in raw form, intended for tools that process the data.

They contain the following columns:

Column	Description
host	Host that the client connected from, or <code>background</code> for background threads (where the <code>HOST</code> column in the underlying Performance Schema table is <code>NULL</code>).
event_name	File I/O event name.
total	Total number of occurrences of the file I/O event for the host.
total_latency	Total wait time of timed occurrences of the file I/O event for the host.
max_latency	Maximum single wait time of timed occurrences of the file I/O event for the host.

Example

```

SELECT * FROM sys.host_summary_by_file_io_type;
+-----+-----+-----+-----+-----+
| host      | event_name                                     | total | total_latency | max_latency |
+-----+-----+-----+-----+-----+
| background | wait/io/file/innodb/innodb_log_file         | 45    | 109.80 ms     | 26.48 ms    |
| background | wait/io/file/innodb/innodb_data_file        | 195   | 29.47 ms      | 1.23 ms     |
| background | wait/io/file/sql/global_ddl_log             | 4     | 4.45 ms       | 4.33 ms     |
...
| localhost  | wait/io/file/csv/data                        | 4     | 25.98 us      | 9.60 us     |
| localhost  | wait/io/file/partition/ha_partition::parfile | 1     | 14.19 us      | 14.19 us    |
| localhost  | wait/io/file/myisam/kfile                    | 1     | 11.95 us      | 11.95 us    |
+-----+-----+-----+-----+-----+

SELECT * FROM sys.x$host_summary_by_file_io_type;

| host      | event_name                                     | total | total_latency | max_latency |
+-----+-----+-----+-----+-----+
| background | wait/io/file/innodb/innodb_log_file         | 45    | 109804643160 | 26478157582 |
| background | wait/io/file/innodb/innodb_data_file        | 195   | 29469738630  | 1226986584  |
| background | wait/io/file/sql/global_ddl_log             | 4     | 4447263252   | 4327780456  |
| localhost  | wait/io/file/csv/data                        | 4     | 25978718     | 9603922     |
| localhost  | wait/io/file/partition/ha_partition::parfile | 1     | 14191190     | 14191190    |
| localhost  | wait/io/file/myisam/kfile                    | 1     | 11954300     | 11954300    |
+-----+-----+-----+-----+-----+

```

1.1.1.2.9.4.4.5 host_summary_by_statement_latency and x\$host_summary_by_statement_latency Sys Schema Views

MariaDB starting with [10.6](#)
These [Sys Schema](#) views were introduced in [MariaDB 10.6](#).

Description

The `host_summary_by_statement_latency` and `x$host_summary_by_statement_latency` views summarize statement statistics, grouped by host. Rows are sorted by descending total latency by default. The `host_summary_by_statement_latency` view is intended to be easier for human reading, while the `x$host_summary_by_statement_latency` view provides the data in raw form, intended for tools that process the data.

They contain the following columns:

Column	Description
host	Host that the client connected from, or <code>background</code> for background threads (where the <code>HOST</code> column in the underlying Performance Schema table is <code>NULL</code>).
total	Total number of statements for the host.
max_latency	Maximum single wait time of timed statements for the host.
lock_latency	Total time spent by timed statements for the host waiting for locks.
total_latency	Total wait time of timed statements for the host.
rows_sent	Total number of rows returned by statements for the host.
rows_examined	Total number of rows read from storage engines by statements for the host.
rows_affected	Total number of rows affected by statements for the host.
full_scans	Total number of full table scans by statements for the host.

Example

```

SELECT * FROM sys.host_summary_by_statement_latency\G
***** 1. row *****
      host: localhost
      total: 1042
total_latency: 816.89 ms
      max_latency: 64.51 ms
      lock_latency: 215.64 ms
      rows_sent: 750599937895985
rows_examined: 13548
rows_affected: 6
      full_scans: 33
***** 2. row *****
      host: background
      total: 0
total_latency: 0 ps
      max_latency: 0 ps
      lock_latency: 0 ps
      rows_sent: 0
rows_examined: 0
rows_affected: 0
      full_scans: 0

SELECT * FROM sys.x$host_summary_by_statement_latency\G
***** 1. row *****
      host: localhost
      total: 1041
total_latency: 812132706000
      max_latency: 64507216000
      lock_latency: 215301000000
      rows_sent: 750599937895983
rows_examined: 13110
rows_affected: 6
      full_scans: 32
***** 2. row *****

rows_examined: 0
rows_affected: 0
      full_scans: 0

```

1.1.1.2.9.4.4.6

host_summary_by_statement_type and x\$host_summary_by_statement_type Sys Schema Views

MariaDB starting with [10.6](#)

These [Sys Schema](#) views were introduced in [MariaDB 10.6](#).

Description

The `host_summary_by_statement_type` and `x$host_summary_by_statement_type` views summarize information about executed statements, grouped by host and statement type. Rows are sorted by host and descending total latency by default.

The `host_summary_by_statement_type` view is intended to be easier for human reading, while the `x$host_summary_by_statement_type` view provides the data in raw form, intended for tools that process the data.

They contain the following columns:

Column	Description
--------	-------------

host	Host that the client connected from, or <code>background</code> for background threads (where the <code>HOST</code> column in the underlying Performance Schema table is <code>NULL</code>).
statement	Final component of the statement event name, for example <code>create_table</code> or <code>select</code> .
total	Total number of statement occurrences for the host.
total_latency	Total wait time of timed statements of the statement event for the host.
max_latency	Maximum single wait time of timed occurrences of the statement event for the host.
lock_latency	Total time spent by timed occurrences of the statement event for the host waiting for locks.
rows_sent	Total number of rows returned by occurrences of the statement event for the host.
rows_examined	Total number of rows read from storage engines by occurrences of the statement event for the host.
rows_affected	Total number of rows affected by occurrences of the statement event for the host.
full_scans	Total number of full table scans by occurrences of the statement event for the host.

Example

```

SELECT * FROM sys.host_summary_by_statement_type\G
***** 1. row *****
      host: localhost
      statement: create_table
      total: 18
total_latency: 366.93 ms
      max_latency: 48.02 ms
      lock_latency: 3.16 ms
      rows_sent: 0
rows_examined: 0
rows_affected: 0
      full_scans: 0
***** 2. row *****
      host: localhost
      statement: select
      total: 27
total_latency: 339.16 ms
      max_latency: 64.51 ms
      lock_latency: 205.61 ms
      rows_sent: 750599937895926
rows_examined: 13925
rows_affected: 0
      full_scans: 21
...

SELECT * FROM sys.x$host_summary_by_statement_type\G
***** 1. row *****
      host: localhost
      statement: create_table
      total: 18
total_latency: 366927804000
      max_latency: 48023563000
      lock_latency: 3156000000
      rows_sent: 0
rows_examined: 0
rows_affected: 0
      full_scans: 0
***** 2. row *****
      host: localhost
      statement: select
      total: 28
total_latency: 343873182000
      max_latency: 64507216000
      lock_latency: 205984000000
      rows_sent: 750678474440767
rows_examined: 14370
rows_affected: 0
      full_scans: 22

```

1.1.1.2.9.4.4.7 innodb_buffer_stats_by_schema and x\$innodb_buffer_stats_by_schema Sys Schema Views

MariaDB starting with [10.6](#)

These [Sys Schema](#) views were introduced in [MariaDB 10.6](#).

Querying these views can have a noticeable performance impact on a production server.

Description

The `innodb_buffer_stats_by_schema` and `x$innodb_buffer_stats_by_schema` views summarize information from the [Information Schema INNODB_BUFFER_PAGE](#) table, grouped by schema. Rows are sorted by descending buffer size by default.

The `innodb_buffer_stats_by_schema` view is intended to be easier for human reading, while the `x$innodb_buffer_stats_by_schema` view provides the data in raw form, intended for tools that process the data.

They contain the following columns:

Column	Description
<code>object_schema</code>	Object schema name, or <code>InnoDB System</code> if the table belongs to the InnoDB storage engine .
<code>allocated</code>	Total number of bytes allocated for the schema.
<code>data</code>	Total number of data bytes allocated for the schema.
<code>pages</code>	Total number of pages allocated for the schema.
<code>pages_hashed</code>	Total number of hashed pages allocated for the schema.
<code>pages_old</code>	Total number of old pages allocated for the schema.
<code>rows_cached</code>	Total number of cached rows for the schema.

Example

```

SELECT * FROM sys.innodb_buffer_stats_by_schema\G
***** 1. row *****
object_schema: InnoDB System
  allocated: 160.00 KiB
    data: 6.21 KiB
    pages: 10
  pages_hashed: 10
    pages_old: 10
  rows_cached: 21
***** 2. row *****
object_schema: mysql
  allocated: 112.00 KiB
    data: 1.73 KiB
    pages: 7
  pages_hashed: 7
    pages_old: 7
  rows_cached: 5
***** 3. row *****
object_schema: test
  allocated: 64.00 KiB
    data: 0 bytes
    pages: 4
  pages_hashed: 4
    pages_old: 4
  rows_cached: 0

SELECT * FROM sys.x$innodb_buffer_stats_by_schema\G
***** 1. row *****
object_schema: InnoDB System
  allocated: 163840
    data: 6362
    pages: 10
  pages_hashed: 0
    pages_old: 0
  rows_cached: 21
***** 2. row *****
object_schema: mysql
  allocated: 114688
    data: 1775
    pages: 7
  pages_hashed: 0
    pages_old: 0
  rows_cached: 5
***** 3. row *****
object_schema: test
  allocated: 65536
    data: 0
    pages: 4
  pages_hashed: 0
    pages_old: 0
  rows_cached: 0

```

1.1.1.2.9.4.4.8 innodb_buffer_stats_by_table and x\$innodb_buffer_stats_by_table Sys Schema Views

MariaDB starting with [10.6](#)

These [Sys Schema](#) views were introduced in [MariaDB 10.6](#).

Querying these views can have a noticeable performance impact on a production server.

Description

The `innodb_buffer_stats_by_table` and `x$innodb_buffer_stats_by_table` views summarize information from the

[Information Schema INNODB_BUFFER_PAGE table](#), grouped by schema and table. Rows are sorted by descending buffer size by default.

The `innodb_buffer_stats_by_table` view is intended to be easier for human reading, while the `x$innodb_buffer_stats_by_table` view provides the data in raw form, intended for tools that process the data.

They contain the following columns:

Column	Description
<code>object_schema</code>	Object schema name, or <code>InnoDB System</code> if the table belongs to the InnoDB storage engine .
<code>object_name</code>	Table name.
<code>allocated</code>	Total number of bytes allocated for the table.
<code>data</code>	Number of data bytes allocated for the table.
<code>pages</code>	Total number of pages allocated for the table.
<code>pages_hashed</code>	Total number of hashed pages allocated for the table.
<code>pages_old</code>	Total number of old pages allocated for the table.
<code>rows_cached</code>	Total number of cached rows for the table.

Example

```

SELECT * FROM sys.innodb_buffer_stats_by_table\G
***** 1. row *****
object_schema: mysql
  object_name: transaction_registry
    allocated: 64.00 KiB
      data: 0 bytes
        pages: 4
pages_hashed: 4
  pages_old: 4
    rows_cached: 0
***** 2. row *****
object_schema: InnoDB System
  object_name: SYS_FOREIGN
    allocated: 48.00 KiB
      data: 0 bytes
        pages: 3
pages_hashed: 3
  pages_old: 3
    rows_cached: 0
***** 3. row *****
object_schema: InnoDB System
  object_name: SYS_TABLES
    allocated: 32.00 KiB
      data: 1.07 KiB
        pages: 2
pages_hashed: 2
  pages_old: 2
    rows_cached: 10
...

SELECT * FROM sys.x$innodb_buffer_stats_by_table\G
***** 1. row *****
object_schema: mysql
  object_name: transaction_registry
    allocated: 65536
      data: 0
        pages: 4
pages_hashed: 0
  pages_old: 0
    rows_cached: 0
***** 2. row *****
object_schema: InnoDB System
  object_name: SYS_FOREIGN
    allocated: 49152
      data: 0
        pages: 3
pages_hashed: 0
  pages_old: 0
    rows_cached: 0
***** 3. row *****
object_schema: InnoDB System
  object_name: SYS_TABLES
    allocated: 32768
      data: 1100
        pages: 2
pages_hashed: 0
  pages_old: 0
    rows_cached: 10
....

```

1.1.1.2.9.4.4.9 innodb_lock_waits and x\$innodb_lock_waits Sys Schema Views

MariaDB starting with [10.6](#)

These [Sys Schema](#) views were introduced in [MariaDB 10.6](#).

Description

The `innodb_lock_waits` and `x$innodb_lock_waits` views summarize InnoDB locks that transactions are waiting upon, by default sorted in descending buffer size.

The `innodb_lock_waits` view is intended to be easier for human reading, while the `x$innodb_lock_waits` view provides the data in raw form, intended for tools that process the data.

They contain the following columns:

Column	Description
<code>wait_started</code>	Time that lock wait began.
<code>wait_age</code>	TIME value for the length of the lock wait.
<code>wait_age_secs</code>	Seconds value for the length of the lock wait.
<code>locked_table_schema</code>	Schema containing the locked table.
<code>locked_table_name</code>	Name of the locked table.
<code>locked_table_partition</code>	Name of the locked partition, or NULL if none.
<code>locked_table_subpartition</code>	Name of the locked subpartition, or NULL if none.
<code>locked_index</code>	Name of the locked index.
<code>locked_type</code>	Type of the waiting lock.
<code>waiting_trx_id</code>	ID of the waiting transaction.
<code>waiting_trx_started</code>	Time that the waiting transaction started.
<code>waiting_trx_age</code>	TIME value for the length of time that the transaction has been waiting.
<code>waiting_trx_rows_locked</code>	Number of rows locked by the waiting transaction.
<code>waiting_trx_rows_modified</code>	Number of rows modified by the waiting transaction.
<code>waiting_pid</code>	Processlist ID of the waiting transaction.
<code>waiting_query</code>	Statement waiting for the lock.
<code>waiting_lock_id</code>	ID of the waiting lock.
<code>waiting_lock_mode</code>	Mode of the waiting lock.
<code>blocking_trx_id</code>	ID of the transaction blocking the waiting lock.
<code>blocking_pid</code>	Processlist ID of the blocking transaction.
<code>blocking_query</code>	Statement the blocking transaction is executing, or NULL if the session that issued the blocking query has become idle.
<code>blocking_lock_id</code>	ID of the lock blocking the waiting lock.
<code>blocking_lock_mode</code>	Mode of the lock blocking the waiting lock.
<code>blocking_trx_started</code>	Time the blocking transaction started.
<code>blocking_trx_age</code>	TIME value for how long the blocking transaction has been executing.
<code>blocking_trx_rows_locked</code>	Number of rows locked by the blocking transaction.
<code>blocking_trx_rows_modified</code>	Number of rows modified by the blocking transaction.
<code>sql_kill_blocking_query</code>	KILL statement that could be used to kill the blocking statement.
<code>sql_kill_blocking_connection</code>	KILL statement that could be used to kill the blocking statement session.

1.1.1.2.9.4.4.10 `io_by_thread_by_latency` and `x$io_by_thread_by_latency` Sys Schema Views

MariaDB starting with [10.6](#)

These [Sys Schema](#) views were introduced in [MariaDB 10.6](#).

Description

The `io_by_thread_by_latency` and `x$io_by_thread_by_latency` view summarize I/O consumers to display time waiting for I/O, grouped by thread. Rows are sorted by descending total I/O latency by default.

The `io_by_thread_by_latency` view is intended to be easier for human reading, while the `x$io_by_thread_by_latency` view provides the data in raw form, intended for tools that process the data.

They contain the following columns:

Column	Description
user	The account associated with a foreground thread, or the background thread name
total	Total number of I/O events allocated for the thread.
total_latency	Total wait time of timed I/O events for the thread.
min_latency	Minimum single wait time of timed I/O events for the thread.
avg_latency	Average wait time per timed I/O event for the thread.
max_latency	Maximum single wait time of timed I/O events for the thread.
thread_id	Thread id.
processlist_id	Processlist id for foreground threads, or NULL for background threads.

Example

```
SELECT * FROM sys.io_by_thread_by_latency\G
***** 1. row *****
      user: main
      total: 378
total_latency: 40.11 ms
  min_latency: 570.21 ns
   avg_latency: 206.02 us
   max_latency: 4.33 ms
     thread_id: 1
processlist_id: NULL
***** 2. row *****
      user: msandbox@localhost
      total: 521
total_latency: 10.28 ms
  min_latency: 775.04 ns
   avg_latency: 21.79 us
   max_latency: 977.79 us
     thread_id: 89
processlist_id: 7
...

SELECT * FROM sys.x$io_by_thread_by_latency\G
***** 1. row *****
      user: main
      total: 378
total_latency: 40106340880
  min_latency: 570208
   avg_latency: 206016046.6000
   max_latency: 4327780456
     thread_id: 1
processlist_id: NULL
***** 2. row *****
      user: msandbox@localhost
      total: 498
total_latency: 9637694714
  min_latency: 775040
   avg_latency: 21364289.0000
   max_latency: 977787350
     thread_id: 89
processlist_id: 7

```

1.1.1.2.9.4.4.11 io_global_by_file_by_bytes and x\$io_global_by_file_by_bytes Sys Schema Views

MariaDB starting with [10.6](#)

These [Sys Schema](#) views were introduced in [MariaDB 10.6](#).

Description

The `io_global_by_file_by_bytes` and `x$io_global_by_file_by_bytes` views summarize global I/O consumers showing I/O in bytes, grouped by file. Rows are sorted by descending total I/O (bytes read and written) by default.

The `io_global_by_file_by_bytes` view is intended to be easier for human reading, while the `x$io_global_by_file_by_bytes` view provides the data in raw form, intended for tools that process the data.

They contain the following columns:

Column	Description
file	File path name.
count_read	Total number of read events for the file.
total_read	Total number of bytes read from the file.
avg_read	Average number of bytes per read from the file.
count_write	Total number of write events for the file.
total_written	Total number of bytes written to the file.
avg_write	Average number of bytes per write to the file.
total	Total number of bytes read and written for the file.
write_pct	Percentage of total I/O bytes that were writes.

Example

```

SELECT * FROM sys.io_global_by_file_by_bytes\G
...
***** 3. row *****
      file: @@datadir/ddl_recovery.log
      count_read: 0
      total_read: 0 bytes

1.1.1.2.9.4.4.12 io_global_by_file_by_latency and x\$io_global_by_file_by_latency Sys Schema Views

MariaDB starting with [10.6](#)

These [Sys Schema](#) views were introduced in [MariaDB 10.6](#).

Description

The `io_global_by_file_by_latency` and `x$io_global_by_file_by_latency` views summarize global I/O consumers to display time waiting for I/O, grouped by file. Rows are sorted by descending total latency by default.

The `io_global_by_file_by_latency` view is intended to be easier for human reading, while the `x$io_global_by_file_by_latency` view provides the data in raw form, intended for tools that process the data.

They contain the following columns:

Column	Description
--------	-------------

file	File path name.
total	Total number of I/O events for the file.
total_latency	Total wait time of timed I/O events for the file.
count_read	Total number of read I/O events for the file.
read_latency	Total wait time of timed read I/O events for the file.
count_write	Total number of write I/O events for the file.
write_latency	Total wait time of timed write I/O events for the file.
count_misc	Total number of other I/O events for the file.
misc_latency	Total wait time of timed other I/O events for the file.

Example

```

SELECT * FROM sys.io_global_by_file_by_latency\G
***** 1. row *****
      file: @@datadir/ddl_recovery.log
      total: 222

1.1.1.2.9.4.4.13 io_global_by_wait_by_bytes and x\$io_global_by_wait_by_bytes Sys Schema

Views

MariaDB starting with [10.6](#)

These [Sys Schema](#) views were introduced in [MariaDB 10.6](#).

Description

The `io_global_by_wait_by_bytes` and `x$io_global_by_wait_by_bytes` views summarize global I/O consumers, displaying amount of I/O and time waiting for I/O, grouped by event. Rows are sorted by descending total I/O (bytes read and written) by default.

The `io_global_by_wait_by_bytes` view is intended to be easier for human reading, while the `x$io_global_by_wait_by_bytes` view provides the data in raw form, intended for tools that process the data.

They contain the following columns:

Column	Description
<code>event_name</code>	I/O event name. The wait/io/file prefix is stripped.
<code>total</code>	Total number of occurrences of the I/O event.
<code>total_latency</code>	Total wait time of timed occurrences of the I/O event
<code>min_latency</code>	Minimum single wait time of timed occurrences of the I/O event.
<code>avg_latency</code>	Average wait time per timed occurrence of the I/O event.
<code>max_latency</code>	Maximum single wait time of timed occurrences of the I/O event.
<code>count_read</code>	Total number of read I/O events for the file.
<code>total_read</code>	Total number of bytes read for the I/O event.
<code>avg_read</code>	Average number of bytes per read for the I/O event.
<code>count_write</code>	Total number of write requests for the I/O event.
<code>total_written</code>	Number of bytes written for the I/O event.
<code>avg_written</code>	Average number of bytes per write for the I/O event.
<code>total_requested</code>	Total number of bytes (read and write) for the I/O event.

Example

```

SELECT * FROM sys.io_global_by_wait_by_bytes\G
***** 1. row *****
    event_name: innodb/innodb_data_file
        total: 220

1.1.1.2.9.4.4.14 latest_file_io and x\$latest_file_io Sys Schema Views

MariaDB starting with [10.6](#)

These [Sys Schema](#) views were introduced in [MariaDB 10.6](#).

Description

The `latest_file_io` and `x$latest_file_io` views summarize file I/O activity, grouped by file and thread. Rows are sorted by most recent I/O by default.

The `latest_file_io` view is intended to be easier for human reading, while the `x$latest_file_io` view provides the data in raw form, intended for tools that process the data.

They contain the following columns:

Column	Description
thread	Account associated with the thread for foreground threads (port number for TCP/IP connections), or thread name and thread ID for background threads.
total	Total number of occurrences of the I/O event.
file	File path name.
latency	Wait time of the file I/O event.
operation	Type of operation
requested	Number of bytes requested for the file I/O event.

1.1.1.2.9.4.4.15 io_global_by_wait_by_latency and x\$io_global_by_wait_by_latency Sys Schema Views

MariaDB starting with [10.6](#)
These [Sys Schema](#) views were introduced in [MariaDB 10.6](#).

Description

The `io_global_by_wait_by_latency` and `x$io_global_by_wait_by_latency` views summarize global I/O consumers, displaying I/O and time waiting for I/O, grouped by event. Rows are sorted by descending total latency by default.

The `io_global_by_wait_by_latency` view is intended to be easier for human reading, while the `x$io_global_by_wait_by_latency` view provides the data in raw form, intended for tools that process the data.

They contain the following columns:

Column	Description
event_name	I/O event name. The wait/io/file prefix is stripped.
total	Total number of occurrences of the I/O event.
total_latency	Total wait time of timed occurrences of the I/O event.
min_latency	Minimum single wait time of timed occurrences of the I/O event.
avg_latency	Average wait time per timed occurrence of the I/O event.
max_latency	Maximum single wait time of timed occurrences of the I/O event.
count_read	Total number of read request for the I/O event.
total_read	Total number of bytes read for the I/O event.
avg_read	Average number of bytes per read for the I/O event.
count_write	Total number of write requests for the I/O event.
total_written	Number of bytes written for the I/O event.
avg_written	Average number of bytes per write for the I/O event.
total_requested	Total number of bytes (read and write) for the I/O event.

Example

```
SELECT * FROM sys.io_global_by_wait_by_latency\G
***** 1. row *****
  event_name: sql/global_ddl_log
    total: 223
total_latency: 288.66 ms

1.1.1.2.9.4.4.16

memory_by_host_by_current_bytes and x\$memory_by_host_by_current_bytes Views

MariaDB starting with [10.6](#)

These [Sys Schema](#) views were introduced in [MariaDB 10.6](#).

Description

The `memory_by_host_by_current_bytes` and `x$memory_by_host_by_current_bytes` summarize memory use grouped by host. Rows by default are sorted by descending amount of memory used.

The `memory_by_host_by_current_bytes` view is intended to be easier for human reading, while the `x$memory_by_host_by_current_bytes` view provides the data in raw form, intended for tools that process the data.

They contain the following columns:

Column	Description
host	Host from which the client connected. If the HOST column in the underlying Performance Schema table is NULL, rows are assumed to be for background threads, and the background host name is used.
current_count_used	Current number of allocated memory blocks that have not yet been freed for the host.
current_allocated	Current number of allocated bytes that have not yet been freed for the host.
current_avg_alloc	Current number of allocated bytes per memory block for the host.
current_max_alloc	Largest single current memory allocation in bytes for the host.
total_allocated	Total memory allocation in bytes for the host.

1.1.1.2.9.4.4.17 metrics Sys Schema View

MariaDB starting with [10.6](#)

The [Sys Schema](#) was introduced in [MariaDB 10.6](#)

Description

The `metrics` view contains global status variables (as found in the [Performance Schema global_status Table](#)), InnoDB metrics (as found in the [Information Schema INNODB_METRICS Table](#), current and total memory allocation, based on the Performance Schema memory instrumentation, as well the current time in human readable and Unix timestamp formats.

It contains the following columns:

Column	Description
Variable_name	The name of the metric. One of the VARIABLE_NAME column if a global_status table, the NAME column if an InnoDB metric, or a description for other metrics.
Variable_value	The metric value. One of the VARIABLE_VALUE column if a global status variable, the COUNT column for InnoDB metrics, the related column from the Performance Schema memory_summary_global_by_event_name table , the value of NOW(3) or UNIX_TIMESTAMP(NOW(3)) .
Type	Metric type. One of <code>Global Status</code> , <code>InnoDB Metrics - %</code> (with % being the value of the SUBSYSTEM column in the INNODB_METRICS table, <code>Performance Schema</code> or <code>System Time</code>
Enabled	Whether the metric is enabled. Always <code>YES</code> for global status variables and the current time. For InnoDB metrics, <code>YES</code> only if the STATUS column of the INNODB_METRICS table, otherwise <code>NO</code> . For memory metrics: <code>YES</code> , <code>NO</code> or <code>PARTIAL</code> (for metrics where not all memory/% instruments are enabled). Performance Schema memory instruments are always enabled)

Example

```

SELECT * FROM sys.metrics\G
***** 1. row *****
Variable_name: aborted_clients
Variable_value: 0
Type: Global Status
Enabled: YES
***** 2. row *****
Variable_name: aborted_connects
Variable_value: 0
Type: Global Status
Enabled: YES

...

***** 578. row *****
Variable_name: trx_undo_slots_used
Variable_value: 0
Type: InnoDB Metrics - transaction
Enabled: YES
***** 579. row *****
Variable_name: NOW()
Variable_value: 2024-09-09 16:16:08.745
Type: System Time
Enabled: YES
***** 580. row *****
Variable_name: UNIX_TIMESTAMP()
Variable_value: 1725891368.745
Type: System Time
Enabled: YES

```

1.1.1.2.9.4.4.18 privileges_by_table_by_level Sys Schema View

MariaDB starting with [11.4](#)

This [Sys Schema](#) view was introduced in [MariaDB 11.4.0](#).

Description

Shows granted privileges broken down by table on which they allow access and level on which they were granted.

For example, if a user `x` has `SELECT` privilege granted `ON db.*`, this view will list all tables in the `db` schema with the user `x` having `SELECT` privilege on them. This is different from `INFORMATION_SCHEMA.TABLE_PRIVILEGES`, which only lists privileges granted on the table level.

Column	Description
TABLE_SCHEMA	Database name.
TABLE_NAME	Table name.
GRANTEE	Account name that was granted the privilege.
PRIVILEGE	Privilege, such as <code>SELECT</code> or <code>DROP</code> .
LEVEL	Privilege level, such as <code>GLOBAL</code> or <code>SCHEMA</code> .

Example

```

SELECT * FROM sys.privileges_by_table_by_level;
+-----+-----+-----+-----+
| TABLE_SCHEMA | TABLE_NAME | GRANTEE          | PRIVILEGE | LEVEL |
+-----+-----+-----+-----+
...
| test         | t2          | 'root'@'localhost' | SELECT    | GLOBAL |

schema_auto_increment_columns Sys Schema View

MariaDB starting with [10.6](#)
The [Sys Schema](#) was introduced in [MariaDB 10.6](#)

Description

Information about [AUTO_INCREMENT](#) columns, sorted by descending usage ratio and maximum column value. Does not include columns in the mysql, sys, information_schema and performance_schema schemas.

Contains the following columns:

Column	Description
table_schema	Schema name containing the table with the auto_increment attribute.
table_name	Table containing the auto_increment attribute.
column_name	Name of the column containing the auto_increment attribute.
data_type	Data type of the auto_increment column, for example tinyint .
column_type	Data type of the auto_increment column, plus additional information for example <code>tinyint(3) unsigned</code> .
is_signed	1 if the column is signed , 0 if not.
is_unsigned	1 if the column is unsigned, 0 if it is.
max_value	Maximum possible value for the column, for example <code>255</code> for an unsigned tinyint .
auto_increment	Current auto_increment value for the column.
auto_increment_ratio	Ratio of used to maximum value for the auto_increment column.

Example

```
CREATE OR REPLACE TABLE animals (  
  id TINYINT NOT NULL AUTO_INCREMENT,  
  name CHAR(30) NOT NULL,  
  PRIMARY KEY (id)  
);  
  
INSERT INTO animals (name) VALUES  
  ('dog'),('cat'),('penguin'),  
  ('fox'),('whale'),('ostrich');  
  
SELECT * FROM sys.schema_auto_increment_columns\G  
***** 1. row *****  
  table_schema: test  
    table_name: animals  
   column_name: id  
    data_type: tinyint  
   column_type: tinyint(4)  
     is_signed: 1  
   is_unsigned: 0  
      max_value: 127  
   auto_increment: 7  
auto_increment_ratio: 0.0551
```

1.1.1.2.9.4.4.20 schema_object_overview Sys Schema View

MariaDB starting with [10.6](#)
The [Sys Schema](#) was introduced in [MariaDB 10.6](#)

Description

A count of the number of objects within each schema, sorted by schema and object.

Contains the following columns:

Column	Description
db	Schema name
object_type	Object name
count	Count of the number of objects

Example

```
SELECT * FROM sys.schema_object_overview;
+-----+-----+-----+
| db          | object_type | count |
+-----+-----+-----+
| information_schema | SYSTEM VIEW | 79 |
| mysql       | BASE TABLE | 30 |
| mysql       | INDEX (BTREE) | 76 |
| mysql       | PROCEDURE   | 2 |
| mysql       | VIEW        | 1 |
| performance_schema | BASE TABLE | 81 |
| sys         | BASE TABLE | 1 |
| sys         | FUNCTION    | 22 |
| sys         | INDEX (BTREE) | 1 |
| sys         | PROCEDURE   | 26 |
| sys         | VIEW        | 100 |
+-----+-----+-----+
```

1.1.1.2.9.5 mariadb_schema

Contents

1. History

`mariadb_schema` is a data type qualifier that allows one to create MariaDB native date types in an `SQL_MODE` that has conflicting data type translations.

`mariadb_schema` was introduced in [MariaDB 10.3.24](#), [MariaDB 10.4.14](#) and [MariaDB 10.5.5](#).

For example, in `SQL_MODE=ORACLE`, if one creates a table with the `DATE` type, it will actually create a `DATETIME` column to match what an Oracle user is expecting. To be able to create a MariaDB `DATE` in Oracle mode one would have to use `mariadb_schema`:

```
CREATE TABLE t1 (d mariadb_schema.DATE);
```

`mariadb_schema` is also shown if one creates a table with `DATE` in MariaDB native mode and then does a `SHOW CREATE TABLE` in `ORACLE` mode:

```
SET sql_mode=DEFAULT;
CREATE OR REPLACE TABLE t1 (
  d DATE
);
SET SQL_mode=ORACLE;
SHOW CREATE TABLE t1;
+-----+-----+-----+
| Table | Create Table |
+-----+-----+-----+
| t1    | CREATE TABLE "t1" (
  "d" mariadb_schema.date DEFAULT NULL
) |
+-----+-----+-----+
```

When the server sees the `mariadb_schema` qualifier, it disables `sql_mode`-specific data type translation and interprets the data type literally, so for example `mariadb_schema.DATE` is interpreted as the traditional MariaDB `DATE` data type, no matter what the current `sql_mode` is.

The `mariadb_schema` prefix is displayed only when the data type name would be ambiguous otherwise. The prefix is displayed together with MariaDB `DATE` when [SHOW CREATE TABLE](#) is executed in `SQL_MODE=ORACLE`. The prefix is not displayed when [SHOW CREATE TABLE](#) is executed in `SQL_MODE=DEFAULT`, or when a non-ambiguous data type is displayed.

Note, the `mariadb_schema` prefix can be used with any data type, including non-ambiguous ones:

```
CREATE OR REPLACE TABLE t1 (a mariadb_schema.INT);
SHOW CREATE TABLE t1;
+-----+-----+
| Table | Create Table |
+-----+-----+
| t1    | CREATE TABLE "t1" (
|      | "a" int(11) DEFAULT NULL
|      | ) |
+-----+-----+
```

Currently the `mariadb_schema` prefix is only used in the following case:

- For a MariaDB native `DATE` type when running [SHOW CREATE TABLE](#) in [Oracle mode](#).

History

When running with `SQL_MODE=ORACLE`, MariaDB server translates the data type `DATE` to `DATETIME`, for better Oracle compatibility:

```
SET SQL_mode=ORACLE;
CREATE OR REPLACE TABLE t1 (
  d DATE
);
SHOW CREATE TABLE t1;
+-----+-----+
| Table | Create Table |
+-----+-----+
| t1    | CREATE TABLE "t1" (
|      | "d" datetime DEFAULT NULL
|      | ) |
+-----+-----+
```

Notice, `DATE` was translated to `DATETIME`.

This translation may cause some ambiguity. Suppose a user creates a table with a column of the traditional MariaDB `DATE` data type using the default `sql_mode`, but then switches to `SQL_MODE=ORACLE` and runs a [SHOW CREATE TABLE](#) statement:

```
SET sql_mode=DEFAULT;
CREATE OR REPLACE TABLE t1 (
  d DATE
);
SET SQL_mode=ORACLE;
SHOW CREATE TABLE t1;
```

Before `mariadb_schema` was introduced, the above script displayed:

```
CREATE TABLE "t1" (
  "d" date DEFAULT NULL
);
```

which had two problems:

- It was confusing for the reader: its not clear if it is the traditional MariaDB `DATE`, or is it Oracle-alike date (which is actually `DATETIME`);
- It broke replication and caused data type mismatch on the master and on the slave (see [MDEV-19632](#) [↗](#)).

To address this problem, starting from the mentioned versions, MariaDB uses the idea of qualified data types:

```

SET sql_mode=DEFAULT;
CREATE OR REPLACE TABLE t1 (
  d DATE
);
SET SQL_mode=ORACLE;
SHOW CREATE TABLE t1;
+-----+-----+
| Table | Create Table |
+-----+-----+
| t1    | CREATE TABLE "t1" (
  "d" mariadb_schema.date DEFAULT NULL
) |
+-----+-----+

```

1.1.1.2.9.6 Writing Logs Into Tables

By default, all logs are disabled or written into files. The [general query log](#) and the [slow query log](#) can also be written to special tables in the `mysql` database. During the startup, entries will always be written into files.

Note that [EXPLAIN output](#) will only be recorded if the slow query log is written to a file and not to a table.

To write logs into tables, the `log_output` server system variable is used. Allowed values are `FILE`, `TABLE` and `NONE`. It is possible to specify multiple values, separated with commas, to write the logs into both tables and files. `NONE` disables logging and has precedence over the other values.

So, to write logs into tables, one of the following settings can be used:

```

SET GLOBAL log_output = 'TABLE';
SET GLOBAL log_output = 'FILE, TABLE';

```

The general log will be written into the [general_log](#) table, and the slow query log will be written into the [slow_log](#) table. Only a limited set of operations are supported for those special tables. For example, direct DML statements (like `INSERT`) on those tables will fail with an error similar to the following:

```

ERROR 1556 (HY000): You can't use locks with log tables.

```

To flush data to the tables, use [FLUSH TABLES](#) instead of [FLUSH LOGS](#).

To empty the contents of the log tables, [TRUNCATE TABLE](#) can be used.

The log tables use the [CSV](#) storage engine by default. This allows an external program to read the files if needed: normal CSV files are stored in the `mysql` subdirectory, in the data dir. However that engine is slow because it does not support indexes, so you can convert the tables to [MyISAM](#) (but not other storage engines). To do so, first temporarily disable logging:

```

SET GLOBAL general_log = 'OFF';
ALTER TABLE mysql.general_log ENGINE = MyISAM;
ALTER TABLE mysql.slow_log ENGINE = MyISAM;
SET GLOBAL general_log = @old_log_state;

```

[CHECK TABLE](#) and [CHECKSUM TABLE](#) are supported.

[CREATE TABLE](#) is supported. [ALTER TABLE](#), [RENAME TABLE](#) and [DROP TABLE](#) are supported when logging is disabled, but log tables cannot be partitioned.

Contents of log tables are not logged in the [binary log](#), thus cannot be replicated.

1.1.1.2.10 BINLOG

Syntax

```

BINLOG 'str'

```

Description

`BINLOG` is an internal-use statement. It is generated by the [mariadb-binlog](#) program as the printable representation of certain events in [binary log](#) files. The `'str'` value is a base 64-encoded string that the server decodes to determine the data change indicated by the corresponding event. This statement requires the [SUPER](#) privilege ([<= MariaDB 10.5.1](#)) or the [BINLOG REPLAY](#) privilege ([>= MariaDB 10.5.2](#)).

1.1.1.2.11 PURGE BINARY LOGS

Syntax

```
PURGE { BINARY | MASTER } LOGS
      { TO 'log_name' | BEFORE datetime_expr }
```

Description

The `PURGE BINARY LOGS` statement deletes all the [binary log](#) files listed in the log index file prior to the specified log file name or date. `BINARY` and `MASTER` are synonyms. Deleted log files also are removed from the list recorded in the index file, so that the given log file becomes the first in the list.

The datetime expression is in the format 'YYYY-MM-DD hh:mm:ss'.

If a replica is active but has yet to read from a binary log file you attempt to delete, the statement will fail with an error. However, if the replica is not connected and has yet to read from a log file you delete, the file will be deleted, but the replica will be unable to continue replicating once it connects again.

This statement has no effect if the server was not started with the `--log-bin` option to enable binary logging.

To list the binary log files on the server, use [SHOW BINARY LOGS](#). To see which files they are reading, use [SHOW SLAVE STATUS](#) (or [SHOW REPLICA STATUS](#) from [MariaDB 10.5.1](#)). You can only delete the files that are older than the oldest file that is used by the slaves.

To delete all binary log files, use [RESET MASTER](#). To move to a new log file (for example if you want to remove the current log file), use [FLUSH LOGS](#) before you execute `PURGE LOGS`.

If the `expire_logs_days` server system variable is not set to 0, the server automatically deletes binary log files after the given number of days. From [MariaDB 10.6](#), the `binlog_expire_logs_seconds` variable allows more precise control over binlog deletion, and takes precedence if both are non-zero.

Requires the [SUPER](#) privilege or, from [MariaDB 10.5.2](#), the [BINLOG ADMIN](#) privilege, to run.

Examples

```
PURGE BINARY LOGS TO 'mariadb-bin.000063';
```

```
PURGE BINARY LOGS BEFORE '2013-04-21';
```

```
PURGE BINARY LOGS BEFORE '2013-04-22 09:55:22';
```

1.1.1.2.12 CACHE INDEX

Syntax

```
CACHE INDEX
      tbl_index_list [, tbl_index_list] ...
      IN key_cache_name

tbl_index_list:
      tbl_name [[INDEX|KEY] (index_name[, index_name] ...)]
```

Description

The `CACHE INDEX` statement assigns table indexes to a specific key cache. It is used only for [MyISAM](#) tables.

A default key cache exists and cannot be destroyed. To create more key caches, the [key_buffer_size](#) server system variable.

The associations between tables indexes and key caches are lost on server restart. To recreate them automatically, it is necessary to configure caches in a [configuration file](#) and include some `CACHE INDEX` (and optionally `LOAD INDEX`) statements in the init file.

Examples

The following statement assigns indexes from the tables t1, t2, and t3 to the key cache named hot_cache:

```
CACHE INDEX t1, t2, t3 IN hot_cache;
+-----+-----+-----+-----+
| Table  | Op           | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.t1 | assign_to_keycache | status  | OK      |
| test.t2 | assign_to_keycache | status  | OK      |
| test.t3 | assign_to_keycache | status  | OK      |
+-----+-----+-----+-----+
```

Implementation (for MyISAM)

Normally `CACHE INDEX` should not take a long time to execute. Internally it's implemented the following way:

- Find the right key cache (under `LOCK_global_system_variables`)
- Open the table with a `TL_READ_NO_INSERT` lock.
- Flush the original key cache for the given file (under key cache lock)
- Flush the new key cache for the given file (safety)
- Move the file to the new key cache (under file share lock)

The only possible long operations are getting the locks for the table and flushing the original key cache, if there were many key blocks for the file in it.

We plan to also add `CACHE INDEX` for Aria tables if there is a need for this.

1.1.1.2.13 DESCRIBE

Syntax

```
{DESCRIBE | DESC} tbl_name [col_name | wild]
```

Contents

1. [Syntax](#)
2. [Description](#)

Description

`DESCRIBE` provides information about the columns in a table. It is a shortcut for `SHOW COLUMNS FROM`. These statements also display information for [views](#).

`col_name` can be a column name, or a string containing the SQL `" % "` and `" _ "` wildcard characters to obtain output only for the columns with names matching the string. There is no need to enclose the string within quotes unless it contains spaces or other special characters.

```
DESCRIBE city;
```

Field	Type	Null	Key	Default	Extra
Id	int(11)	NO	PRI	NULL	auto_increment
Name	char(35)	YES		NULL	
Country	char(3)	NO	UNI		
District	char(20)	YES	MUL		
Population	int(11)	YES		NULL	

The description for [SHOW COLUMNS](#) provides more information about the output columns.

1.1.1.2.14 EXECUTE Statement

Syntax

```
EXECUTE stmt_name  
  [USING expression[, expression] ...]
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Example](#)

Description

After preparing a statement with [PREPARE](#), you execute it with an `EXECUTE` statement that refers to the prepared statement name. If the prepared statement contains any parameter markers, you must supply a `USING` clause that lists user variables containing the values to be bound to the parameters. Parameter values can be supplied only by user variables, and the `USING` clause must name exactly as many variables as the number of parameter markers in the statement.

You can execute a given prepared statement multiple times, passing different variables to it or setting the variables to different values before each execution.

If the specified statement has not been PREPARED, an error similar to the following is produced:

```
ERROR 1243 (HY000): Unknown prepared statement handler (stmt_name) given to EXECUTE
```

`EXECUTE` with expression as parameters was introduced in [MariaDB 10.2.3](#). Prior to that one could only use variables (`@var_name`) as parameters.

Example

See [example in PREPARE](#).

1.1.1.2.15 HELP Command

Syntax

```
HELP search_string
```

Description

The `HELP` command can be used in any MariaDB client, such as the `mariadb` command-line client, to get basic syntax help and a short description for most commands and functions.

If you provide an argument to the `HELP` command, the `mariadb` client uses it as a search string to access server-side help.

The proper operation of this command requires that the help tables in the `mysql` database be initialized with help topic information.

If there is no match for the search string, the search fails. Use `HELP contents` to see a list of the help categories:

```
HELP contents
You asked for help about help category: "Contents"
For more information, type 'help <item>', where <item> is one of the following
categories:
  Account Management
  Administration
  Compound Statements
  Data Definition
  Data Manipulation
  Data Types
  Functions
  Functions and Modifiers for Use with GROUP BY
  Geographic Features
  Help Metadata
  Language Structure
  Plugins
  Procedures
  Sequences
  Table Maintenance
  Transactions
  User-Defined Functions
  Utility
```

If a search string matches multiple items, MariaDB shows a list of matching topics:

```
HELP drop
Many help items for your request exist.
To make a more specific request, please type 'help <item>',
where <item> is one of the following
topics:
  ALTER TABLE
  DROP DATABASE
  DROP EVENT
  DROP FUNCTION
  DROP FUNCTION UDF
  DROP INDEX
  DROP PACKAGE
  DROP PACKAGE BODY
  DROP PROCEDURE
  DROP ROLE
  DROP SEQUENCE
  DROP SERVER
  DROP TABLE
  DROP TRIGGER
  DROP USER
  DROP VIEW
```

Then you can enter a topic as the search string to see the help entry for that topic.

The help is provided with the MariaDB server and makes use of four help tables found in the `mysql` database: [help_relation](#), [help_topic](#), [help_category](#) and [help_keyword](#). These tables are populated by the `mariadb-install-db` or `fill_help_table.sql` scripts.

1.1.1.2.16 KILL [CONNECTION | QUERY]

Syntax

```
KILL [HARD | SOFT] { {CONNECTION|QUERY} thread_id | QUERY ID query_id | USER user_name }
```

Contents

1. [Syntax](#)
2. [Description](#)

Description

Each connection to mariadb runs in a separate thread. You can see which threads are running with the `SHOW PROCESSLIST` statement and kill a thread with the `KILL thread_id` statement. `KILL` allows the optional `CONNECTION` or `QUERY` modifier:

- `KILL CONNECTION` is the same as `KILL` with no modifier: It terminates the connection associated with the given thread or query id.
- `KILL QUERY` terminates the statement that the connection thread_id is currently executing, but leaves the connection itself intact.
- `KILL QUERY ID` terminates the query by query_id, leaving the connection intact.

If a connection is terminated that has an active transaction, the transaction will be rolled back. If only a query is killed, the current transaction will stay active. See also [idle_transaction_timeout](#).

If you have the `PROCESS` privilege, you can see all threads. If you have the `SUPER` privilege, or, from [MariaDB 10.5.2](#), the `CONNECTION ADMIN` privilege, you can kill all threads and statements. Otherwise, you can see and kill only your own threads and statements.

Killing queries that repair or create indexes on MyISAM and Aria tables may result in corrupted tables. Use the `SOFT` option to avoid this!

The `HARD` option (default) kills a command as soon as possible. If you use `SOFT`, then critical operations that may leave a table in an inconsistent state will not be interrupted. Such operations include `REPAIR` and `INDEX` creation for [MyISAM](#) and [Aria](#) tables ([REPAIR TABLE](#), [OPTIMIZE TABLE](#)).

`KILL ... USER username` will kill all connections/queries for a given user. `USER` can be specified one of the following ways:

- username (Kill without regard to hostname)
- username@hostname
- `CURRENT_USER` or `CURRENT_USER()`

If you specify a thread id and that thread does not exist, you get the following error:

```
ERROR 1094 (HY000): Unknown thread id: <thread_id>
```

If you specify a query id that doesn't exist, you get the following error:

```
ERROR 1957 (HY000): Unknown query id: <query_id>
```

However, if you specify a user name, no error is issued for non-connected (or even non-existing) users. To check if the connection/query has been killed, you can use the [ROW_COUNT\(\)](#) function.

A client whose connection is killed receives the following error:

```
ERROR 1317 (70100): Query execution was interrupted
```

To obtain a list of existing sessions, use the `SHOW PROCESSLIST` statement or query the [Information Schema PROCESSLIST](#) table.

Note: You cannot use `KILL` with the Embedded MariaDB Server library because the embedded server merely runs inside the threads of the host application. It does not create any connection threads of its own.

Note: You can also use `mariadb-admin kill thread_id [,thread_id...]` to kill connections. To get a list of running queries, use `mariadb-admin processlist`. See [mariadb-admin](#).

[Percona Toolkit](#) contains a program, `pt-kill` that can be used to automatically kill connections that match certain criteria. For example, it can be used to terminate idle connections, or connections that have been busy for more than 60 seconds.

1.1.1.2.17 LOAD INDEX

Syntax

```
LOAD INDEX INTO CACHE
  tbl_index_list [, tbl_index_list] ...

tbl_index_list:
  tbl_name
  [[INDEX|KEY] (index_name[, index_name] ...)]
  [IGNORE LEAVES]
```

Description

The `LOAD INDEX INTO CACHE` statement preloads a table index into the key cache to which it has been assigned by an explicit `CACHE INDEX` statement, or into the default key cache otherwise. `LOAD INDEX INTO CACHE` is used only for [MyISAM](#) or [Aria](#) tables.

The `IGNORE LEAVES` modifier causes only blocks for the nonleaf nodes of the index to be preloaded.

1.1.1.2.18 RESET

Syntax

```
RESET reset_option [, reset_option] ...
```

Description

The `RESET` statement is used to clear the state of various server operations. You must have the `RELOAD` privilege to execute `RESET`.

`RESET` acts as a stronger version of the `FLUSH` statement.

The different `RESET` options are:

Option	Description
<code>SLAVE</code> ["connection_name"] [ALL]	Deletes all relay logs from the slave and reset the replication position in the master binary log .
<code>MASTER</code>	Deletes all old binary logs, makes the binary index file (<code>--log-bin-index</code>) empty and creates a new binary log file. This is useful when you want to reset the master to an initial state. If you want to just delete old, not used binary logs, you should use the PURGE BINARY LOGS  command.
<code>QUERY CACHE</code>	Removes all queries from the query cache . See also FLUSH QUERY CACHE .

1.1.1.2.19 SHUTDOWN

Contents

- [1. Syntax](#)
- [2. Description](#)
- [3. WAIT FOR ALL REPLICAS / SLAVES](#)
- [4. Required Permissions](#)
- [5. Shutdown for Upgrades](#)
- [6. Example](#)
- [7. Other Ways to Stop mariadb](#)

Syntax

```
SHUTDOWN [WAIT FOR ALL { SLAVES | REPLICAS } ]
```

Description

The `SHUTDOWN` command shuts the server down.

WAIT FOR ALL REPLICAS / SLAVES

The `WAIT FOR ALL SLAVES` option was first added in [MariaDB 10.4.4](#). `WAIT FOR ALL REPLICAS` has been a synonym since [MariaDB 10.5.1](#).

When a primary server is shutdown and it goes through the normal shutdown process, the primary kills client threads in random order. By default, the primary also considers its binary log dump threads to be regular client threads. As a consequence, the binary log dump threads can be killed while client threads still exist, and this means that data can be written on the primary during a normal shutdown that won't be replicated. This is true even if [semi-synchronous replication](#) is being used.

This problem can be solved by shutting down the server with the `SHUTDOWN` command and by providing the `WAIT FOR ALL REPLICAS / WAIT FOR ALL SLAVES` option to the command. For example:

```
SHUTDOWN WAIT FOR ALL REPLICAS;
```

When the `WAIT FOR ALL REPLICAS` option is provided, the server only kills its binary log dump threads after all client threads have been killed, and it only completes the shutdown after the last [binary log](#) has been sent to all connected replicas.

See [Replication Threads: Binary Log Dump Threads and the Shutdown Process](#) for more information.

Required Permissions

One must have a `SHUTDOWN` privilege (see [GRANT](#)) to use this command. It is the same privilege one needs to use the `mariadb-admin shutdown` command.

Shutdown for Upgrades

If you are doing a shutdown to [migrate to another major version of MariaDB](#), please ensure that the `innodb_fast_shutdown` variable is not 2 (fast crash shutdown). The default of this variable is 1.

Example

The following example shows how to create an [event](#) which turns off the server at a certain time:

```
CREATE EVENT `test`.`shutd`
  ON SCHEDULE
    EVERY 1 DAY
    STARTS '2014-01-01 20:00:00'
    COMMENT 'Shutdown Maria when the office is closed'
  DO BEGIN
    SHUTDOWN;
  END;
```

Other Ways to Stop mariadb

You can use the `mariadb-admin shutdown` command to take down mariadb cleanly.

You can also use the system kill command on Unix with signal SIGTERM (15)

```
kill -SIGTERM pid-of-mariadb-process
```

You can find the process number of the server process in the file that ends with `.pid` in your data directory.

The above is identical to `mariadb-admin shutdown`.

On windows you should use:

```
NET STOP MariaDB
```

1.1.1.2.20 USE [DATABASE]

Syntax

```
USE db_name
```

Description

The 'USE db_name' statement tells MariaDB to use the db_name database as the default (current) database for subsequent statements. The database remains the default until the end of the session or another USE statement is issued:

```
USE db1;
SELECT COUNT(*) FROM mytable; # selects from db1.mytable
USE db2;
SELECT COUNT(*) FROM mytable; # selects from db2.mytable
```

The DATABASE() function (SCHEMA() is a synonym) returns the default database.

Another way to set the default database is specifying its name at mariadb command line client startup.

One cannot use USE DATABASE to a database one has no privileges to. The reason is that a user with no privileges to a database should not be able to know if a database exists or not.

1.1.1.3 Data Definition

SQL Commands for defining data, such as ALTER, CREATE, DROP, RENAME etc.

CREATE

[Articles on the various CREATE statements.](#)

ALTER

[The various ALTER statements in MariaDB.](#)

DROP

[Articles on various DROP commands.](#)

Atomic DDL

[Making DDL Atomic/Crash-safe.](#)

CONSTRAINT

[Define a CHECK or FOREIGN KEY constraint.](#)

MERGE

[Allows you to access a collection of identical MyISAM tables as one.](#)

RENAME TABLE

[Change a table's name.](#)

TRUNCATE TABLE

[DROP and re-CREATE a table.](#)

There are [3 related questions](#).

1.1.1.3.1 CREATE

Articles on the various CREATE statements.

CREATE DATABASE

[Create a database.](#)

CREATE TABLE

Creates a new table.

CREATE VIEW

Create or replace a view.

CREATE CATALOG

Create a catalog. [↗](#)

CREATE USER

Create new MariaDB accounts.

CREATE TRIGGER

Create a new trigger.

CREATE EVENT

Create and schedule a new event.

CREATE FUNCTION

Creates a stored function.

CREATE FUNCTION UDF

Create a user-defined function.

CREATE INDEX

Create an index on one or more columns.

CREATE LOGFILE GROUP

The CREATE LOGFILE GROUP statement is not supported by MariaDB. It was orig...

CREATE PACKAGE

Create a stored package.

CREATE PACKAGE BODY

Creates the package body for a stored package.

CREATE PROCEDURE

Creates a stored procedure.

CREATE ROLE

Add new roles.

CREATE SEQUENCE

Creates a sequence that generates new values when called with NEXT VALUE FOR.

CREATE SERVER

Define a server.

CREATE TABLESPACE

CREATE TABLESPACE is not available in MariaDB.

Silent Column Changes

MariaDB silently changes column specifications in certain situations.

Generated (Virtual and Persistent/Stored) Columns

Generated (virtual and persistent/stored) columns.

Invisible Columns

Invisible columns are hidden in certain contexts.

There are [1 related questions](#) [↗](#).

1.1.1.3.1.1 CREATE DATABASE

Syntax

```
CREATE [OR REPLACE] {DATABASE | SCHEMA} [IF NOT EXISTS] db_name  
    [create_specification] ...
```

create_specification:

```
[DEFAULT] CHARACTER SET [=] charset_name  
| [DEFAULT] COLLATE [=] collation_name  
| COMMENT [=] 'comment'
```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [OR REPLACE](#)
 2. [IF NOT EXISTS](#)
 3. [COMMENT](#)
3. [Examples](#)

Description

`CREATE DATABASE` creates a database with the given name. To use this statement, you need the [CREATE privilege](#) for the database. `CREATE SCHEMA` is a synonym for `CREATE DATABASE`.

For valid identifiers to use as database names, see [Identifier Names](#).

OR REPLACE

If the optional `OR REPLACE` clause is used, it acts as a shortcut for:

```
DROP DATABASE IF EXISTS db_name;  
CREATE DATABASE db_name ...;
```

IF NOT EXISTS

When the `IF NOT EXISTS` clause is used, MariaDB will return a warning instead of an error if the specified database already exists.

COMMENT

MariaDB starting with [10.5.0](#)

From [MariaDB 10.5.0](#), it is possible to add a comment of a maximum of 1024 bytes. If the comment length exceeds this length, a error/warning code 4144 is thrown. The database comment is also added to the `db.opt` file, as well as to the [information_schema.schemata](#) table.

Examples

```

CREATE DATABASE db1;
Query OK, 1 row affected (0.18 sec)

CREATE DATABASE db1;
ERROR 1007 (HY000): Can't create database 'db1'; database exists

CREATE OR REPLACE DATABASE db1;
Query OK, 2 rows affected (0.00 sec)

CREATE DATABASE IF NOT EXISTS db1;
Query OK, 1 row affected, 1 warning (0.01 sec)

SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Note  | 1007 | Can't create database 'db1'; database exists |
+-----+-----+-----+

```

Setting the [character sets and collation](#). See [Setting Character Sets and Collations](#) for more details.

```

CREATE DATABASE czech_slovak_names
CHARACTER SET = 'keybcs2'
COLLATE = 'keybcs2_bin';

```

Comments, from [MariaDB 10.5.0](#):

```

CREATE DATABASE presentations COMMENT 'Presentations for conferences';

```

1.1.1.3.1.2 CREATE EVENT

Syntax

```

CREATE [OR REPLACE]
  [DEFINER = { user | CURRENT_USER | role | CURRENT_ROLE }]
  EVENT
  [IF NOT EXISTS]
  event_name
  ON SCHEDULE schedule
  [ON COMPLETION [NOT] PRESERVE]
  [ENABLE | DISABLE | DISABLE ON SLAVE]
  [COMMENT 'comment']
  DO sql_statement;

schedule:
  AT timestamp [+ INTERVAL interval] ...
| EVERY interval
  [STARTS timestamp [+ INTERVAL interval] ...]
  [ENDS timestamp [+ INTERVAL interval] ...]

interval:
  quantity {YEAR | QUARTER | MONTH | DAY | HOUR | MINUTE |
            WEEK | SECOND | YEAR_MONTH | DAY_HOUR | DAY_MINUTE |
            DAY_SECOND | HOUR_MINUTE | HOUR_SECOND | MINUTE_SECOND}

```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [OR REPLACE](#)
 2. [IF NOT EXISTS](#)
 3. [ON SCHEDULE](#)
 4. [AT](#)
 5. [ON COMPLETION \[NOT\] PRESERVE](#)
 6. [ENABLE/DISABLE/DISABLE ON SLAVE](#)
 7. [COMMENT](#)
3. [Examples](#)

Description

This statement creates and schedules a new [event](#). It requires the [EVENT](#) privilege for the schema in which the event is to be created.

The minimum requirements for a valid CREATE EVENT statement are as follows:

- The keywords `CREATE EVENT` plus an event name, which uniquely identifies the event in the current schema. (Prior to MySQL 5.1.12, the event name needed to be unique only among events created by the same user on a given database.)
- An `ON SCHEDULE` clause, which determines when and how often the event executes.
- A `DO` clause, which contains the SQL statement to be executed by an event.

Here is an example of a minimal `CREATE EVENT` statement:

```
CREATE EVENT myevent
ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 HOUR
DO
UPDATE myschema.mytable SET mycol = mycol + 1;
```

The previous statement creates an event named `myevent`. This event executes once — one hour following its creation — by running an SQL statement that increments the value of the `myschema.mytable` table's `mycol` column by 1.

The `event_name` must be a valid MariaDB identifier with a maximum length of 64 characters. It may be delimited using back ticks, and may be qualified with the name of a database schema. An event is associated with both a MariaDB user (the definer) and a schema, and its name must be unique among names of events within that schema. In general, the rules governing event names are the same as those for names of stored routines. See [Identifier Names](#).

If no schema is indicated as part of `event_name`, the default (current) schema is assumed.

For valid identifiers to use as event names, see [Identifier Names](#).

OR REPLACE

The `OR REPLACE` clause was included in [MariaDB 10.1.4](#). If used and the event already exists, instead of an error being returned, the existing event will be dropped and replaced by the newly defined event.

IF NOT EXISTS

If the `IF NOT EXISTS` clause is used, MariaDB will return a warning instead of an error if the event already exists. Cannot be used together with `OR REPLACE`.

ON SCHEDULE

The `ON SCHEDULE` clause can be used to specify when the event must be triggered.

AT

If you want to execute the event only once (one time event), you can use the `AT` keyword, followed by a timestamp. If you use `CURRENT_TIMESTAMP`, the event acts as soon as it is created. As a convenience, you can add one or more intervals to that timestamp. You can also specify a timestamp in the past, so that the event is stored but not triggered, until you modify it via [ALTER EVENT](#).

The following example shows how to create an event that will be triggered tomorrow at a certain time:

```
CREATE EVENT example
ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 DAY + INTERVAL 3 HOUR
DO something;
```

You can also specify that an event must be triggered at a regular interval (recurring event). In such cases, use the `EVERY` clause followed by the interval.

If an event is recurring, you can specify when the first execution must happen via the `STARTS` clause and a maximum time for the last execution via the `ENDS` clause. `STARTS` and `ENDS` clauses are followed by a timestamp and, optionally, one or more intervals. The `ENDS` clause can specify a timestamp in the past, so that the event is stored but not executed until you modify it via [ALTER EVENT](#).

In the following example, next month a recurring event will be triggered hourly for a week:

```
CREATE EVENT example
ON SCHEDULE EVERY 1 HOUR
STARTS CURRENT_TIMESTAMP + INTERVAL 1 MONTH
ENDS CURRENT_TIMESTAMP + INTERVAL 1 MONTH + INTERVAL 1 WEEK
DO some_task;
```

Intervals consist of a quantity and a time unit. The time units are the same used for other statements and time functions, except that you can't use microseconds for events. For simple time units, like `hour` or `minute`, the quantity is an integer number, for example '10 MINUTE'. For composite time units, like `hour_minute` or `hour_second`, the quantity must be a string with all involved simple values and their separators, for example '2:30' or '2:30:30'.

ON COMPLETION [NOT] PRESERVE

The `ON COMPLETION` clause can be used to specify if the event must be deleted after its last execution (that is, after its `AT` or `ENDS` timestamp is past). By default, events are dropped when they are expired. To explicitly state that this is the desired behaviour, you can use `ON COMPLETION NOT PRESERVE`. Instead, if you want the event to be preserved, you can use `ON COMPLETION PRESERVE`.

In you specify `ON COMPLETION NOT PRESERVE`, and you specify a timestamp in the past for `AT` or `ENDS` clause, the event will be immediately dropped. In such cases, you will get a Note 1558: "Event execution time is in the past and ON COMPLETION NOT PRESERVE is set. The event was dropped immediately after creation".

ENABLE/DISABLE/DISABLE ON SLAVE

Events are `ENABLE`d by default. If you want to stop MariaDB from executing an event, you may specify `DISABLE`. When it is ready to be activated, you may enable it using `ALTER EVENT`. Another option is `DISABLE ON SLAVE`, which indicates that an event was created on a master and has been replicated to the slave, which is prevented from executing the event. If `DISABLE ON SLAVE` is specifically set, the event will be disabled everywhere. It will not be executed on the master or the slaves.

COMMENT

The `COMMENT` clause may be used to set a comment for the event. Maximum length for comments is 64 characters. The comment is a string, so it must be quoted. To see events comments, you can query the [INFORMATION_SCHEMA.EVENTS](#) table (the column is named `EVENT_COMMENT`).

Examples

Minimal `CREATE EVENT` statement:

```
CREATE EVENT myevent
ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 HOUR
DO
UPDATE myschema.mytable SET mycol = mycol + 1;
```

An event that will be triggered tomorrow at a certain time:

```
CREATE EVENT example
ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 DAY + INTERVAL 3 HOUR
DO something;
```

Next month a recurring event will be triggered hourly for a week:

```
CREATE EVENT example
ON SCHEDULE EVERY 1 HOUR
STARTS CURRENT_TIMESTAMP + INTERVAL 1 MONTH
ENDS CURRENT_TIMESTAMP + INTERVAL 1 MONTH + INTERVAL 1 WEEK
DO some_task;
```

OR REPLACE and IF NOT EXISTS:

```
CREATE EVENT myevent
ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 HOUR
DO
UPDATE myschema.mytable SET mycol = mycol + 1;
ERROR 1537 (HY000): Event 'myevent' already exists

CREATE OR REPLACE EVENT myevent
ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 HOUR
DO
UPDATE myschema.mytable SET mycol = mycol + 1;;
Query OK, 0 rows affected (0.00 sec)

CREATE EVENT IF NOT EXISTS myevent
ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 HOUR
DO
UPDATE myschema.mytable SET mycol = mycol + 1;
Query OK, 0 rows affected, 1 warning (0.00 sec)

SHOW WARNINGS;
+-----+-----+-----+-----+
| Level | Code | Message                               |
+-----+-----+-----+-----+
| Note  | 1537 | Event 'myevent' already exists        |
+-----+-----+-----+-----+
```

1.1.1.3.1.3 CREATE FUNCTION

Syntax

```
CREATE [OR REPLACE]
  [DEFINER = {user | CURRENT_USER | role | CURRENT_ROLE }]
  [AGGREGATE] FUNCTION [IF NOT EXISTS] func_name ([func_parameter[,...]])
  RETURNS type
  [characteristic ...]
  RETURN func_body

func_parameter:
  [ IN | OUT | INOUT | IN OUT ] param_name type

type:
  Any valid MariaDB data type

characteristic:
  LANGUAGE SQL
  | [NOT] DETERMINISTIC
  | { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
  | SQL SECURITY { DEFINER | INVOKER }
  | COMMENT 'string'

func_body:
  Valid SQL procedure statement
```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [IN | OUT | INOUT | IN OUT](#)
 2. [AGGREGATE](#)
 3. [RETURNS](#)
 4. [LANGUAGE SQL](#)
 5. [OR REPLACE](#)
 6. [IF NOT EXISTS](#)
 7. [\[NOT\] DETERMINISTIC](#)
 8. [MODIFIES SQL DATA](#)
 9. [READS SQL DATA](#)
 10. [CONTAINS SQL](#)
 11. [NO SQL](#)
 12. [Oracle Mode](#)
3. [Security](#)
4. [Character sets and collations](#)
5. [Examples](#)

Description

Use the `CREATE FUNCTION` statement to create a new [stored function](#). You must have the [CREATE ROUTINE](#) database privilege to use `CREATE FUNCTION`. A function takes any number of arguments and returns a value from the function body. The function body can be any valid SQL expression as you would use, for example, in any select expression. If you have the appropriate privileges, you can call the function exactly as you would any built-in function. See [Security](#) below for details on privileges.

You can also use a variant of the `CREATE FUNCTION` statement to install a user-defined function (UDF) defined by a plugin. See [CREATE FUNCTION \(UDF\)](#) for details.

You can use a [SELECT](#) statement for the function body by enclosing it in parentheses, exactly as you would to use a subselect for any other expression. The `SELECT` statement must return a single value. If more than one column is returned when the function is called, error 1241 results. If more than one row is returned when the function is called, error 1242 results. Use a `LIMIT` clause to ensure only one row is returned.

You can also replace the `RETURN` clause with a [BEGIN...END](#) compound statement. The compound statement must contain a `RETURN` statement. When the function is called, the `RETURN` statement immediately returns its result, and any statements after `RETURN` are effectively ignored.

By default, a function is associated with the current database. To associate the function explicitly with a given database, specify the fully-qualified name as `db_name.func_name` when you create it. If the function name is the same as the name of a built-in function, you must use the fully qualified name when you call it.

The parameter list enclosed within parentheses must always be present. If there are no parameters, an empty parameter list of `()` should be used. Parameter names are not case sensitive.

Each parameter can be declared to use any valid data type, except that the `COLLATE` attribute cannot be used.

For valid identifiers to use as function names, see [Identifier Names](#).

IN | OUT | INOUT | IN OUT

MariaDB starting with [10.8.0](#) [↗](#)

The function parameter qualifiers for `IN`, `OUT`, `INOUT`, and `IN OUT` were added in a 10.8.0 preview release. Prior to 10.8.0 quantifiers were supported only in procedures.

`OUT`, `INOUT` and its equivalent `IN OUT`, are only valid if called from `SET` and not `SELECT`. These quantifiers are especially useful for creating functions with more than one return value. This allows functions to be more complex and nested.

```

DELIMITER $$
CREATE FUNCTION add_func3(IN a INT, IN b INT, OUT c INT) RETURNS INT
BEGIN
    SET c = 100;
    RETURN a + b;
END;
$$
DELIMITER ;

SET @a = 2;
SET @b = 3;
SET @c = 0;
SET @res= add_func3(@a, @b, @c);

SELECT add_func3(@a, @b, @c);
ERROR 4186 (HY000): OUT or INOUT argument 3 for function add_func3 is not allowed here

DELIMITER $$
CREATE FUNCTION add_func4(IN a INT, IN b INT, d INT) RETURNS INT
BEGIN
    DECLARE c, res INT;
    SET res = add_func3(a, b, c) + d;
    if (c > 99) then
        return 3;
    else
        return res;
    end if;
END;
$$
DELIMITER ;

SELECT add_func4(1,2,3);
+-----+
| add_func4(1,2,3) |
+-----+
|                3 |
+-----+

```

AGGREGATE

It is possible to create stored aggregate functions as well. See [Stored Aggregate Functions](#) for details.

RETURNS

The `RETURNS` clause specifies the return type of the function. `NULL` values are permitted with all return types.

What happens if the `RETURN` clause returns a value of a different type? It depends on the `SQL_MODE` in effect at the moment of the function creation.

If the `SQL_MODE` is strict (`STRICT_ALL_TABLES` or `STRICT_TRANS_TABLES` flags are specified), a 1366 error will be produced.

Otherwise, the value is coerced to the proper type. For example, if a function specifies an `ENUM` or `SET` value in the `RETURNS` clause, but the `RETURN` clause returns an integer, the value returned from the function is the string for the corresponding `ENUM` member of set of `SET` members.

MariaDB stores the `SQL_MODE` system variable setting that is in effect at the time a routine is created, and always executes the routine with this setting in force, regardless of the server SQL mode in effect when the routine is invoked.

LANGUAGE SQL

`LANGUAGE SQL` is a standard SQL clause, and it can be used in MariaDB for portability. However that clause has no meaning, because SQL is the only supported language for stored functions.

A function is deterministic if it can produce only one result for a given list of parameters. If the result may be affected by stored data, server variables, random numbers or any value that is not explicitly passed, then the function is not deterministic. Also, a function is non-deterministic if it uses non-deterministic functions like `NOW()` or `CURRENT_TIMESTAMP()`. The optimizer may choose a faster execution plan if it known that the function is deterministic. In such cases, you should declare the routine using the `DETERMINISTIC` keyword. If you want to explicitly state that the function is not deterministic (which is the default) you can use the `NOT DETERMINISTIC` keywords.

If you declare a non-deterministic function as `DETERMINISTIC`, you may get incorrect results. If you declare a deterministic function as `NOT DETERMINISTIC`, in some cases the queries will be slower.

OR REPLACE

If the optional `OR REPLACE` clause is used, it acts as a shortcut for:

```
DROP FUNCTION IF EXISTS function_name;
CREATE FUNCTION function_name ...;
```

with the exception that any existing [privileges](#) for the function are not dropped.

IF NOT EXISTS

If the `IF NOT EXISTS` clause is used, MariaDB will return a warning instead of an error if the function already exists. Cannot be used together with `OR REPLACE`.

[NOT] DETERMINISTIC

The `[NOT] DETERMINISTIC` clause also affects [binary logging](#), because the `STATEMENT` format can not be used to store or replicate non-deterministic statements.

`CONTAINS SQL`, `NO SQL`, `READS SQL DATA`, and `MODIFIES SQL DATA` are informative clauses that tell the server what the function does. MariaDB does not check in any way whether the specified clause is correct. If none of these clauses are specified, `CONTAINS SQL` is used by default.

MODIFIES SQL DATA

`MODIFIES SQL DATA` means that the function contains statements that may modify data stored in databases. This happens if the function contains statements like [DELETE](#), [UPDATE](#), [INSERT](#), [REPLACE](#) or DDL.

READS SQL DATA

`READS SQL DATA` means that the function reads data stored in databases, but does not modify any data. This happens if [SELECT](#) statements are used, but there no write operations are executed.

CONTAINS SQL

`CONTAINS SQL` means that the function contains at least one SQL statement, but it does not read or write any data stored in a database. Examples include [SET](#) or [DO](#).

NO SQL

`NO SQL` means nothing, because MariaDB does not currently support any language other than SQL.

Oracle Mode

A subset of Oracle's PL/SQL language is supported in addition to the traditional SQL/PSM-based MariaDB syntax. See [Oracle mode](#) for details on changes when running Oracle mode.

Security

You must have the [EXECUTE](#) privilege on a function to call it. MariaDB automatically grants the `EXECUTE` and `ALTER ROUTINE` privileges to the account that called `CREATE FUNCTION`, even if the `DEFINER` clause was used.

Each function has an account associated as the definer. By default, the definer is the account that created the function. Use the `DEFINER` clause to specify a different account as the definer. You must have the [SUPER](#) privilege, or, from [MariaDB 10.5.2](#), the [SET USER](#) privilege, to use the `DEFINER` clause. See [Account Names](#) for details on specifying accounts.

The `SQL SECURITY` clause specifies what privileges are used when a function is called. If `SQL SECURITY` is `INVOKER`, the function body will be evaluated using the privileges of the user calling the function. If `SQL SECURITY` is `DEFINER`, the function body is always evaluated using the privileges of the definer account. `DEFINER` is the default.

This allows you to create functions that grant limited access to certain data. For example, say you have a table that stores some employee information, and that you've granted `SELECT` privileges [only on certain columns](#) to the user account `roger`.

```
CREATE TABLE employees (name TINYTEXT, dept TINYTEXT, salary INT);
GRANT SELECT (name, dept) ON employees TO roger;
```

To allow the user to get the maximum salary for a department, define a function and grant the `EXECUTE` privilege:

```
CREATE FUNCTION max_salary (dept TINYTEXT) RETURNS INT RETURN
(SELECT MAX(salary) FROM employees WHERE employees.dept = dept);
GRANT EXECUTE ON FUNCTION max_salary TO roger;
```

Since `SQL SECURITY` defaults to `DEFINER`, whenever the user `roger` calls this function, the subselect will execute with your privileges. As long as you have privileges to select the salary of each employee, the caller of the function will be able to get the maximum salary for each department without being able to see individual salaries.

Character sets and collations

Function return types can be declared to use any valid [character set and collation](#). If used, the `COLLATE` attribute needs to be preceded by a `CHARACTER SET` attribute.

If the character set and collation are not specifically set in the statement, the database defaults at the time of creation will be used. If the database defaults change at a later stage, the stored function character set/collation will not be changed at the same time; the stored function needs to be dropped and recreated to ensure the same character set/collation as the database is used.

Examples

The following example function takes a parameter, performs an operation using an SQL function, and returns the result.

```
CREATE FUNCTION hello (s CHAR(20))
  RETURNS CHAR(50) DETERMINISTIC
  RETURN CONCAT('Hello, ',s,'!');

SELECT hello('world');
+-----+
| hello('world') |
+-----+
| Hello, world!  |
+-----+
```

You can use a compound statement in a function to manipulate data with statements like `INSERT` and `UPDATE`. The following example creates a counter function that uses a temporary table to store the current value. Because the compound statement contains statements terminated with semicolons, you have to first change the statement delimiter with the `DELIMITER` statement to allow the semicolon to be used in the function body. See [Delimiters in the mariadb client](#) for more.

```
CREATE TEMPORARY TABLE counter (c INT);
INSERT INTO counter VALUES (0);
DELIMITER //
CREATE FUNCTION counter () RETURNS INT
BEGIN
  UPDATE counter SET c = c + 1;
  RETURN (SELECT c FROM counter LIMIT 1);
END //
DELIMITER ;
```

Character set and collation:

```
CREATE FUNCTION hello2 (s CHAR(20))
  RETURNS CHAR(50) CHARACTER SET 'utf8' COLLATE 'utf8_bin' DETERMINISTIC
  RETURN CONCAT('Hello, ',s,'!');
```

1.1.1.3.1.4 CREATE FUNCTION UDF

Syntax

```
CREATE [OR REPLACE] [AGGREGATE] FUNCTION [IF NOT EXISTS] function_name
  RETURNS {STRING|INTEGER|REAL|DECIMAL}
  SONAME shared_library_name
```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [RETURNS](#)
 2. [shared_library_name](#)
 3. [AGGREGATE](#)
 4. [OR REPLACE](#)
 5. [IF NOT EXISTS](#)
 6. [Upgrading a UDF](#)
 7. [Examples](#)

Description

A user-defined function (UDF) is a way to extend MariaDB with a new function that works like a native (built-in) MariaDB function such as [ABS\(\)](#) or [CONCAT\(\)](#).

`function_name` is the name that should be used in SQL statements to invoke the function.

To create a function, you must have the [INSERT privilege](#) for the mysql database. This is necessary because `CREATE FUNCTION` adds a row to the [mysql.func system table](#) that records the function's name, type, and shared library name. If you do not have this table, you should run the [mariadb-upgrade](#) command to create it.

UDFs need to be written in C, C++ or another language that uses C calling conventions, MariaDB needs to have been dynamically compiled, and your operating system must support dynamic loading.

For an example, see `sql/udf_example.cc` in the source tree. For a collection of existing UDFs see <https://github.com/pluots/sql-udf>.

Statements making use of user-defined functions are not [safe for replication](#).

For creating a stored function as opposed to a user-defined function, see [CREATE FUNCTION](#).

For valid identifiers to use as function names, see [Identifier Names](#).

RETURNS

The `RETURNS` clause indicates the type of the function's return value, and can be one of [STRING](#), [INTEGER](#), [REAL](#) or [DECIMAL](#). `DECIMAL` functions currently return string values and should be written like [STRING](#) functions.

shared_library_name

`shared_library_name` is the basename of the shared object file that contains the code that implements the function. The file must be located in the plugin directory. This directory is given by the value of the `plugin_dir` system variable. Note that before MariaDB/MySQL 5.1, the shared object could be located in any directory that was searched by your system's dynamic linker.

AGGREGATE

Aggregate functions are summary functions such as [SUM\(\)](#) and [AVG\(\)](#). Aggregate UDF functions can be used as [window functions](#).

OR REPLACE

If the optional `OR REPLACE` clause is used, it acts as a shortcut for:

```
DROP FUNCTION IF EXISTS function_name;
CREATE FUNCTION name ...;
```

IF NOT EXISTS

When the `IF NOT EXISTS` clause is used, MariaDB will return a warning instead of an error if the specified function already exists. Cannot be used together with `OR REPLACE`.

Upgrading a UDF

To upgrade the UDF's shared library, first run a [DROP FUNCTION](#) statement, then upgrade the shared library and finally run the CREATE FUNCTION statement. If you upgrade without following this process, you may crash the server.

Examples

```
CREATE FUNCTION jsoncontains_path RETURNS integer SONAME 'ha_connect.so';
Query OK, 0 rows affected (0.00 sec)
```

OR REPLACE and IF NOT EXISTS:

```
CREATE FUNCTION jsoncontains_path RETURNS integer SONAME 'ha_connect.so';
ERROR 1125 (HY000): Function 'jsoncontains_path' already exists

CREATE OR REPLACE FUNCTION jsoncontains_path RETURNS integer SONAME 'ha_connect.so';
Query OK, 0 rows affected (0.00 sec)

CREATE FUNCTION IF NOT EXISTS jsoncontains_path RETURNS integer SONAME 'ha_connect.so';
Query OK, 0 rows affected, 1 warning (0.00 sec)

SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Note  | 1125 | Function 'jsoncontains_path' already exists |
+-----+-----+-----+
```

1.1.1.3.1.5 CREATE INDEX

Syntax

```
CREATE [OR REPLACE] [UNIQUE|FULLTEXT|SPATIAL] INDEX
  [IF NOT EXISTS] index_name
  [index_type]
  ON tbl_name (index_col_name,...)
  [WAIT n | NOWAIT]
  [index_option]
  [algorithm_option | lock_option] ...

index_col_name:
  col_name [(length)] [ASC | DESC]

index_type:
  USING {BTREE | HASH | RTREE}

index_option:
  [ KEY_BLOCK_SIZE [=] value
  | index_type
  | WITH PARSER parser_name
  | COMMENT 'string'
  | CLUSTERING={YES| NO} ]
  [ IGNORED | NOT IGNORED ]

algorithm_option:
  ALGORITHM [=] {DEFAULT|INPLACE|COPY|NOCOPY|INSTANT}

lock_option:
  LOCK [=] {DEFAULT|NONE|SHARED|EXCLUSIVE}
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Privileges](#)
4. [Online DDL](#)
5. [CREATE OR REPLACE INDEX](#)
6. [CREATE INDEX IF NOT EXISTS](#)
7. [Index Definitions](#)
8. [WAIT/NOWAIT](#)
9. [ALGORITHM](#)
10. [LOCK](#)
11. [Progress Reporting](#)
12. [WITHOUT OVERLAPS](#)
13. [Examples](#)

Description

The `CREATE INDEX` statement is used to add indexes to a table. Indexes can be created at the same as the table, with the [CREATE TABLE](#) statement. In some cases, such as for InnoDB primary keys, doing so during creation is preferable, as adding a primary key will involve rebuilding the table.

The statement is mapped to an ALTER TABLE statement to create [indexes](#). See [ALTER TABLE](#). `CREATE INDEX` cannot be used to create a [PRIMARY KEY](#); use ALTER TABLE instead.

If another connection is using the table, a [metadata lock](#) is active, and this statement will wait until the lock is released. This is also true for non-transactional tables.

Another shortcut, [DROP INDEX](#), allows the removal of an index.

For valid identifiers to use as index names, see [Identifier Names](#).

For limits on InnoDB indexes, see [InnoDB Limitations](#).

Note that `KEY_BLOCK_SIZE` is currently ignored in `CREATE INDEX`, although it is included in the output of [SHOW CREATE TABLE](#).

Privileges

Executing the `CREATE INDEX` statement requires the [INDEX](#) privilege for the table or the database.

Online DDL

Online DDL is supported with the [ALGORITHM](#) and [LOCK](#) clauses.

See [InnoDB Online DDL Overview](#) for more information on online DDL with [InnoDB](#).

CREATE OR REPLACE INDEX

If the `OR REPLACE` clause is used and if the index already exists, then instead of returning an error, the server will drop the existing index and replace it with the newly defined index.

CREATE INDEX IF NOT EXISTS

If the `IF NOT EXISTS` clause is used, then the index will only be created if an index with the same name does not already exist. If the index already exists, then a warning will be triggered by default.

Index Definitions

See [CREATE TABLE: Index Definitions](#) for information about index definitions.

WAIT/NOWAIT

Set the lock wait timeout. See [WAIT and NOWAIT](#).

ALGORITHM

See [ALTER TABLE: ALGORITHM](#) for more information.

LOCK

See [ALTER TABLE: LOCK](#) for more information.

Progress Reporting

MariaDB provides progress reporting for `CREATE INDEX` statement for clients that support the new progress reporting protocol. For example, if you were using the `mariadb` client, then the progress report might look like this::

```
CREATE INDEX i ON tab (num);
Stage: 1 of 2 'copy to tmp table'    46% of stage
```

The progress report is also shown in the output of the `SHOW PROCESSLIST` statement and in the contents of the `information_schema.PROCESSLIST` table.

See [Progress Reporting](#) for more information.

WITHOUT OVERLAPS

MariaDB starting with [10.5.3](#)

The `WITHOUT OVERLAPS` clause allows one to constrain a primary or unique index such that [application-time periods](#) cannot overlap.

Examples

Creating a unique index:

```
CREATE UNIQUE INDEX HomePhone ON Employees (Home_Phone);
```

OR REPLACE and IF NOT EXISTS:

```
CREATE INDEX xi ON xx5 (x);
Query OK, 0 rows affected (0.03 sec)

CREATE INDEX xi ON xx5 (x);
ERROR 1061 (42000): Duplicate key name 'xi'

CREATE OR REPLACE INDEX xi ON xx5 (x);
Query OK, 0 rows affected (0.03 sec)

CREATE INDEX IF NOT EXISTS xi ON xx5 (x);
Query OK, 0 rows affected, 1 warning (0.00 sec)

SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Note  | 1061 | Duplicate key name 'xi' |
+-----+-----+-----+
```

From [MariaDB 10.5.3](#), creating a unique index for an [application-time period table](#) with a `WITHOUT OVERLAPS` constraint:

```
CREATE UNIQUE INDEX u ON rooms (room_number, p WITHOUT OVERLAPS);
```

1.1.1.3.1.6 CREATE LOGFILE GROUP

The `CREATE LOGFILE GROUP` statement is not supported by MariaDB. It was originally inherited from MySQL NDB

1.1.1.3.1.7 CREATE PACKAGE

The `CREATE PACKAGE` statement can be used when `Oracle SQL_MODE` is set, or in any mode from [MariaDB 11.4](#).

In Oracle mode, the PL/SQL dialect is used, while if Oracle mode is not set (the default), SQL/PSM is used.

Syntax (Oracle mode)

```
CREATE
  [ OR REPLACE]

Contents

1. [Syntax \(Oracle mode\)](#)
2. [Syntax \(non-Oracle mode\)](#)
3. [Description](#)
4. [Function parameter quantifiers IN | OUT | INOUT | IN OUT](#)
5. [Examples](#)

Description

The `CREATE PACKAGE` statement can be used when [Oracle SQL_MODE](#) is set, or in any mode from [MariaDB 11.4](#).

`CREATE PACKAGE` creates the specification for a stored package (a collection of logically related stored objects). A stored package specification declares public routines (procedures and functions) of the package, but does not implement these routines.

A package whose specification was created by the `CREATE PACKAGE` statement, should later be implemented using the [CREATE PACKAGE BODY](#) statement.

Function parameter quantifiers IN | OUT | INOUT | IN OUT

MariaDB starting with [10.8.0](#) [↗](#)

The function parameter quantifiers for `IN`, `OUT`, `INOUT`, and `IN OUT` were added in a 10.8.0 preview release. Prior to 10.8.0 quantifiers were supported only in procedures.

OUT , INOUT and its equivalent IN OUT , are only valid if called from SET and not SELECT . These quantifiers are especially useful for creating functions and procedures with more than one return value. This allows functions and procedures to be more complex and nested.

Examples

Oracle mode:

```
SET sql_mode=ORACLE;
DELIMITER $$
CREATE OR REPLACE PACKAGE employee_tools AS
    FUNCTION getSalary(eid INT) RETURN DECIMAL(10,2);
    PROCEDURE raiseSalary(eid INT, amount DECIMAL(10,2));
    PROCEDURE raiseSalaryStd(eid INT);
    PROCEDURE hire(ename TEXT, esalary DECIMAL(10,2));
END;
$$
DELIMITER ;
```

From [MariaDB 11.4](#), non-Oracle mode:

```
SET sql_mode='';
DELIMITER $$
CREATE OR REPLACE PACKAGE pkg
    PROCEDURE p1();
    FUNCTION f1() RETURNS INT;
END;
$$
DELIMITER ;
```

1.1.1.3.1.8 CREATE PACKAGE BODY

The CREATE PACKAGE BODY statement can be used when [Oracle SQL_MODE](#) is set, or in any mode from [MariaDB 11.4](#).

In Oracle mode, the PL/SQL dialect is used, while in non-Oracle mode, SQL/PSM is used.

Syntax (Oracle mode)

```
CREATE [ OR REPLACE ]
    [DEFINER = { user | CURRENT_USER | role | CURRENT_ROLE }]
    PACKAGE BODY
    [ IF NOT EXISTS ]
    [ db_name . ] package_name
    [ package_characteristic... ]

Contents

1. [Syntax \(Oracle mode\)](#)
2. [Description](#)
3. [Examples](#)

Description

The `CREATE PACKAGE BODY` statement can be used when [Oracle SQL_MODE](#) is set, or in any mode from [MariaDB 11.4](#).

The `CREATE PACKAGE BODY` statement creates the package body for a stored package. The package specification must be previously created using the [CREATE PACKAGE](#) statement.

A package body provides implementations of the package public routines and can optionally have:

- package-wide private variables

- package private routines
- forward declarations for private routines
- an executable initialization section

Examples

Oracle mode:

```

SET sql_mode=ORACLE;
DELIMITER $$
CREATE OR REPLACE PACKAGE employee_tools AS
  FUNCTION getSalary(eid INT) RETURN DECIMAL(10,2);
  PROCEDURE raiseSalary(eid INT, amount DECIMAL(10,2));
  PROCEDURE raiseSalaryStd(eid INT);
  PROCEDURE hire(ename TEXT, esalary DECIMAL(10,2));
END;
$$
CREATE PACKAGE BODY employee_tools AS
  -- package body variables
  stdRaiseAmount DECIMAL(10,2):=500;

  -- private routines
  PROCEDURE log (eid INT, ecmnt TEXT) AS
  BEGIN
    INSERT INTO employee_log (id, cmnt) VALUES (eid, ecmnt);
  END;

  -- public routines
  PROCEDURE hire(ename TEXT, esalary DECIMAL(10,2)) AS
  eid INT;
  BEGIN
    INSERT INTO employee (name, salary) VALUES (ename, esalary);
    eid:= last_insert_id();
    log(eid, 'hire ' || ename);
  END;

  FUNCTION getSalary(eid INT) RETURN DECIMAL(10,2) AS
  nSalary DECIMAL(10,2);
  BEGIN
    SELECT salary INTO nSalary FROM employee WHERE id=eid;
    log(eid, 'getSalary id=' || eid || ' salary=' || nSalary);
    RETURN nSalary;
  END;

  PROCEDURE raiseSalary(eid INT, amount DECIMAL(10,2)) AS
  BEGIN
    UPDATE employee SET salary=salary+amount WHERE id=eid;
    log(eid, 'raiseSalary id=' || eid || ' amount=' || amount);
  END;

  PROCEDURE raiseSalaryStd(eid INT) AS
  BEGIN
    raiseSalary(eid, stdRaiseAmount);
    log(eid, 'raiseSalaryStd id=' || eid);
  END;

BEGIN
  -- This code is executed when the current session
  -- accesses any of the package routines for the first time
  log(0, 'Session ' || connection_id() || ' ' || current_user || ' started');
END;
$$

DELIMITER ;

```

Non-Oracle mode, from [MariaDB 11.4](#):

```

DELIMITER $$

CREATE OR REPLACE PACKAGE pkg
  PROCEDURE p1();
  FUNCTION f1() RETURNS INT;
END;

$$

DELIMITER ;

DELIMITER $$

CREATE OR REPLACE PACKAGE BODY pkg

  -- variable declarations
  DECLARE a INT DEFAULT 11;
  DECLARE b INT DEFAULT 10;

  -- routine declarations
  PROCEDURE p1()
  BEGIN
    SELECT CURRENT_USER;
  END;

  FUNCTION f1() RETURNS INT
  BEGIN
    RETURN a;
  END;

  -- package initialization section
  SET a=a-b;
END;
$$

DELIMITER ;

```

1.1.1.3.1.9 CREATE PROCEDURE

Syntax

```

4. [Examples](#)

Description

Creates a [stored procedure](#). By default, a routine is associated with the default database. To associate the routine explicitly with a given database, specify the name as `db_name.sp_name` when you create it.

When the routine is invoked, an implicit `USE db_name` is performed (and undone when the routine terminates). This causes the routine to have the given default database while it executes. `USE` statements within stored routines are disallowed.

When a stored procedure has been created, you invoke it by using the `CALL` statement (see [CALL](#)).

To execute the `CREATE PROCEDURE` statement, it is necessary to have the `CREATE ROUTINE` privilege. By default, MariaDB automatically grants the `ALTER ROUTINE` and `EXECUTE` privileges to the routine creator. See also [Stored Routine Privileges](#).

The `DEFINER` and `SQL SECURITY` clauses specify the security context to be used when checking access privileges at routine execution time, as described [here](#). Requires the `SUPER` privilege, or, from [MariaDB 10.5.2](#), the `SET USER` privilege.

If the routine name is the same as the name of a built-in SQL function, you must use a space between the name and the following parenthesis when defining the routine, or a syntax error occurs. This is also true when you invoke the routine later. For this reason, we suggest that it is better to avoid re-using the names of existing SQL functions for your own stored routines.

The `IGNORE_SPACE` SQL mode applies to built-in functions, not to stored routines. It is always allowable to have spaces after a routine name, regardless of whether `IGNORE_SPACE` is enabled.

The parameter list enclosed within parentheses must always be present. If there are no parameters, an empty parameter list of `()` should be used. Parameter names are not case sensitive.

Each parameter can be declared to use any valid data type, except that the `COLLATE` attribute cannot be used.

For valid identifiers to use as procedure names, see [Identifier Names](#).

Things to be Aware of With CREATE OR REPLACE

- One can't use `OR REPLACE` together with `IF EXISTS`.

CREATE PROCEDURE IF NOT EXISTS

If the `IF NOT EXISTS` clause is used, then the procedure will only be created if a procedure with the same name does not already exist. If the procedure already exists, then a warning will be triggered by default.

IN/OUT/INOUT

Each parameter is an `IN` parameter by default. To specify otherwise for a parameter, use the keyword `OUT` or `INOUT` before the parameter name.

An `IN` parameter passes a value into a procedure. The procedure might modify the value, but the modification is not visible to the caller when the procedure returns. An `OUT` parameter passes a value from the procedure back to the caller. Its initial value is `NULL` within the procedure, and its value is visible to the caller when the procedure returns. An `INOUT` parameter is initialized by the caller, can be modified by the procedure, and any change made by the procedure is visible to the caller when the procedure returns.

For each `OUT` or `INOUT` parameter, pass a user-defined variable in the `CALL` statement that invokes the procedure so

that you can obtain its value when the procedure returns. If you are calling the procedure from within another stored procedure or function, you can also pass a routine parameter or local routine variable as an `IN` or `INOUT` parameter.

DETERMINISTIC/NOT DETERMINISTIC

`DETERMINISTIC` and `NOT DETERMINISTIC` apply only to [functions](#). Specifying `DETERMINISTIC` or `NON-DETERMINISTIC` in procedures has no effect. The default value is `NOT DETERMINISTIC`. Functions are `DETERMINISTIC` when they always return the same value for the same input. For example, a truncate or substring function. Any function involving data, therefore, is always `NOT DETERMINISTIC`.

CONTAINS SQL/NO SQL/READS SQL DATA/MODIFIES SQL DATA

`CONTAINS SQL`, `NO SQL`, `READS SQL DATA`, and `MODIFIES SQL DATA` are informative clauses that tell the server what the function does. MariaDB does not check in any way whether the specified clause is correct. If none of these clauses are specified, `CONTAINS SQL` is used by default.

`MODIFIES SQL DATA` means that the function contains statements that may modify data stored in databases. This happens if the function contains statements like [DELETE](#), [UPDATE](#), [INSERT](#), [REPLACE](#) or DDL.

`READS SQL DATA` means that the function reads data stored in databases, but does not modify any data. This happens if [SELECT](#) statements are used, but there no write operations are executed.

`CONTAINS SQL` means that the function contains at least one SQL statement, but it does not read or write any data stored in a database. Examples include [SET](#) or [DO](#).

`NO SQL` means nothing, because MariaDB does not currently support any language other than SQL.

The routine_body consists of a valid SQL procedure statement. This can be a simple statement such as [SELECT](#) or [INSERT](#), or it can be a compound statement written using [BEGIN and END](#). Compound statements can contain declarations, loops, and other control structure statements. See [Programmatic and Compound Statements](#) for syntax details.

MariaDB allows routines to contain DDL statements, such as `CREATE` and `DROP`. MariaDB also allows [stored procedures](#) (but not [stored functions](#)) to contain SQL transaction statements such as `COMMIT`.

For additional information about statements that are not allowed in stored routines, see [Stored Routine Limitations](#).

Invoking stored procedure from within programs

For information about invoking [stored procedures](#) from within programs written in a language that has a MariaDB/MySQL interface, see [CALL](#).

OR REPLACE

If the optional `OR REPLACE` clause is used, it acts as a shortcut for:

```
DROP PROCEDURE IF EXISTS name;  
CREATE PROCEDURE name ...;
```

with the exception that any existing [privileges](#) for the procedure are not dropped.

sql_mode

MariaDB stores the `sql_mode` system variable setting that is in effect at the time a routine is created, and always executes the routine with this setting in force, regardless of the server [SQL mode](#) in effect when the routine is invoked.

Character Sets and Collations

Procedure parameters can be declared with any character set/collation. If the character set and collation are not specifically set, the database defaults at the time of creation will be used. If the database defaults change at a later stage, the stored procedure character set/collation will not be changed at the same time; the stored procedure needs to be dropped and recreated to ensure the same character set/collation as the database is used.

Oracle Mode

A subset of Oracle's PL/SQL language is supported in addition to the traditional SQL/PSM-based MariaDB syntax. See

Examples

The following example shows a simple stored procedure that uses an `OUT` parameter. It uses the `DELIMITER` command to set a new delimiter for the duration of the process — see [Delimiters in the mariadb client](#).

```
DELIMITER //

CREATE PROCEDURE simpleproc (OUT param1 INT)
BEGIN
    SELECT COUNT(*) INTO param1 FROM t;
END;
//

DELIMITER ;

CALL simpleproc(@a);

SELECT @a;
+-----+
| @a    |
+-----+
|     1 |
+-----+
```

Character set and collation:

```
DELIMITER //

CREATE PROCEDURE simpleproc2 (
    OUT param1 CHAR(10) CHARACTER SET 'utf8' COLLATE 'utf8_bin'
)
BEGIN
    SELECT CONCAT('a'),f1 INTO param1 FROM t;
END;
//

DELIMITER ;
```

CREATE OR REPLACE:

```
DELIMITER //

CREATE PROCEDURE simpleproc2 (
    OUT param1 CHAR(10) CHARACTER SET 'utf8' COLLATE 'utf8_bin'
)
BEGIN
    SELECT CONCAT('a'),f1 INTO param1 FROM t;
END;
//
ERROR 1304 (42000): PROCEDURE simpleproc2 already exists

DELIMITER ;

DELIMITER //

CREATE OR REPLACE PROCEDURE simpleproc2 (
    OUT param1 CHAR(10) CHARACTER SET 'utf8' COLLATE 'utf8_bin'
)
BEGIN
    SELECT CONCAT('a'),f1 INTO param1 FROM t;
END;
//
ERROR 1304 (42000): PROCEDURE simpleproc2 already exists

DELIMITER ;
Query OK, 0 rows affected (0.03 sec)
```

1.1.1.1.8 CREATE ROLE

1.1.6.2 CREATE SEQUENCE

1.1.1.3.1.12 CREATE SERVER

Syntax

```
CREATE [OR REPLACE] SERVER [IF NOT EXISTS] server_name
    FOREIGN DATA WRAPPER wrapper_name
    OPTIONS (option [, option] ...)
```

option: <= MariaDB 11.6

```
{ HOST character-literal
| DATABASE character-literal
| USER character-literal
| PASSWORD character-literal
| SOCKET character-literal
| OWNER character-literal
| PORT numeric-literal }
```

option: >= MariaDB 11.7

```
{ HOST character-literal
| DATABASE character-literal
| USER character-literal
| PASSWORD character-literal
| SOCKET character-literal
| OWNER character-literal
| PORT numeric-literal
| PORT quoted-numerical-literal
| identifier character-literal}
```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [OR REPLACE](#)
 2. [IF NOT EXISTS](#)
3. [Examples](#)

Description

This statement creates the definition of a server for use with the [Spider](#), [Connect](#), [FEDERATED](#) or [FederatedX](#) storage engine. The CREATE SERVER statement creates a new row within the `servers` table within the `mysql` database. This statement requires the `SUPER` privilege or, from [MariaDB 10.5.2](#), the `FEDERATED ADMIN` privilege.

The `server_name` should be a unique reference to the server. Server definitions are global within the scope of the server, it is not possible to qualify the server definition to a specific database. `server_name` has a maximum length of 64 characters (names longer than 64 characters are silently truncated), and is case insensitive. You may specify the name as a quoted string.

The `wrapper_name` may be quoted with single quotes. Supported values are:

- `mysql`
- `mariadb` (in [MariaDB 10.3](#) and later)

For each option you must specify either a character literal or numeric literal. Character literals are UTF-8, support a maximum length of 64 characters and default to a blank (empty) string. String literals are silently truncated to 64 characters. Numeric literals must be a number between 0 and 9999, default value is 0.

Note: The `OWNER` option is currently not applied, and has no effect on the ownership or operation of the server connection that is created.

The CREATE SERVER statement creates an entry in the `mysql.servers` table that can later be used with the CREATE TABLE statement when creating a [Spider](#), [Connect](#), [FederatedX](#) or [FEDERATED](#) table. The options that you specify will be used to populate the columns in the `mysql.servers` table. The table columns are `Server_name`, `Host`, `Db`, `Username`, `Password`, `Port` and `Socket`.

`DROP SERVER` removes a previously created server definition.

`CREATE SERVER` is not written to the [binary log](#), irrespective of the [binary log format](#) being used and therefore will not replicate. From [MariaDB 10.1.13](#), [Galera](#) replicates the `CREATE SERVER`, `ALTER SERVER` and `DROP SERVER` statements.

For valid identifiers to use as server names, see [Identifier Names](#).

MariaDB starting with 11.7

From [MariaDB 11.7](#), the `SHOW CREATE SERVER` statement can be used to show the `CREATE SERVER` statement that created a given server definition.

OR REPLACE

If the optional `OR REPLACE` clause is used, it acts as a shortcut for:

```
DROP SERVER IF EXISTS name;
CREATE SERVER server_name ...;
```

IF NOT EXISTS

If the `IF NOT EXISTS` clause is used, MariaDB will return a warning instead of an error if the server already exists. Cannot be used together with `OR REPLACE`.

Examples

```
CREATE SERVER s
FOREIGN DATA WRAPPER mariadb
OPTIONS (USER 'Remote', HOST '192.168.1.106', DATABASE 'test');
```

`OR REPLACE` and `IF NOT EXISTS`:

```
CREATE SERVER s
FOREIGN DATA WRAPPER mariadb
OPTIONS (USER 'Remote', HOST '192.168.1.106', DATABASE 'test');
ERROR 1476 (HY000): The foreign server, s, you are trying to create already exists

CREATE OR REPLACE SERVER s
FOREIGN DATA WRAPPER mariadb
OPTIONS (USER 'Remote', HOST '192.168.1.106', DATABASE 'test');
Query OK, 0 rows affected (0.00 sec)

CREATE SERVER IF NOT EXISTS s
FOREIGN DATA WRAPPER mariadb
OPTIONS (USER 'Remote', HOST '192.168.1.106', DATABASE 'test');
Query OK, 0 rows affected, 1 warning (0.00 sec)

SHOW WARNINGS;
+-----+-----+-----+-----+
| Level | Code | Message                                                                 |
+-----+-----+-----+-----+
| Note  | 1476 | The foreign server, s, you are trying to create already exists |
+-----+-----+-----+-----+
```

1.1.1.2.1.6 CREATE TABLE

1.1.1.3.1.14 CREATE TABLESPACE

The `CREATE TABLESPACE` statement is not supported by MariaDB. It was originally inherited from MySQL NDB Cluster. In MySQL 5.7 and later, the statement is also supported for InnoDB. However, MariaDB has chosen not to include that specific feature. See [MDEV-19294](#) for more information.

1.1.1.3.1.15 CREATE TRIGGER

Syntax

```
CREATE [OR REPLACE]
  [DEFINER = { user | CURRENT_USER | role | CURRENT_ROLE }]
  TRIGGER [IF NOT EXISTS] trigger_name trigger_time trigger_event
  ON tbl_name FOR EACH ROW
  [{ FOLLOWS | PRECEDES } other_trigger_name ]
  trigger_stmt;

trigger time:
  BEFORE
  | AFTER

trigger_event:
  INSERT
  | UPDATE
  | DELETE
```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [OR REPLACE](#)
 2. [DEFINER](#)
 3. [IF NOT EXISTS](#)
 4. [trigger_time](#)
 5. [trigger_event](#)
 1. [FOLLOWS/PRECEDES other_trigger_name](#)
 6. [Atomic DDL](#)
3. [Examples](#)

Description

This statement creates a new [trigger](#). A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. The trigger becomes associated with the table named `tbl_name`, which must refer to a permanent table. You cannot associate a trigger with a `TEMPORARY` table or a view.

`CREATE TRIGGER` requires the [TRIGGER](#) privilege for the table associated with the trigger.

You can have multiple triggers for the same `trigger_time` and `trigger_event`.

For valid identifiers to use as trigger names, see [Identifier Names](#).

OR REPLACE

If used and the trigger already exists, instead of an error being returned, the existing trigger will be dropped and replaced by the newly defined trigger.

DEFINER

The `DEFINER` clause determines the security context to be used when checking access privileges at trigger activation time. Usage requires the [SUPER](#) privilege, or, from [MariaDB 10.5.2](#), the [SET USER](#) privilege.

IF NOT EXISTS

If the `IF NOT EXISTS` clause is used, the trigger will only be created if a trigger of the same name does not exist. If the trigger already exists, by default a warning will be returned.

trigger_time

`trigger_time` is the trigger action time. It can be `BEFORE` or `AFTER` to indicate that the trigger activates before or after each row to be modified.

trigger_event

`trigger_event` indicates the kind of statement that activates the trigger. The `trigger_event` can be one of the following:

- `INSERT` : The trigger is activated whenever a new row is inserted into the table; for example, through `INSERT`, `LOAD DATA`, and `REPLACE` statements.
- `UPDATE` : The trigger is activated whenever a row is modified; for example, through `UPDATE` statements.
- `DELETE` : The trigger is activated whenever a row is deleted from the table; for example, through `DELETE` and `REPLACE` statements. However, `DROP TABLE` and `TRUNCATE` statements on the table do not activate this trigger, because they do not use `DELETE`. Dropping a partition does not activate `DELETE` triggers, either.

FOLLOWS/PRECEDES other_trigger_name

The `FOLLOWS other_trigger_name` and `PRECEDES other_trigger_name` options were added in [MariaDB 10.2.3](#) as part of supporting multiple triggers per action time. This is the same syntax used by MySQL 5.7, although MySQL 5.7 does not have multi-trigger support.

`FOLLOWS` adds the new trigger after another trigger while `PRECEDES` adds the new trigger before another trigger. If neither option is used, the new trigger is added last for the given action and time.

`FOLLOWS` and `PRECEDES` are not stored in the trigger definition. However the trigger order is guaranteed to not change over time. `mysql_dump` and other backup methods will not change trigger order. You can verify the trigger order from the `ACTION_ORDER` column in `INFORMATION_SCHEMA.TRIGGERS` table.

```
SELECT trigger_name, action_order FROM information_schema.triggers
WHERE event_object_table='t1';
```

Atomic DDL

MariaDB starting with [10.6.1](#)

[MariaDB 10.6.1](#) supports [Atomic DDL](#) and `CREATE TRIGGER` is atomic.

Examples

```
CREATE DEFINER=`root`@`localhost` TRIGGER increment_animal
AFTER INSERT ON animals FOR EACH ROW
UPDATE animal_count SET animal_count.animals = animal_count.animals+1;
```

OR REPLACE and IF NOT EXISTS

```
CREATE DEFINER=`root`@`localhost` TRIGGER increment_animal
AFTER INSERT ON animals FOR EACH ROW
UPDATE animal_count SET animal_count.animals = animal_count.animals+1;
ERROR 1359 (HY000): Trigger already exists
```

```
CREATE OR REPLACE DEFINER=`root`@`localhost` TRIGGER increment_animal
AFTER INSERT ON animals FOR EACH ROW
UPDATE animal_count SET animal_count.animals = animal_count.animals+1;
Query OK, 0 rows affected (0.12 sec)
```

```
CREATE DEFINER=`root`@`localhost` TRIGGER IF NOT EXISTS increment_animal
AFTER INSERT ON animals FOR EACH ROW

1.1.1.1.1 CREATE USER

1.1.1.3.1.17 CREATE VIEW

Syntax

```
CREATE
  [OR REPLACE]
  [ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]
  [DEFINER = { user | CURRENT_USER | role | CURRENT_ROLE }]
  [SQL SECURITY { DEFINER | INVOKER }]
  VIEW [IF NOT EXISTS] view_name [(column_list)]
  AS select_statement
  [WITH [CASCADED | LOCAL] CHECK OPTION]
```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [WITH CHECK OPTION](#)
 2. [IF NOT EXISTS](#)
 3. [Atomic DDL](#)
3. [Examples](#)

Description

The CREATE VIEW statement creates a new [view](#), or replaces an existing one if the OR REPLACE clause is given. If the view does not exist, CREATE OR REPLACE VIEW is the same as CREATE VIEW. If the view does exist, CREATE OR REPLACE VIEW is the same as [ALTER VIEW](#).

The select_statement is a [SELECT](#) statement that provides the definition of the view. (When you select from the view, you select in effect using the SELECT statement.) select_statement can select from base tables or other views.

The view definition is "frozen" at creation time, so changes to the underlying tables afterwards do not affect the view definition. For example, if a view is defined as SELECT * on a table, new columns added to the table later do not become part of the view. A [SHOW CREATE VIEW](#) shows that such queries are rewritten and column names are included in the view definition.

The view definition must be a query that does not return errors at view creation times. However, the base tables used by the views might be altered later and the query may not be valid anymore. In this case, querying the view will result in an error. [CHECK TABLE](#) helps in finding this kind of problems.

The [ALGORITHM clause](#) affects how MariaDB processes the view. The DEFINER and SQL SECURITY clauses specify the security context to be used when checking access privileges at view invocation time. The WITH CHECK OPTION clause can be given to constrain inserts or updates to rows in tables referenced by the view. These clauses are described later in this section.

The CREATE VIEW statement requires the CREATE VIEW privilege for the view, and some privilege for each column selected by the SELECT statement. For columns used elsewhere in the SELECT statement you must have the SELECT privilege. If the OR REPLACE clause is present, you must also have the DROP privilege for the view.

A view belongs to a database. By default, a new view is created in the default database. To create the view explicitly in a given database, specify the name as db_name.view_name when you create it.

```
CREATE VIEW test.v AS SELECT * FROM t;
```

Base tables and views share the same namespace within a database, so a database cannot contain a base table and a view that have the same name.

Views must have unique column names with no duplicates, just like base tables. By default, the names of the columns retrieved by the SELECT statement are used for the view column names. To define explicit names for the view columns, the optional column_list clause can be given as a list of comma-separated identifiers. The number of names in column_list must be the same as the number of columns retrieved by the SELECT statement.

Columns retrieved by the SELECT statement can be simple references to table columns. They can also be expressions that use functions, constant values, operators, and so forth.

Unqualified table or view names in the SELECT statement are interpreted with respect to the default database. A view can

refer to tables or views in other databases by qualifying the table or view name with the proper database name.

A view can be created from many kinds of SELECT statements. It can refer to base tables or other views. It can use joins, UNION, and subqueries. The SELECT need not even refer to any tables. The following example defines a view that selects two columns from another table, as well as an expression calculated from those columns:

```
CREATE TABLE t (qty INT, price INT);

INSERT INTO t VALUES(3, 50);

CREATE VIEW v AS SELECT qty, price, qty*price AS value FROM t;

SELECT * FROM v;
+-----+-----+-----+
| qty | price | value |
+-----+-----+-----+
| 3 | 50 | 150 |
+-----+-----+-----+
```

A view definition is subject to the following restrictions:

- The SELECT statement cannot contain a subquery in the FROM clause.
- The SELECT statement cannot refer to system or user variables.
- Within a stored program, the definition cannot refer to program parameters or local variables.
- The SELECT statement cannot refer to prepared statement parameters.
- Any table or view referred to in the definition must exist. However, after a view has been created, it is possible to drop a table or view that the definition refers to. In this case, use of the view results in an error. To check a view definition for problems of this kind, use the CHECK TABLE statement.
- The definition cannot refer to a TEMPORARY table, and you cannot create a TEMPORARY view.
- Any tables named in the view definition must exist at definition time.
- You cannot associate a trigger with a view.
- For valid identifiers to use as view names, see [Identifier Names](#).

ORDER BY is allowed in a view definition, but it is ignored if you select from a view using a statement that has its own ORDER BY.

For other options or clauses in the definition, they are added to the options or clauses of the statement that references the view, but the effect is undefined. For example, if a view definition includes a LIMIT clause, and you select from the view using a statement that has its own LIMIT clause, it is undefined which limit applies. This same principle applies to options such as ALL, DISTINCT, or SQL_SMALL_RESULT that follow the SELECT keyword, and to clauses such as INTO, FOR UPDATE, and LOCK IN SHARE MODE.

The PROCEDURE clause cannot be used in a view definition, and it cannot be used if a view is referenced in the FROM clause.

If you create a view and then change the query processing environment by changing system variables, that may affect the results that you get from the view:

```
CREATE VIEW v (mycol) AS SELECT 'abc';

SET sql_mode = '';

SELECT "mycol" FROM v;
+-----+
| mycol |
+-----+
| mycol |
+-----+

SET sql_mode = 'ANSI_QUOTES';

SELECT "mycol" FROM v;
+-----+
| mycol |
+-----+
| abc   |
+-----+
```

The DEFINER and SQL SECURITY clauses determine which MariaDB account to use when checking access privileges for the view when a statement is executed that references the view. They were added in MySQL 5.1.2. The legal SQL SECURITY characteristic values are DEFINER and INVOKER. These indicate that the required privileges must be held by the user who defined or invoked the view, respectively. The default SQL SECURITY value is DEFINER.

If a user value is given for the DEFINER clause, it should be a MariaDB account in 'user_name'@'host_name' format (the same format used in the GRANT statement). The user_name and host_name values both are required. The definer can also be given as CURRENT_USER or CURRENT_USER(). The default DEFINER value is the user who executes the CREATE VIEW statement. This is the same as specifying DEFINER = CURRENT_USER explicitly.

If you specify the DEFINER clause, these rules determine the legal DEFINER user values:

- If you do not have the [SUPER](#) privilege, or, from [MariaDB 10.5.2](#), the [SET USER](#) privilege, the only legal user value is your own account, either specified literally or by using CURRENT_USER. You cannot set the definer to some other account.
- If you have the [SUPER](#) privilege, or, from [MariaDB 10.5.2](#), the [SET USER](#) privilege, you can specify any syntactically legal account name. If the account does not actually exist, a warning is generated.
- If the SQL SECURITY value is DEFINER but the definer account does not exist when the view is referenced, an error occurs.

Within a view definition, CURRENT_USER returns the view's DEFINER value by default. For views defined with the SQL SECURITY INVOKER characteristic, CURRENT_USER returns the account for the view's invoker. For information about user auditing within views, see <http://dev.mysql.com/doc/refman/5.1/en/account-activity-auditing.html>.

Within a stored routine that is defined with the SQL SECURITY DEFINER characteristic, CURRENT_USER returns the routine's DEFINER value. This also affects a view defined within such a program, if the view definition contains a DEFINER value of CURRENT_USER.

View privileges are checked like this:

- At view definition time, the view creator must have the privileges needed to use the top-level objects accessed by the view. For example, if the view definition refers to table columns, the creator must have privileges for the columns, as described previously. If the definition refers to a stored function, only the privileges needed to invoke the function can be checked. The privileges required when the function runs can be checked only as it executes: For different invocations of the function, different execution paths within the function might be taken.
- When a view is referenced, privileges for objects accessed by the view are checked against the privileges held by the view creator or invoker, depending on whether the SQL SECURITY characteristic is DEFINER or INVOKER, respectively.
- If reference to a view causes execution of a stored function, privilege checking for statements executed within the function depend on whether the function is defined with a SQL SECURITY characteristic of DEFINER or INVOKER. If the security characteristic is DEFINER, the function runs with the privileges of its creator. If the characteristic is INVOKER, the function runs with the privileges determined by the view's SQL SECURITY characteristic.

Example: A view might depend on a stored function, and that function might invoke other stored routines. For example, the following view invokes a stored function f():

```
CREATE VIEW v AS SELECT * FROM t WHERE t.id = f(t.name);
```

Suppose that f() contains a statement such as this:

```
IF name IS NULL then
  CALL p1();
ELSE
  CALL p2();
END IF;
```

The privileges required for executing statements within f() need to be checked when f() executes. This might mean that privileges are needed for p1() or p2(), depending on the execution path within f(). Those privileges must be checked at runtime, and the user who must possess the privileges is determined by the SQL SECURITY values of the view v and the function f().

The DEFINER and SQL SECURITY clauses for views are extensions to standard SQL. In standard SQL, views are handled using the rules for SQL SECURITY INVOKER.

If you invoke a view that was created before MySQL 5.1.2, it is treated as though it was created with a SQL SECURITY DEFINER clause and with a DEFINER value that is the same as your account. However, because the actual definer is unknown, MySQL issues a warning. To make the warning go away, it is sufficient to re-create the view so that the view definition includes a DEFINER clause.

The optional ALGORITHM clause is an extension to standard SQL. It affects how MariaDB processes the view. ALGORITHM takes three values: MERGE, TEMPTABLE, or UNDEFINED. The default algorithm is UNDEFINED if no ALGORITHM clause is present. See [View Algorithms](#) for more information.

Some views are updatable. That is, you can use them in statements such as UPDATE, DELETE, or INSERT to update the contents of the underlying table. For a view to be updatable, there must be a one-to-one relationship between the rows in the view and the rows in the underlying table. There are also certain other constructs that make a view non-updatable. See [Inserting and Updating with Views](#).

WITH CHECK OPTION

The WITH CHECK OPTION clause can be given for an updatable view to prevent inserts or updates to rows except those for which the WHERE clause in the select_statement is true.

In a WITH CHECK OPTION clause for an updatable view, the LOCAL and CASCADED keywords determine the scope of check testing when the view is defined in terms of another view. The LOCAL keyword restricts the CHECK OPTION only to the view being defined. CASCADED causes the checks for underlying views to be evaluated as well. When neither keyword is given, the default is CASCADED.

For more information about updatable views and the WITH CHECK OPTION clause, see [Inserting and Updating with Views](#).

IF NOT EXISTS

When the IF NOT EXISTS clause is used, MariaDB will return a warning instead of an error if the specified view already exists. Cannot be used together with the OR REPLACE clause.

Atomic DDL

MariaDB starting with [10.6.1](#)

[MariaDB 10.6.1](#) supports [Atomic DDL](#) and CREATE VIEW is atomic.

Examples

```
CREATE TABLE t (a INT, b INT) ENGINE = InnoDB;
```

```
INSERT INTO t VALUES (1,1), (2,2), (3,3);
```

```
CREATE VIEW v AS SELECT a, a*2 AS a2 FROM t;
```

```
SELECT * FROM v;
```

```
+-----+-----+
| a    | a2   |
+-----+-----+
| 1    | 2    |
| 2    | 4    |
| 3    | 6    |
+-----+-----+
```

OR REPLACE and IF NOT EXISTS:

```
CREATE VIEW v AS SELECT a, a*2 AS a2 FROM t;
```

```
ERROR 1050 (42S01): Table 'v' already exists
```

```
CREATE OR REPLACE VIEW v AS SELECT a, a*2 AS a2 FROM t;
```

```
Query OK, 0 rows affected (0.04 sec)
```

```
CREATE VIEW IF NOT EXISTS v AS SELECT a, a*2 AS a2 FROM t;
```

```
Query OK, 0 rows affected, 1 warning (0.01 sec)
```

```
SHOW WARNINGS;
```

```
+-----+-----+
| Level | Code | Message |
+-----+-----+
| Note  | 1050 | Table 'v' already exists |
+-----+-----+
```

1.1.1.3.1.18 Silent Column Changes

When a CREATE TABLE or ALTER TABLE command is issued, MariaDB will silently change a column specification in the following cases:

- PRIMARY KEY columns are always NOT NULL.
- Any trailing spaces from SET and ENUM values are discarded.
- TIMESTAMP columns are always NOT NULL, and display sizes are discarded
- A row-size limit of 65535 bytes applies

- If [strict SQL mode](#) is not enabled (it is enabled by default from [MariaDB 10.2](#)), a [VARCHAR](#) column longer than 65535 become [TEXT](#), and a [VARBINARY](#) columns longer than 65535 becomes a [BLOB](#). If strict mode is enabled the silent changes will not be made, and an error will occur.
- If a [USING](#) clause specifies an index that's not permitted by the storage engine, the engine will instead use another available index type that can be applied without affecting results.
- If the [CHARACTER SET](#) binary attribute is specified, the column is created as the matching binary data type. A [TEXT](#) becomes a [BLOB](#), [CHAR](#) a [BINARY](#) and [VARCHAR](#) a [VARBINARY](#). [ENUMs](#) and [SETs](#) are created as defined.

To ease imports from other RDBMSs, MariaDB will also silently map the following data types:

Other Vendor Type	MariaDB Type
BOOL	TINYINT
BOOLEAN	TINYINT
CHARACTER VARYING(M)	VARCHAR(M)
FIXED	DECIMAL
FLOAT4	FLOAT
FLOAT8	DOUBLE
INT1	TINYINT
INT2	SMALLINT
INT3	MEDIUMINT
INT4	INT
INT8	BIGINT
LONG VARBINARY	MEDIUMBLOB
LONG VARCHAR	MEDIUMTEXT
LONG	MEDIUMTEXT
MIDDLEINT	MEDIUMINT
NUMERIC	DECIMAL

Currently, all MySQL types are supported in MariaDB.

For type mapping between Cassandra and MariaDB, see [Cassandra storage engine](#).

Example

Silent changes in action:

```

CREATE TABLE SilenceIsGolden
(
  f1 TEXT CHARACTER SET binary,
  f2 VARCHAR(15) CHARACTER SET binary,
  f3 CHAR CHARACTER SET binary,
  f4 ENUM('x','y','z') CHARACTER SET binary,
  f5 VARCHAR (65536),
  f6 VARBINARY (65536),
  f7 INT1
);
Query OK, 0 rows affected, 2 warnings (0.31 sec)

SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Note  | 1246 | Converting column 'f5' from VARCHAR to TEXT |
| Note  | 1246 | Converting column 'f6' from VARBINARY to BLOB |
+-----+-----+-----+

DESCRIBE SilenceIsGolden;
+-----+-----+-----+-----+-----+-----+
| Field | Type                | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| f1    | blob                | YES  |     | NULL    |       |
| f2    | varbinary(15)       | YES  |     | NULL    |       |
| f3    | binary(1)           | YES  |     | NULL    |       |
| f4    | enum('x','y','z')   | YES  |     | NULL    |       |
| f5    | mediumtext          | YES  |     | NULL    |       |
| f6    | mediumblob          | YES  |     | NULL    |       |
| f7    | tinyint(4)          | YES  |     | NULL    |       |
+-----+-----+-----+-----+-----+-----+

```

1.1.1.3.1.19 Generated (Virtual and Persistent/Stored) Columns

Syntax

```

<type> [GENERATED ALWAYS] AS ( <expression> )
[VIRTUAL | PERSISTENT | STORED] [UNIQUE] [UNIQUE KEY] [COMMENT <text>]

```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Supported Features](#)
 1. [Storage Engine Support](#)
 2. [Data Type Support](#)
 3. [Index Support](#)
 4. [Statement Support](#)
 5. [Expression Support](#)
 6. [Making Stored Values Consistent](#)
 7. [MySQL Compatibility Support](#)
4. [Implementation Differences](#)
 1. [Implementation Differences Compared to Microsoft SQL Server](#)
5. [Development History](#)
6. [Examples](#)

MariaDB's generated columns syntax is designed to be similar to the syntax for [Microsoft SQL Server's computed columns](#) and [Oracle Database's virtual columns](#). In [MariaDB 10.2](#) and later, the syntax is also compatible with the syntax for [MySQL's generated columns](#).

Description

A generated column is a column in a table that cannot explicitly be set to a specific value in a [DML query](#). Instead, its value

is automatically generated based on an expression. This expression might generate the value based on the values of other columns in the table, or it might generate the value by calling [built-in functions](#) or [user-defined functions \(UDFs\)](#).

There are two types of generated columns:

- `PERSISTENT` (a.k.a. `STORED`): This type's value is actually stored in the table.
- `VIRTUAL`: This type's value is not stored at all. Instead, the value is generated dynamically when the table is queried. This type is the default.

Generated columns are also sometimes called computed columns or virtual columns.

Supported Features

Storage Engine Support

- Generated columns can only be used with storage engines which support them. If you try to use a storage engine that does not support them, then you will see an error similar to the following:

```
ERROR 1910 (HY000): TokuDB storage engine does not support computed columns
```

- [InnoDB](#), [Aria](#), [MyISAM](#) and [CONNECT](#) support generated columns.
- A column in a [MERGE](#) table can be built on a `PERSISTENT` generated column.
 - However, a column in a MERGE table can **not** be defined as a `VIRTUAL` and `PERSISTENT` generated column.

Data Type Support

- All data types are supported when defining generated columns.
- Using the [ZEROFILL](#) column option is supported when defining generated columns.
- Using the [AUTO_INCREMENT](#) column option is **not** supported when defining generated columns. Until [MariaDB 10.2.25](#) [↗](#), it was supported, but this support was removed, because it would not work correctly. See [MDEV-11117](#) [↗](#).

Index Support

- Using a generated column as a table's primary key is **not** supported. See [MDEV-5590](#) [↗](#) for more information. If you try to use one as a primary key, then you will see an error similar to the following:

```
ERROR 1903 (HY000): Primary key cannot be defined upon a computed column
```

- Using `PERSISTENT` generated columns as part of a [foreign key](#) is supported.
- Referencing `PERSISTENT` generated columns as part of a [foreign key](#) is also supported.
 - However, using the `ON UPDATE CASCADE`, `ON UPDATE SET NULL`, or `ON DELETE SET NULL` clauses is **not** supported. If you try to use an unsupported clause, then you will see an error similar to the following:

```
ERROR 1905 (HY000): Cannot define foreign key with ON UPDATE SET NULL clause on a computed column
```

- Defining indexes on both `VIRTUAL` and `PERSISTENT` generated columns is supported.
 - If an index is defined on a generated column, then the optimizer considers using it in the same way as indexes based on "real" columns.
- From [MariaDB 11.8](#), the optimizer can recognize use of indexed virtual column expressions in the WHERE clause and use them to construct range and `ref(const)` accesses. See [Virtual Column Support in the Optimizer](#).

Statement Support

- Generated columns are used in [DML queries](#) just as if they were "real" columns.
 - However, `VIRTUAL` and `PERSISTENT` generated columns differ in how their data is stored.
 - Values for `PERSISTENT` generated columns are generated whenever a [DML queries](#) inserts or updates the row with the special `DEFAULT` value. This generates the column's value, and it is stored in the table like the other "real" columns. This value can be read by other [DML queries](#) just like the other "real" columns.
 - Values for `VIRTUAL` generated columns are not stored in the table. Instead, the value is generated

dynamically whenever the column is queried. If other columns in a row are queried, but the `VIRTUAL` generated column is not one of the queried columns, then the column's value is not generated.

- The `SELECT` statement supports generated columns.
- Generated columns can be referenced in the `INSERT`, `UPDATE`, and `DELETE` statements.
 - However, `VIRTUAL` or `PERSISTENT` generated columns cannot be explicitly set to any other values than `NULL` or `DEFAULT`. If a generated column is explicitly set to any other value, then the outcome depends on whether `strict mode` is enabled in `sql_mode`. If it is not enabled, then a warning will be raised and the default generated value will be used instead. If it is enabled, then an error will be raised instead.
- The `CREATE TABLE` statement has limited support for generated columns.
 - It supports defining generated columns in a new table.
 - It supports using generated columns to [partition tables](#).
 - It does **not** support using the [versioning clauses](#) with generated columns.
- The `ALTER TABLE` statement has limited support for generated columns.
 - It supports the `MODIFY` and `CHANGE` clauses for `PERSISTENT` generated columns.
 - It does **not** support the `MODIFY` clause for `VIRTUAL` generated columns if `ALGORITHM` is not set to `COPY`. See [MDEV-15476](#) for more information.
 - It does **not** support the `CHANGE` clause for `VIRTUAL` generated columns if `ALGORITHM` is not set to `COPY`. See [MDEV-17035](#) for more information.
 - It does **not** support altering a table if `ALGORITHM` is not set to `COPY` if the table has a `VIRTUAL` generated column that is indexed. See [MDEV-14046](#) for more information.
 - It does **not** support adding a `VIRTUAL` generated column with the `ADD` clause if the same statement is also adding other columns if `ALGORITHM` is not set to `COPY`. See [MDEV-17468](#) for more information.
 - It also does **not** support altering an existing column into a `VIRTUAL` generated column.
 - It supports using generated columns to [partition tables](#).
 - It does **not** support using the [versioning clauses](#) with generated columns.
- The `SHOW CREATE TABLE` statement supports generated columns.
- The `DESCRIBE` statement can be used to check whether a table has generated columns.
 - You can tell which columns are generated by looking for the ones where the `Extra` column is set to either `VIRTUAL` or `PERSISTENT`. For example:

```
DESCRIBE table1;
+-----+-----+-----+-----+-----+-----+
| Field | Type          | Null | Key | Default | Extra          |
+-----+-----+-----+-----+-----+-----+
| a     | int(11)       | NO   |     | NULL    |               |
| b     | varchar(32)   | YES  |     | NULL    |               |
| c     | int(11)       | YES  |     | NULL    | VIRTUAL       |
| d     | varchar(5)    | YES  |     | NULL    | PERSISTENT    |
+-----+-----+-----+-----+-----+-----+
```

- Generated columns can be properly referenced in the `NEW` and `OLD` rows in [triggers](#).
- [Stored procedures](#) support generated columns.
- The `HANDLER` statement supports generated columns.

Expression Support

- Most legal, deterministic expressions which can be calculated are supported in expressions for generated columns.
- Most [built-in functions](#) are supported in expressions for generated columns.
 - However, some [built-in functions](#) can't be supported for technical reasons. For example, If you try to use an unsupported function in an expression, an error is generated similar to the following:

```
ERROR 1901 (HY000): Function or expression 'dayname()' cannot be used in the GENERATED ALWAYS AS clause of `v`
```

- [Subqueries](#) are **not** supported in expressions for generated columns because the underlying data can change.
- Using anything that depends on data outside the row is **not** supported in expressions for generated columns.
- [Stored functions](#) are **not** supported in expressions for generated columns. See [MDEV-17587](#) for more information.
- Non-deterministic [built-in functions](#) are supported in expressions for not indexed `VIRTUAL` generated columns.
- Non-deterministic [built-in functions](#) are **not** supported in expressions for `PERSISTENT` or indexed `VIRTUAL`

generated columns.

- **User-defined functions (UDFs)** are supported in expressions for generated columns.
 - However, MariaDB can't check whether a UDF is deterministic, so it is up to the user to be sure that they do not use non-deterministic UDFs with `VIRTUAL` generated columns.
- Defining a generated column based on other generated columns defined before it in the table definition is supported. For example:

```
CREATE TABLE t1 (a int as (1), b int as (a));
```

- However, defining a generated column based on other generated columns defined after in the table definition is **not** supported in expressions for generation columns because generated columns are calculated in the order they are defined.
- Using an expression that exceeds 255 characters in length is supported in expressions for generated columns. The new limit for the entire table definition, including all expressions for generated columns, is 65,535 bytes.
- Using constant expressions is supported in expressions for generated columns. For example:

```
CREATE TABLE t1 (a int as (1));
```

Making Stored Values Consistent

When a generated column is `PERSISTENT` or indexed, the value of the expression needs to be consistent regardless of the [SQL Mode](#) flags in the current session. If it is not, then the table will be seen as corrupted when the value that should actually be returned by the computed expression and the value that was previously stored and/or indexed using a different `sql_mode` setting disagree.

There are currently two affected classes of inconsistencies: character padding and unsigned subtraction:

- For a `VARCHAR` or `TEXT` generated column the length of the value returned can vary depending on the `PAD_CHAR_TO_FULL_LENGTH sql_mode` flag. To make the value consistent, create the generated column using an `RTRIM()` or `RPAD()` function. Alternately, create the generated column as a `CHAR` column so that its data is always fully padded.
- If a `SIGNED` generated column is based on the subtraction of an `UNSIGNED` value, the resulting value can vary depending on how large the value is and the `NO_UNSIGNED_SUBTRACTION sql_mode` flag. To make the value consistent, use `CAST()` to ensure that each `UNSIGNED` operand is `SIGNED` before the subtraction.

MariaDB starting with 10.5

Beginning in [MariaDB 10.5](#), there is a fatal error generated when trying to create a generated column whose value can change depending on the [SQL Mode](#) when its data is `PERSISTENT` or indexed.

For an existing generated column that has a potentially inconsistent value, a warning about a bad expression is generated the first time it is used (if warnings are enabled).

Beginning in [MariaDB 10.4.8](#), [MariaDB 10.3.18](#), and [MariaDB 10.2.27](#) a potentially inconsistent generated column outputs a warning when created or first used (without restricting their creation).

Here is an example of two tables that would be rejected in [MariaDB 10.5](#) and warned about in the other listed versions:

```
CREATE TABLE bad_pad (
  txt CHAR(5),
  -- CHAR -> VARCHAR or CHAR -> TEXT can't be persistent or indexed:
  txt VARCHAR(5) AS (txt) PERSISTENT
);

CREATE TABLE bad_sub (
  num1 BIGINT UNSIGNED,
  num2 BIGINT UNSIGNED,
  -- The resulting value can vary for some large values
  vnum BIGINT AS (num1 - num2) VIRTUAL,
  KEY(vnum)
);
```

The warnings for the above tables look like this:

```
Warning (Code 1901): Function or expression '`txt`' cannot be used in the GENERATED ALWAYS AS clause of `txt`
Warning (Code 1105): Expression depends on the @@sql_mode value PAD_CHAR_TO_FULL_LENGTH

Warning (Code 1901): Function or expression '`num1` - `num2`' cannot be used in the GENERATED ALWAYS AS clause of `vnum`
Warning (Code 1105): Expression depends on the @@sql_mode value NO_UNSIGNED_SUBTRACTION
```

To work around the issue, force the padding or type to make the generated column's expression return a consistent value. For example:

```
CREATE TABLE good_pad (
  txt CHAR(5),
  -- Using RTRIM() or RPAD() makes the value consistent:
  txt VARCHAR(5) AS (RTRIM(txt)) PERSISTENT,
  -- When not persistent or indexed, it is OK for the value to vary by mode:
  txt2 VARCHAR(5) AS (txt) VIRTUAL,
  -- CHAR -> CHAR is always OK:
  txt2 CHAR(5) AS (txt) PERSISTENT
);

CREATE TABLE good_sub (
  num1 BIGINT UNSIGNED,
  num2 BIGINT UNSIGNED,
  -- The indexed value will always be consistent in this expression:
  vnum BIGINT AS (CAST(num1 AS SIGNED) - CAST(num2 AS SIGNED)) VIRTUAL,
  KEY(vnum)
);
```

MySQL Compatibility Support

- The `STORED` keyword is supported as an alias for the `PERSISTENT` keyword.
- Tables created with MySQL 5.7 or later that contain [MySQL's generated columns](#) can be imported into MariaDB without a dump and restore.

Implementation Differences

Generated columns are subject to various constraints in other DBMSs that are not present in MariaDB's implementation. Generated columns may also be called computed columns or virtual columns in different implementations. The various details for a specific implementation can be found in the documentation for each specific DBMS.

Implementation Differences Compared to Microsoft SQL Server

MariaDB's generated columns implementation does not enforce the following restrictions that are present in [Microsoft SQL Server's computed columns](#) implementation:

- MariaDB allows [server variables](#) in generated column expressions, including those that change dynamically, such as `warning_count`.
- MariaDB allows the `CONVERT_TZ()` function to be called with a named [time zone](#) as an argument, even though time zone names and time offsets are configurable.
- MariaDB allows the `CAST()` function to be used with non-unicode [character sets](#), even though character sets are configurable and differ between binaries/versions.
- MariaDB allows `FLOAT` expressions to be used in generated columns. Microsoft SQL Server considers these expressions to be "imprecise" due to potential cross-platform differences in floating-point implementations and precision.
- Microsoft SQL Server requires the [ARITHABORT](#) mode to be set, so that division by zero returns an error, and not a NULL.
- Microsoft SQL Server requires `QUOTED_IDENTIFIER` to be set in `sql_mode`. In MariaDB, if data is inserted without `ANSI_QUOTES` set in `sql_mode`, then it will be processed and stored differently in a generated column that contains quoted identifiers.

Microsoft SQL Server enforces the above restrictions by doing one of the following things:

- Refusing to create computed columns.
- Refusing to allow updates to a table containing them.
- Refusing to use an index over such a column if it can not be guaranteed that the expression is fully deterministic.

In MariaDB, as long as the `sql_mode`, language, and other settings that were in effect during the `CREATE TABLE` remain

unchanged, the generated column expression will always be evaluated the same. If any of these things change, then please be aware that the generated column expression might not be evaluated the same way as it previously was.

If you try to update a virtual column, you will get an error if the default `strict mode` is enabled in `sql_mode`, or a warning otherwise.

Development History

Generated columns was originally developed by Andrey Zhakov. It was then modified by Sanja Byelkin and Igor Babaev at Monty Program for inclusion in MariaDB. Monty did the work on [MariaDB 10.2](#) to lift a some of the old limitations.

Examples

Here is an example table that uses both `VIRTUAL` and `PERSISTENT` virtual columns:

```
USE TEST;

CREATE TABLE table1 (
  a INT NOT NULL,
  b VARCHAR(32),
  c INT AS (a mod 10) VIRTUAL,
  d VARCHAR(5) AS (left(b,5)) PERSISTENT);
```

If you describe the table, you can easily see which columns are virtual by looking in the "Extra" column:

```
DESCRIBE table1;
+-----+-----+-----+-----+-----+-----+
| Field | Type          | Null | Key | Default | Extra          |
+-----+-----+-----+-----+-----+-----+
| a     | int(11)       | NO   |     | NULL    |                |
| b     | varchar(32)   | YES  |     | NULL    |                |
| c     | int(11)       | YES  |     | NULL    | VIRTUAL        |
| d     | varchar(5)    | YES  |     | NULL    | PERSISTENT     |
+-----+-----+-----+-----+-----+-----+
```

To find out what function(s) generate the value of the virtual column you can use `SHOW CREATE TABLE` :

```
SHOW CREATE TABLE table1;

| table1 | CREATE TABLE `table1` (
  `a` int(11) NOT NULL,
  `b` varchar(32) DEFAULT NULL,
  `c` int(11) AS (a mod 10) VIRTUAL,
  `d` varchar(5) AS (left(b,5)) PERSISTENT
) ENGINE=MyISAM DEFAULT CHARSET=latin1 |
```

If you try to insert non-default values into a virtual column, you will receive a warning and what you tried to insert will be ignored and the derived value inserted instead:

```

WARNINGS;
Show warnings enabled.

INSERT INTO table1 VALUES (1, 'some text', default, default);
Query OK, 1 row affected (0.00 sec)

INSERT INTO table1 VALUES (2, 'more text',5,default);
Query OK, 1 row affected, 1 warning (0.00 sec)

Warning (Code 1645): The value specified for computed column 'c' in table 'table1' has been ignored

INSERT INTO table1 VALUES (123, 'even more text', default, 'something');
Query OK, 1 row affected, 2 warnings (0.00 sec)

Warning (Code 1645): The value specified for computed column 'd' in table 'table1' has been ignored
Warning (Code 1265): Data truncated for column 'd' at row 1

SELECT * FROM table1;
+-----+-----+-----+-----+
| a | b | c | d |
+-----+-----+-----+-----+
| 1 | some text | 1 | some |
| 2 | more text | 2 | more |
| 123 | even more text | 3 | even |
+-----+-----+-----+-----+
3 rows in set (0.00 sec)

```

If the `ZEROFILL` clause is specified, it should be placed directly after the type definition, before the `AS (<expression>)` :

```

CREATE TABLE table2 (a INT, b INT ZEROFILL AS (a*2) VIRTUAL);
INSERT INTO table2 (a) VALUES (1);

SELECT * FROM table2;
+-----+-----+
| a | b |
+-----+-----+
| 1 | 0000000002 |
+-----+-----+
1 row in set (0.00 sec)

```

You can also use virtual columns to implement a "poor man's partial index". See example at the end of [Unique Index](#).

1.1.1.3.1.20 Invisible Columns

Invisible columns (sometimes also called hidden columns) are hidden in certain contexts.

Columns can be given an `INVISIBLE` attribute in a `CREATE TABLE` or `ALTER TABLE` statement. These columns will then not be listed in the results of a `SELECT *` statement, nor do they need to be assigned a value in an `INSERT` statement, unless `INSERT` explicitly mentions them by name.

Since `SELECT *` does not return the invisible columns, new tables or views created in this manner will have no trace of the invisible columns. If specifically referenced in the `SELECT` statement, the columns will be brought into the view/new table, but the `INVISIBLE` attribute will not.

Invisible columns can be declared as `NOT NULL`, but then require a `DEFAULT` value.

It is not possible for all columns in a table to be invisible.

Examples

```

CREATE TABLE t (x INT INVISIBLE);
ERROR 1113 (42000): A table must have at least 1 column

CREATE TABLE t (x INT, y INT INVISIBLE, z INT INVISIBLE NOT NULL);
ERROR 4106 (HY000): Invisible column `z` must have a default value

CREATE TABLE t (x INT, y INT INVISIBLE, z INT INVISIBLE NOT NULL DEFAULT 4);

INSERT INTO t VALUES (1),(2);

INSERT INTO t (x,y) VALUES (3,33);

SELECT * FROM t;
+-----+
| x     |
+-----+
| 1     |
| 2     |
| 3     |
+-----+

SELECT x,y,z FROM t;
+-----+-----+-----+
| x     | y     | z     |
+-----+-----+-----+
| 1     | NULL  | 4     |
| 2     | NULL  | 4     |
| 3     | 33    | 4     |
+-----+-----+-----+

DESC t;
+-----+-----+-----+-----+-----+-----+
| Field | Type   | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| x     | int(11)| YES  |     | NULL    |       |
| y     | int(11)| YES  |     | NULL    | INVISIBLE |
| z     | int(11)| NO   |     | 4       | INVISIBLE |
+-----+-----+-----+-----+-----+-----+

ALTER TABLE t MODIFY x INT INVISIBLE, MODIFY y INT, MODIFY z INT NOT NULL DEFAULT 4;

DESC t;
+-----+-----+-----+-----+-----+-----+
| Field | Type   | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| x     | int(11)| YES  |     | NULL    | INVISIBLE |
| y     | int(11)| YES  |     | NULL    |           |
| z     | int(11)| NO   |     | 4       |           |
+-----+-----+-----+-----+-----+-----+

```

Creating a view from a table with hidden columns:

```

CREATE VIEW v1 AS SELECT * FROM t;

DESC v1;
+-----+-----+-----+-----+-----+-----+
| Field | Type   | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| y     | int(11)| YES  |     | NULL    |       |
| z     | int(11)| NO   |     | 4       |       |
+-----+-----+-----+-----+-----+-----+

CREATE VIEW v2 AS SELECT x,y,z FROM t;

DESC v2;
+-----+-----+-----+-----+-----+-----+
| Field | Type   | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| x     | int(11)| YES  |     | NULL    |       |
| y     | int(11)| YES  |     | NULL    |       |
| z     | int(11)| NO   |     | 4       |       |
+-----+-----+-----+-----+-----+-----+

```

```
create table t1 (x bigint unsigned not null, y varchar(16), z text);

insert into t1 values (123, 'qq11', 'ipsum');

insert into t1 values (123, 'qq22', 'lorem');

alter table t1 add pkid serial primary key invisible first;

insert into t1 values (123, 'qq33', 'amet');

select * from t1;
+-----+-----+-----+
| x   | y   | z   |
+-----+-----+-----+
| 123 | qq11 | ipsum |
| 123 | qq22 | lorem |
| 123 | qq33 | amet  |
+-----+-----+-----+

select pkid, z from t1;
+-----+-----+
| pkid | z   |
+-----+-----+
| 1   | ipsum |
| 2   | lorem |
| 3   | amet  |
+-----+-----+
```

1.1.1.2.1.1 ALTER

1.1.1.2.1.1.1 ALTER TABLE

1.1.1.2.1.1.2 ALTER DATABASE

1.1.1.2.1.1.3 ALTER EVENT

1.1.1.2.1.1.4 ALTER FUNCTION

1.1.1.1.2 ALTER USER

1.1.1.2.1.1.11 ALTER VIEW

1.1.1.3.3 DROP

Articles on various DROP commands.

DROP DATABASE

Drop all tables and delete database.

DROP EVENT

Removes an existing event.

DROP FUNCTION

Drop a stored function.

DROP FUNCTION UDF

Drop a user-defined function.

DROP INDEX

Drops an index from a table.

DROP LOGFILE GROUP

The DROP LOGFILE GROUP statement is not supported by MariaDB. It was origin...

DROP PACKAGE

Drops a stored package entirely.

DROP PACKAGE BODY

Drops a package body (i.e the implementation) previously created using the CREATE PACKAGE BODY.

DROP PROCEDURE

Drop stored procedure.

DROP ROLE

Drop a role.

DROP SEQUENCE

Deleting a SEQUENCE.

DROP SERVER

Dropping a server definition.

DROP TABLE

Removes definition and data from one or more tables.

DROP TABLESPACE

DROP TABLESPACE is not available in MariaDB.

DROP TRIGGER

Drops a trigger.

DROP USER

Remove one or more MariaDB accounts.

DROP VIEW

Removes one or more views.

DROP CATALOG

Deletes a catalog. [↗](#)

There are [1 related questions](#) [↗](#).

1.1.1.3.3.1 DROP DATABASE

Syntax

```
DROP {DATABASE | SCHEMA} [IF EXISTS] db_name
```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [IF EXISTS](#)
 2. [Atomic DDL](#)
3. [Examples](#)

Description

`DROP DATABASE` drops all tables in the database and deletes the database. Be very careful with this statement! To use `DROP DATABASE`, you need the [DROP privilege](#) on the database. `DROP SCHEMA` is a synonym for `DROP DATABASE`.

Important: When a database is dropped, user privileges on the database are not automatically dropped. See [GRANT](#).

IF EXISTS

Use `IF EXISTS` to prevent an error from occurring for databases that do not exist. A `NOTE` is generated for each non-existent database when using `IF EXISTS`. See [SHOW WARNINGS](#).

Atomic DDL

MariaDB starting with [10.6.1](#)

MariaDB [10.6.1](#) supports [Atomic DDL](#).

`DROP DATABASE` is implemented as

```
loop over all tables
DROP TABLE table
```

Each individual [DROP TABLE](#) is atomic while `DROP DATABASE` as a whole is crash-safe.

Examples

```
DROP DATABASE bufg;
Query OK, 0 rows affected (0.39 sec)

DROP DATABASE bufg;
ERROR 1008 (HY000): Can't drop database 'bufg'; database doesn't exist

\w
Show warnings enabled.

DROP DATABASE IF EXISTS bufg;
Query OK, 0 rows affected, 1 warning (0.00 sec)
Note (Code 1008): Can't drop database 'bufg'; database doesn't exist
```

1.1.1.3.3.2 DROP EVENT

Syntax

```
DROP EVENT [IF EXISTS] event_name
```

Description

This statement drops the [event](#) named `event_name`. The event immediately ceases being active, and is deleted completely from the server.

If the event does not exist, the error `ERROR 1517 (HY000): Unknown event 'event_name'` results. You can override

this and cause the statement to generate a `NOTE` for non-existent events instead by using `IF EXISTS`. See [SHOW WARNINGS](#).

This statement requires the `EVENT` privilege. In MySQL 5.1.11 and earlier, an event could be dropped only by its definer, or by a user having the `SUPER` privilege.

Examples

```
DROP EVENT myevent3;
```

Using the `IF EXISTS` clause:

```
DROP EVENT IF EXISTS myevent3;
Query OK, 0 rows affected, 1 warning (0.01 sec)

SHOW WARNINGS;
+-----+-----+-----+-----+
| Level | Code | Message                                |
+-----+-----+-----+-----+
| Note  | 1305 | Event myevent3 does not exist |
+-----+-----+-----+-----+
```

1.1.1.3.3.3 DROP FUNCTION

Syntax

```
DROP FUNCTION [IF EXISTS] f_name
```

Contents

- [Syntax](#)
- [Description](#)
 - [IF EXISTS](#)
- [Examples](#)

Description

The `DROP FUNCTION` statement is used to drop a [stored function](#) or a user-defined function (UDF). That is, the specified routine is removed from the server, along with all privileges specific to the function. You must have the `ALTER ROUTINE` [privilege](#) for the routine in order to drop it. If the `automatic_sp_privileges` server system variable is set, both the `ALTER ROUTINE` and `EXECUTE` privileges are granted automatically to the routine creator - see [Stored Routine Privileges](#).

IF EXISTS

The `IF EXISTS` clause is a MySQL/MariaDB extension. It prevents an error from occurring if the function does not exist. A `NOTE` is produced that can be viewed with [SHOW WARNINGS](#).

For dropping a [user-defined functions](#) (UDF), see [DROP FUNCTION UDF](#).

Examples

```

DROP FUNCTION hello;
Query OK, 0 rows affected (0.042 sec)

DROP FUNCTION hello;
ERROR 1305 (42000): FUNCTION test.hello does not exist

DROP FUNCTION IF EXISTS hello;
Query OK, 0 rows affected, 1 warning (0.000 sec)

SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Note  | 1305 | FUNCTION test.hello does not exist |
+-----+-----+-----+

```

1.1.1.3.3.4 DROP FUNCTION UDF

Syntax

```
DROP FUNCTION [IF EXISTS] function_name
```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [Upgrading a UDF](#)
3. [Examples](#)

Description

This statement drops the [user-defined function](#) (UDF) named `function_name`.

To drop a function, you must have the [DELETE privilege](#) for the `mysql` database. This is because `DROP FUNCTION` removes the row from the `mysql.func` system table that records the function's name, type and shared library name.

For dropping a stored function, see [DROP FUNCTION](#).

Upgrading a UDF

To upgrade the UDF's shared library, first run a [DROP FUNCTION](#) statement, then upgrade the shared library and finally run the `CREATE FUNCTION` statement. If you upgrade without following this process, you may crash the server.

Examples

```
DROP FUNCTION jsoncontains_path;
```

IF EXISTS:

```

DROP FUNCTION jsoncontains_path;
ERROR 1305 (42000): FUNCTION test.jsoncontains_path does not exist

DROP FUNCTION IF EXISTS jsoncontains_path;
Query OK, 0 rows affected, 1 warning (0.00 sec)

SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Note  | 1305 | FUNCTION test.jsoncontains_path does not exist |
+-----+-----+-----+

```

1.1.1.3.3.5 DROP INDEX

Syntax

```
DROP INDEX [IF EXISTS] index_name ON tbl_name
        [WAIT n | NOWAIT]
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Privileges](#)
4. [Online DDL](#)
5. [DROP INDEX IF EXISTS ...](#)
6. [WAIT/NOWAIT](#)
7. [Progress Reporting](#)

Description

`DROP INDEX` drops the [index](#) named `index_name` from the table `tbl_name`. This statement is mapped to an `ALTER TABLE` statement to drop the index.

If another connection is using the table, a [metadata lock](#) is active, and this statement will wait until the lock is released. This is also true for non-transactional tables.

See [ALTER TABLE](#).

Another shortcut, [CREATE INDEX](#), allows the creation of an index.

To remove the primary key, ``PRIMARY`` must be specified as `index_name`. Note that [the quotes](#) are necessary, because `PRIMARY` is a keyword.

Privileges

Executing the `DROP INDEX` statement requires the [INDEX](#) privilege for the table or the database.

Online DDL

Online DDL is used by default with InnoDB, when the drop index operation supports it.

See [InnoDB Online DDL Overview](#) for more information on online DDL with [InnoDB](#).

DROP INDEX IF EXISTS ...

If the `IF EXISTS` clause is used, then MariaDB will return a warning instead of an error if the index does not exist.

WAIT/NOWAIT

Sets the lock wait timeout. See [WAIT and NOWAIT](#).

Progress Reporting

MariaDB provides progress reporting for `DROP INDEX` statement for clients that support the new progress reporting protocol. For example, if you were using the [mariadb](#) client, then the progress report might look like this::

1.1.1.3.3.6 DROP LOGFILE GROUP

The `DROP LOGFILE GROUP` statement is not supported by MariaDB. It was originally inherited from MySQL NDB Cluster. See [MDEV-19295](#) [🔗](#) for more information.

1.1.1.3.3.7 DROP PACKAGE

Syntax

```
DROP PACKAGE [IF EXISTS] [ db_name . ] package_name
```

Contents

1. [Syntax](#)
2. [Description](#)

Description

The `DROP PACKAGE` statement can be used when [Oracle SQL_MODE](#) is set.

The `DROP PACKAGE` statement drops a stored package entirely:

- Drops the package specification (earlier created using the [CREATE PACKAGE](#) statement).
- Drops the package implementation, if the implementation was already created using the [CREATE PACKAGE BODY](#) statement.

1.1.1.3.3.8 DROP PACKAGE BODY

Syntax

```
DROP PACKAGE BODY [IF EXISTS] [ db_name . ] package_name
```

Contents

1. [Syntax](#)
2. [Description](#)

Description

The `DROP PACKAGE BODY` statement can be used when [Oracle SQL_MODE](#) is set.

The `DROP PACKAGE BODY` statement drops the package body (i.e the implementation), previously created using the [CREATE PACKAGE BODY](#) statement.

Note, `DROP PACKAGE BODY` drops only the package implementation, but does not drop the package specification. Use [DROP PACKAGE](#) to drop the package entirely (i.e. both implementation and specification).

1.1.1.3.3.9 DROP PROCEDURE

Syntax

```
DROP PROCEDURE [IF EXISTS] sp_name
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

Description

This statement is used to drop a [stored procedure](#). That is, the specified routine is removed from the server along with all privileges specific to the [procedure](#). You must have the `ALTER ROUTINE` privilege for the routine. If the `automatic_sp_privileges` server system variable is set, that privilege and `EXECUTE` are granted automatically to the routine creator - see [Stored Routine Privileges](#).

The `IF EXISTS` clause is a MySQL/MariaDB extension. It prevents an error from occurring if the procedure or function does not exist. A `NOTE` is produced that can be viewed with `SHOW WARNINGS`.

While this statement takes effect immediately, threads which are executing a procedure can continue execution.

Examples

```
DROP PROCEDURE simpleproc;
```

IF EXISTS:

```
DROP PROCEDURE simpleproc;
ERROR 1305 (42000): PROCEDURE test.simpleproc does not exist
```

```
DROP PROCEDURE IF EXISTS simpleproc;
Query OK, 0 rows affected, 1 warning (0.00 sec)
```

```
SHOW WARNINGS;
```

```
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Note  | 1305 | PROCEDURE test.simpleproc does not exist |
+-----+-----+-----+
```

1.1.1.1.9 DROP ROLE

1.1.6.5 DROP SEQUENCE

1.1.1.3.3.12 DROP SERVER

Syntax

```
DROP SERVER [ IF EXISTS ] server_name
```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [IF EXISTS](#)
3. [Examples](#)

Description

Drops the server definition for the server named `server_name`. The corresponding row within the `mysql.servers` table will be deleted. This statement requires the `SUPER` privilege or, from [MariaDB 10.5.2](#), the `FEDERATED ADMIN` privilege.

Dropping a server for a table does not affect any [FederatedX](#), [FEDERATED](#), [Connect](#) or [Spider](#) tables that used this connection information when they were created.

`DROP SERVER` is not written to the `binary log`, irrespective of the `binary log format` being used. From [MariaDB 10.1.13](#), [Galera](#) replicates the `CREATE SERVER`, `ALTER SERVER` and `DROP SERVER` statements.

IF EXISTS

If the `IF EXISTS` clause is used, MariaDB will not return an error if the server does not exist. Unlike all other statements, `DROP SERVER IF EXISTS` does not issue a note if the server does not exist. See [MDEV-9400](#).

Examples

```
DROP SERVER s;
```

IF EXISTS:

```
DROP SERVER s;  
ERROR 1477 (HY000): The foreign server name you are trying to reference  
does not exist. Data source error: s  
  
DROP SERVER IF EXISTS s;  
Query OK, 0 rows affected (0.00 sec)
```

1.1.1.2.1.8 DROP TABLE

1.1.1.3.3.14 DROP TABLESPACE

The `DROP TABLESPACE` statement is not supported by MariaDB. It was originally inherited from MySQL NDB Cluster. In MySQL 5.7 and later, the statement is also supported for InnoDB. However, MariaDB has chosen not to include that specific feature. See [MDEV-19294](#) for more information.

1.1.1.3.3.15 DROP TRIGGER

Syntax

```
DROP TRIGGER [IF EXISTS] [schema_name.]trigger_name
```

Contents

- 1. [Syntax](#)
- 2. [Description](#)
 - 1. [Atomic DDL](#)
- 3. [Examples](#)

Description

This statement drops a [trigger](#). The schema (database) name is optional. If the schema is omitted, the trigger is dropped from the default schema. Its use requires the `TRIGGER` privilege for the table associated with the trigger.

Use `IF EXISTS` to prevent an error from occurring for a trigger that does not exist. A `NOTE` is generated for a non-existent trigger when using `IF EXISTS`. See [SHOW WARNINGS](#).

Note: Triggers for a table are also dropped if you drop the table.

Atomic DDL

MariaDB starting with [10.6.1](#)
MariaDB 10.6.1 supports [Atomic DDL](#) and `DROP TRIGGER` is atomic.

Examples

```
DROP TRIGGER test.example_trigger;
```

Using the `IF EXISTS` clause:

```
DROP TRIGGER IF EXISTS test.example_trigger;
Query OK, 0 rows affected, 1 warning (0.01 sec)
```

```
SHOW WARNINGS;
```

```
+-----+-----+-----+
| Level | Code | Message                |
+-----+-----+-----+
| Note  | 1360 | Trigger does not exist |
+-----+-----+-----+
```

1.1.1.1.3 DROP USER

1.1.1.3.3.17 DROP VIEW

Syntax

```
DROP VIEW [IF EXISTS]
  view_name [, view_name] ...
  [RESTRICT | CASCADE]
```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [Atomic DDL](#)
3. [Examples](#)

Description

`DROP VIEW` removes one or more [views](#). You must have the `DROP` privilege for each view. If any of the views named in the argument list do not exist, MariaDB returns an error indicating by name which non-existing views it was unable to drop, but it also drops all of the views in the list that do exist.

The `IF EXISTS` clause prevents an error from occurring for views that don't exist. When this clause is given, a `NOTE` is generated for each non-existent view. See [SHOW WARNINGS](#).

`RESTRICT` and `CASCADE`, if given, are parsed and ignored.

It is possible to specify view names as `db_name.view_name`. This is useful to delete views from multiple databases with one statement. See [Identifier Qualifiers](#) for details.

The [DROP privilege](#) is required to use `DROP TABLE` on non-temporary tables. For temporary tables, no privilege is required, because such tables are only visible for the current session.

If a view references another view, it will be possible to drop the referenced view. However, the other view will reference a view which does not exist any more. Thus, querying it will produce an error similar to the following:

```
ERROR 1356 (HY000): View 'db_name.view_name' references invalid table(s) or
column(s) or function(s) or definer/invoker of view lack rights to use them
```

This problem is reported in the output of [CHECK TABLE](#).

Note that it is not necessary to use `DROP VIEW` to replace an existing view, because [CREATE VIEW](#) has an `OR REPLACE` clause.

Atomic DDL

MariaDB starting with [10.6.1](#)

[MariaDB 10.6.1](#) supports [Atomic DDL](#) and `DROP VIEW` for a singular view is atomic. Dropping multiple views is crash-safe.

Examples

```
DROP VIEW v,v2;
```

Given views `v` and `v2`, but no view `v3`

```
DROP VIEW v,v2,v3;  
ERROR 1051 (42S02): Unknown table 'v3'
```

```
DROP VIEW IF EXISTS v,v2,v3;  
Query OK, 0 rows affected, 1 warning (0.01 sec)
```

```
SHOW WARNINGS;
```

```
+-----+-----+-----+  
| Level | Code | Message |  
+-----+-----+-----+  
| Note | 1051 | Unknown table 'test.v3' |  
+-----+-----+-----+
```

1.1.1.3.4 Atomic DDL

From [MariaDB 10.6.1](#), we have improved readability for DDL (Data Definition Language) operations to make most of them atomic, and the rest crash-safe, even if the server crashes in the middle of an operation.

The design of Atomic/Crash-safe DDL ([MDEV-17567](#)) allows it to work with all storage engines.

Definitions

- Atomic means that either the operation succeeds (and is logged to the [binary log](#) or is completely reversed.
- Crash-safe means that in case of a crash, after the server has restarted, all tables are consistent, there are no temporary files or tables on disk and the binary log matches the status of the server.
- DDL Data definition language.
- DML Data manipulation language.
- 'DDL recovery log' or 'DDL log' for short, is the new log file, `ddl_recovery.log` by default, that stores all DDL operations in progress. This is used to recover the state of the server in case of sudden crash.

Background

Before 10.6, in case of a crash, there was a small possibility that one of the following things could happen:

- There could be temporary tables starting with `#sql-alter` or `#sql-shadow` or temporary files ending with " left.
- The table in the storage engine and the table's `.frm` file could be out of sync.
- During a multi-table rename, only some of the tables were renamed.

Which DDL Operations are Now Atomic

- [CREATE TABLE](#), except when used with [CREATE OR REPLACE](#), which is only crash safe.
- [RENAME TABLE](#) and [RENAME TABLES](#).
- [CREATE VIEW](#)
- [CREATE SEQUENCE](#)
- [CREATE TRIGGER](#)
- [DROP TRIGGER](#)
- [DROP TABLE](#) and [DROP VIEW](#). Dropping multiple tables is only crash safe.
- [ALTER TABLE](#)
- [ALTER SEQUENCE](#) is not listed above as it is internally implemented as a DML.

Which DDL Operations are Now Crash Safe

DROP TABLE of Multiple Tables.

[DROP TABLE](#) over multiple tables is treated as if every DROP is a separate, atomic operation. This means that after a crash, all fully, or partly, dropped tables will be dropped and logged to the binary log. The undropped tables will be left untouched.

CREATE OR REPLACE TABLE

`CREATE OR REPLACE TABLE foo` is implemented as:

```
DROP TABLE IF EXISTS foo;
CREATE TABLE foo ...
```

This means that if there is a crash during `CREATE TABLE` then the original table 'foo' will be dropped even if the new table was not created. If the table was not re-created, the binary log will contain the `DROP TABLE`.

DROP DATABASE

`DROP DATABASE` is implemented as:

```
loop over all tables
  DROP TABLE table
```

Each `DROP TABLE` is atomic, but in case of a crash, things will work the same way as `DROP TABLE` with multiple tables.

Atomic with Different Storage Engines

Atomic/Crash-safe DDL works with all storage engines that either have atomic DDLs internally or are able to re-execute `DROP` or `RENAME` in case of failure.

This should be true for most storage engines. The ones that still need some work are:

- The [S3 storage engine](#).
- The [partitioning engine](#). Partitioning should be atomic for most cases, but there are still some known issues that need to be tested and fixed.

The DDL Log Recovery File

The new startup option `--log-ddl-recovery=path` (`ddl_recovery.log` by default) can be used to specify the place for the DDL log file. This is mainly useful in the case when one has a filesystem on persistent memory, as there is a lot of sync on this file during DDL operations.

This file contains all DDL operations that are in progress.

At MariaDB server startup, the DDL log file is copied to a file with the same base name but with a `-backup.log` suffix. This is mainly done to be able to find out what went wrong if recovery fails.

If the server crashes during recovery (unlikely but possible), the recovery will continue where it was before. The recovery will retry each entry up to 3 times before giving up and proceeding with the next entry.

Conclusions

- We believe that a clean separation of layers leads to an easier-to-maintain solution. The Atomic DDL implementation in [MariaDB 10.6](#) introduced minimal changes to the storage engine API, mainly for native `ALTER TABLE`.
- In our InnoDB implementation, no file format changes were needed on top of the `RENAME` undo log that was introduced in [MariaDB 10.2.19](#) for a backup-safe `TRUNCATE` re-implementation. Correct use of sound design principles (write-ahead logging and transactions; also file creation now follows the ARIES protocol) is sufficient. We removed the hacks (at most one `CREATE` or `DROP` per transaction) and correctly implemented `rollback` and `purge` triggers for the InnoDB `SYS_INDEXES` table.
- Numerous DDL recovery bugs in InnoDB were found and fixed quickly thanks to <https://rr-project.org>. We are still working on one: data files must not be deleted before the DDL transaction is committed.

Thanks to Atomic/Crash-safe DDL, the MariaDB server is now much more stable and reliable in unstable environments. There is still ongoing work to fix the few remaining issues mentioned above to make all DDL operations Atomic. The target for these is [MariaDB 10.7](#).

1.1.1.3.5 CONSTRAINT

MariaDB supports the implementation of constraints at the table-level using either `CREATE TABLE` or `ALTER TABLE` statements. A table constraint restricts the data you can add to the table. If you attempt to insert invalid data on a column, MariaDB throws an error.

Syntax

```
[CONSTRAINT [symbol]] constraint_expression

constraint_expression:
| PRIMARY KEY [index_type] (index_col_name, ...) [index_option] ...
| FOREIGN KEY [index_name] (index_col_name, ...)
  REFERENCES tbl_name (index_col_name, ...)
  [ON DELETE reference_option]
  [ON UPDATE reference_option]
| UNIQUE [INDEX|KEY] [index_name]
  [index_type] (index_col_name, ...) [index_option] ...
| CHECK (check_constraints)

index_type:
  USING {BTREE | HASH | RTREE}

index_col_name:
  col_name [(length)] [ASC | DESC]

index_option:
| KEY_BLOCK_SIZE [=] value
| index_type
| WITH PARSER parser_name
| COMMENT 'string'
| CLUSTERING={YES|NO}

reference_option:
  RESTRICT | CASCADE | SET NULL | NO ACTION | SET DEFAULT
```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [FOREIGN KEY Constraints](#)
 2. [CHECK Constraints](#)
 3. [Replication](#)
 4. [Auto_increment](#)
3. [Examples](#)

Description

Constraints provide restrictions on the data you can add to a table. This allows you to enforce data integrity from MariaDB, rather than through application logic. When a statement violates a constraint, MariaDB throws an error.

There are four types of table constraints:

Constraint	Description
PRIMARY KEY	Sets the column for referencing rows. Values must be unique and not null.
FOREIGN KEY	Sets the column to reference the primary key on another table.
UNIQUE	Requires values in column or columns only occur once in the table.
CHECK	Checks whether the data meets the given condition.

The [Information Schema TABLE_CONSTRAINTS Table](#) contains information about tables that have constraints.

FOREIGN KEY Constraints

InnoDB supports [foreign key](#) constraints. The syntax for a foreign key constraint definition in InnoDB looks like this:

```
[CONSTRAINT [symbol]] FOREIGN KEY
  [index_name] (index_col_name, ...)
  REFERENCES tbl_name (index_col_name,...)
  [ON DELETE reference_option]
  [ON UPDATE reference_option]

reference_option:
  RESTRICT | CASCADE | SET NULL | NO ACTION
```

The [Information Schema REFERENTIAL_CONSTRAINTS](#) table has more information about foreign keys.

CHECK Constraints

Constraints are enforced. Before [MariaDB 10.2.1](#) [↗](#) constraint expressions were accepted in the syntax but ignored.

You can define constraints in 2 different ways:

- `CHECK (expression)` given as part of a column definition.
- `CONSTRAINT [constraint_name] CHECK (expression)`

Before a row is inserted or updated, all constraints are evaluated in the order they are defined. If any constraint expression returns false, then the row will not be inserted or updated. One can use most deterministic functions in a constraint, including [UDFs](#).

```
CREATE TABLE t1 (a INT CHECK (a>2), b INT CHECK (b>2), CONSTRAINT a_greater CHECK (a>b));
```

If you use the second format and you don't give a name to the constraint, then the constraint will get an automatically generated name. This is done so that you can later delete the constraint with [ALTER TABLE DROP constraint_name](#).

One can disable all constraint expression checks by setting the `check_constraint_checks` variable to `OFF`. This is useful for example when loading a table that violates some constraints that you want to later find and fix in SQL.

Replication

In [row-based replication](#), only the master checks constraints, and failed statements will not be replicated. In [statement-based replication](#), the slaves will also check constraints. Constraints should therefore be identical, as well as deterministic, in a replication environment.

Auto_increment

`auto_increment` columns are not permitted in check constraints. Before [MariaDB 10.2.6](#) [↗](#), they were permitted, but would not work correctly. See [MDEV-11117](#) [↗](#).

Examples

```
CREATE TABLE product (category INT NOT NULL, id INT NOT NULL,
                        price DECIMAL,
                        PRIMARY KEY(category, id)) ENGINE=INNODB;
CREATE TABLE customer (id INT NOT NULL,
                        PRIMARY KEY (id)) ENGINE=INNODB;
CREATE TABLE product_order (no INT NOT NULL AUTO_INCREMENT,
                              product_category INT NOT NULL,
                              product_id INT NOT NULL,
                              customer_id INT NOT NULL,
                              PRIMARY KEY(no),
                              INDEX (product_category, product_id),
                              FOREIGN KEY (product_category, product_id)
                                REFERENCES product(category, id)
                                ON UPDATE CASCADE ON DELETE RESTRICT,
                              INDEX (customer_id),
                              FOREIGN KEY (customer_id)
                                REFERENCES customer(id)) ENGINE=INNODB;
```

The following examples will work from [MariaDB 10.2.1](#) [↗](#) onwards.

Numeric constraints and comparisons:

```
CREATE TABLE t1 (a INT CHECK (a>2), b INT CHECK (b>2), CONSTRAINT a_greater CHECK (a>b));

INSERT INTO t1(a) VALUES (1);
ERROR 4022 (23000): CONSTRAINT `a` failed for `test`.`t1`

INSERT INTO t1(a,b) VALUES (3,4);
ERROR 4022 (23000): CONSTRAINT `a_greater` failed for `test`.`t1`

INSERT INTO t1(a,b) VALUES (4,3);
Query OK, 1 row affected (0.04 sec)
```

Dropping a constraint:

```
ALTER TABLE t1 DROP CONSTRAINT a_greater;
```

Adding a constraint:

```
ALTER TABLE t1 ADD CONSTRAINT a_greater CHECK (a>b);
```

Date comparisons and character length:

```
CREATE TABLE t2 (name VARCHAR(30) CHECK (CHAR_LENGTH(name)>2), start_date DATE,
  end_date DATE CHECK (start_date IS NULL OR end_date IS NULL OR start_date<end_date));

INSERT INTO t2(name, start_date, end_date) VALUES('Ione', '2003-12-15', '2014-11-09');
Query OK, 1 row affected (0.04 sec)

INSERT INTO t2(name, start_date, end_date) VALUES('Io', '2003-12-15', '2014-11-09');
ERROR 4022 (23000): CONSTRAINT `name` failed for `test`.`t2`

INSERT INTO t2(name, start_date, end_date) VALUES('Ione', NULL, '2014-11-09');
Query OK, 1 row affected (0.04 sec)

INSERT INTO t2(name, start_date, end_date) VALUES('Ione', '2015-12-15', '2014-11-09');
ERROR 4022 (23000): CONSTRAINT `end_date` failed for `test`.`t2`
```

A misplaced parenthesis:

```
CREATE TABLE t3 (name VARCHAR(30) CHECK (CHAR_LENGTH(name)>2)), start_date DATE,
  end_date DATE CHECK (start_date IS NULL OR end_date IS NULL OR start_date<end_date));
Query OK, 0 rows affected (0.32 sec)

INSERT INTO t3(name, start_date, end_date) VALUES('Io', '2003-12-15', '2014-11-09');
Query OK, 1 row affected, 1 warning (0.04 sec)

SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1292 | Truncated incorrect DOUBLE value: 'Io' |
+-----+-----+-----+
```

Compare the definition of table `t2` to table `t3`. `CHAR_LENGTH(name)>2` is very different to `CHAR_LENGTH(name>2)` as the latter mistakenly performs a numeric comparison on the `name` field, leading to unexpected results.

 10. [SKIP LOCKED](#)
 11. [Optimizer Hints](#)
 12. [max_statement_time clause](#)
 13. [WAIT/NOWAIT](#)
3. [Examples](#)

Description

`SELECT` is used to retrieve rows selected from one or more tables, and can include [UNION](#) statements and [subqueries](#).

- Each `select_expr` expression indicates a column or data that you want to retrieve. You must have at least one select expression. See [Select Expressions](#) below.
- The `FROM` clause indicates the table or tables from which to retrieve rows. Use either a single table name or a `JOIN` expression. See [JOIN](#) for details. If no table is involved, [FROM DUAL](#) can be specified.
- Each table can also be specified as `db_name.tbl_name`. Each column can also be specified as `tbl_name.col_name` or even `db_name.tbl_name.col_name`. This allows one to write queries which involve multiple databases. See [Identifier Qualifiers](#) for syntax details.

- The `WHERE` clause, if given, indicates the condition or conditions that rows must satisfy to be selected. `where_condition` is an expression that evaluates to true for each row to be selected. The statement selects all rows if there is no `WHERE` clause.
 - In the `WHERE` clause, you can use any of the functions and operators that MariaDB supports, except for aggregate (summary) functions. See [Functions and Operators](#) and [Functions and Modifiers for use with GROUP BY](#) (aggregate).
- Use the `ORDER BY` clause to order the results.
- Use the `LIMIT` clause allows you to restrict the results to only a certain number of rows, optionally with an offset.
- Use the `GROUP BY` and `HAVING` clauses to group rows together when they have columns or computed values in common.

`SELECT` can also be used to retrieve rows computed without reference to any table.

Select Expressions

A `SELECT` statement must contain one or more select expressions, separated by commas. Each select expression can be one of the following:

- The name of a column.
- Any expression using [functions and operators](#).
- `*` to select all columns from all tables in the `FROM` clause.
- `tbl_name.*` to select all columns from just the table `tbl_name`.

When specifying a column, you can either use just the column name or qualify the column name with the name of the table using `tbl_name.col_name`. The qualified form is useful if you are joining multiple tables in the `FROM` clause. If you do not qualify the column names when selecting from multiple tables, MariaDB will try to find the column in each table. It is an error if that column name exists in multiple tables.

You can quote column names using backticks. If you are qualifying column names with table names, quote each part separately as ``tbl_name`.`col_name``.

If you use any [grouping functions](#) in any of the select expressions, all rows in your results will be implicitly grouped, as if you had used `GROUP BY NULL`. `GROUP BY NULL` being an expression behaves specially such that the entire result set is treated as a group.

DISTINCT

A query may produce some identical rows. By default, all rows are retrieved, even when their values are the same. To explicitly specify that you want to retrieve identical rows, use the `ALL` option. If you want duplicates to be removed from the resultset, use the `DISTINCT` option. `DISTINCTROW` is a synonym for `DISTINCT`. See also [COUNT DISTINCT](#) and [SELECT UNIQUE in Oracle mode](#).

INTO

The `INTO` clause is used to specify that the query results should be written to a file or variable.

- [SELECT INTO OUTFILE](#) - formatting and writing the result to an external file.
- [SELECT INTO DUMPFILE](#) - binary-safe writing of the unformatted results to an external file.
- [SELECT INTO Variable](#) - selecting and setting variables.

The reverse of `SELECT INTO OUTFILE` is [LOAD DATA](#).

LIMIT

Restricts the number of returned rows. See [LIMIT](#) and [LIMIT ROWS EXAMINED](#) for details.

LOCK IN SHARE MODE/FOR UPDATE

See [LOCK IN SHARE MODE](#) and [FOR UPDATE](#) for details on the respective locking clauses.

OFFSET ... FETCH

MariaDB starting with [10.6](#)
See [SELECT ... OFFSET ... FETCH](#).

ORDER BY

Order a resultset. See [ORDER BY](#) for details.

PARTITION

Specifies to the optimizer which partitions are relevant for the query. Other partitions will not be read. See [Partition Pruning and Selection](#) for details.

PROCEDURE

Passes the whole result set to a C Procedure. See [PROCEDURE](#) and [PROCEDURE ANALYSE](#) (the only built-in procedure not requiring the server to be recompiled).

SKIP LOCKED

MariaDB starting with [10.6](#)

The SKIP LOCKED clause was introduced in [MariaDB 10.6.0](#).

This causes those rows that couldn't be locked ([LOCK IN SHARE MODE](#) or [FOR UPDATE](#)) to be excluded from the result set. An explicit `NOWAIT` is implied here. This is only implemented on [InnoDB](#) tables and ignored otherwise.

Optimizer Hints

These include [HIGH_PRIORITY](#), [STRAIGHT_JOIN](#), [SQL_SMALL_RESULT](#) | [SQL_BIG_RESULT](#), [SQL_BUFFER_RESULT](#), [SQL_CACHE](#) | [SQL_NO_CACHE](#), and [SQL_CALC_FOUND_ROWS](#).

See [Optimizer Hints](#) for details.

max_statement_time clause

By using [max_statement_time](#) in conjunction with [SET STATEMENT](#), it is possible to limit the execution time of individual queries. For example:

```
SET STATEMENT max_statement_time=100 FOR
SELECT field1 FROM table_name ORDER BY field1;
```

WAIT/NOWAIT

Set the lock wait timeout. See [WAIT and NOWAIT](#).

Examples

```
SELECT f1, f2 FROM t1 WHERE (f3<=10) AND (f4='y');
```

See [Getting Data from MariaDB](#) (Beginner tutorial), or the various sub-articles, for more examples.

1.1.1.4.1.2.1.2 More Advanced Joins

Contents

1. [The Employee Database](#)
2. [Working with the Employee Database](#)
 1. [Filtering by Name](#)
 2. [Filtering by Name, Date and Time](#)
 3. [Displaying Total Work Hours per Day](#)

This article is a follow up to the [Introduction to JOINS](#) page. If you're just getting started with JOINS, go through that page first and then come back here.

The Employee Database

Let us begin by using an example employee database of a fairly small family business, which does not anticipate expanding in the future.

First, we create the table that will hold all of the employees and their contact information:

```
CREATE TABLE `Employees` (
  `ID` TINYINT(3) UNSIGNED NOT NULL AUTO_INCREMENT,
  `First_Name` VARCHAR(25) NOT NULL,
  `Last_Name` VARCHAR(25) NOT NULL,
  `Position` VARCHAR(25) NOT NULL,
  `Home_Address` VARCHAR(50) NOT NULL,
  `Home_Phone` VARCHAR(12) NOT NULL,
  PRIMARY KEY (`ID`)
) ENGINE=MyISAM;
```

Next, we add a few employees to the table:

```
INSERT INTO `Employees` (`First_Name`, `Last_Name`, `Position`, `Home_Address`, `Home_Phone`)
VALUES
('Mustapha', 'Mond', 'Chief Executive Officer', '692 Promiscuous Plaza', '326-555-3492'),
('Henry', 'Foster', 'Store Manager', '314 Savage Circle', '326-555-3847'),
('Bernard', 'Marx', 'Cashier', '1240 Ambient Avenue', '326-555-8456'),
('Lenina', 'Crowne', 'Cashier', '281 Bumblepuppy Boulevard', '328-555-2349'),
('Fanny', 'Crowne', 'Restocker', '1023 Bokanovsky Lane', '326-555-6329'),
('Helmholtz', 'Watson', 'Janitor', '944 Soma Court', '329-555-2478');
```

Now, we create a second table, containing the hours which each employee clocked in and out during the week:

```
CREATE TABLE `Hours` (
  `ID` TINYINT(3) UNSIGNED NOT NULL,
  `Clock_In` DATETIME NOT NULL,
  `Clock_Out` DATETIME NOT NULL
) ENGINE=MyISAM;
```

Finally, although it is a lot of information, we add a full week of hours for each of the employees into the second table that we created:

```
INSERT INTO `Hours`
VALUES
('1', '2005-08-08 07:00:42', '2005-08-08 17:01:36'),
('1', '2005-08-09 07:01:34', '2005-08-09 17:10:11'),
('1', '2005-08-10 06:59:56', '2005-08-10 17:09:29'),
('1', '2005-08-11 07:00:17', '2005-08-11 17:00:47'),
('1', '2005-08-12 07:02:29', '2005-08-12 16:59:12'),
('2', '2005-08-08 07:00:25', '2005-08-08 17:03:13'),
('2', '2005-08-09 07:00:57', '2005-08-09 17:05:09'),

('6', '2005-08-12 07:02:07', '2005-08-12 16:58:23');
```

Working with the Employee Database

Now that we have a cleanly structured database to work with, let us begin this tutorial by stepping up one notch from the last tutorial and filtering our information a little.

Filtering by Name

Earlier in the week, an anonymous employee reported that Helmholtz came into work almost four minutes late; to verify this, we will begin our investigation by filtering out employees whose first names are "Helmholtz":

```

SELECT
  `Employees`.`First_Name`,
  `Employees`.`Last_Name`,
  `Hours`.`Clock_In`,
  `Hours`.`Clock_Out`
FROM `Employees`
INNER JOIN `Hours` ON `Employees`.`ID` = `Hours`.`ID`
WHERE `Employees`.`First_Name` = 'Helmholtz';

```

The result:

```

+-----+-----+-----+-----+
| First_Name | Last_Name | Clock_In          | Clock_Out          |
+-----+-----+-----+-----+
| Helmholtz  | Watson    | 2005-08-08 07:00:12 | 2005-08-08 17:01:02 |
| Helmholtz  | Watson    | 2005-08-09 07:03:44 | 2005-08-09 17:00:00 |
| Helmholtz  | Watson    | 2005-08-10 06:54:19 | 2005-08-10 17:03:31 |
| Helmholtz  | Watson    | 2005-08-11 07:00:05 | 2005-08-11 17:02:57 |
| Helmholtz  | Watson    | 2005-08-12 07:02:07 | 2005-08-12 16:58:23 |
+-----+-----+-----+-----+
5 rows in set (0.00 sec)

```

This is obviously more information than we care to trudge through, considering we only care about when he arrived past 7:00:59 on any given day within this week; thus, we need to add a couple more conditions to our WHERE clause.

Filtering by Name, Date and Time

In the following example, we will filter out all of the times which Helmholtz clocked in that were before 7:01:00 and during the work week that lasted from the 8th to the 12th of August:

```

SELECT
  `Employees`.`First_Name`,
  `Employees`.`Last_Name`,
  `Hours`.`Clock_In`,
  `Hours`.`Clock_Out`
FROM `Employees`
INNER JOIN `Hours` ON `Employees`.`ID` = `Hours`.`ID`
WHERE `Employees`.`First_Name` = 'Helmholtz'
AND DATE_FORMAT(`Hours`.`Clock_In`, '%Y-%m-%d') >= '2005-08-08'
AND DATE_FORMAT(`Hours`.`Clock_In`, '%Y-%m-%d') <= '2005-08-12'
AND DATE_FORMAT(`Hours`.`Clock_In`, '%H:%i:%S') > '07:00:59';

```

The result:

```

+-----+-----+-----+-----+
| First_Name | Last_Name | Clock_In          | Clock_Out          |
+-----+-----+-----+-----+
| Helmholtz  | Watson    | 2005-08-09 07:03:44 | 2005-08-09 17:00:00 |
| Helmholtz  | Watson    | 2005-08-12 07:02:07 | 2005-08-12 16:58:23 |
+-----+-----+-----+-----+
2 rows in set (0.00 sec)

```

We have now, by merely adding a few more conditions, eliminated all of the irrelevant information; Helmholtz was late to work on the 9th and the 12th of August.

Displaying Total Work Hours per Day

Suppose you would like to—based on the information stored in both of our tables in the employee database—develop a quick list of the total hours each employee has worked for each day recorded; a simple way to estimate the time each employee worked per day is exemplified below:

```

SELECT
  `Employees`.`ID`,
  `Employees`.`First_Name`,
  `Employees`.`Last_Name`,
  `Hours`.`Clock_In`,
  `Hours`.`Clock_Out`,
  DATE_FORMAT(`Hours`.`Clock_Out`, '%T')-DATE_FORMAT(`Hours`.`Clock_In`, '%T') AS 'Total_Hours'
FROM `Employees` INNER JOIN `Hours` ON `Employees`.`ID` = `Hours`.`ID`;

```

The result (limited by 10):

```

+-----+-----+-----+-----+-----+-----+
| ID | First_Name | Last_Name | Clock_In          | Clock_Out          | Total_Hours |
+-----+-----+-----+-----+-----+-----+
| 1 | Mustapha   | Mond     | 2005-08-08 07:00:42 | 2005-08-08 17:01:36 | 10 |
| 1 | Mustapha   | Mond     | 2005-08-09 07:01:34 | 2005-08-09 17:10:11 | 10 |
| 1 | Mustapha   | Mond     | 2005-08-10 06:59:56 | 2005-08-10 17:09:29 | 11 |
| 1 | Mustapha   | Mond     | 2005-08-11 07:00:17 | 2005-08-11 17:00:47 | 10 |
| 1 | Mustapha   | Mond     | 2005-08-12 07:02:29 | 2005-08-12 16:59:12 | 9 |
| 2 | Henry      | Foster   | 2005-08-08 07:00:25 | 2005-08-08 17:03:13 | 10 |
| 2 | Henry      | Foster   | 2005-08-09 07:00:57 | 2005-08-09 17:05:09 | 10 |
| 2 | Henry      | Foster   | 2005-08-10 06:58:43 | 2005-08-10 16:58:24 | 10 |
| 2 | Henry      | Foster   | 2005-08-11 07:01:58 | 2005-08-11 17:00:45 | 10 |
| 2 | Henry      | Foster   | 2005-08-12 07:02:12 | 2005-08-12 16:58:57 | 9 |
+-----+-----+-----+-----+-----+-----+
10 rows in set (0.00 sec)

```

1.1.1.4.1.2.1.3 JOIN Syntax

Description

MariaDB supports the following `JOIN` syntaxes for the `table_references` part of `SELECT` statements and multiple-table `DELETE` and `UPDATE` statements:

```

table_references:
    table_reference [, table_reference] ...

table_reference:
    table_factor
  | join_table

table_factor (<= MariaDB 11.6):
    tbl_name [PARTITION (partition_list)]
      [query_system_time_period_specification] [[AS] alias] [index_hint_list]
  | table_subquery [query_system_time_period_specification] [AS] alias
  | ( table_references )
  | { ON table_reference LEFT OUTER JOIN table_reference
      ON conditional_expr }

table_factor (>= MariaDB 11.7):
    tbl_name [PARTITION (partition_list)]
      [query_system_time_period_specification] [[AS] alias] [index_hint_list]
  | table_subquery [query_system_time_period_specification] [AS] alias [(column_name_list)]
  | ( table_references )
  | { ON table_reference LEFT OUTER JOIN table_reference
      ON conditional_expr }

join_table:
    table_reference [INNER | CROSS] JOIN table_factor [join_condition]
  | table_reference STRAIGHT_JOIN table_factor
  | table_reference STRAIGHT_JOIN table_factor ON conditional_expr
  | table_reference {LEFT|RIGHT} [OUTER] JOIN table_reference join_condition
  | table_reference NATURAL [{LEFT|RIGHT} [OUTER]] JOIN table_factor

join_condition:
    ON conditional_expr
  | USING (column_list)

query_system_time_period_specification:
    FOR SYSTEM_TIME AS OF point_in_time
  | FOR SYSTEM_TIME BETWEEN point_in_time AND point_in_time
  | FOR SYSTEM_TIME FROM point_in_time TO point_in_time
  | FOR SYSTEM_TIME ALL

point_in_time:
    [TIMESTAMP] expression
  | TRANSACTION expression

index_hint_list:
    index_hint [, index_hint] ...

index_hint:
    USE {INDEX|KEY}
      [{FOR {JOIN|ORDER BY|GROUP BY}} ([index_list])]
  | IGNORE {INDEX|KEY}
      [{FOR {JOIN|ORDER BY|GROUP BY}} (index_list)]
  | FORCE {INDEX|KEY}
      [{FOR {JOIN|ORDER BY|GROUP BY}} (index_list)]

index_list:
    index_name [, index_name] ...

```

A table reference is also known as a join expression.

Each table can also be specified as `db_name.tbl_name`. This allows to write queries which involve multiple databases. See [Identifier Qualifiers](#) for syntax details.

The syntax of `table_factor` is extended in comparison with the SQL Standard. The latter accepts only `table_reference`, not a list of them inside a pair of parentheses.

This is a conservative extension if we consider each comma in a list of `table_reference` items as equivalent to an inner join. For example:

```

SELECT * FROM t1 LEFT JOIN (t2, t3, t4)
      ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)

```

is equivalent to:

```
SELECT * FROM t1 LEFT JOIN (t2 CROSS JOIN t3 CROSS JOIN t4)
    ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)
```

In MariaDB, `CROSS JOIN` is a syntactic equivalent to `INNER JOIN` (they can replace each other). In standard SQL, they are not equivalent. `INNER JOIN` is used with an `ON` clause, `CROSS JOIN` is used otherwise.

In general, parentheses can be ignored in join expressions containing only inner join operations. MariaDB also supports nested joins (see <http://dev.mysql.com/doc/refman/5.1/en/nested-join-optimization.html>).

Subqueries

A table subquery is specified as a parenthesized query and must contain a following derived table name (specified as *alias* in the above syntax specification). From MariaDB 11.7 onwards, we can optionally specify a list of column names in parenthesis.

```
select ic1, ic2, ic3 from
(
    select c1, c2, c3 from t1 group by c1
) dt2 (ic1, ic2, ic3)
join t2 on t2.c1 = dt2.ic1
where c2 > 0
group by ic1
```

Here, the table subquery for `t1` will be materialized and named `dt2`, with column names `ic1`, `ic2`, `ic3`. These column names are used outside the subquery.

See also [Subqueries in a FROM Clause \(Derived Tables\)#Correlation Column List](#).

System-Versioned Tabled

See [System-versioned tables](#) for more information about `FOR SYSTEM_TIME` syntax.

Index Hints

Index hints can be specified to affect how the MariaDB optimizer makes use of indexes. For more information, see [How to force query plans](#).

Examples

```
SELECT left_tbl.*
FROM left_tbl LEFT JOIN right_tbl ON left_tbl.id = right_tbl.id
WHERE right_tbl.id IS NULL;
```

1.1.1.4.1.2.1.4 Comma vs JOIN

A query to grab the list of phone numbers for clients who ordered in the last two weeks might be written in a couple of ways. Here are two:

```
SELECT *
FROM
    clients,
    orders,
    phoneNumbers
WHERE
    clients.id = orders.clientId
    AND clients.id = phoneNumbers.clientId
    AND orderPlaced >= NOW() - INTERVAL 2 WEEK;
```

```

SELECT *
FROM
  clients
  INNER JOIN orders ON clients.id = orders.clientId
  INNER JOIN phoneNumbers ON clients.id = phoneNumbers.clientId
WHERE
  orderPlaced >= NOW() - INTERVAL 2 WEEK;

```

Does it make a difference? Not much as written. But you should use the second form. Why?

- **Readability.** Once the WHERE clause contains more than two conditions, it becomes tedious to pick out the difference between business logic (only dates in the last two weeks) and relational logic (which fields relate clients to orders). Using the JOIN syntax with an ON clause makes the WHERE list shorter, and makes it very easy to see how tables relate to each other.
- **Flexibility.** Let's say we need to see all clients even if they don't have a phone number in the system. With the second version, it's easy; just change `INNER JOIN phoneNumbers` to `LEFT JOIN phoneNumbers`. Try that with the first version, and MySQL version 5.0.12+ will issue a syntax error because of the change in precedence between the comma operator and the JOIN keyword. The solution is to rearrange the FROM clause or add parentheses to override the precedence, and that quickly becomes frustrating.
- **Portability.** The changes in 5.0.12 were made to align with SQL:2003. If your queries use standard syntax, you will have an easier time switching to a different database should the need ever arise.

1.1.1.4.1.2.2 Subqueries

A subquery is a query nested in another query.

Scalar Subqueries

Subquery returning a single value.

Row Subqueries

Subquery returning a row.

Subqueries and ALL

Return true if the comparison returns true for each row, or the subquery returns no rows.

Subqueries and ANY

Return true if the comparison returns true for at least one row returned by the subquery.

Subqueries and EXISTS

Returns true if the subquery returns any rows.

Subqueries in a FROM Clause (Derived Tables)

Subqueries are more commonly placed in a WHERE clause, but can also form part of the FROM clause.

Subquery Optimizations

Articles about subquery optimizations in MariaDB.

Subqueries and JOINS

Rewriting subqueries as JOINS, and using subqueries instead of JOINS.

Subquery Limitations

There are a number of limitations regarding subqueries.

There are [1 related questions](#) .

1.1.1.4.1.2.2.1 Scalar Subqueries

A scalar subquery is a [subquery](#) that returns a single value. This is the simplest form of a subquery, and can be used in most places a literal or single column value is valid.

The data type, length and [character set and collation](#) are all taken from the result returned by the subquery. The result of a subquery can always be NULL, that is, no result returned. Even if the original value is defined as NOT NULL, this is

disregarded.

A subquery cannot be used where only a literal is expected, for example [LOAD DATA INFILE](#) expects a literal string containing the file name, and [LIMIT](#) requires a literal integer.

Examples

```
CREATE TABLE sq1 (num TINYINT);

CREATE TABLE sq2 (num TINYINT);

INSERT INTO sq1 VALUES (1);

INSERT INTO sq2 VALUES (10* (SELECT num FROM sq1));

SELECT * FROM sq2;
+-----+
| num  |
+-----+
|   10 |
+-----+
```

Inserting a second row means the subquery is no longer a scalar, and this particular query is not valid:

```
INSERT INTO sq1 VALUES (2);

INSERT INTO sq2 VALUES (10* (SELECT num FROM sq1));
ERROR 1242 (21000): Subquery returns more than 1 row
```

No rows in the subquery, so the scalar is NULL:

```
INSERT INTO sq2 VALUES (10* (SELECT num FROM sq3 WHERE num='3'));

SELECT * FROM sq2;
+-----+
| num  |
+-----+
|   10 |
| NULL |
+-----+
```

A more traditional scalar subquery, as part of a WHERE clause:

```
SELECT * FROM sq1 WHERE num = (SELECT MAX(num)/10 FROM sq2);
+-----+
| num  |
+-----+
|    1 |
+-----+
```

1.1.1.4.1.2.2.2 Row Subqueries

A row subquery is a [subquery](#) returning a single row, as opposed to a [scalar subquery](#), which returns a single column from a row, or a literal.

Examples

```

CREATE TABLE staff (name VARCHAR(10), age TINYINT);

CREATE TABLE customer (name VARCHAR(10), age TINYINT);

INSERT INTO staff VALUES ('Bilhah',37), ('Valerius',61), ('Maia',25);

INSERT INTO customer VALUES ('Thanasis',48), ('Valerius',61), ('Brion',51);

SELECT * FROM staff WHERE (name,age) = (SELECT name,age FROM customer WHERE name='Valerius');
+-----+-----+
| name   | age   |
+-----+-----+
| Valerius | 61   |
+-----+-----+

```

Finding all rows in one table also in another:

```

SELECT name,age FROM staff WHERE (name,age) IN (SELECT name,age FROM customer);
+-----+-----+
| name   | age   |
+-----+-----+
| Valerius | 61   |
+-----+-----+

```

1.1.1.4.1.2.2.3 Subqueries and ALL

Contents

1. [Syntax](#)
2. [Examples](#)

Subqueries using the ALL keyword will return `true` if the comparison returns `true` for each row returned by the subquery, or the subquery returns no rows.

Syntax

```
scalar_expression comparison_operator ALL <Table subquery>
```

- `scalar_expression` may be any expression that evaluates to a single value
- `comparison_operator` may be any one of: `=`, `>`, `<`, `>=`, `<=`, `<>` or `!=`

ALL returns:

- `NULL` if the comparison operator returns `NULL` for at least one row returned by the Table subquery or `scalar_expression` returns `NULL`.
- `FALSE` if the comparison operator returns `FALSE` for at least one row returned by the Table subquery.
- `TRUE` if the comparison operator returns `TRUE` for all rows returned by the Table subquery, or if Table subquery returns no rows.

`NOT IN` is an alias for `<> ALL`.

Examples

```

CREATE TABLE sq1 (num TINYINT);

CREATE TABLE sq2 (num2 TINYINT);

INSERT INTO sq1 VALUES (100);

INSERT INTO sq2 VALUES (40), (50), (60);

SELECT * FROM sq1 WHERE num > ALL (SELECT * FROM sq2);
+-----+
| num |
+-----+
| 100 |
+-----+

```

Since 100 > all of 40, 50 and 60, the evaluation is true and the row is returned

Adding a second row to sq1, where the evaluation for that record is false:

```

INSERT INTO sq1 VALUES (30);

SELECT * FROM sq1 WHERE num > ALL (SELECT * FROM sq2);
+-----+
| num |
+-----+
| 100 |
+-----+

```

Adding a new row to sq2, causing all evaluations to be false:

```

INSERT INTO sq2 VALUES (120);

SELECT * FROM sq1 WHERE num > ALL (SELECT * FROM sq2);
Empty set (0.00 sec)

```

When the subquery returns no results, the evaluation is still true:

```

SELECT * FROM sq1 WHERE num > ALL (SELECT * FROM sq2 WHERE num2 > 300);
+-----+
| num |
+-----+
| 100 |
| 30  |
+-----+

```

Evaluating against a NULL will cause the result to be unknown, or not true, and therefore return no rows:

```

INSERT INTO sq2 VALUES (NULL);

SELECT * FROM sq1 WHERE num > ALL (SELECT * FROM sq2);

```

1.1.1.4.1.2.2.4 Subqueries and ANY

Contents

1. [Syntax](#)
2. [Examples](#)

Subqueries using the ANY keyword will return `true` if the comparison returns `true` for at least one row returned by the subquery.

Syntax

The required syntax for an ANY or SOME quantified comparison is:

```

scalar_expression comparison_operator ANY <Table subquery>

```

Or:

```
scalar_expression comparison_operator SOME <Table subquery>
```

- `scalar_expression` may be any expression that evaluates to a single value.
- `comparison_operator` may be any one of `=`, `>`, `<`, `>=`, `<=`, `<>` or `!=`.

ANY returns:

- `TRUE` if the comparison operator returns `TRUE` for at least one row returned by the Table subquery.
- `FALSE` if the comparison operator returns `FALSE` for all rows returned by the Table subquery, or Table subquery has zero rows.
- `NULL` if the comparison operator returns `NULL` for at least one row returned by the Table subquery and doesn't return `TRUE` for any of them, or if `scalar_expression` returns `NULL`.

`SOME` is a synonym for `ANY`, and `IN` is a synonym for `= ANY`

Examples

```
CREATE TABLE sq1 (num TINYINT);

CREATE TABLE sq2 (num2 TINYINT);

INSERT INTO sq1 VALUES (100);

INSERT INTO sq2 VALUES (40), (50), (120);

SELECT * FROM sq1 WHERE num > ANY (SELECT * FROM sq2);
+-----+
| num |
+-----+
| 100 |
+-----+
```

100 is greater than two of the three values, and so the expression evaluates as true.

`SOME` is a synonym for `ANY`:

```
SELECT * FROM sq1 WHERE num < SOME (SELECT * FROM sq2);
+-----+
| num |
+-----+
| 100 |
+-----+
```

`IN` is a synonym for `= ANY`, and here there are no matches, so no results are returned:

```
SELECT * FROM sq1 WHERE num IN (SELECT * FROM sq2);
Empty set (0.00 sec)
```

```
INSERT INTO sq2 VALUES (100);
Query OK, 1 row affected (0.05 sec)

SELECT * FROM sq1 WHERE num <> ANY (SELECT * FROM sq2);
+-----+
| num |
+-----+
| 100 |
+-----+
```

Reading this query, the results may be counter-intuitive. It may seem to read as "SELECT * FROM sq1 WHERE num does not match any results in sq2. Since it does match 100, it could seem that the results are incorrect. However, the query returns a result if the match does not match any of sq2. Since 100 already does not match 40, the expression evaluates to true immediately, regardless of the 100's matching. It may be more easily readable to use `SOME` in a case such as this:

```
SELECT * FROM sq1 WHERE num <> SOME (SELECT * FROM sq2);
+-----+
| num |
+-----+
| 100 |
+-----+
```

1.1.1.4.1.2.2.5 Subqueries and EXISTS

Syntax

```
SELECT ... WHERE EXISTS <Table subquery>
```

Description

Subqueries using the `EXISTS` keyword will return `true` if the subquery returns any rows. Conversely, subqueries using `NOT EXISTS` will return `true` only if the subquery returns no rows from the table.

`EXISTS` subqueries ignore the columns specified by the `SELECT` of the subquery, since they're not relevant. For example,

```
SELECT col1 FROM t1 WHERE EXISTS (SELECT * FROM t2);
```

and

```
SELECT col1 FROM t1 WHERE EXISTS (SELECT col2 FROM t2);
```

produce identical results.

Examples

```
CREATE TABLE sq1 (num TINYINT);
CREATE TABLE sq2 (num2 TINYINT);
INSERT INTO sq1 VALUES(100);
INSERT INTO sq2 VALUES(40),(50),(60);

SELECT * FROM sq1 WHERE EXISTS (SELECT * FROM sq2 WHERE num2>50);
+-----+
| num |
+-----+
| 100 |
+-----+

SELECT * FROM sq1 WHERE NOT EXISTS (SELECT * FROM sq2 GROUP BY num2 HAVING MIN(num2)=40);
Empty set (0.00 sec)
```

1.1.1.4.1.2.2.6 Subqueries in a FROM Clause (Derived Tables)

Contents

1. [ORACLE mode](#)
2. [Correlation Column List](#)
3. [Examples](#)

Although **subqueries** are more commonly placed in a `WHERE` clause, they can also form part of the `FROM` clause. Such subqueries are commonly called derived tables.

If a subquery is used in this way, you must also use an `AS` clause to name the result of the subquery.

ORACLE mode

MariaDB starting with [10.6.0](#)

From [MariaDB 10.6.0](#), [anonymous subqueries in a FROM clause](#) (no AS clause) are permitted in [ORACLE mode](#).

Correlation Column List

MariaDB starting with [11.7.0](#)

From [MariaDB 11.7](#), it is possible to assign column names in the derived table name syntax element.

Examples

```
CREATE TABLE student (name CHAR(10), test CHAR(10), score TINYINT);
```

```
INSERT INTO student VALUES
('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
('Tatiana', 'SQL', 87), ('Tatiana', 'Tuning', 83);
```

Assume that, given the data above, you want to return the average total for all students. In other words, the average of Chun's 148 (75+73), Esben's 74 (43+31), etc.

You cannot do the following:

```
SELECT AVG(SUM(score)) FROM student GROUP BY name;
ERROR 1111 (HY000): Invalid use of group function
```

A subquery in the FROM clause is however permitted:

```
SELECT AVG(sq_sum) FROM (SELECT SUM(score) AS sq_sum FROM student GROUP BY name) AS t;
+-----+
| AVG(sq_sum) |
+-----+
|    134.0000 |
+-----+
```

From [MariaDB 10.6](#) in [ORACLE mode](#), the following is permitted:

```
SELECT * FROM (SELECT 1 FROM DUAL), (SELECT 2 FROM DUAL);
```

From [MariaDB 11.7](#). In this example, the second column of the derived table `dt` is used both within (WHERE `c2 > 0`), and outside, (WHERE `a2 > 10`), the specification. Both conditions apply to `t1.c2`.

```
CREATE OR REPLACE TABLE t1(c1 INT, c2 INT, c3 INT);
SELECT a1, a2 FROM (SELECT c1, c2, c3 FROM t1 WHERE c2 > 0) AS dt (a1, a2, a3);
```

3.3.4.2 Subquery Optimizations

3.3.4.2.2 Semi-join Subquery Optimizations

3.3.4.2.3 Table Pullout Optimization

3.3.4.2.4 Non-semi-join Subquery Optimizations

3.3.4.2.5 Subquery Cache

3.3.4.2.6 Condition Pushdown Into IN subqueries

3.3.4.2.7 Conversion of Big IN Predicates Into Subqueries

3.3.4.2.8 EXISTS-to-IN Optimization

3.3.4.2.9 Optimizing GROUP BY and DISTINCT Clauses in Subqueries

1.1.1.4.1.2.2.8 Subqueries and JOINS

A [subquery](#) can quite often, but not in all cases, be rewritten as a [JOIN](#).

Contents

1. [Rewriting Subqueries as JOINS](#)
2. [Using Subqueries instead of JOINS](#)

Rewriting Subqueries as JOINS

A subquery using `IN` can be rewritten with the `DISTINCT` keyword, for example:

```
SELECT * FROM table1 WHERE col1 IN (SELECT col1 FROM table2);
```

can be rewritten as:

```
SELECT DISTINCT table1.* FROM table1, table2 WHERE table1.col1=table2.col1;
```

`NOT IN` or `NOT EXISTS` queries can also be rewritten. For example, these two queries returns the same result:

```
SELECT * FROM table1 WHERE col1 NOT IN (SELECT col1 FROM table2);
SELECT * FROM table1 WHERE NOT EXISTS (SELECT col1 FROM table2 WHERE table1.col1=table2.col1);
```

and both can be rewritten as:

```
SELECT table1.* FROM table1 LEFT JOIN table2 ON table1.id=table2.id WHERE table2.id IS NULL;
```

Subqueries that can be rewritten as a `LEFT JOIN` are sometimes more efficient.

Using Subqueries instead of JOINS

There are some scenarios, though, which call for subqueries rather than joins:

- When you want duplicates, but not false duplicates. Suppose `Table_1` has three rows — { 1, 1, 2 } — and `Table_2` has two rows — { 1, 2, 2 }. If you need to list the rows in `Table_1` which are also in `Table_2`, only this subquery-based `SELECT` statement will give the right answer (1, 1, 2):

```
SELECT Table_1.column_1
FROM Table_1
WHERE Table_1.column_1 IN
  (SELECT Table_2.column_1
   FROM Table_2);
```

This SQL statement won't work:

```
SELECT Table_1.column_1
FROM Table_1, Table_2
WHERE Table_1.column_1 = Table_2.column_1;
```

because the result will be { 1, 1, 2, 2 } — and the duplication of 2 is an error. This SQL statement won't work either:

```
SELECT DISTINCT Table_1.column_1
FROM Table_1, Table_2
WHERE Table_1.column_1 = Table_2.column_1;
```

because the result will be { 1, 2 } — and the removal of the duplicated 1 is an error too.

- When the outermost statement is not a query. The SQL statement:

```
UPDATE Table_1 SET column_1 = (SELECT column_1 FROM Table_2);
```

can't be expressed using a join unless some rare SQL3 features are used.

- When the join is over an expression. The SQL statement:

```
SELECT * FROM Table_1
WHERE column_1 + 5 =
  (SELECT MAX(column_1) FROM Table_2);
```

is hard to express with a join. In fact, the only way we can think of is this SQL statement:

```
SELECT Table_1.*
FROM Table_1,
  (SELECT MAX(column_1) AS max_column_1 FROM Table_2) AS Table_2
WHERE Table_1.column_1 + 5 = Table_2.max_column_1;
```

which still involves a parenthesized query, so nothing is gained from the transformation.

- When you want to see the exception. For example, suppose the question is: what books are longer than *Das Kapital*? These two queries are effectively almost the same:

```
SELECT DISTINCT Bookcolumn_1.*
FROM Books AS Bookcolumn_1 JOIN Books AS Bookcolumn_2 USING (page_count)
WHERE title = 'Das Kapital';

SELECT DISTINCT Bookcolumn_1.*
FROM Books AS Bookcolumn_1
WHERE Bookcolumn_1.page_count >
  (SELECT DISTINCT page_count
   FROM Books AS Bookcolumn_2
   WHERE title = 'Das Kapital');
```

The difference is between these two SQL statements is, if there are two editions of *Das Kapital* (with different page counts), then the self-join example will return the books which are longer than the shortest edition of *Das Kapital*. That might be the wrong answer, since the original question didn't ask for "... longer than *ANY* book named *Das Kapital*" (it seems to contain a false assumption that there's only one edition).

1.1.1.4.1.2.2.9 Subquery Limitations

Contents

1. [ORDER BY and LIMIT](#)
2. [Modifying and Selecting from the Same Table](#)
3. [Row Comparison Operations](#)
4. [Correlated Subqueries](#)
5. [Stored Functions](#)

There are a number of limitations regarding [subqueries](#), which are discussed below.

The following tables and data will be used in the examples that follow:

```
CREATE TABLE staff(name VARCHAR(10),age TINYINT);
```

```
CREATE TABLE customer(name VARCHAR(10),age TINYINT);
```

```
INSERT INTO staff VALUES  
( 'Bilhah',37), ( 'Valerius',61), ( 'Maia',25);
```

```
INSERT INTO customer VALUES  
( 'Thanasis',48), ( 'Valerius',61), ( 'Brion',51);
```

ORDER BY and LIMIT

To use [ORDER BY](#) or limit [LIMIT](#) in [subqueries](#) both must be used.. For example:

```
SELECT * FROM staff WHERE name IN (SELECT name FROM customer ORDER BY name);  
+-----+-----+  
| name   | age |  
+-----+-----+  
| Valerius | 61 |  
+-----+-----+
```

is valid, but

```
SELECT * FROM staff WHERE name IN (SELECT NAME FROM customer ORDER BY name LIMIT 1);  
ERROR 1235 (42000): This version of MariaDB doesn't  
yet support 'LIMIT & IN/ALL/ANY/SOME subquery'
```

is not.

Modifying and Selecting from the Same Table

It's not possible to both modify and select from the same table in a subquery. For example:

```
DELETE FROM staff WHERE name = (SELECT name FROM staff WHERE age=61);  
ERROR 1093 (HY000): Table 'staff' is specified twice, both  
as a target for 'DELETE' and as a separate source for data
```

Row Comparison Operations

There is only partial support for row comparison operations. The expression in

```
expr op {ALL|ANY|SOME} subquery,
```

must be scalar and the subquery can only return a single column.

However, because of the way `IN` is implemented (it is rewritten as a sequence of `=` comparisons and `AND`), the expression in

```
expression [NOT] IN subquery
```

is permitted to be an n-tuple and the subquery can return rows of n-tuples.

For example:

```
SELECT * FROM staff WHERE (name,age) NOT IN (  
  SELECT name,age FROM customer WHERE age >=51  
);  
+-----+-----+  
| name   | age |  
+-----+-----+  
| Bilhah | 37 |  
| Maia   | 25 |  
+-----+-----+
```

is permitted, but

```
SELECT * FROM staff WHERE (name,age) = ALL (
  SELECT name,age FROM customer WHERE age >=51
);
ERROR 1241 (21000): Operand should contain 1 column(s)
```

is not.

Correlated Subqueries

Subqueries in the FROM clause cannot be correlated subqueries. They cannot be evaluated for each row of the outer query since they are evaluated to produce a result set during when the query is executed.

Stored Functions

A subquery can refer to a [stored function](#) which modifies data. This is an extension to the SQL standard, but can result in indeterminate outcomes. For example, take:

```
SELECT ... WHERE x IN (SELECT f() ...);
```

where $f()$ inserts rows. The function $f()$ could be executed a different number of times depending on how the optimizer chooses to handle the query.

This sort of construct is therefore not safe to use in replication that is not [row-based](#), as there could be different results on the master and the slave.

1.1.1.4.1.2.3 UNION

UNION is used to combine the results from multiple [SELECT](#) statements into a single result set.

Syntax

```
SELECT ...
UNION [ALL | DISTINCT] SELECT ...
[UNION [ALL | DISTINCT] SELECT ...]
[ORDER BY [column [, column ...]]]
[LIMIT [{offset,} row_count | row_count OFFSET offset]]
```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [ALL/DISTINCT](#)
 2. [ORDER BY and LIMIT](#)
 3. [HIGH_PRIORITY](#)
 4. [SELECT ... INTO ...](#)
 5. [Parentheses](#)
3. [Examples](#)

Description

UNION is used to combine the results from multiple [SELECT](#) statements into a single result set.

The column names from the first [SELECT](#) statement are used as the column names for the results returned. Selected columns listed in corresponding positions of each [SELECT](#) statement should have the same data type. (For example, the first column selected by the first statement should have the same type as the first column selected by the other statements.)

If they don't, the type and length of the columns in the result take into account the values returned by all of the [SELECT](#)s, so there is no need for explicit casting. Note that currently this is not the case for [recursive CTEs](#) - see [MDEV-12325](#).

Table names can be specified as `db_name.tbl_name`. This permits writing [UNION](#) s which involve multiple databases. See [Identifier Qualifiers](#) for syntax details.

[UNION](#) queries cannot be used with [aggregate functions](#).

[EXCEPT](#) and [UNION](#) have the same operation precedence and [INTERSECT](#) has a higher precedence, unless [running in Oracle mode](#), in which case all three have the same precedence.

ALL/DISTINCT

The `ALL` keyword causes duplicate rows to be preserved. The `DISTINCT` keyword (the default if the keyword is omitted) causes duplicate rows to be removed by the results.

`UNION ALL` and `UNION DISTINCT` can both be present in a query. In this case, `UNION DISTINCT` will override any `UNION ALL`s to its left.

The server can in most cases execute `UNION ALL` without creating a temporary table (see [MDEV-334](#) .

ORDER BY and LIMIT

Individual `SELECT`s can contain their own `ORDER BY` and `LIMIT` clauses. In this case, the individual queries need to be wrapped between parentheses. However, this does not affect the order of the `UNION`, so they only are useful to limit the record read by one `SELECT`.

The `UNION` can have global `ORDER BY` and `LIMIT` clauses, which affect the whole resultset. If the columns retrieved by individual `SELECT` statements have an alias (`AS`), the `ORDER BY` must use that alias, not the real column names.

HIGH_PRIORITY

Specifying a query as `HIGH_PRIORITY` will not work inside a `UNION`. If applied to the first `SELECT`, it will be ignored. Applying to a later `SELECT` results in a syntax error:

```
ERROR 1234 (42000): Incorrect usage/placement of 'HIGH_PRIORITY'
```

SELECT ... INTO ...

Individual `SELECT`s cannot be written `INTO DUMPFILE` or `INTO OUTFILE`. If the last `SELECT` statement specifies `INTO DUMPFILE` or `INTO OUTFILE`, the entire result of the `UNION` will be written. Placing the clause after any other `SELECT` will result in a syntax error.

If the result is a single row, `SELECT ... INTO @var_name` can also be used.

Parentheses

Parentheses can be used to specify precedence. Prior to [MariaDB 10.4](#), a syntax error would be returned.

Examples

`UNION` between tables having different column names:

```
(SELECT e_name AS name, email FROM employees)
UNION
(SELECT c_name AS name, email FROM customers);
```

Specifying the `UNION`'s global order and limiting total rows:

```
(SELECT name, email FROM employees)
UNION
(SELECT name, email FROM customers)
ORDER BY name LIMIT 10;
```

Adding a constant row:

```
(SELECT 'John Doe' AS name, '[email protected]' AS email)
UNION
(SELECT name, email FROM customers);
```

Differing types:

```
SELECT CAST('x' AS CHAR(1)) UNION SELECT REPEAT('y',4);
+-----+
| CAST('x' AS CHAR(1)) |
+-----+
| x                     |
| yyy                    |
+-----+
```

Returning the results in order of each individual SELECT by use of a sort column:

```
(SELECT 1 AS sort_column, e_name AS name, email FROM employees)
UNION
(SELECT 2, c_name AS name, email FROM customers) ORDER BY sort_column;
```

Difference between UNION, **EXCEPT** and **INTERSECT**. **INTERSECT ALL** and **EXCEPT ALL** are available from [MariaDB 10.5.0](#).

```

CREATE TABLE seqs (i INT);
INSERT INTO seqs VALUES (1), (2), (2), (3), (3), (4), (5), (6);

SELECT i FROM seqs WHERE i <= 3 UNION SELECT i FROM seqs WHERE i>=3;
+-----+
| i     |
+-----+
| 1     |
| 2     |
| 3     |
| 4     |
| 5     |
| 6     |
+-----+

SELECT i FROM seqs WHERE i <= 3 UNION ALL SELECT i FROM seqs WHERE i>=3;
+-----+
| i     |
+-----+
| 1     |
| 2     |
| 2     |
| 3     |
| 3     |
| 3     |
| 3     |
| 4     |
| 5     |
| 6     |
+-----+

SELECT i FROM seqs WHERE i <= 3 EXCEPT SELECT i FROM seqs WHERE i>=3;
+-----+
| i     |
+-----+
| 1     |
| 2     |
+-----+

SELECT i FROM seqs WHERE i <= 3 EXCEPT ALL SELECT i FROM seqs WHERE i>=3;
+-----+
| i     |
+-----+
| 1     |
| 2     |
| 2     |
+-----+

SELECT i FROM seqs WHERE i <= 3 INTERSECT SELECT i FROM seqs WHERE i>=3;
+-----+
| i     |
+-----+
| 3     |
+-----+

SELECT i FROM seqs WHERE i <= 3 INTERSECT ALL SELECT i FROM seqs WHERE i>=3;
+-----+
| i     |
+-----+
| 3     |
| 3     |
+-----+

```

```

CREATE OR REPLACE TABLE t1 (a INT);
CREATE OR REPLACE TABLE t2 (b INT);
CREATE OR REPLACE TABLE t3 (c INT);

INSERT INTO t1 VALUES (1), (2), (3), (4);
INSERT INTO t2 VALUES (5), (6);
INSERT INTO t3 VALUES (1), (6);

((SELECT a FROM t1) UNION (SELECT b FROM t2)) INTERSECT (SELECT c FROM t3);
+-----+
| a     |
+-----+
| 1     |
| 6     |
+-----+

(SELECT a FROM t1) UNION ((SELECT b FROM t2) INTERSECT (SELECT c FROM t3));
+-----+
| a     |
+-----+
| 1     |
| 2     |
| 3     |
| 4     |
| 6     |
+-----+

```

1.1.1.4.1.2.4 EXCEPT

The result of `EXCEPT` is all records of the left `SELECT` result set except records which are in right `SELECT` result set, i.e. it is subtraction of two result sets. From [MariaDB 10.6.1](#), `MINUS` is a synonym when `SQL_MODE=ORACLE` is set.

Syntax

```

SELECT ...
(INTERSECT [ALL | DISTINCT] | EXCEPT [ALL | DISTINCT] | UNION [ALL | DISTINCT])
  SELECT ...
[(INTERSECT [ALL | DISTINCT] | EXCEPT [ALL | DISTINCT] | UNION [ALL | DISTINCT])
  SELECT ...]
[ORDER BY [{col_name | expr | position} [ASC | DESC]
  [, {col_name | expr | position} [ASC | DESC] ...]]]
[LIMIT {[offset,] row_count | row_count OFFSET offset}
| OFFSET start { ROW | ROWS }
| FETCH { FIRST | NEXT } [ count ] { ROW | ROWS } { ONLY | WITH TIES } ]

```

Contents

1. [Syntax](#)
 1. [Description](#)
 1. [Parentheses](#)
 2. [ALL/DISTINCT](#)
 2. [Examples](#)

Please note:

- Brackets for explicit operation precedence are not supported; use a subquery in the `FROM` clause as a workaround).

Description

MariaDB has supported `EXCEPT` and `INTERSECT` in addition to `UNION` since [MariaDB 10.3](#).

The queries before and after `EXCEPT` must be `SELECT` or `VALUES` statements.

All behavior for naming columns, `ORDER BY` and `LIMIT` is the same as for `UNION`. Note that the alternative `SELECT ... OFFSET ... FETCH` syntax is only supported. This allows us to use the `WITH TIES` clause.

`EXCEPT` implicitly supposes a `DISTINCT` operation.

The result of `EXCEPT` is all records of the left `SELECT` result except records which are in right `SELECT` result set, i.e. it is subtraction of two result sets.

`EXCEPT` and `UNION` have the same operation precedence and `INTERSECT` has a higher precedence, unless [running in Oracle mode](#), in which case all three have the same precedence.

MariaDB starting with [10.4.0](#)

Parentheses

From [MariaDB 10.4.0](#), parentheses can be used to specify precedence. Before this, a syntax error would be returned.

MariaDB starting with [10.5.0](#)

ALL/DISTINCT

`EXCEPT ALL` and `EXCEPT DISTINCT` were introduced in [MariaDB 10.5.0](#). The `ALL` operator leaves duplicates intact, while the `DISTINCT` operator removes duplicates. `DISTINCT` is the default behavior if neither operator is supplied, and the only behavior prior to [MariaDB 10.5](#).

Examples

Show customers which are not employees:

```
(SELECT e_name AS name, email FROM customers)
EXCEPT
(SELECT c_name AS name, email FROM employees);
```

Difference between [UNION](#), `EXCEPT` and [INTERSECT](#). `INTERSECT ALL` and `EXCEPT ALL` are available from [MariaDB 10.5.0](#).

```

CREATE TABLE seqs (i INT);
INSERT INTO seqs VALUES (1), (2), (2), (3), (3), (4), (5), (6);

SELECT i FROM seqs WHERE i <= 3 UNION SELECT i FROM seqs WHERE i>=3;
+-----+
| i     |
+-----+
| 1     |
| 2     |
| 3     |
| 4     |
| 5     |
| 6     |
+-----+

SELECT i FROM seqs WHERE i <= 3 UNION ALL SELECT i FROM seqs WHERE i>=3;
+-----+
| i     |
+-----+
| 1     |
| 2     |
| 2     |
| 3     |
| 3     |
| 3     |
| 3     |
| 4     |
| 5     |
| 6     |
+-----+

SELECT i FROM seqs WHERE i <= 3 EXCEPT SELECT i FROM seqs WHERE i>=3;
+-----+
| i     |
+-----+
| 1     |
| 2     |
+-----+

SELECT i FROM seqs WHERE i <= 3 EXCEPT ALL SELECT i FROM seqs WHERE i>=3;
+-----+
| i     |
+-----+
| 1     |
| 2     |
| 2     |
+-----+

SELECT i FROM seqs WHERE i <= 3 INTERSECT SELECT i FROM seqs WHERE i>=3;
+-----+
| i     |
+-----+
| 3     |
+-----+

SELECT i FROM seqs WHERE i <= 3 INTERSECT ALL SELECT i FROM seqs WHERE i>=3;
+-----+
| i     |
+-----+
| 3     |
| 3     |
+-----+

```

Parentheses for specifying precedence, from [MariaDB 10.4.0](#)

```

CREATE OR REPLACE TABLE t1 (a INT);
CREATE OR REPLACE TABLE t2 (b INT);
CREATE OR REPLACE TABLE t3 (c INT);

INSERT INTO t1 VALUES (1), (2), (3), (4);
INSERT INTO t2 VALUES (5), (6);
INSERT INTO t3 VALUES (1), (6);

((SELECT a FROM t1) UNION (SELECT b FROM t2)) EXCEPT (SELECT c FROM t3);
+-----+
| a     |
+-----+
| 2     |
| 3     |
| 4     |
| 5     |
+-----+

(SELECT a FROM t1) UNION ((SELECT b FROM t2) EXCEPT (SELECT c FROM t3));
+-----+
| a     |
+-----+
| 1     |
| 2     |
| 3     |
| 4     |
| 5     |
+-----+

```

Here is an example that makes use of the [SEQUENCE](#) storage engine and the [VALUES](#) statement, to generate a numeric sequence and remove some arbitrary numbers from it:

```

(SELECT seq FROM seq_1_to_10) EXCEPT VALUES (2), (3), (4);
+-----+
| seq |
+-----+
| 1   |
| 5   |
| 6   |
| 7   |
| 8   |
| 9   |
| 10  |
+-----+

```

1.1.1.4.1.2.5 INTERSECT

The result of an intersect is the intersection of right and left `SELECT` results, i.e. only records that are present in both result sets will be included in the result of the operation.

Syntax

```

SELECT ...
(INTERSECT [ALL | DISTINCT] | EXCEPT [ALL | DISTINCT] | UNION [ALL | DISTINCT]) SELECT ...
[(INTERSECT [ALL | DISTINCT] | EXCEPT [ALL | DISTINCT] | UNION [ALL | DISTINCT]) SELECT ...]
[ORDER BY [column [, column ...]]]
[LIMIT {[offset,] row_count | row_count OFFSET offset}]

```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [Parentheses](#)
 2. [ALL/DISTINCT](#)
3. [Examples](#)

Description

MariaDB has supported `INTERSECT` (as well as `EXCEPT`) in addition to `UNION` since [MariaDB 10.3](#).

All behavior for naming columns, `ORDER BY` and `LIMIT` is the same as for `UNION`.

`INTERSECT` implicitly supposes a `DISTINCT` operation.

The result of an intersect is the intersection of right and left `SELECT` results, i.e. only records that are present in both result sets will be included in the result of the operation.

`INTERSECT` has higher precedence than `UNION` and `EXCEPT` (unless running [running in Oracle mode](#), in which case all three have the same precedence). If possible it will be executed linearly but if not it will be translated to a subquery in the `FROM` clause:

```
(select a,b from t1)
union
(select c,d from t2)
intersect
(select e,f from t3)
union
(select 4,4);
```

will be translated to:

```
(select a,b from t1)
union
select c,d from
((select c,d from t2)
 intersect
 (select e,f from t3)) dummy_subselect
union
(select 4,4)
```

Parentheses

Parentheses can be used to specify precedence. Prior to [MariaDB 10.4](#), a syntax error would be returned.

MariaDB starting with [10.5.0](#)

ALL/DISTINCT

`INTERSECT ALL` and `INTERSECT DISTINCT` were introduced in [MariaDB 10.5.0](#). The `ALL` operator leaves duplicates intact, while the `DISTINCT` operator removes duplicates. `DISTINCT` is the default behavior if neither operator is supplied, and the only behavior prior to [MariaDB 10.5](#).

Examples

Show customers which are employees:

```
(SELECT e_name AS name, email FROM employees)
INTERSECT
(SELECT c_name AS name, email FROM customers);
```

Difference between `UNION`, `EXCEPT` and `INTERSECT`. `INTERSECT ALL` and `EXCEPT ALL` are available from [MariaDB 10.5.0](#).

```

CREATE TABLE seqs (i INT);
INSERT INTO seqs VALUES (1), (2), (2), (3), (3), (4), (5), (6);

SELECT i FROM seqs WHERE i <= 3 UNION SELECT i FROM seqs WHERE i>=3;
+-----+
| i     |
+-----+
| 1     |
| 2     |
| 3     |
| 4     |
| 5     |
| 6     |
+-----+

SELECT i FROM seqs WHERE i <= 3 UNION ALL SELECT i FROM seqs WHERE i>=3;
+-----+
| i     |
+-----+
| 1     |
| 2     |
| 2     |
| 3     |
| 3     |
| 3     |
| 3     |
| 4     |
| 5     |
| 6     |
+-----+

SELECT i FROM seqs WHERE i <= 3 EXCEPT SELECT i FROM seqs WHERE i>=3;
+-----+
| i     |
+-----+
| 1     |
| 2     |
+-----+

SELECT i FROM seqs WHERE i <= 3 EXCEPT ALL SELECT i FROM seqs WHERE i>=3;
+-----+
| i     |
+-----+
| 1     |
| 2     |
| 2     |
+-----+

SELECT i FROM seqs WHERE i <= 3 INTERSECT SELECT i FROM seqs WHERE i>=3;
+-----+
| i     |
+-----+
| 3     |
+-----+

SELECT i FROM seqs WHERE i <= 3 INTERSECT ALL SELECT i FROM seqs WHERE i>=3;
+-----+
| i     |
+-----+
| 3     |
| 3     |
+-----+

```

Parentheses for specifying precedence:

```

CREATE OR REPLACE TABLE t1 (a INT);
CREATE OR REPLACE TABLE t2 (b INT);
CREATE OR REPLACE TABLE t3 (c INT);

INSERT INTO t1 VALUES (1), (2), (3), (4);
INSERT INTO t2 VALUES (5), (6);
INSERT INTO t3 VALUES (1), (6);

((SELECT a FROM t1) UNION (SELECT b FROM t2)) INTERSECT (SELECT c FROM t3);
+-----+
| a     |
+-----+
| 1     |
| 6     |
+-----+

(SELECT a FROM t1) UNION ((SELECT b FROM t2) INTERSECT (SELECT c FROM t3));
+-----+
| a     |
+-----+
| 1     |
| 2     |
| 3     |
| 4     |
| 6     |
+-----+

```

1.1.1.4.1.2.6 Precedence Control in Table Operations

MariaDB starting with [10.4.0](#)

Beginning in [MariaDB 10.4](#), you can control the ordering of execution on table operations using parentheses.

Syntax

```

( expression )
[ORDER BY [column[, column...]]]
[LIMIT {[offset,] row_count | row_count OFFSET offset}]

```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Example](#)

Description

Using parentheses in your SQL allows you to control the order of execution for [SELECT](#) statements and [Table Value Constructor](#), including [UNION](#), [EXCEPT](#), and [INTERSECT](#) operations. MariaDB executes the parenthetical expression before the rest of the statement. You can then use [ORDER BY](#) and [LIMIT](#) clauses the further organize the result-set.

Note: In practice, the Optimizer may rearrange the exact order in which MariaDB executes different parts of the statement. When it calculates the result-set, however, it returns values as though the parenthetical expression were executed first.

Example

```

CREATE TABLE test.t1 (num INT);

INSERT INTO test.t1 VALUES (1), (2), (3);

(SELECT * FROM test.t1
 UNION
 VALUES (10))
INTERSECT
VALUES (1), (3), (10), (11);
+-----+
| num |
+-----+
|  1  |
|  3  |
| 10  |
+-----+

((SELECT * FROM test.t1
  UNION
  VALUES (10))
 INTERSECT
 VALUES (1), (3), (10), (11))
ORDER BY 1 DESC;
+-----+
| num |
+-----+
| 10  |
|  3  |
|  1  |
+-----+

```

1.1.1.4.1.2.7 MINUS

MariaDB starting with [10.6.1](#)

`MINUS` was introduced as a synonym for `EXCEPT` from [MariaDB 10.6.1](#) when `SQL_MODE=ORACLE` is set.

```

CREATE TABLE seqs (i INT);
INSERT INTO seqs VALUES (1), (2), (2), (3), (3), (4), (5), (6);

SET SQL_MODE='ORACLE';

SELECT i FROM seqs WHERE i <= 3 MINUS SELECT i FROM seqs WHERE i >= 3;
+-----+
| i   |
+-----+
|  1  |
|  2  |
+-----+

```

1.1.1.4.1.3 LIMIT

Contents

1. [Description](#)
 1. [Multi-Table Updates](#)
 2. [GROUP_CONCAT](#)
2. [Examples](#)

Description

Use the `LIMIT` clause to restrict the number of returned rows. When you use a single integer `n` with `LIMIT`, the first `n` rows will be returned. Use the `ORDER BY` clause to control which rows come first. You can also select a number of rows after an offset using either of the following:

```
LIMIT offset, row_count
LIMIT row_count OFFSET offset
```

When you provide an offset m with a limit n , the first m rows will be ignored, and the following n rows will be returned.

Executing an [UPDATE](#) with the `LIMIT` clause is not safe for replication. `LIMIT 0` is an exception to this rule (see [MDEV-6170](#)).

There is a [LIMIT ROWS EXAMINED](#) optimization which provides the means to terminate the execution of `SELECT` statements which examine too many rows, and thus use too many resources. See [LIMIT ROWS EXAMINED](#).

Multi-Table Updates

Until [MariaDB 10.3.1](#), it was not possible to use `LIMIT` (or `ORDER BY`) in a multi-table `UPDATE` statement. This restriction was lifted in [MariaDB 10.3.2](#).

GROUP_CONCAT

Starting from [MariaDB 10.3.3](#), it is possible to use `LIMIT` with `GROUP_CONCAT()`.

Examples

```
CREATE TABLE members (name VARCHAR(20));
INSERT INTO members VALUES ('Jagdish'), ('Kenny'), ('Rokuro'), ('Immaculada');

SELECT * FROM members;
+-----+
| name  |
+-----+
| Jagdish |
| Kenny  |
| Rokuro  |
| Immaculada |
+-----+
```

Select the first two names (no ordering specified):

```
SELECT * FROM members LIMIT 2;
+-----+
| name  |
+-----+
| Jagdish |
| Kenny  |
+-----+
```

All the names in alphabetical order:

```
SELECT * FROM members ORDER BY name;
+-----+
| name      |
+-----+
| Immaculada |
| Jagdish    |
| Kenny      |
| Rokuro     |
+-----+
```

The first two names, ordered alphabetically:

```
SELECT * FROM members ORDER BY name LIMIT 2;
+-----+
| name      |
+-----+
| Immaculada |
| Jagdish    |
+-----+
```

The third name, ordered alphabetically (the first name would be offset zero, so the third is offset two):

```
SELECT * FROM members ORDER BY name LIMIT 2,1;
+-----+
| name |
+-----+
| Kenny |
+-----+
```

From [MariaDB 10.3.2](#), LIMIT can be used in a multi-table update:

```
CREATE TABLE warehouse (product_id INT, qty INT);
INSERT INTO warehouse VALUES (1,100), (2,100), (3,100), (4,100);

CREATE TABLE store (product_id INT, qty INT);
INSERT INTO store VALUES (1,5), (2,5), (3,5), (4,5);

UPDATE warehouse,store SET warehouse.qty = warehouse.qty-2, store.qty = store.qty+2
WHERE (warehouse.product_id = store.product_id AND store.product_id >= 1)
ORDER BY store.product_id DESC LIMIT 2;

SELECT * FROM warehouse;
+-----+-----+
| product_id | qty |
+-----+-----+
|          1 | 100 |
|          2 | 100 |
|          3 |  98 |
|          4 |  98 |
+-----+-----+

SELECT * FROM store;
+-----+-----+
| product_id | qty |
+-----+-----+
|          1 |   5 |
|          2 |   5 |
|          3 |   7 |
|          4 |   7 |
+-----+-----+
```

From [MariaDB 10.3.3](#), LIMIT can be used with GROUP_CONCAT, so, for example, given the following table:

```
CREATE TABLE d (dd DATE, cc INT);

INSERT INTO d VALUES ('2017-01-01',1);
INSERT INTO d VALUES ('2017-01-02',2);
INSERT INTO d VALUES ('2017-01-04',3);
```

the following query:

```
SELECT SUBSTRING_INDEX(GROUP_CONCAT(CONCAT_WS(':',dd,cc) ORDER BY cc DESC),",",1) FROM d;
+-----+-----+-----+
| SUBSTRING_INDEX(GROUP_CONCAT(CONCAT_WS(':',dd,cc) ORDER BY cc DESC),",",1) |
+-----+-----+-----+
| 2017-01-04:3 |
+-----+-----+-----+
```

can be more simply rewritten as:

```
SELECT GROUP_CONCAT(CONCAT_WS(':',dd,cc) ORDER BY cc DESC LIMIT 1) FROM d;
+-----+-----+-----+
| GROUP_CONCAT(CONCAT_WS(':',dd,cc) ORDER BY cc DESC LIMIT 1) |
+-----+-----+-----+
| 2017-01-04:3 |
+-----+-----+-----+
```

1.1.1.4.1.4 ORDER BY

Contents

1. [Description](#)
2. [Examples](#)

Description

Use the `ORDER BY` clause to order a resultset, such as that are returned from a `SELECT` statement. You can specify just a column or use any expression with functions. If you are using the `GROUP BY` clause, you can use grouping functions in `ORDER BY`. Ordering is done after grouping.

You can use multiple ordering expressions, separated by commas. Rows will be sorted by the first expression, then by the second expression if they have the same value for the first, and so on.

You can use the keywords `ASC` and `DESC` after each ordering expression to force that ordering to be ascending or descending, respectively. Ordering is ascending by default.

You can also use a single integer as the ordering expression. If you use an integer n , the results will be ordered by the n th column in the select expression.

When string values are compared, they are compared as if by the `STRCMP` function. `STRCMP` ignores trailing whitespace and may normalize characters and ignore case, depending on the `collation` in use.

Duplicated entries in the `ORDER BY` clause are removed.

`ORDER BY` can also be used to order the activities of a `DELETE` or `UPDATE` statement (usually with the `LIMIT` clause).

Until [MariaDB 10.3.1](#), it was not possible to use `ORDER BY` (or `LIMIT`) in a multi-table `UPDATE` statement. This restriction was lifted in [MariaDB 10.3.2](#).

MariaDB starting with 10.5

From [MariaDB 10.5](#), MariaDB allows packed sort keys and values of non-sorted fields in the sort buffer. This can make filesort temporary files much smaller when `VARCHAR`, `CHAR` or `BLOBs` are used, notably speeding up some `ORDER BY` sorts.

Examples

```
CREATE TABLE seq (i INT, x VARCHAR(1));
INSERT INTO seq VALUES (1,'a'), (2,'b'), (3,'b'), (4,'f'), (5,'e');
```

```
SELECT * FROM seq ORDER BY i;
```

```
+-----+-----+
| i    | x    |
+-----+-----+
|  1  | a    |
|  2  | b    |
|  3  | b    |
|  4  | f    |
|  5  | e    |
+-----+-----+
```

```
SELECT * FROM seq ORDER BY i DESC;
```

```
+-----+-----+
| i    | x    |
+-----+-----+
|  5  | e    |
|  4  | f    |
|  3  | b    |
|  2  | b    |
|  1  | a    |
+-----+-----+
```

```
SELECT * FROM seq ORDER BY x,i;
```

```
+-----+-----+
| i    | x    |
+-----+-----+
|  1  | a    |
|  2  | b    |
|  3  | b    |
|  5  | e    |
|  4  | f    |
+-----+-----+
```

ORDER BY in an [UPDATE](#) statement, in conjunction with [LIMIT](#):

```
UPDATE seq SET x='z' WHERE x='b' ORDER BY i DESC LIMIT 1;
```

```
SELECT * FROM seq;
```

```
+-----+-----+
| i    | x    |
+-----+-----+
|  1  | a    |
|  2  | b    |
|  3  | z    |
|  4  | f    |
|  5  | e    |
+-----+-----+
```

From [MariaDB 10.3.2](#), ORDER BY can be used in a multi-table update:

```

CREATE TABLE warehouse (product_id INT, qty INT);
INSERT INTO warehouse VALUES (1,100), (2,100), (3,100), (4,100);

CREATE TABLE store (product_id INT, qty INT);
INSERT INTO store VALUES (1,5), (2,5), (3,5), (4,5);

UPDATE warehouse,store SET warehouse.qty = warehouse.qty-2, store.qty = store.qty+2
WHERE (warehouse.product_id = store.product_id AND store.product_id >= 1)
ORDER BY store.product_id DESC LIMIT 2;

SELECT * FROM warehouse;
+-----+-----+
| product_id | qty |
+-----+-----+
|          1 | 100 |
|          2 | 100 |
|          3 |  98 |
|          4 |  98 |
+-----+-----+

SELECT * FROM store;
+-----+-----+
| product_id | qty |
+-----+-----+
|          1 |   5 |
|          2 |   5 |
|          3 |   7 |
|          4 |   7 |
+-----+-----+

```

1.1.1.4.1.5 GROUP BY

Contents

1. [WITH ROLLUP](#)
2. [GROUP BY Examples](#)

Use the `GROUP BY` clause in a `SELECT` statement to group rows together that have the same value in one or more column, or the same computed value using expressions with any [functions and operators](#) except [grouping functions](#). When you use a `GROUP BY` clause, you will get a single result row for each group of rows that have the same value for the expression given in `GROUP BY`.

When grouping rows, grouping values are compared as if by the `=` operator. For string values, the `=` operator ignores trailing whitespace and may normalize characters and ignore case, depending on the [collation](#) in use.

You can use any of the grouping functions in your select expression. Their values will be calculated based on all the rows that have been grouped together for each result row. If you select a non-grouped column or a value computed from a non-grouped column, it is undefined which row the returned value is taken from. This is not permitted if the `ONLY_FULL_GROUP_BY` [SQL_MODE](#) is used.

You can use multiple expressions in the `GROUP BY` clause, separated by commas. Rows are grouped together if they match on each of the expressions.

You can also use a single integer as the grouping expression. If you use an integer `n`, the results will be grouped by the `n`th column in the select expression.

The `WHERE` clause is applied before the `GROUP BY` clause. It filters non-aggregated rows before the rows are grouped together. To filter grouped rows based on aggregate values, use the `HAVING` clause. The `HAVING` clause takes any expression and evaluates it as a boolean, just like the `WHERE` clause. You can use grouping functions in the `HAVING` clause. As with the select expression, if you reference non-grouped columns in the `HAVING` clause, the behavior is undefined.

By default, if a `GROUP BY` clause is present, the rows in the output will be sorted by the expressions used in the `GROUP BY`. You can also specify `ASC` or `DESC` (ascending, descending) after those expressions, like in [ORDER BY](#). The default is `ASC`.

If you want the rows to be sorted by another field, you can add an explicit [ORDER BY](#). If you don't want the result to be ordered, you can add [ORDER BY NULL](#).

WITH ROLLUP

The `WITH ROLLUP` modifier adds extra rows to the resultset that represent super-aggregate summaries. For a full description with examples, see [SELECT WITH ROLLUP](#).

GROUP BY Examples

Consider the following table that records how many times each user has played and won a game:

```
CREATE TABLE plays (name VARCHAR(16), plays INT, wins INT);
INSERT INTO plays VALUES
  ("John", 20, 5),
  ("Robert", 22, 8),
  ("Wanda", 32, 8),
  ("Susan", 17, 3);
```

Get a list of win counts along with a count:

```
SELECT wins, COUNT(*) FROM plays GROUP BY wins;
+-----+-----+
| wins | COUNT(*) |
+-----+-----+
| 3 | 1 |
| 5 | 1 |
| 8 | 2 |
+-----+-----+
3 rows in set (0.00 sec)
```

The `GROUP BY` expression can be a computed value, and can refer back to an identifier specified with `AS`. Get a list of win averages along with a count:

```
SELECT (wins / plays) AS winavg, COUNT(*) FROM plays GROUP BY winavg;
+-----+-----+
| winavg | COUNT(*) |
+-----+-----+
| 0.1765 | 1 |
| 0.2500 | 2 |
| 0.3636 | 1 |
+-----+-----+
3 rows in set (0.00 sec)
```

You can use any [grouping function](#) in the select expression. For each win average as above, get a list of the average play count taken to get that average:

```
SELECT (wins / plays) AS winavg, AVG(plays) FROM plays
GROUP BY winavg;
+-----+-----+
| winavg | AVG(plays) |
+-----+-----+
| 0.1765 | 17.0000 |
| 0.2500 | 26.0000 |
| 0.3636 | 22.0000 |
+-----+-----+
3 rows in set (0.00 sec)
```

You can filter on aggregate information using the `HAVING` clause. The `HAVING` clause is applied after `GROUP BY` and allows you to filter on aggregate data that is not available to the `WHERE` clause. Restrict the above example to results that involve an average number of plays over 20:

```
SELECT (wins / plays) AS winavg, AVG(plays) FROM plays
GROUP BY winavg HAVING AVG(plays) > 20;
+-----+-----+
| winavg | AVG(plays) |
+-----+-----+
| 0.2500 | 26.0000 |
| 0.3636 | 22.0000 |
+-----+-----+
2 rows in set (0.00 sec)
```

1.1.1.4.1.6 Common Table Expressions

WITH

Allows reference to subqueries as temporary tables within queries.

Non-Recursive Common Table Expressions Overview

Common Table Expressions (CTEs) are essentially Temporary Named Result Sets.

Recursive Common Table Expressions Overview

A recursive CTE will repeatedly execute subsets of the data until obtaining the complete results.

There are [1 related questions](#).

1.1.1.4.1.6.1 WITH

Syntax

```
WITH [RECURSIVE] table_reference [(columns_list)] AS (  
    SELECT ...  
)  
[CYCLE cycle_column_list RESTRICT]  
SELECT ...
```

Contents

- [Syntax](#)
- [Description](#)
 - [CYCLE ... RESTRICT](#)
- [Examples](#)

Description

The `WITH` keyword signifies a [Common Table Expression](#) (CTE). It allows you to refer to a subquery expression many times in a query, as if having a temporary table that only exists for the duration of a query.

There are two kinds of CTEs:

- [Non-Recursive](#)
- [Recursive](#) (signified by the `RECURSIVE` keyword, supported since [MariaDB 10.2.2](#))

You can use `table_reference` as any normal table in the external `SELECT` part. You can also use `WITH` in subqueries, as well as with [EXPLAIN](#) and [SELECT](#).

Poorly-formed recursive CTEs can in theory cause infinite loops. The `max_recursive_iterations` system variable limits the number of recursions.

CYCLE ... RESTRICT

MariaDB starting with [10.5.2](#)

The `CYCLE` clause enables CTE cycle detection, avoiding excessive or infinite loops, MariaDB supports a relaxed, non-standard grammar.

The SQL Standard permits a `CYCLE` clause, as follows:

```
WITH RECURSIVE ... (  
    ...  
)  
CYCLE <cycle column list>  
SET <cycle mark column> TO <cycle mark value> DEFAULT <non-cycle mark value>  
USING <path column>
```

where all clauses are mandatory.

MariaDB does not support this, but from 10.5.2 permits a non-standard relaxed grammar, as follows:

```
WITH RECURSIVE ... (
    ...
)
CYCLE <cycle column list> RESTRICT
```

With the use of `CYCLE ... RESTRICT` it makes no difference whether the CTE uses `UNION ALL` or `UNION DISTINCT` anymore. `UNION ALL` means "all rows, but without cycles", which is exactly what the `CYCLE` clause enables. And `UNION DISTINCT` means all rows should be different, which, again, is what will happen — as uniqueness is enforced over a subset of columns, complete rows will automatically all be different.

Examples

Below is an example with the `WITH` at the top level:

```
WITH t AS (SELECT a FROM t1 WHERE b >= 'c')
SELECT * FROM t2, t WHERE t2.c = t.a;
```

The example below uses `WITH` in a subquery:

```
SELECT t1.a, t1.b FROM t1, t2
WHERE t1.a > t2.c
AND t2.c IN(WITH t AS (SELECT * FROM t1 WHERE t1.a < 5)
            SELECT t2.c FROM t2, t WHERE t2.c = t.a);
```

Below is an example of a Recursive CTE:

```
WITH RECURSIVE ancestors AS
( SELECT * FROM folks
  WHERE name="Alex"
  UNION
  SELECT f.*
  FROM folks AS f, ancestors AS a
  WHERE f.id = a.father OR f.id = a.mother )
SELECT * FROM ancestors;
```

Take the following structure, and data,

```
CREATE TABLE t1 (from_ int, to_ int);
INSERT INTO t1 VALUES (1,2), (1,100), (2,3), (3,4), (4,1);
SELECT * FROM t1;
+-----+-----+
| from_ | to_  |
+-----+-----+
| 1     | 2    |
| 1     | 100  |
| 2     | 3    |
| 3     | 4    |
| 4     | 1    |
+-----+-----+
```

Given the above, the following query would theoretically result in an infinite loop due to the last record in `t1` (note that `max_recursive_iterations` is set to 10 for the purposes of this example, to avoid the excessive number of cycles):

```

SET max_recursive_iterations=10;

WITH RECURSIVE cte (depth, from_, to_) AS (
  SELECT 0,1,1 UNION DISTINCT SELECT depth+1, t1.from_, t1.to_
  FROM t1, cte WHERE t1.from_ = cte.to_
)
SELECT * FROM cte;
+-----+-----+-----+
| depth | from_ | to_ |
+-----+-----+-----+
| 0 | 1 | 1 |
| 1 | 1 | 2 |
| 1 | 1 | 100 |
| 2 | 2 | 3 |
| 3 | 3 | 4 |
| 4 | 4 | 1 |
| 5 | 1 | 2 |
| 5 | 1 | 100 |
| 6 | 2 | 3 |
| 7 | 3 | 4 |
| 8 | 4 | 1 |
| 9 | 1 | 2 |
| 9 | 1 | 100 |
| 10 | 2 | 3 |
+-----+-----+-----+

```

However, the CYCLE ... RESTRICT clause (from [MariaDB 10.5.2](#)) can overcome this:

```

WITH RECURSIVE cte (depth, from_, to_) AS (
  SELECT 0,1,1 UNION SELECT depth+1, t1.from_, t1.to_
  FROM t1, cte WHERE t1.from_ = cte.to_
)
CYCLE from_, to_ RESTRICT
SELECT * FROM cte;
+-----+-----+-----+
| depth | from_ | to_ |
+-----+-----+-----+
| 0 | 1 | 1 |
| 1 | 1 | 2 |
| 1 | 1 | 100 |
| 2 | 2 | 3 |
| 3 | 3 | 4 |
| 4 | 4 | 1 |
+-----+-----+-----+

```

1.1.1.4.1.6.2 Non-Recursive Common Table Expressions Overview

Contents

1. [Non-Recursive CTEs](#)
 1. [A CTE referencing Another CTE](#)
 2. [Multiple Uses of a CTE](#)

Common Table Expressions (CTEs) are a standard SQL feature, and are essentially temporary named result sets. There are two kinds of CTEs: Non-Recursive, which this article covers; and [Recursive](#).

Non-Recursive CTEs

The [WITH](#) keyword signifies a CTE. It is given a name, followed by a body (the main query) as follows:

```

WITH
with engineers as (
  select *
  from employees
  where dept='Engineering'
)
select *
from engineers
where ...

```

Annotations in the image:

- WITH** points to the word `WITH`.
- CTE name** points to `engineers`.
- CTE Body** points to the subquery: `select * from employees where dept='Engineering'`.
- CTE Usage** points to `from engineers`.

CTEs are similar to derived tables. For example

```

WITH engineers AS
( SELECT * FROM employees
  WHERE dept = 'Engineering' )

SELECT * FROM engineers
WHERE ...

```

```

SELECT * FROM
( SELECT * FROM employees
  WHERE dept = 'Engineering' ) AS engineers
WHERE
...

```

A non-recursive CTE is basically a query-local [VIEW](#). There are several advantages and caveats to them. The syntax is more readable than nested `FROM (SELECT ...)`. A CTE can refer to another and it can be referenced from multiple places.

A CTE referencing Another CTE

Using this format makes for a more readable SQL than a nested `FROM(SELECT ...)` clause. Below is an example of this:

```

WITH engineers AS (
  SELECT * FROM employees
  WHERE dept IN ('Development', 'Support') ),
  eu_engineers AS ( SELECT * FROM engineers WHERE country IN ('NL', ...) )
SELECT
...
FROM eu_engineers;

```

Multiple Uses of a CTE

This can be an 'anti-self join', for example:

```

WITH engineers AS (
  SELECT * FROM employees
  WHERE dept IN ('Development', 'Support') )

SELECT * FROM engineers E1
WHERE NOT EXISTS
( SELECT 1 FROM engineers E2
  WHERE E2.country=E1.country
  AND E2.name <> E1.name );

```

Or, for year-over-year comparisons, for example:

```

WITH sales_product_year AS (
SELECT product, YEAR(ship_date) AS year,
SUM(price) AS total_amt
FROM item_sales
GROUP BY product, year )

SELECT *
FROM sales_product_year CUR,
sales_product_year PREV,
WHERE CUR.product=PREV.product
AND CUR.year=PREV.year + 1
AND CUR.total_amt > PREV.total_amt

```

Another use is to compare individuals against their group. Below is an example of how this might be executed:

```

WITH sales_product_year AS (
SELECT product,
YEAR(ship_date) AS year,
SUM(price) AS total_amt
FROM item_sales
GROUP BY product, year
)

SELECT *
FROM sales_product_year S1
WHERE
total_amt >
(SELECT 0.1 * SUM(total_amt)
FROM sales_product_year S2
WHERE S2.year = S1.year)

```

1.1.1.4.1.6.3 Recursive Common Table Expressions Overview

Contents

1. [Syntax example](#)
2. [Computation](#)
3. [Summary so far](#)
4. [CAST to avoid truncating data](#)
5. [Examples](#)
 1. [Transitive closure - determining bus destinations](#)
 2. [Computing paths - determining bus routes](#)
 3. [CAST to avoid data truncation](#)

Common Table Expressions (CTEs) are a standard SQL feature, and are essentially temporary named result sets. CTEs first appeared in the SQL standard in 1999, and the first implementations began appearing in 2007.

There are two kinds of CTEs:

- [Non-recursive](#)
- Recursive, which this article covers.

SQL is generally poor at recursive structures.

CTEs permit a query to reference itself. A recursive CTE will repeatedly execute subsets of the data until it obtains the complete result set. This makes it particularly useful for handling hierarchical or tree-structured data.

[max_recursive_iterations](#) avoids infinite loops.

Syntax example

`WITH RECURSIVE` signifies a recursive CTE. It is given a name, followed by a body (the main query) as follows:

```

    "recursive"
    ↙
with recursive ancestors as (
  select * from folks
  where name = 'Alex' ← Anchor part
  union [all]
  select f.*
  from folks as f, ancestors AS a ← Recursive use of CTE
  where ← Recursive part
    f.id = a.father or f.id = a.mother
)
select * from ancestors;
  
```

```

    WITH
    ↙
with engineers as (
  select *
  from employees
  where dept='Engineering' ← CTE Body
)
select *
from engineers ← CTE Usage
where ...
  
```

Computation

Given the following structure:

Recursive CTE computation

id	name	father	mother
100	Alex	20	30
20	Dad	10	NULL
30	Mom	NULL	NULL
10	Grandpa Bill	NULL	NULL
98	Sister Amy	20	30

First execute the anchor part of the query:

Computation

```
with recursive ancestors as (  
  select * from folks  
  where name = 'Alex'  
  union  
  select f.*  
  from folks as f, ancestors AS a  
  where  
    f.id = a.father or f.id = a.mother  
)  
select * from ancestors;
```

Result table

id	name	father	mother
100	Alex	20	30

Step #1: execution of the anchor part

Next, execute the recursive part of the query:

Computation

```
with recursive ancestors as (  
  select * from folks  
  where name = 'Alex'  
  union  
  select f.*  
  from folks as f, ancestors AS a  
  where  
    f.id = a.father or f.id = a.mother  
)  
select * from ancestors;
```

Result table

id	name	father	mother
100	Alex	20	30

id	name	father	mother
100	Alex	20	30
20	Dad	10	NULL
30	Mom	NULL	NULL
10	Grandpa Bill	NULL	NULL
98	Sister Amy	20	30

Step #2: execution of the recursive part

Computation

```
with recursive ancestors as (  
  select * from folks  
  where name = 'Alex'  
  union  
  select f.*  
  from folks as f, ancestors AS a  
  where  
    f.id = a.father or f.id = a.mother  
)  
select * from ancestors;
```

Result table

id	name	father	mother
100	Alex	20	30
20	Dad	10	NULL
30	Mom	NULL	NULL

id	name	father	mother
100	Alex	20	30
20	Dad	10	NULL
30	Mom	NULL	NULL
10	Grandpa Bill	NULL	NULL
98	Sister Amy	20	30

Computation

```
with recursive ancestors as (  
  select * from folks  
  where name = 'Alex'  
  union  
  select f.*  
  from folks as f, ancestors AS a  
  where  
    f.id = a.father or f.id = a.mother  
)  
select * from ancestors;
```

Result table

id	name	father	mother
100	Alex	20	30
20	Dad	10	NULL
30	Mom	NULL	NULL

id	name	father	mother
100	Alex	20	30
20	Dad	10	NULL
30	Mom	NULL	NULL
10	Grandpa Bill	NULL	NULL
98	Sister Amy	20	30

Computation

```
with recursive ancestors as (
  select * from folks
  where name = 'Alex'
  union
  select f.*
  from folks as f, ancestors AS a
  where
    f.id = a.father or f.id = a.mother
)
select * from ancestors;
```

Result table

id	name	father	mother
100	Alex	20	30
20	Dad	10	NULL
30	Mom	NULL	NULL
10	Grandpa Bill	NULL	NULL

id	name	father	mother
100	Alex	20	30
20	Dad	10	NULL
30	Mom	NULL	NULL
10	Grandpa Bill	NULL	NULL
98	Sister Amy	20	30

Computation

```
with recursive ancestors as (
  select * from folks
  where name = 'Alex'
  union
  select f.*
  from folks as f, ancestors AS a
  where
    f.id = a.father or f.id = a.mother
)
select * from ancestors;
```

Result table

id	name	father	mother
100	Alex	20	30
20	Dad	10	NULL
30	Mom	NULL	NULL
10	Grandpa Bill	NULL	NULL

id	name	father	mother
100	Alex	20	30
20	Dad	10	NULL
30	Mom	NULL	NULL
10	Grandpa Bill	NULL	NULL
98	Sister Amy	20	30

No results!

Summary so far

```
with recursive R as (
  select anchor_data
  union [all]
  select recursive_part
  from R, ...
)
select ...
```

1. Compute anchor_data
2. Compute recursive_part to get the new data
3. if (new data is non-empty) goto 2;

CAST to avoid truncating data

As currently implemented by MariaDB and by the SQL Standard, data may be truncated if not correctly cast. It is necessary to **CAST** the column to the correct width if the CTE's recursive part produces wider values for a column than the CTE's nonrecursive part. Some other DBMS give an error in this situation, and MariaDB's behavior may change in future - see [MDEV-12325](#). See the [examples below](#).

Examples

Transitive closure - determining bus destinations

Sample data:

origin	dst
New York	Boston
Boston	New York
New York	Washington
Washington	Boston
Washington	Raleigh

```
CREATE TABLE bus_routes (origin varchar(50), dst varchar(50));
INSERT INTO bus_routes VALUES
('New York', 'Boston'),
('Boston', 'New York'),
('New York', 'Washington'),
('Washington', 'Boston'),
('Washington', 'Raleigh');
```

Now, we want to return the bus destinations with New York as the origin:

```
WITH RECURSIVE bus_dst as (
  SELECT origin as dst FROM bus_routes WHERE origin='New York'
  UNION
  SELECT bus_routes.dst FROM bus_routes JOIN bus_dst ON bus_dst.dst= bus_routes.origin
)
SELECT * FROM bus_dst;
+-----+
| dst      |
+-----+
| New York |
| Boston   |
| Washington |
| Raleigh  |
+-----+
```

The above example is computed as follows:

First, the anchor data is calculated:

- Starting from New York
- Boston and Washington are added

Next, the recursive part:

- Starting from Boston and then Washington
- Raleigh is added
- UNION excludes nodes that are already present.

Computing paths - determining bus routes

This time, we are trying to get bus routes such as “New York -> Washington -> Raleigh”.

Using the same sample data as the previous example:

```
WITH RECURSIVE paths (cur_path, cur_dest) AS (
  SELECT origin, origin FROM bus_routes WHERE origin='New York'
  UNION
  SELECT CONCAT(paths.cur_path, ',', bus_routes.dst), bus_routes.dst
  FROM paths
  JOIN bus_routes
  ON paths.cur_dest = bus_routes.origin AND
  NOT FIND_IN_SET(bus_routes.dst, paths.cur_path)
)
SELECT * FROM paths;
+-----+-----+
| cur_path          | cur_dest |
+-----+-----+
| New York          | New York |
| New York,Boston  | Boston   |
| New York,Washington | Washington |
| New York,Washington,Boston | Boston   |
| New York,Washington,Raleigh | Raleigh  |
+-----+-----+
```

CAST to avoid data truncation

In the following example, data is truncated because the results are not specifically cast to a wide enough type:

```

WITH RECURSIVE tbl AS (
  SELECT NULL AS col
  UNION
  SELECT "THIS NEVER SHOWS UP" AS col FROM tbl
)
SELECT col FROM tbl
+-----+
| col   |
+-----+
| NULL  |
|       |
+-----+

```

Explicitly use [CAST](#) to overcome this:

```

WITH RECURSIVE tbl AS (
  SELECT CAST(NULL AS CHAR(50)) AS col
  UNION SELECT "THIS NEVER SHOWS UP" AS col FROM tbl
)
SELECT * FROM tbl;
+-----+
| col           |
+-----+
| NULL          |
| THIS NEVER SHOWS UP |
+-----+

```

1.1.1.4.1.7 SELECT WITH ROLLUP

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

Syntax

See [SELECT](#) for the full syntax.

Description

The `WITH ROLLUP` modifier adds extra rows to the resultset that represent super-aggregate summaries. The super-aggregated column is represented by a `NULL` value. Multiple aggregates over different columns will be added if there are multiple `GROUP BY` columns.

The `LIMIT` clause can be used at the same time, and is applied after the `WITH ROLLUP` rows have been added.

`WITH ROLLUP` cannot be used with [ORDER BY](#). Some sorting is still possible by using `ASC` or `DESC` clauses with the `GROUP BY` column, although the super-aggregate rows will always be added last.

Examples

These examples use the following sample table

```

CREATE TABLE booksales (
  country VARCHAR(35), genre ENUM('fiction','non-fiction'), year YEAR, sales INT);

INSERT INTO booksales VALUES
  ('Senegal','fiction',2014,12234), ('Senegal','fiction',2015,15647),
  ('Senegal','non-fiction',2014,64980), ('Senegal','non-fiction',2015,78901),
  ('Paraguay','fiction',2014,87970), ('Paraguay','fiction',2015,76940),
  ('Paraguay','non-fiction',2014,8760), ('Paraguay','non-fiction',2015,9030);

```

The addition of the `WITH ROLLUP` modifier in this example adds an extra row that aggregates both years:

```

SELECT year, SUM(sales) FROM booksales GROUP BY year;
+-----+-----+
| year | SUM(sales) |
+-----+-----+
| 2014 | 173944 |
| 2015 | 180518 |
+-----+-----+
2 rows in set (0.08 sec)

SELECT year, SUM(sales) FROM booksales GROUP BY year WITH ROLLUP;
+-----+-----+
| year | SUM(sales) |
+-----+-----+
| 2014 | 173944 |
| 2015 | 180518 |
| NULL | 354462 |
+-----+-----+

```

In the following example, each time the genre, the year or the country change, another super-aggregate row is added:

```

SELECT country, year, genre, SUM(sales)
FROM booksales GROUP BY country, year, genre;
+-----+-----+-----+-----+
| country | year | genre      | SUM(sales) |
+-----+-----+-----+-----+
| Paraguay | 2014 | fiction     | 87970 |
| Paraguay | 2014 | non-fiction | 8760 |
| Paraguay | 2015 | fiction     | 76940 |
| Paraguay | 2015 | non-fiction | 9030 |
| Senegal  | 2014 | fiction     | 12234 |
| Senegal  | 2014 | non-fiction | 64980 |
| Senegal  | 2015 | fiction     | 15647 |
| Senegal  | 2015 | non-fiction | 78901 |
+-----+-----+-----+-----+

SELECT country, year, genre, SUM(sales)
FROM booksales GROUP BY country, year, genre WITH ROLLUP;
+-----+-----+-----+-----+
| country | year | genre      | SUM(sales) |
+-----+-----+-----+-----+
| Paraguay | 2014 | fiction     | 87970 |
| Paraguay | 2014 | non-fiction | 8760 |
| Paraguay | 2014 | NULL       | 96730 |
| Paraguay | 2015 | fiction     | 76940 |
| Paraguay | 2015 | non-fiction | 9030 |
| Paraguay | 2015 | NULL       | 85970 |
| Paraguay | NULL  | NULL       | 182700 |
| Senegal  | 2014 | fiction     | 12234 |
| Senegal  | 2014 | non-fiction | 64980 |
| Senegal  | 2014 | NULL       | 77214 |
| Senegal  | 2015 | fiction     | 15647 |
| Senegal  | 2015 | non-fiction | 78901 |
| Senegal  | 2015 | NULL       | 94548 |
| Senegal  | NULL  | NULL       | 171762 |
| NULL     | NULL  | NULL       | 354462 |
+-----+-----+-----+-----+

```

The LIMIT clause, applied after WITH ROLLUP:

```

SELECT country, year, genre, SUM(sales)
FROM booksales GROUP BY country, year, genre WITH ROLLUP LIMIT 4;
+-----+-----+-----+-----+
| country | year | genre      | SUM(sales) |
+-----+-----+-----+-----+
| Paraguay | 2014 | fiction     | 87970 |
| Paraguay | 2014 | non-fiction | 8760 |
| Paraguay | 2014 | NULL       | 96730 |
| Paraguay | 2015 | fiction     | 76940 |
+-----+-----+-----+-----+

```

Sorting by year descending:

```
SELECT country, year, genre, SUM(sales)
FROM booksales GROUP BY country, year DESC, genre WITH ROLLUP;
```

country	year	genre	SUM(sales)
Paraguay	2015	fiction	76940
Paraguay	2015	non-fiction	9030
Paraguay	2015	NULL	85970
Paraguay	2014	fiction	87970
Paraguay	2014	non-fiction	8760
Paraguay	2014	NULL	96730
Paraguay	NULL	NULL	182700
Senegal	2015	fiction	15647
Senegal	2015	non-fiction	78901
Senegal	2015	NULL	94548
Senegal	2014	fiction	12234
Senegal	2014	non-fiction	64980
Senegal	2014	NULL	77214
Senegal	NULL	NULL	171762
NULL	NULL	NULL	354462

1.1.1.4.1.8 SELECT INTO OUTFILE

Syntax

```
SELECT ... INTO OUTFILE 'file_name'
    [CHARACTER SET charset_name]
    [export_options]

export_options:
    [{FIELDS | COLUMNS}
     [TERMINATED BY 'string']
     [[OPTIONALLY] ENCLOSED BY 'char']
     [ESCAPED BY 'char']
    ]
    [LINES
     [STARTING BY 'string']
     [TERMINATED BY 'string']
    ]
]
```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [Character-sets](#)
3. [Example](#)

Description

`SELECT INTO OUTFILE` writes the resulting rows to a file, and allows the use of column and row terminators to specify a particular output format. The default is to terminate fields with tabs (`\t`) and lines with newlines (`\n`).

The file must not exist. It cannot be overwritten. A user needs the `FILE` privilege to run this statement. Also, MariaDB needs permission to write files in the specified location. If the `secure_file_priv` system variable is set to a non-empty directory name, the file can only be written to that directory.

The `LOAD DATA INFILE` statement complements `SELECT INTO OUTFILE` .

Character-sets

The `CHARACTER SET` clause specifies the `character set` in which the results are to be written. Without the clause, no conversion takes place (the binary character set). In this case, if there are multiple character sets, the output will contain these too, and may not easily be able to be reloaded.

In cases where you have two servers using different character-sets, using `SELECT INTO OUTFILE` to transfer data from one to the other can have unexpected results. To ensure that MariaDB correctly interprets the escape sequences, use the

`CHARACTER SET` clause on both the `SELECT INTO OUTFILE` statement and the subsequent `LOAD DATA INFILE` statement.

Example

The following example produces a file in the CSV format:

```
SELECT customer_id, firstname, surname from customer
INTO OUTFILE '/exportdata/customers.txt'
FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"'
LINES TERMINATED BY '\n';
```

The following ANSI syntax is also supported for simple `SELECT` without `UNION`

```
SELECT customer_id, firstname, surname INTO OUTFILE '/exportdata/customers.txt'
FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"'
LINES TERMINATED BY '\n'
FROM customers;
```

If you want to use the ANSI syntax with `UNION` or similar construct you have to use the syntax:

```
SELECT * INTO OUTFILE "/tmp/skr3" FROM (SELECT * FROM t1 UNION SELECT * FROM t1);
```

1.1.1.4.1.9 SELECT INTO DUMPFIL

Contents

1. [Syntax](#)
2. [Description](#)
3. [Example](#)

Syntax

```
SELECT ... INTO DUMPFIL 'file_path'
```

Description

`SELECT ... INTO DUMPFIL` is a `SELECT` clause which writes the resultset into a single unformatted row, without any separators, in a file. The results will not be returned to the client.

`file_path` can be an absolute path, or a relative path starting from the data directory. It can only be specified as a [string literal](#), not as a variable. However, the statement can be dynamically composed and executed as a prepared statement to work around this limitation.

This statement is binary-safe and so is particularly useful for writing `BLOB` values to file. It can be used, for example, to copy an image or an audio document from the database to a file.

The file must not exist. It cannot be overwritten. A user needs the `FILE` privilege to run this statement. Also, MariaDB needs permission to write files in the specified location. If the `secure_file_priv` system variable is set to a non-empty directory name, the file can only be written to that directory.

Since [MariaDB 5.1](#), the `character_set_filesystem` system variable has controlled interpretation of file names that are given as literal strings.

Example

```
SELECT _utf8'Hello world!' INTO DUMPFIL '/tmp/world';

SELECT LOAD_FILE('/tmp/world') AS world;
+-----+
| world      |
+-----+
| Hello world! |
+-----+
```

1.1.1.4.1.10 FOR UPDATE

InnoDB supports row-level locking. Selected rows can be locked using [LOCK IN SHARE MODE](#) or [FOR UPDATE](#). In both cases, a lock is acquired on the rows read by the query, and it will be released when the current transaction is committed.

The [FOR UPDATE](#) clause of [SELECT](#) applies only when [autocommit](#) is set to 0 or the [SELECT](#) is enclosed in a transaction. A lock is acquired on the rows, and other transactions are prevented from writing the rows, acquire locks, and from reading them (unless their isolation level is [READ UNCOMMITTED](#)).

If [autocommit](#) is set to 1, the [LOCK IN SHARE MODE](#) and [FOR UPDATE](#) clauses have no effect in InnoDB. For non-transactional storage engines like MyISAM and ARIA, a table level lock will be taken even if [autocommit](#) is set to 1.

If the isolation level is set to [SERIALIZABLE](#), all plain [SELECT](#) statements are converted to [SELECT ... LOCK IN SHARE MODE](#).

Example

```
SELECT * FROM trans WHERE period=2001 FOR UPDATE;
```

1.1.1.4.1.11 LOCK IN SHARE MODE

InnoDB supports row-level locking. Selected rows can be locked using [LOCK IN SHARE MODE](#) or [FOR UPDATE](#). In both cases, a lock is acquired on the rows read by the query, and it will be released when the current transaction is committed.

When [LOCK IN SHARE MODE](#) is specified in a [SELECT](#) statement, MariaDB will wait until all transactions that have modified the rows are committed. Then, a write lock is acquired. All transactions can read the rows, but if they want to modify them, they have to wait until your transaction is committed.

If [autocommit](#) is set to 1 (the default), the [LOCK IN SHARE MODE](#) and [FOR UPDATE](#) clauses have no effect in InnoDB. For non-transactional storage engines like MyISAM and ARIA, a table level lock will be taken even if [autocommit](#) is set to 1.

 - [SUBQUERY Hint](#)
 - [SEMIJOIN and NO_SEMIJOIN](#)

Optimizer hints are options available that affect the execution plan.

SELECT Modifiers

HIGH PRIORITY

`HIGH_PRIORITY` gives the statement a higher priority. If the table is locked, high priority `SELECT` s will be executed as soon as the lock is released, even if other statements are queued. `HIGH_PRIORITY` applies only if the storage engine only supports table-level locking (`MyISAM` , `MEMORY` , `MERGE`). See [HIGH_PRIORITY and LOW_PRIORITY clauses](#) for details.

SQL_CACHE / SQL_NO_CACHE

If the `query_cache_type` system variable is set to 2 or `DEMAND` , and the current statement is cacheable, `SQL_CACHE` causes the query to be cached and `SQL_NO_CACHE` causes the query not to be cached. For `UNION` s, `SQL_CACHE` or `SQL_NO_CACHE` should be specified for the first query. See also [The Query Cache](#) for more detail and a list of the types of statements that aren't cacheable.

SQL_BUFFER_RESULT

`SQL_BUFFER_RESULT` forces the optimizer to use a temporary table to process the result. This is useful to free locks as soon as possible.

SQL_SMALL_RESULT / SQL_BIG_RESULT

`SQL_SMALL_RESULT` and `SQL_BIG_RESULT` tell the optimizer whether the result is very big or not. Usually, `GROUP BY` and `DISTINCT` operations are performed using a temporary table. Only if the result is very big, using a temporary table is not convenient. The optimizer automatically knows if the result is too big, but you can force the optimizer to use a temporary table with `SQL_SMALL_RESULT` , or avoid the temporary table using `SQL_BIG_RESULT` .

STRAIGHT_JOIN

`STRAIGHT_JOIN` applies to the `JOIN` queries, and tells the optimizer that the tables must be read in the order they appear in the `SELECT` . For `const` and `system` table this options is sometimes ignored.

SQL_CALC_FOUND_ROWS

`SQL_CALC_FOUND_ROWS` is only applied when using the `LIMIT` clause. If this option is used, MariaDB will count how many rows would match the query, without the `LIMIT` clause. That number can be retrieved in the next query, using [FOUND_ROWS\(\)](#).

USE/FORCE/IGNORE INDEX

`USE INDEX` , `FORCE INDEX` and `IGNORE INDEX` constrain the query planning to a specific index.

For further information about some of these options, see [How to force query plans](#).

MariaDB starting with [12.0](#) 

Expanded Optimizer Hints

[MariaDB 12.0](#)  features an extensive expansion of optimizer hints.

Syntax

1. Hint syntax Hints are placed after the main statement verb

```
UPDATE /*+ hints */ table ... ;
DELETE /*+ hints */ FROM table... ;
SELECT /*+ hints */ ...
```

or after the `SELECT` keyword in any subquery:

```
SELECT * FROM t1 WHERE a IN (SELECT /*+ hints */ ...)
```

There can be one or more hints separated with space

```
hints: hint hint ...
```

Description

Each individual hint is hint name and arguments. In case there are no arguments, the () brackets are still present:

```
hint: hint_name([arguments])
```

Incorrect hints produce warnings (a setting to make them errors is not implemented yet).

Hints that are not ignored are kept in the query text (you can see them in SHOW PROCESSLIST, Slow Query Log, EXPLAIN EXTENDED) Hints that were incorrect and were ignored are removed from there.

Hint Hierarchy

Hints can be

- global - applies to whole query
- table-level - applies to a table
- index-level - applies to an index in a table

Table-Level Hints

```
hint_name([table_name [table_name [,...]] )
```

Index-Level Hints

Index-level hints apply to index(es).

Possible syntax variants:

```
hint_name(table_name [index_name [, index_name] ...])  
hint_name(table_name@query_block [index_name [, index_name] ...])  
hint_name(@query_block table_name [index_name [, index_name] ...])
```

Query Block Naming

The `QB_NAME` hint is used to assign a name to the query block the hint is in. The Query Block is either a SELECT or a top-level construct of UPDATE or DELETE statement.

```
SELECT /*+ QB_NAME(foo) */ select_list FROM ...
```

The name can then be used

- to refer to the query block
- to refer to a table in the query block as `table_name@query_block_name`.

Query block scope is the whole statement. It is invalid to use the same name for multiple query blocks. One can refer to the query block "down into subquery", "down into derived table", "up to the parent" and "to a right sibling in the UNION". One cannot refer "to a left sibling in a UNION".

Hints inside VIEWS are not supported, yet. One can neither use hints in VIEW definitions, nor control query plans inside non-merged VIEWS (This is because QB_NAME binding is done "early", before we know that some tables are VIEWS)

SELECT#N NAMES

Besides the given name, any query block is given a name `select#n`. It is printed in EXPLAIN EXTENDED output:

Warnings:

```
Note 1003 select /*+ NO_RANGE_OPTIMIZATION('t3'@`select#1` `PRIMARY`) */ ...
```

At the moment it is NOT yet possible to use it in the hint text:

```
SELECT /*+ BKA(tbl1@`select#1`) */ 1 FROM tbl1 ...;
```

QB_NAME in CTEs

Hints that control `@name` will control the first use of the CTE.

Effect of Optimizer Hints

The optimizer can be controlled by

1. Server variables - `optimizer_switch`, `join_cache_level`, etc, etc
2. Old-style hints
3. New-style hints

Old-style hints did not overlap with server variable settings.

New-style hints are more specific than server variable settings, so they override the server variable settings.

Hints are "narrowly interpreted" and "best effort" - if a hint dictates to do something, like

```
SELECT /*+ MRR(t1 t1_index1) */ ... FROM t1 ...
```

that means:

When considering a query plan that involves using t1_index1 in a way that one can use MRR, use MRR.

if the query planning is such that use of t1_index1 doesn't allow to use MRR, it won't be used. The optimizer may also consider using t1_index2 and pick that over using t1_index1. In such cases the hint is effectively ignored and no warning is given.

List of Hints

NO_RANGE_OPTIMIZATION

An index-level hint that disables range optimization for certain index(es):

```
SELECT /*+ NO_RANGE_OPTIMIZATION(tbl index1 index2) */ * FROM tbl ...
```

NO_ICP

An index-level hint that disables Index Condition Pushdown for the indexes. ICP+BKA is disabled as well.

```
SELECT /*+ NO_ICP(tbl index1 index2) */ * FROM tbl ...
```

MRR and NO_MRR

Index-level hints to force or disable use of MRR.

```
SELECT /*+ MRR(tbl index1 index2) */ * FROM tbl ...
```

```
SELECT /*+ NO_MRR(tbl index1 index2) */ * FROM tbl ...
```

This controls:

- MRR optimization for range access (mdev35483-mrr-is-narrow.sql)
- BKA mdev35483-mrr-controls-bka-partially.sql

BKA() and NO_BKA()

Query block or table-level hints.

BKA() also enables MRR to make BKA possible. (This is different from session variables, where one needs to enable MRR separately).

This also enables BKAH.

BNL() and NO_BNL()

Controls BNL-H.

The implementation is "BNL() hint effectively increases join_cache_level up to 4 " .. for the table(s) it applies to.

MAX_EXECUTION_TIME()

Global-level hint to limit query execution time

```
SELECT /*+ MAX_EXECUTION_TIME(milliseconds) */ ... ;
```

A query that doesn't finish in the time specified will be aborted with an error.

If @@max_statement_time is set, the hint will be ignored and a warning produced. Note that this contradicts the stated principle that "New-style hints are more specific than server variable settings, so they override the server variable settings".

Subquery Hints

SUBQUERY Hint

Query block-level hint.

```
SUBQUERY([@query_block_name] MATERIALIZATION)
```

```
SUBQUERY([@query_block_name] INTOEXISTS)
```

This controls non-semi-join subqueries. The parameter specifies which subquery to use. Use of this hint disables conversion of subquery into semi-join.

SEMIJOIN and NO_SEMIJOIN

Query block-level hints. This controls the conversion of subqueries to semi-joins and which semi-join strategies are allowed.

```
[NO_]SEMIJOIN([@query_block_name] [strategy [, strategy] ...])
```

where the strategy is one of DUPSWEEDEOUT, FIRSTMATCH, LOOSESCAN, MATERIALIZATION.

1.1.1.4.1.13 PROCEDURE

The `PROCEDURE` clause of `SELECT` passes the whole result set to a Procedure which will process it. These Procedures are not [Stored Procedures](#), and can only be written in the C language, so it is necessary to recompile the server.

Currently, the only available procedure is `ANALYSE`, which examines the resultset and suggests the optimal datatypes for each column. It is defined in the `sql/sql_analyse.cc` file, and can be used as an example to create more Procedures.

This clause cannot be used in a `view`'s definition.

1.1.4.2 HANDLER

1.1.1.4.1.15 DUAL

Description

You are allowed to specify `DUAL` as a dummy table name in situations where no tables are referenced, such as the following `SELECT` statement:

```
SELECT 1 + 1 FROM DUAL;
+-----+
| 1 + 1 |
+-----+
|     2 |
+-----+
```

`DUAL` is purely for the convenience of people who require that all `SELECT` statements should have `FROM` and possibly other clauses. MariaDB ignores the clauses. MariaDB does not require `FROM DUAL` if no tables are referenced.

`FROM DUAL` could be used when you only `SELECT` computed values, but require a `WHERE` clause, perhaps to test that a script correctly handles empty resultsets:

```
SELECT 1 FROM DUAL WHERE FALSE;
Empty set (0.00 sec)
```

1.1.1.4.1.16 SELECT ... OFFSET ... FETCH

MariaDB starting with [10.6.0](#)

`SELECT ... OFFSET ... FETCH` was introduced in [MariaDB 10.6](#).

Syntax

```
OFFSET start { ROW | ROWS }
FETCH { FIRST | NEXT } [ count ] { ROW | ROWS } { ONLY | WITH TIES }
```

Description

The `OFFSET` clause allows one to return only those elements of a resultset that come after a specified offset. The `FETCH` clause specifies the number of rows to return, while `ONLY` or `WITH TIES` specifies whether or not to also return any further results that tie for last place according to the ordered resultset.

Either the singular `ROW` or the plural `ROWS` can be used after the `OFFSET` and `FETCH` clauses; the choice has no impact on the results.

`FIRST` and `NEXT` gives the same result.

In the case of `WITH TIES`, an `ORDER BY` clause is required, otherwise an `ERROR` will be returned.

```
SELECT i FROM t1 FETCH FIRST 2 ROWS WITH TIES;
ERROR 4180 (HY000): FETCH ... WITH TIES requires ORDER BY clause to be present
```

Examples

Given a table with 6 rows:

```
CREATE OR REPLACE TABLE t1 (i INT);
INSERT INTO t1 VALUES (1), (2), (3), (4), (4), (5);
SELECT i FROM t1 ORDER BY i ASC;
+-----+
| i     |
+-----+
| 1     |
| 2     |
| 3     |
| 4     |
| 4     |
| 5     |
+-----+
```

`OFFSET 2` allows one to skip the first two results.

```
SELECT i FROM t1 ORDER BY i ASC OFFSET 2 ROWS;
+-----+
| i     |
+-----+
| 3     |
| 4     |
| 4     |
| 5     |
+-----+
```

`FETCH FIRST 3 ROWS ONLY` limits the results to three rows only

```
SELECT i FROM t1 ORDER BY i ASC OFFSET 1 ROWS FETCH FIRST 3 ROWS ONLY;
+-----+
| i     |
+-----+
| 2     |
| 3     |
| 4     |
+-----+
```

The same outcome can also be achieved with the `LIMIT` clause:

```
SELECT i FROM t1 ORDER BY i ASC LIMIT 3 OFFSET 1;
+-----+
| i     |
+-----+
| 2     |
| 3     |
| 4     |
+-----+
```

`WITH TIES` ensures the tied result `4` is also returned.

```
SELECT i FROM t1 ORDER BY i ASC OFFSET 1 ROWS FETCH FIRST 3 ROWS WITH TIES;
```

```
+-----+  
| i     |  
+-----+  
| 2     |  
| 3     |  
| 4     |  
| 4     |  
+-----+
```

1.1.1.4.2 Inserting & Loading Data

The `INSERT` statement is the primary SQL statement for adding data into a table in MariaDB.

INSERT

Insert rows into a table.

INSERT DELAYED

Queue row to be inserted when thread is free.

INSERT SELECT

Insert the rows returned by a SELECT into a table

LOAD Data into Tables or Index

Loading data quickly into MariaDB

Concurrent Inserts

Under some circumstances, MyISAM allows INSERTs and SELECTs to be executed concurrently.

HIGH_PRIORITY and LOW_PRIORITY

Modifying statement priority in storage engines supporting table-level locks.

IGNORE

Suppress errors while trying to violate a UNIQUE constraint.

INSERT - Default & Duplicate Values

Default and duplicate values when inserting.

INSERT IGNORE

Convert errors to warnings, permitting inserts of additional rows to continue.

INSERT ON DUPLICATE KEY UPDATE

INSERT if no duplicate key is found, otherwise UPDATE.

INSERT...RETURNING

Returns a resultset of the inserted rows.

There are [3 related questions](#).

1.1.1.4.2.1 INSERT

Syntax

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]  
[INTO] tbl_name [PARTITION (partition_list)] [(col,...)]  
{VALUES | VALUE} ({expr | DEFAULT},...), (...), ...  
[ ON DUPLICATE KEY UPDATE  
  col=expr  
  [, col=expr] ... ] [RETURNING select_expr  
  [, select_expr ...]]
```

Or:

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
[INTO] tbl_name [PARTITION (partition_list)]
SET col={expr | DEFAULT}, ...
[ ON DUPLICATE KEY UPDATE
  col=expr
  [, col=expr] ... ] [RETURNING select_expr
[, select_expr ...]]
```

Or:

```
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
[INTO] tbl_name [PARTITION (partition_list)] [(col,...)]
SELECT ...
[ ON DUPLICATE KEY UPDATE
  col=expr
  [, col=expr] ... ] [RETURNING select_expr
[, select_expr ...]]
```

Contents

1. [Syntax](#)
2. [INSERT DELAYED](#)
3. [HIGH PRIORITY and LOW PRIORITY](#)
4. [Defaults and Duplicate Values](#)
5. [INSERT IGNORE](#)
6. [INSERT ON DUPLICATE KEY UPDATE](#)
7. [Examples](#)
8. [INSERT ... RETURNING](#)
 1. [Examples](#)

The `INSERT` statement is used to insert new rows into an existing table. The `INSERT ... VALUES` and `INSERT ... SET` forms of the statement insert rows based on explicitly specified values. The `INSERT ... SELECT` form inserts rows selected from another table or tables. `INSERT ... SELECT` is discussed further in the [INSERT ... SELECT](#) article.

The table name can be specified in the form `db_name.tbl_name` or, if a default database is selected, in the form `tbl_name` (see [Identifier Qualifiers](#)). This allows to use `INSERT ... SELECT` to copy rows between different databases.

The `PARTITION` clause can be used in both the `INSERT` and the `SELECT` part. See [Partition Pruning and Selection](#) for details.

----- MariaDB starting with 10.5

The `RETURNING` clause was introduced in [MariaDB 10.5](#).

The columns list is optional. It specifies which values are explicitly inserted, and in which order. If this clause is not specified, all values must be explicitly specified, in the same order they are listed in the table definition.

The list of value follow the `VALUES` or `VALUE` keyword (which are interchangeable, regardless how much values you want to insert), and is wrapped by parenthesis. The values must be listed in the same order as the columns list. It is possible to specify more than one list to insert more than one rows with a single statement. If many rows are inserted, this is a speed optimization.

For one-row statements, the `SET` clause may be more simple, because you don't need to remember the columns order. All values are specified in the form `col = expr`.

Values can also be specified in the form of a SQL expression or subquery. However, the subquery cannot access the same table that is named in the `INTO` clause.

If you use the `LOW_PRIORITY` keyword, execution of the `INSERT` is delayed until no other clients are reading from the table. If you use the `HIGH_PRIORITY` keyword, the statement has the same priority as `SELECT` s. This affects only storage engines that use only table-level locking (MyISAM, MEMORY, MERGE). However, if one of these keywords is specified, [concurrent inserts](#) cannot be used. See [HIGH_PRIORITY and LOW_PRIORITY clauses](#) for details.

INSERT DELAYED

For more details on the `DELAYED` option, see [INSERT DELAYED](#).

HIGH PRIORITY and LOW PRIORITY

See [HIGH_PRIORITY](#) and [LOW_PRIORITY](#).

Defaults and Duplicate Values

See [INSERT - Default & Duplicate Values](#) for details..

INSERT IGNORE

See [INSERT IGNORE](#).

INSERT ON DUPLICATE KEY UPDATE

See [INSERT ON DUPLICATE KEY UPDATE](#).

Examples

Specifying the column names:

```
INSERT INTO person (first_name, last_name) VALUES ('John', 'Doe');
```

Inserting more than 1 row at a time:

```
INSERT INTO tbl_name VALUES (1, "row 1"), (2, "row 2");
```

Using the SET clause:

```
INSERT INTO person SET first_name = 'John', last_name = 'Doe';
```

SELECTing from another table:

```
INSERT INTO contractor SELECT * FROM person WHERE status = 'c';
```

See [INSERT ON DUPLICATE KEY UPDATE](#) and [INSERT IGNORE](#) for further examples.

INSERT ... RETURNING

INSERT ... RETURNING returns a resultset of the inserted rows.

This returns the listed columns for all the rows that are inserted, or alternatively, the specified SELECT expression. Any SQL expressions which can be calculated can be used in the select expression for the RETURNING clause, including virtual columns and aliases, expressions which use various operators such as bitwise, logical and arithmetic operators, string functions, date-time functions, numeric functions, control flow functions, secondary functions and stored functions. Along with this, statements which have subqueries and prepared statements can also be used.

Examples

Simple INSERT statement

```
INSERT INTO t2 VALUES (1, 'Dog'), (2, 'Lion'), (3, 'Tiger'), (4, 'Leopard')
RETURNING id2, id2+id2, id2&id2, id2||id2;
+-----+-----+-----+-----+
| id2 | id2+id2 | id2&id2 | id2||id2 |
+-----+-----+-----+-----+
| 1 | 2 | 1 | 1 |
| 2 | 4 | 2 | 2 |
| 3 | 6 | 3 | 3 |
| 4 | 8 | 4 | 4 |
+-----+-----+-----+-----+
```

Using stored functions in RETURNING

```

DELIMITER |
CREATE FUNCTION f(arg INT) RETURNS INT
BEGIN
    RETURN (SELECT arg+arg);
END|

DELIMITER ;

PREPARE stmt FROM "INSERT INTO t1 SET id1=1, animal1='Bear' RETURNING f(id1), UPPER(animal1)";

EXECUTE stmt;
+-----+-----+
| f(id1) | UPPER(animal1) |
+-----+-----+
|      2 | BEAR           |
+-----+-----+

```

Subqueries in the RETURNING clause that return more than one row or column cannot be used.

Aggregate functions cannot be used in the RETURNING clause. Since aggregate functions work on a set of values, and if the purpose is to get the row count, ROW_COUNT() with SELECT can be used or it can be used in INSERT...SELECT...RETURNING if the table in the RETURNING clause is not the same as the INSERT table.

1.1.1.4.2.2 INSERT DELAYED

Syntax

```
INSERT DELAYED ...
```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [Limitations](#)

Description

The `DELAYED` option for the `INSERT` statement is a MariaDB/MySQL extension to standard SQL that is very useful if you have clients that cannot or need not wait for the `INSERT` to complete. This is a common situation when you use MariaDB for logging and you also periodically run `SELECT` and `UPDATE` statements that take a long time to complete.

When a client uses `INSERT DELAYED`, it gets an okay from the server at once, and the row is queued to be inserted when the table is not in use by any other thread.

Another major benefit of using `INSERT DELAYED` is that inserts from many clients are bundled together and written in one block. This is much faster than performing many separate inserts.

Note that `INSERT DELAYED` is slower than a normal `INSERT` if the table is not otherwise in use. There is also the additional overhead for the server to handle a separate thread for each table for which there are delayed rows. This means that you should use `INSERT DELAYED` only when you are really sure that you need it.

The queued rows are held only in memory until they are inserted into the table. This means that if you terminate mariadb forcibly (for example, with kill -9) or if mariadb dies unexpectedly, any queued rows that have not been written to disk are lost.

The number of concurrent `INSERT DELAYED` threads is limited by the `max_delayed_threads` server system variables. If it is set to 0, `INSERT DELAYED` is disabled. The session value can be equal to the global value, or 0 to disable this statement for the current session. If this limit has been reached, the `DELAYED` clause will be silently ignore for subsequent statements (no error will be produced).

Limitations

There are some limitations on the use of `DELAYED`:

- `INSERT DELAYED` works only with `MyISAM`, `MEMORY`, `ARCHIVE`, and `BLACKHOLE` tables. If you execute `INSERT DELAYED` with another storage engine, you will get an error like this: `ERROR 1616 (HY000): DELAYED option`

not supported for table 'tab_name'

- For MyISAM tables, if there are no free blocks in the middle of the data file, concurrent `SELECT` and `INSERT` statements are supported. Under these circumstances, you very seldom need to use `INSERT DELAYED` with MyISAM.
- `INSERT DELAYED` should be used only for `INSERT` statements that specify value lists. The server ignores `DELAYED` for `INSERT ... SELECT` or `INSERT ... ON DUPLICATE KEY UPDATE` statements.
- Because the `INSERT DELAYED` statement returns immediately, before the rows are inserted, you cannot use `LAST_INSERT_ID()` to get the `AUTO_INCREMENT` value that the statement might generate.
- `DELAYED` rows are not visible to `SELECT` statements until they actually have been inserted.
- After `INSERT DELAYED`, `ROW_COUNT()` returns the number of the rows you tried to insert, not the number of the successful writes.
- `DELAYED` is ignored on slave replication servers, so that `INSERT DELAYED` is treated as a normal `INSERT` on slaves. This is because `DELAYED` could cause the slave to have different data than the master. `INSERT DELAYED` statements are not [safe for replication](#).
- Pending `INSERT DELAYED` statements are lost if a table is write locked and `ALTER TABLE` is used to modify the table structure.
- `INSERT DELAYED` is not supported for views. If you try, you will get an error like this: `ERROR 1347 (HY000): 'view_name' is not BASE TABLE`
- `INSERT DELAYED` is not supported for [partitioned tables](#).
- `INSERT DELAYED` is not supported within [stored programs](#).
- `INSERT DELAYED` does not work with [triggers](#).
- `INSERT DELAYED` does not work if there is a check constraint in place.
- `INSERT DELAYED` does not work if [skip-new](#) mode is active.

1.1.1.4.2.3 INSERT SELECT

Syntax

```
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
  [INTO] tbl_name [(col_name,...)]
  SELECT ...
  [ ON DUPLICATE KEY UPDATE col_name=expr, ... ]
```

Contents

1. [Syntax](#)
2. [Description](#)

Description

With `INSERT ... SELECT`, you can quickly insert many rows into a table from one or more other tables. For example:

```
INSERT INTO tbl_temp2 (fld_id)
  SELECT tbl_temp1.fld_order_id
  FROM tbl_temp1 WHERE tbl_temp1.fld_order_id > 100;
```

`tbl_name` can also be specified in the form `db_name.tbl_name` (see [Identifier Qualifiers](#)). This allows to copy rows between different databases.

If the new table has a primary key or `UNIQUE` indexes, you can use `IGNORE` to handle duplicate key errors during the query. The newer values will not be inserted if an identical value already exists.

`REPLACE` can be used instead of `INSERT` to prevent duplicates on `UNIQUE` indexes by deleting old values. In that case, `ON DUPLICATE KEY UPDATE` cannot be used.

`INSERT ... SELECT` works for tables which already exist. To create a table for a given resultset, you can use [CREATE TABLE ... SELECT](#).

1.1.1.4.2.4 LOAD Data into Tables or Index

Loading data quickly into MariaDB

LOAD DATA INFILE

14 [Read rows from a text file into a table.](#)

LOAD INDEX

Loads one or more indexes from one or more MyISAM/Aria tables into a key buffer.

LOAD XML

Load XML data into a table.

LOAD_FILE

Returns file contents as a string.

There are [4 related questions](#)

1.1.1.4.2.4.1 LOAD DATA INFILE

Syntax

```
LOAD DATA [LOW_PRIORITY | CONCURRENT] [LOCAL] INFILE 'file_name'
[REPLACE | IGNORE]
INTO TABLE tbl_name
[CHARACTER SET charset_name]
[{FIELDS | COLUMNS}
  [TERMINATED BY 'string']
  [[OPTIONALLY] ENCLOSED BY 'char']
  [ESCAPED BY 'char']
]
[LINES
  [STARTING BY 'string']
  [TERMINATED BY 'string']
]
[IGNORE number {LINES|ROWS}]
[(col_name_or_user_var,...)]
[SET col_name = expr,...]
```

Contents

- [1. Syntax](#)
- [2. Description](#)
 - [1. LOAD DATA LOCAL INFILE](#)
 - [2. REPLACE and IGNORE](#)
 - [3. IGNORE number {LINES|ROWS}](#)

 - [5. Preprocessing Inputs](#)
 - [6. Priority and Concurrency](#)
 - [7. Progress Reporting](#)
 - [8. Using mariadb-import](#)
 - [9. Indexing](#)
- [3. Examples](#)

Description

`LOAD DATA INFILE` is unsafe for statement-based replication.

Reads rows from a text file into the designated table on the database at a very high speed. The file name must be given as a literal string.

Files are written to disk using the `SELECT INTO OUTFILE` statement. You can then read the files back into a table using the `LOAD DATA INFILE` statement. The `FIELDS` and `LINES` clauses are the same in both statements and by default fields are expected to be terminated with tabs (`\t`) and lines with newlines (`\n`). These clauses are optional, but if both are specified then the `FIELDS` clause must precede `LINES` .

Executing this statement activates `INSERT` triggers.

One must have the `FILE` privilege to be able to execute `LOAD DATA INFILE`. This is to ensure normal users cannot read system files. `LOAD DATA LOCAL INFILE` does not have this requirement.

If the `secure_file_priv` system variable is set (by default it is not), the loaded file must be present in the specified directory.

Note that MariaDB's `systemd` unit file restricts access to `/home`, `/root`, and `/run/user` by default. See [Configuring access to home directories](#).

LOAD DATA LOCAL INFILE

When you execute the `LOAD DATA INFILE` statement, MariaDB Server attempts to read the input file from its own file system. By contrast, when you execute the `LOAD DATA LOCAL INFILE` statement, the client attempts to read the input file from its file system, and it sends the contents of the input file to the MariaDB Server. This allows you to load files from the client's local file system into the database.

If you don't want to permit this operation (perhaps for security reasons), you can disable the `LOAD DATA LOCAL INFILE` statement on either the server or the client.

- The `LOAD DATA LOCAL INFILE` statement can be disabled on the server by setting the `local_infile` system variable to `0`.
- The `LOAD DATA LOCAL INFILE` statement can be disabled on the client. If you are using [MariaDB Connector/C](#), this can be done by unsetting the `CLIENT_LOCAL_FILES` capability flag with the `mysql_real_connect` function or by unsetting the `MYSQL_OPT_LOCAL_INFILE` option with `mysql_optionsv` function. If you are using a different client or client library, then see the documentation for your specific client or client library to determine how it handles the `LOAD DATA LOCAL INFILE` statement.
- The `LOAD DATA LOCAL INFILE` strict modes like `STRICT_TRANS_TABLES` are disabled with keyword "local". (<https://jira.mariadb.org/browse/MDEV-11235>)

If the `LOAD DATA LOCAL INFILE` statement is disabled by either the server or the client and if the user attempts to execute it, then the server will cause the statement to fail with the following error message:

```
The used command is not allowed with this MariaDB version
```

Note that it is not entirely accurate to say that the MariaDB version does not support the command. It would be more accurate to say that the MariaDB configuration does not support the command. See [MDEV-20500](#) for more information.

From [MariaDB 10.5.2](#), the error message is more accurate:

```
The used command is not allowed because the MariaDB server or client
has disabled the local infile capability
```

REPLACE and IGNORE

If you load data from a file into a table that already contains data and has a [primary key](#), you may encounter issues where the statement attempts to insert a row with a primary key that already exists. When this happens, the statement fails with Error 1064, protecting the data already on the table. If you want MariaDB to overwrite duplicates, use the `REPLACE` keyword.

The `REPLACE` keyword works like the `REPLACE` statement. Here, the statement attempts to load the data from the file. If the row does not exist, it adds it to the table. If the row contains an existing primary key, it replaces the table data. That is, in the event of a conflict, it assumes the file contains the desired row.

This operation can cause a degradation in load speed by a factor of 20 or more if the part that has already been loaded is larger than the capacity of the [InnoDB Buffer Pool](#). This happens because it causes a lot of turnaround in the buffer pool.

Use the `IGNORE` keyword when you want to skip any rows that contain a conflicting primary key. Here, the statement attempts to load the data from the file. If the row does not exist, it adds it to the table. If the row contains an existing primary key, it ignores the addition request and moves on to the next. That is, in the event of a conflict, it assumes the table contains the desired row.

```
IGNORE number {LINES|ROWS}
```

The `IGNORE number LINES` syntax can be used to ignore a number of rows from the beginning of the file. Most often this is needed when the file starts with one row that includes the column headings.

Character-sets

When the statement opens the file, it attempts to read the contents using the default character-set, as defined by the `character_set_database` system variable.

In the cases where the file was written using a character-set other than the default, you can specify the character-set to use with the `CHARACTER SET` clause in the statement. It ignores character-sets specified by the `SET NAMES` statement and by the `character_set_client` system variable. Setting the `CHARACTER SET` clause to a value of `binary` indicates "no conversion."

The statement interprets all fields in the file as having the same character-set, regardless of the column data type. To properly interpret file contents, you must ensure that it was written with the correct character-set. If you write a data file with `mariadb-dump -T` or with the `SELECT INTO OUTFILE` statement with the `mariadb` client, be sure to use the `--default-character-set` option, so that the output is written with the desired character-set.

When using mixed character sets, use the `CHARACTER SET` clause in both `SELECT INTO OUTFILE` and `LOAD DATA INFILE` to ensure that MariaDB correctly interprets the escape sequences.

The `character_set_filesystem` system variable controls the interpretation of the filename. It is currently not possible to load data files that use the `ucs2` character set.

Preprocessing Inputs

`col_name_or_user_var` can be a column name, or a user variable. In the case of a variable, the `SET` statement can be used to preprocess the value before loading into the table.

Priority and Concurrency

In storage engines that perform table-level locking (`MyISAM`, `MEMORY` and `MERGE`), using the `LOW_PRIORITY` keyword, MariaDB delays insertions until no other clients are reading from the table. Alternatively, when using the `MyISAM` storage engine, you can use the `CONCURRENT` keyword to perform concurrent insertion.

The `LOW_PRIORITY` and `CONCURRENT` keywords are mutually exclusive. They cannot be used in the same statement.

Progress Reporting

The `LOAD DATA INFILE` statement supports [progress reporting](#). You may find this useful when dealing with long-running operations. Using another client you can issue a `SHOW PROCESSLIST` query to check the progress of the data load.

Using mariadb-import

MariaDB ships with a separate utility for loading data from files: `mariadb-import` (or `mysqlimport` before [MariaDB 10.5](#)). It operates by sending `LOAD DATA INFILE` statements to the server.

Using `mariadb-import` you can compress the file using the `--compress` option, to get better performance over slow networks, providing both the client and server support the compressed protocol. Use the `--local` option to load from the local file system.

Indexing

In cases where the storage engine supports `ALTER TABLE... DISABLE KEYS` statements (`MyISAM` and `Aria`), the `LOAD DATA INFILE` statement automatically disables indexes during the execution.

Examples

You have a file with this content (note the the separator is `,`, not `tab`, which is the default):

```
2,2
3,3
4,4
5,5
6,8
```

```
CREATE TABLE t1 (a int, b int, c int, d int, PRIMARY KEY (a));
LOAD DATA LOCAL INFILE
'/tmp/loaddata7.dat' INTO TABLE t1 FIELDS TERMINATED BY ',' (a,b) SET c=a+b;
SELECT * FROM t1;
```

a	b	c
2	2	4
3	3	6
4	4	8
5	5	10
6	8	14

Another example, given the following data (the separator is a tab):

```
1      a
2      b
```

The value of the first column is doubled before loading:

```
LOAD DATA INFILE 'ld.txt' INTO TABLE ld (@i,v) SET i=@i*2;

SELECT * FROM ld;
```

i	v
2	a
4	b

1.1.1.2.17 LOAD INDEX

1.1.1.4.2.4.3 LOAD XML

Syntax

```
LOAD XML [LOW_PRIORITY | CONCURRENT] [LOCAL] INFILE 'file_name'
[REPLACE | IGNORE]
INTO TABLE [db_name.]tbl_name
[CHARACTER SET charset_name]
[ROWS IDENTIFIED BY '<tagname>']
[IGNORE number {LINES | ROWS}]
[(column_or_user_var,...)]
[SET col_name = expr,...]
```

Description

The `LOAD XML` statement reads data from an XML file into a table. The `file_name` must be given as a literal string. The `tagname` in the optional `ROWS IDENTIFIED BY` clause must also be given as a literal string, and must be surrounded by angle brackets (`<` and `>`).

`LOAD XML` acts as the complement of running the [mariadb client](#) in XML output mode (that is, starting the client with the `--xml` option). To write data from a table to an XML file, use a command such as the following one from the system shell:

```
shell> mariadb --xml -e 'SELECT * FROM mytable' > file.xml
```

To read the file back into a table, use `LOAD XML INFILE`. By default, the `<row>` element is considered to be the equivalent of a database table row; this can be changed using the `ROWS IDENTIFIED BY` clause.

This statement supports three different XML formats:

- Column names as attributes and column values as attribute values:

```
<row column1="value1" column2="value2" .../>
```

- Column names as tags and column values as the content of these tags:

```
<row>
  <column1>value1</column1>
  <column2>value2</column2>
</row>
```

- Column names are the name attributes of <field> tags, and values are the contents of these tags:

```
<row>
  <field name='column1'>value1</field>
  <field name='column2'>value2</field>
</row>
```

This is the format used by other tools, such as [mariadb-dump](#).

All 3 formats can be used in the same XML file; the import routine automatically detects the format for each row and interprets it correctly. Tags are matched based on the tag or attribute name and the column name.

The following clauses work essentially the same way for LOAD XML as they do for LOAD DATA:

- LOW_PRIORITY or CONCURRENT
- LOCAL
- REPLACE or IGNORE
- CHARACTER SET
- (column_or_user_var,...)
- SET

See [LOAD DATA](#) for more information about these clauses.

The IGNORE number LINES or IGNORE number ROWS clause causes the first number rows in the XML file to be skipped. It is analogous to the LOAD DATA statement's IGNORE ... LINES clause.

If the [LOW_PRIORITY](#) keyword is used, insertions are delayed until no other clients are reading from the table. The [CONCURRENT](#) keyword allows the use of [concurrent inserts](#). These clauses cannot be specified together.

This statement activates INSERT [triggers](#).

1.1.1.4.2.4.4 LOAD_FILE

Syntax

```
LOAD_FILE(file_name)
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

Description

Reads the file and returns the file contents as a string. To use this function, the file must be located on the server host, you must specify the full path name to the file, and you must have the FILE privilege. The file must be readable by all and it must be less than the size, in bytes, of the [max_allowed_packet](#) system variable. If the [secure_file_priv](#) system variable is set to a non-empty directory name, the file to be loaded must be located in that directory.

If the file does not exist or cannot be read because one of the preceding conditions is not satisfied, the function returns NULL.

Since [MariaDB 5.1](#), the [character_set_filesystem](#) system variable has controlled interpretation of file names that are given as literal strings.

Statements using the LOAD_FILE() function are not [safe for statement based replication](#). This is because the slave will execute the LOAD_FILE() command itself. If the file doesn't exist on the slave, the function will return NULL.

Examples

```
UPDATE t SET blob_col=LOAD_FILE('/tmp/picture') WHERE id=1;
```

1.1.1.4.2.5 Concurrent Inserts

Contents

1. Notes

The [MyISAM](#) storage engine supports concurrent inserts. This feature allows [SELECT](#) statements to be executed during [INSERT](#) operations, reducing contention.

Whether concurrent inserts can be used or not depends on the value of the [concurrent_insert](#) server system variable:

- [NEVER](#) (0) disables concurrent inserts.
- [AUTO](#) (1) allows concurrent inserts only when the target table has no free blocks (no data in the middle of the table has been deleted after the last [OPTIMIZE TABLE](#)). This is the default.
- [ALWAYS](#) (2) always enables concurrent inserts, in which case new rows are added at the end of a table if the table is being used by another thread.

If the [binary log](#) is used, [CREATE TABLE ... SELECT](#) and [INSERT ... SELECT](#) statements cannot use concurrent inserts. These statements acquire a read lock on the table, so concurrent inserts will need to wait. This way the log can be safely used to restore data.

Concurrent inserts are not used by replicas with the row based [replication](#) (see [binary log formats](#)).

If an [INSERT](#) statement contain the [HIGH_PRIORITY](#) clause, concurrent inserts cannot be used. [INSERT ... DELAYED](#) is usually unneeded if concurrent inserts are enabled.

[LOAD DATA INFILE](#) uses concurrent inserts if the [CONCURRENT](#) keyword is specified and [concurrent_insert](#) is not [NEVER](#) . This makes the statement slower (even if no other sessions access the table) but reduces contention.

[LOCK TABLES](#) allows non-conflicting concurrent inserts if a [READ LOCAL](#) lock is used. Concurrent inserts are not allowed if the [LOCAL](#) keyword is omitted.

Notes

The decision to enable concurrent insert for a table is done when the table is opened. If you change the value of [concurrent_insert](#) it will only affect new opened tables. If you want it to work for also for tables in use or cached, you should do [FLUSH TABLES](#) after setting the variable.

1.1.1.4.2.6 HIGH_PRIORITY and LOW_PRIORITY

Contents

The [InnoDB](#) storage engine uses row-level locking to ensure data integrity. However some storage engines (such as [MEMORY](#), [MyISAM](#), [Aria](#) and [MERGE](#)) lock the whole table to prevent conflicts. These storage engines use two separate queues to remember pending statements; one is for [SELECTs](#) and the other one is for write statements ([INSERT](#), [DELETE](#), [UPDATE](#)). By default, the latter has a higher priority.

To give write operations a lower priority, the [low_priority_updates](#) server system variable can be set to [ON](#) . The option is available on both the global and session levels, and it can be set at startup or via the [SET](#) statement.

When too many table locks have been set by write statements, some pending [SELECTs](#) are executed. The maximum number of write locks that can be acquired before this happens is determined by the [max_write_lock_count](#) server system variable, which is dynamic.

If write statements have a higher priority (default), the priority of individual write statements ([INSERT](#), [REPLACE](#), [UPDATE](#), [DELETE](#)) can be changed via the [LOW_PRIORITY](#) attribute, and the priority of a [SELECT](#) statement can be raised via the [HIGH_PRIORITY](#) attribute. Also, [LOCK TABLES](#) supports a [LOW_PRIORITY](#) attribute for [WRITE](#) locks.

If read statements have a higher priority, the priority of an [INSERT](#) can be changed via the [HIGH_PRIORITY](#) attribute. However, the priority of other write statements cannot be raised individually.

The use of [LOW_PRIORITY](#) or [HIGH_PRIORITY](#) for an [INSERT](#) prevents [Concurrent Inserts](#) from being used.

1.1.1.2.1.21 IGNORE

1.1.1.4.2.8 INSERT - Default & Duplicate Values

Contents

1. [Default Values](#)
2. [Duplicate Values](#)

Default Values

If the `SQL_MODE` contains `STRICT_TRANS_TABLES` and you are [inserting](#) into a transactional table (like InnoDB), or if the `SQL_MODE` contains `STRICT_ALL_TABLES`, all `NOT NULL` columns which do not have a `DEFAULT` value (and are not `AUTO_INCREMENT`) must be explicitly referenced in `INSERT` statements. If not, an error like this is produced:

```
ERROR 1364 (HY000): Field 'col' doesn't have a default value
```

In all other cases, if a `NOT NULL` column without a `DEFAULT` value is not referenced, an empty value will be inserted (for example, 0 for `INTEGER` columns and "" for `CHAR` columns). See [NULL Values in MariaDB:Inserting](#) for examples.

If a `NOT NULL` column having a `DEFAULT` value is not referenced, `NULL` will be inserted.

If a `NULL` column having a `DEFAULT` value is not referenced, its default value will be inserted. It is also possible to explicitly assign the default value using the `DEFAULT` keyword or the `DEFAULT()` function.

If the `DEFAULT` keyword is used but the column does not have a `DEFAULT` value, an error like this is produced:

```
ERROR 1364 (HY000): Field 'col' doesn't have a default value
```

Duplicate Values

By default, if you try to insert a duplicate row and there is a `UNIQUE` index, `INSERT` stops and an error like this is produced:

```
ERROR 1062 (23000): Duplicate entry 'dup_value' for key 'col'
```

To handle duplicates you can use the `IGNORE` clause, `INSERT ON DUPLICATE KEY UPDATE` or the `REPLACE` statement. Note that the `IGNORE` and `DELAYED` options are ignored when you use `ON DUPLICATE KEY UPDATE`.

1.1.1.4.2.9 INSERT IGNORE

Contents

1. [Ignoring Errors](#)
2. [Examples](#)

Ignoring Errors

Normally `INSERT` stops and rolls back when it encounters an error.

By using the `IGNORE` keyword all errors are converted to warnings, which will not stop inserts of additional rows.

Invalid values are changed to the closest valid value and inserted, with a warning produced.

The `IGNORE` and `DELAYED` options are ignored when you use `ON DUPLICATE KEY UPDATE`.

Prior to MySQL and [MariaDB 5.5.28](#), no warnings were issued for duplicate key errors when using `IGNORE`. You can get the old behavior if you set `OLD_MODE` to `NO_DUP_KEY_WARNINGS_WITH_IGNORE`.

See [IGNORE](#) for a full description of effects.

Examples

```

CREATE TABLE t1 (x INT UNIQUE);

INSERT INTO t1 VALUES (1), (2);

INSERT INTO t1 VALUES (2), (3);
ERROR 1062 (23000): Duplicate entry '2' for key 'x'
SELECT * FROM t1;
+-----+
| x     |
+-----+
| 1     |
| 2     |
+-----+

INSERT IGNORE INTO t1 VALUES (2), (3);
Query OK, 1 row affected, 1 warning (0.04 sec)

SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1062 | Duplicate entry '2' for key 'x' |
+-----+-----+-----+

SELECT * FROM t1;
+-----+
| x     |
+-----+
| 1     |
| 2     |
| 3     |
+-----+

```

Converting values:

```

CREATE OR REPLACE TABLE t2(id INT, t VARCHAR(2) NOT NULL, n INT NOT NULL);

INSERT INTO t2(id) VALUES (1), (2);
ERROR 1364 (HY000): Field 't' doesn't have a default value

INSERT IGNORE INTO t2(id) VALUES (1), (2);
Query OK, 2 rows affected, 2 warnings (0.026 sec)
Records: 2 Duplicates: 0 Warnings: 2

SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1364 | Field 't' doesn't have a default value |
| Warning | 1364 | Field 'n' doesn't have a default value |
+-----+-----+-----+

SELECT * FROM t2;
+-----+-----+-----+
| id | t | n |
+-----+-----+-----+
| 1 |  | 0 |
| 2 |  | 0 |
+-----+-----+-----+

```

See [INSERT ON DUPLICATE KEY UPDATE](#) for further examples using that syntax.

1.1.1.4.2.10 INSERT ON DUPLICATE KEY UPDATE

Syntax

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
[INTO] tbl_name [PARTITION (partition_list)] [(col,...)]
{VALUES | VALUE} ({expr | DEFAULT},...), (...),...
[ ON DUPLICATE KEY UPDATE
  col=expr
  [, col=expr] ... ]
```

Or:

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
[INTO] tbl_name [PARTITION (partition_list)]
SET col={expr | DEFAULT}, ...
[ ON DUPLICATE KEY UPDATE
  col=expr
  [, col=expr] ... ]
```

Or:

```
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
[INTO] tbl_name [PARTITION (partition_list)] [(col,...)]
SELECT ...
[ ON DUPLICATE KEY UPDATE
  col=expr
  [, col=expr] ... ]
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

Description

INSERT ... ON DUPLICATE KEY UPDATE is a MariaDB/MySQL extension to the [INSERT](#) statement that, if it finds a duplicate unique or [primary key](#), will instead perform an [UPDATE](#).

The row/s affected value is reported as 1 if a row is inserted, and 2 if a row is updated, unless the API's `CLIENT_FOUND_ROWS` flag is set.

If more than one unique index is matched, only the first is updated. It is not recommended to use this statement on tables with more than one unique index.

If the table has an [AUTO_INCREMENT primary key](#) and the statement inserts or updates a row, the [LAST_INSERT_ID\(\)](#) function returns its `AUTO_INCREMENT` value.

The [VALUES\(\)](#) function can only be used in a `ON DUPLICATE KEY UPDATE` clause and has no meaning in any other context. It returns the column values from the `INSERT` portion of the statement. This function is particularly useful for multi-rows inserts.

The [IGNORE](#) and [DELAYED](#) options are ignored when you use `ON DUPLICATE KEY UPDATE`.

See [Partition Pruning and Selection](#) for details on the `PARTITION` clause.

This statement activates `INSERT` and `UPDATE` triggers. See [Trigger Overview](#) for details.

See also a similar statement, [REPLACE](#).

Examples

```
CREATE TABLE ins_duplicate (id INT PRIMARY KEY, animal VARCHAR(30));
INSERT INTO ins_duplicate VALUES (1,'Aardvark'), (2,'Cheetah'), (3,'Zebra');
```

If there is no existing key, the statement runs as a regular `INSERT`:

```
INSERT INTO ins_duplicate VALUES (4,'Gorilla')
ON DUPLICATE KEY UPDATE animal='Gorilla';
Query OK, 1 row affected (0.07 sec)
```

```

SELECT * FROM ins_duplicate;
+----+-----+
| id | animal |
+----+-----+
| 1  | Aardvark |
| 2  | Cheetah  |
| 3  | Zebra    |
| 4  | Gorilla  |
+----+-----+

```

A regular INSERT with a primary key value of 1 will fail, due to the existing key:

```

INSERT INTO ins_duplicate VALUES (1,'Antelope');
ERROR 1062 (23000): Duplicate entry '1' for key 'PRIMARY'

```

However, we can use an INSERT ON DUPLICATE KEY UPDATE instead:

```

INSERT INTO ins_duplicate VALUES (1,'Antelope')
ON DUPLICATE KEY UPDATE animal='Antelope';
Query OK, 2 rows affected (0.09 sec)

```

Note that there are two rows reported as affected, but this refers only to the UPDATE.

```

SELECT * FROM ins_duplicate;
+----+-----+
| id | animal |
+----+-----+
| 1  | Antelope |
| 2  | Cheetah  |
| 3  | Zebra    |
| 4  | Gorilla  |
+----+-----+

```

Adding a second unique column:

```

ALTER TABLE ins_duplicate ADD id2 INT;
UPDATE ins_duplicate SET id2=id+10;
ALTER TABLE ins_duplicate ADD UNIQUE KEY(id2);

```

Where two rows match the unique keys match, only the first is updated. This can be unsafe and is not recommended unless you are certain what you are doing.

```

INSERT INTO ins_duplicate VALUES (2,'Lion',13)
ON DUPLICATE KEY UPDATE animal='Lion';
Query OK, 2 rows affected (0.004 sec)

SELECT * FROM ins_duplicate;
+----+-----+-----+
| id | animal | id2 |
+----+-----+-----+
| 1  | Antelope | 11 |
| 2  | Lion     | 12 |
| 3  | Zebra    | 13 |
| 4  | Gorilla  | 14 |
+----+-----+-----+

```

Although the third row with an id of 3 has an id2 of 13, which also matched, it was not updated.

Changing id to an auto_increment field. If a new row is added, the auto_increment is moved forward. If the row is updated, it remains the same.

```

ALTER TABLE `ins_duplicate` CHANGE `id` `id` INT(11 ) NOT NULL AUTO_INCREMENT;
ALTER TABLE ins_duplicate DROP id2;
SELECT Auto_increment FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_NAME='ins_duplicate';
+-----+
| Auto_increment |
+-----+
|                5 |
+-----+

INSERT INTO ins_duplicate VALUES (2,'Leopard')
ON DUPLICATE KEY UPDATE animal='Leopard';
Query OK, 2 rows affected (0.00 sec)

SELECT Auto_increment FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_NAME='ins_duplicate';
+-----+
| Auto_increment |
+-----+
|                5 |
+-----+

INSERT INTO ins_duplicate VALUES (5,'Wild Dog')
ON DUPLICATE KEY UPDATE animal='Wild Dog';
Query OK, 1 row affected (0.09 sec)

SELECT * FROM ins_duplicate;
+----+-----+
| id | animal |
+----+-----+
|  1 | Antelope |
|  2 | Leopard |
|  3 | Zebra |
|  4 | Gorilla |
|  5 | Wild Dog |
+----+-----+

SELECT Auto_increment FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_NAME='ins_duplicate';
+-----+
| Auto_increment |
+-----+
|                6 |
+-----+

```

Referring to column values from the INSERT portion of the statement:

```

INSERT INTO table (a,b,c) VALUES (1,2,3), (4,5,6)
ON DUPLICATE KEY UPDATE c=VALUES(a)+VALUES(b);

```

See the [VALUES\(\)](#) function for more.

1.1.1.4.2.11 INSERT...RETURNING

MariaDB starting with [10.5.0](#)

INSERT ... RETURNING was added in [MariaDB 10.5.0](#), and returns a resultset of the [inserted](#) rows.

Syntax

```

INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
[INTO] tbl_name [PARTITION (partition_list)] [(col,...)]
{VALUES | VALUE} ({expr | DEFAULT},...), (...),...
[ ON DUPLICATE KEY UPDATE
  col=expr
  [, col=expr] ... ] [RETURNING select_expr
  [, select_expr ...]]

```

Or:

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
[INTO] tbl_name [PARTITION (partition_list)]
SET col={expr | DEFAULT}, ...
[ ON DUPLICATE KEY UPDATE
  col=expr
  [, col=expr] ... ] [RETURNING select_expr
[, select_expr ...]]
```

Or:

```
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
[INTO] tbl_name [PARTITION (partition_list)] [(col,...)]
SELECT ...
[ ON DUPLICATE KEY UPDATE
  col=expr
  [, col=expr] ... ] [RETURNING select_expr
[, select_expr ...]]
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

Description

`INSERT ... RETURNING` returns a resultset of the [inserted](#) rows.

This returns the listed columns for all the rows that are inserted, or alternatively, the specified `SELECT` expression. Any SQL expressions which can be calculated can be used in the select expression for the `RETURNING` clause, including virtual columns and aliases, expressions which use various operators such as bitwise, logical and arithmetic operators, string functions, date-time functions, numeric functions, control flow functions, secondary functions and stored functions. Along with this, statements which have subqueries and prepared statements can also be used.

Examples

Simple `INSERT` statements:

```
CREATE OR REPLACE TABLE t2 (id INT, animal VARCHAR(20), t TIMESTAMP);
```

```
INSERT INTO t2 (id) VALUES (2),(3) RETURNING id,t;
```

```
+-----+-----+
| id  | t                |
+-----+-----+
|  2  | 2021-04-28 00:59:32 |
|  3  | 2021-04-28 00:59:32 |
+-----+-----+
```

```
INSERT INTO t2(id,animal) VALUES (1,'Dog'),(2,'Lion'),(3,'Tiger'),(4,'Leopard')
RETURNING id,id+id,id&id,id||id;
```

```
+-----+-----+-----+-----+
| id  | id+id | id&id | id||id |
+-----+-----+-----+-----+
|  1  |    2  |    1  |    1  |
|  2  |    4  |    2  |    1  |
|  3  |    6  |    3  |    1  |
|  4  |    8  |    4  |    1  |
+-----+-----+-----+-----+
```

Using stored functions in `RETURNING`

```

DELIMITER |
CREATE FUNCTION f(arg INT) RETURNS INT
BEGIN
    RETURN (SELECT arg+arg);
END|

DELIMITER ;

PREPARE stmt FROM "INSERT INTO t1 SET id1=1, animal1='Bear' RETURNING f(id1), UPPER(animal1)";

EXECUTE stmt;
+-----+-----+
| f(id1) | UPPER(animal1) |
+-----+-----+
|      2 | BEAR           |
+-----+-----+

```

Subqueries in the RETURNING clause that return more than one row or column cannot be used.

Aggregate functions cannot be used in the RETURNING clause. Since aggregate functions work on a set of values, and if the purpose is to get the row count, ROW_COUNT() with SELECT can be used or it can be used in INSERT...SELECT...RETURNING if the table in the RETURNING clause is not the same as the INSERT table.

1.1.1.4.3 Changing & Deleting Data

DELETE

Delete rows from one or more tables.

HIGH_PRIORITY and LOW_PRIORITY

Modifying statement priority in storage engines supporting table-level locks.

IGNORE

Suppress errors while trying to violate a UNIQUE constraint.

REPLACE

Equivalent to DELETE + INSERT, or just an INSERT if no rows are returned.

REPLACE...RETURNING

Returns a resultset of the replaced rows.

TRUNCATE TABLE

DROP and re-CREATE a table.

UPDATE

Modify rows in one or more tables.

1.1.1.2.1.7 DELETE

1.1.1.4.2.6 HIGH_PRIORITY and LOW_PRIORITY

1.1.1.2.1.21 IGNORE

1.1.1.2.1.15 REPLACE

1.1.1.4.3.5 REPLACE...RETURNING

MariaDB starting with [10.5.0](#)

REPLACE ... RETURNING was added in [MariaDB 10.5.0](#), and returns a resultset of the replaced rows.

```
REPLACE [LOW_PRIORITY | DELAYED]
  [INTO] tbl_name [PARTITION (partition_list)] [(col,...)]
  {VALUES | VALUE} ({expr | DEFAULT},...), (...),...
  [RETURNING select_expr
    [, select_expr ...]]
```

Or:

```
REPLACE [LOW_PRIORITY | DELAYED]
  [INTO] tbl_name [PARTITION (partition_list)]
  SET col={expr | DEFAULT}, ...
  [RETURNING select_expr
    [, select_expr ...]]
```

Or:

```
REPLACE [LOW_PRIORITY | DELAYED]
  [INTO] tbl_name [PARTITION (partition_list)] [(col,...)]
  SELECT ...
  [RETURNING select_expr
    [, select_expr ...]]
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

Description

`REPLACE ... RETURNING` returns a resultset of the replaced rows.

This returns the listed columns for all the rows that are replaced, or alternatively, the specified `SELECT` expression. Any SQL expressions which can be calculated can be used in the select expression for the `RETURNING` clause, including virtual columns and aliases, expressions which use various operators such as bitwise, logical and arithmetic operators, string functions, date-time functions, numeric functions, control flow functions, secondary functions and stored functions. Along with this, statements which have subqueries and prepared statements can also be used.

Examples

Simple `REPLACE` statement

```
REPLACE INTO t2 VALUES (1,'Leopard'),(2,'Dog') RETURNING id2, id2+id2
as Total ,id2|id2, id2&&id2;
+-----+-----+-----+
| id2 | Total | id2|id2 | id2&&id2 |
+-----+-----+-----+
|  1  |    2  |    1  |    1  |
|  2  |    4  |    2  |    1  |
+-----+-----+-----+
```

Using stored functions in `RETURNING`

```

DELIMITER |
CREATE FUNCTION f(arg INT) RETURNS INT
BEGIN
    RETURN (SELECT arg+arg);
END|

DELIMITER ;
PREPARE stmt FROM "REPLACE INTO t2 SET id2=3, animal2='Fox' RETURNING f2(id2),
UPPER(animal2)";

EXECUTE stmt;
+-----+-----+
| f2(id2) | UPPER(animal2) |
+-----+-----+
|        6 | FOX           |
+-----+-----+

```

Subqueries in the statement

```

REPLACE INTO t1 SELECT * FROM t2 RETURNING (SELECT id2 FROM t2 WHERE
id2 IN (SELECT id2 FROM t2 WHERE id2=1)) AS new_id;
+-----+
| new_id |
+-----+
|       1 |
|       1 |
|       1 |
|       1 |
+-----+

```

Subqueries in the RETURNING clause that return more than one row or column cannot be used..

Aggregate functions cannot be used in the RETURNING clause. Since aggregate functions work on a set of values and if the purpose is to get the row count, ROW_COUNT() with SELECT can be used, or it can be used in REPLACE...SELECT...RETURNING if the table in the RETURNING clause is not the same as the REPLACE table.

1.1.1.2.1.19 TRUNCATE TABLE

1.1.1.2.1.20 UPDATE

1.1.1.5 Prepared Statements

In addition to using prepared statements from the libmysqld, you can also do prepared statements from any client by using the text based prepared statement interface.

You first prepare the statement with [PREPARE](#), execute with [EXECUTE](#), and release it with [DEALLOCATE](#) [↗](#).

PREPARE Statement

Define a prepare statement.

EXECUTE Statement

Executes a previously PREPARED statement

DEALLOCATE / DROP PREPARE

Deallocates a prepared statement.

EXECUTE IMMEDIATE

Immediately execute a dynamic SQL statement

Out Parameters in PREPARE

Using question mark placeholders for out-parameters in the PREPARE statement

There are [1 related questions](#) [↗](#).

1.1.1.5.1 PREPARE Statement

Syntax

```
PREPARE stmt_name FROM preparable_stmt
```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [Oracle Mode](#)
3. [Permitted Statements](#)
4. [Example](#)

Description

The `PREPARE` statement prepares a statement and assigns it a name, `stmt_name`, by which to refer to the statement later. Statement names are not case sensitive. `preparable_stmt` is either a string literal or a [user variable](#) (not a [local variable](#), an SQL expression or a subquery) that contains the text of the statement. The text must represent a single SQL statement, not multiple statements. Within the statement, "?" characters can be used as parameter markers to indicate where data values are to be bound to the query later when you execute it. The "?" characters should not be enclosed within quotes, even if you intend to bind them to string values. Parameter markers can be used only where expressions should appear, not for SQL keywords, identifiers, and so forth.

The scope of a prepared statement is the session within which it is created. Other sessions cannot see it.

If a prepared statement with the given name already exists, it is deallocated implicitly before the new statement is prepared. This means that if the new statement contains an error and cannot be prepared, an error is returned and no statement with the given name exists.

Prepared statements can be PREPARED and [EXECUTED](#) in a stored procedure, but not in a stored function or trigger. Also, even if the statement is PREPARED in a procedure, it will not be deallocated when the procedure execution ends.

A prepared statement can access [user-defined variables](#), but not [local variables](#) or procedure's parameters.

If the prepared statement contains a syntax error, PREPARE will fail. As a side effect, stored procedures can use it to check if a statement is valid. For example:

```
CREATE PROCEDURE `test_stmt`(IN sql_text TEXT)
BEGIN
    DECLARE EXIT HANDLER FOR SQLEXCEPTION
    BEGIN
        SELECT CONCAT(sql_text, ' is not valid');
    END;
    SET @SQL := sql_text;
    PREPARE stmt FROM @SQL;
    DEALLOCATE PREPARE stmt;
END;
```

The [FOUND_ROWS\(\)](#) and [ROW_COUNT\(\)](#) functions, if called immediately after EXECUTE, return the number of rows read or affected by the prepared statements; however, if they are called after DEALLOCATE PREPARE, they provide information about this statement. If the prepared statement produces errors or warnings, [GET DIAGNOSTICS](#) [↗](#) return information about them. DEALLOCATE PREPARE shouldn't clear the [diagnostics area](#) [↗](#), unless it produces an error.

A prepared statement is executed with [EXECUTE](#) and released with [DEALLOCATE PREPARE](#) [↗](#).

The [max_prepared_stmt_count](#) server system variable determines the number of allowed prepared statements that can be prepared on the server. If it is set to 0, prepared statements are not allowed. If the limit is reached, an error similar to the following will be produced:

```
ERROR 1461 (42000): Can't create more than max_prepared_stmt_count statements
(current value: 0)
```

Oracle Mode

In [Oracle mode](#), `PREPARE stmt FROM 'SELECT :1, :2'` is used, instead of `?`.

Permitted Statements

MariaDB starting with [10.6.2](#)

All statements can be prepared, except [PREPARE](#), [EXECUTE](#), and [DEALLOCATE / DROP PREPARE](#).

Prior to this, not all statements can be prepared. Only the following SQL commands are permitted:

- [ALTER TABLE](#)
- [ANALYZE TABLE](#)
- [BINLOG](#)
- [CACHE INDEX](#)
- [CALL](#)
- [CHANGE MASTER](#)
- [CHECKSUM {TABLE | TABLES}](#)
- [COMMIT](#)
- [{CREATE | DROP} DATABASE](#)
- [{CREATE | DROP} INDEX](#)
- [{CREATE | RENAME | DROP} TABLE](#)
- [{CREATE | RENAME | DROP} USER](#)
- [{CREATE | DROP} VIEW](#)
- [DELETE](#)
- [DESCRIBE](#)
- [DO](#)
- [EXPLAIN](#)
- [FLUSH {TABLE | TABLES | TABLES WITH READ LOCK | HOSTS | PRIVILEGES | LOGS | STATUS | MASTER | SLAVE | DES_KEY_FILE | USER_RESOURCES | \[QUERY CACHE\]\(#\) | TABLE_STATISTICS | INDEX_STATISTICS | USER_STATISTICS | CLIENT_STATISTICS}](#)
- [GRANT](#)
- [INSERT](#)
- [INSTALL {\[PLUGIN\]\(#\) | \[SONAME\]\(#\)}](#)
- [HANDLER READ](#)
- [KILL](#)
- [LOAD INDEX INTO CACHE](#)
- [OPTIMIZE TABLE](#)
- [REPAIR TABLE](#)
- [REPLACE](#)
- [RESET {MASTER | SLAVE | \[QUERY CACHE\]\(#\)}](#)
- [REVOKE](#)
- [ROLLBACK](#)
- [SELECT](#)
- [SET](#)
- [SET GLOBAL \[SQL_SLAVE_SKIP_COUNTER\]\(#\)](#)
- [SET ROLE](#)
- [SET \[SQL_LOG_BIN\]\(#\)](#)
- [SET TRANSACTION ISOLATION LEVEL](#)
- [SHOW EXPLAIN](#)
- [SHOW {DATABASES | TABLES | OPEN TABLES | TABLE STATUS | COLUMNS | INDEX | TRIGGERS | EVENTS | GRANTS | CHARACTER SET | COLLATION | ENGINES | \[PLUGINS\]\(#\) \[\[SONAME\]\(#\)\] | PRIVILEGES | PROCESSLIST | PROFILE | PROFILES | VARIABLES | STATUS | WARNINGS | ERRORS | TABLE_STATISTICS | INDEX_STATISTICS | USER_STATISTICS | CLIENT_STATISTICS | AUTHORS | CONTRIBUTORS}](#)
- [SHOW CREATE {DATABASE | TABLE | VIEW | PROCEDURE | FUNCTION | TRIGGER | EVENT}](#)
- [SHOW {FUNCTION | PROCEDURE} CODE](#)
- [SHOW BINLOG EVENTS](#)
- [SHOW SLAVE HOSTS](#)
- [SHOW {MASTER | BINARY} LOGS](#)
- [SHOW {MASTER | SLAVE | TABLES | INNODB | FUNCTION | PROCEDURE} STATUS](#)
- [SLAVE {START | STOP}](#)
- [TRUNCATE TABLE](#)
- [SHUTDOWN](#)
- [UNINSTALL {\[PLUGIN\]\(#\) | \[SONAME\]\(#\)}](#)
- [UPDATE](#)

Synonyms are not listed here, but can be used. For example, DESC can be used instead of DESCRIBE.

[Compound statements](#) can be prepared too.

Note that if a statement can be run in a stored routine, it will work even if it is called by a prepared statement. For example, [SIGNAL](#) can't be directly prepared. However, it is allowed in [stored routines](#). If the x() procedure contains SIGNAL, you can

still prepare and execute the 'CALL x();' prepared statement.

PREPARE supports most kinds of expressions as well, for example:

```
PREPARE stmt FROM CONCAT('SELECT * FROM ', table_name);
```

When PREPARE is used with a statement which is not supported, the following error is produced:

```
ERROR 1295 (HY000): This command is not supported in the prepared statement protocol yet
```

Example

```
create table t1 (a int,b char(10));
insert into t1 values (1,"one"),(2, "two"),(3,"three");
prepare test from "select * from t1 where a=?";
set @param=2;
execute test using @param;
+-----+-----+
| a     | b     |
+-----+-----+
| 2    | two   |
+-----+-----+
set @param=3;
execute test using @param;
+-----+-----+
| a     | b     |
+-----+-----+
| 3    | three |
+-----+-----+
deallocate prepare test;
```

Since identifiers are not permitted as prepared statements parameters, sometimes it is necessary to dynamically compose an SQL statement. This technique is called *dynamic SQL*). The following example shows how to use dynamic SQL:

```
CREATE PROCEDURE test.stmt_test(IN tab_name VARCHAR(64))
BEGIN
  SET @sql = CONCAT('SELECT COUNT(*) FROM ', tab_name);
  PREPARE stmt FROM @sql;
  EXECUTE stmt;
  DEALLOCATE PREPARE stmt;
END;

CALL test.stmt_test('mysql.user');
+-----+
| COUNT(*) |
+-----+
| 4        |
+-----+
```

Use of variables in prepared statements:

```
PREPARE stmt FROM 'SELECT @x;';
```

```
SET @x = 1;
```

```
EXECUTE stmt;
```

```
+-----+
```

```
| @x  |
```

```
+-----+
```

```
|  1  |
```

```
+-----+
```

```
SET @x = 0;
```

```
EXECUTE stmt;
```

```
+-----+
```

```
| @x  |
```

```
+-----+
```

```
|  0  |
```

```
+-----+
```

```
DEALLOCATE PREPARE stmt;
```

1.1.1.5.2 Out Parameters in PREPARE

MariaDB [10.1.1](#)

Out parameters in PREPARE were only available in [MariaDB 10.1.1](#)

One can use question mark placeholders for out-parameters in the [PREPARE](#) statement. Only [SELECT ... INTO](#) can be used this way:

```
prepare test from "select id into ? from t1 where val=?";
execute test using @out, @in;
```

This is particularly convenient when used with [compound statements](#):

```
PREPARE stmt FROM "BEGIN NOT ATOMIC
  DECLARE v_res INT;
  SELECT COUNT(*) INTO v_res FROM t1;
  SELECT 'Hello World', v_res INTO ?,?;
END";
```

1.1.1.2.14 EXECUTE STATEMENT

1.1.1.5.4 DEALLOCATE / DROP PREPARE

Syntax

```
{DEALLOCATE | DROP} PREPARE stmt_name
```

Description

To deallocate a prepared statement produced with [PREPARE](#), use a `DEALLOCATE PREPARE` statement that refers to the prepared statement name.

A prepared statement is implicitly deallocated when a new `PREPARE` command is issued. In that case, there is no need to use `DEALLOCATE`.

Attempting to execute a prepared statement after deallocating it results in an error, as if it was not prepared at all:

```
ERROR 1243 (HY000): Unknown prepared statement handler (stmt_name) given to EXECUTE
```

If the specified statement has not been PREPARED, an error similar to the following will be produced:

```
ERROR 1243 (HY000): Unknown prepared statement handler (stmt_name) given to DEALLOCATE PREPARE
```

Example

See [example in PREPARE](#).

1.1.1.5.5 EXECUTE IMMEDIATE

Syntax

```
EXECUTE IMMEDIATE statement
    [USING param[, param] ...]

param:
    expression | IGNORE | DEFAULT
```

Description

`EXECUTE IMMEDIATE` executes a dynamic SQL statement created on the fly, which can reduce performance overhead.

For example:

```
EXECUTE IMMEDIATE 'SELECT 1'
```

which is shorthand for:

```
prepare stmt from "select 1";
execute stmt;
deallocate prepare stmt;
```

`EXECUTE IMMEDIATE` supports complex expressions as prepare source and parameters:

```
EXECUTE IMMEDIATE CONCAT('SELECT COUNT(*) FROM ', 't1', ' WHERE a=?') USING 5+5;
```

Limitations: subselects and stored function calls are not supported as a prepare source.

The following examples return an error:

```
CREATE OR REPLACE FUNCTION f1() RETURNS VARCHAR(64) RETURN 'SELECT * FROM t1';
EXECUTE IMMEDIATE f1();
ERROR 1970 (42000): EXECUTE IMMEDIATE does not support subqueries or stored functions

EXECUTE IMMEDIATE (SELECT 'SELECT * FROM t1');
ERROR 1064 (42000): You have an error in your SQL syntax; check the manual that
corresponds to your MariaDB server version for the right syntax to use near
'SELECT 'SELECT * FROM t1'' at line 1

CREATE OR REPLACE FUNCTION f1() RETURNS INT RETURN 10;
EXECUTE IMMEDIATE 'SELECT * FROM t1 WHERE a=?' USING f1();
ERROR 1970 (42000): EXECUTE..USING does not support subqueries or stored functions

EXECUTE IMMEDIATE 'SELECT * FROM t1 WHERE a=?' USING (SELECT 10);
ERROR 1064 (42000): You have an error in your SQL syntax; check the manual that
corresponds to your MariaDB server version for the right syntax to use near
'SELECT 10)' at line 1
```

One can use a user or an SP variable as a workaround:

```

CREATE OR REPLACE FUNCTION f1() RETURNS VARCHAR(64) RETURN 'SELECT * FROM t1';
SET @stmt=f1();
EXECUTE IMMEDIATE @stmt;

SET @stmt=(SELECT 'SELECT 1');
EXECUTE IMMEDIATE @stmt;

CREATE OR REPLACE FUNCTION f1() RETURNS INT RETURN 10;
SET @param=f1();
EXECUTE IMMEDIATE 'SELECT * FROM t1 WHERE a=?' USING @param;

SET @param=(SELECT 10);
EXECUTE IMMEDIATE 'SELECT * FROM t1 WHERE a=?' USING @param;

```

EXECUTE IMMEDIATE supports user variables and SP variables as OUT parameters

```

DELIMITER $$
CREATE OR REPLACE PROCEDURE p1(OUT a INT)
BEGIN
    SET a:= 10;
END;
$$
DELIMITER ;
SET @a=2;
EXECUTE IMMEDIATE 'CALL p1(?)' USING @a;
SELECT @a;
+-----+
| @a   |
+-----+
|   10 |
+-----+

```

Similar to PREPARE, EXECUTE IMMEDIATE is allowed in stored procedures but is not allowed in stored functions.

This example uses EXECUTE IMMEDIATE inside a stored procedure:

```

DELIMITER $$
CREATE OR REPLACE PROCEDURE p1()
BEGIN
    EXECUTE IMMEDIATE 'SELECT 1';
END;
$$
DELIMITER ;
CALL p1;
+---+
| 1 |
+---+
| 1 |
+---+

```

This script returns an error:

```

DELIMITER $$
CREATE FUNCTION f1() RETURNS INT
BEGIN
    EXECUTE IMMEDIATE 'DO 1';
    RETURN 1;
END;
$$
ERROR 1336 (0A000): Dynamic SQL is not allowed in stored function or trigger

```

EXECUTE IMMEDIATE can use DEFAULT and IGNORE indicators as bind parameters:

```
CREATE OR REPLACE TABLE t1 (a INT DEFAULT 10);
EXECUTE IMMEDIATE 'INSERT INTO t1 VALUES (?)' USING DEFAULT;
SELECT * FROM t1;
+-----+
| a      |
+-----+
| 10     |
+-----+
```

EXECUTE IMMEDIATE increments the `Com_execute_immediate` status variable, as well as the `Com_stmt_prepare`, `Com_stmt_execute` and `Com_stmt_close` status variables.

Note, EXECUTE IMMEDIATE does not increment the `Com_execute_sql` status variable. `Com_execute_sql` is used only for `PREPARE..EXECUTE`.

This session screenshot demonstrates how EXECUTE IMMEDIATE affects status variables:

```
SELECT * FROM INFORMATION_SCHEMA.SESSION_STATUS WHERE VARIABLE_NAME RLIKE
('COM_(EXECUTE|STMT_PREPARE|STMT_EXECUTE|STMT_CLOSE) ');
+-----+-----+
| VARIABLE_NAME          | VARIABLE_VALUE |
+-----+-----+
| COM_EXECUTE_IMMEDIATE | 0              |
| COM_EXECUTE_SQL       | 0              |
| COM_STMT_CLOSE        | 0              |
| COM_STMT_EXECUTE      | 0              |
| COM_STMT_PREPARE      | 0              |
+-----+-----+

EXECUTE IMMEDIATE 'SELECT 1';
+---+
| 1 |
+---+
| 1 |
+---+

SELECT * FROM INFORMATION_SCHEMA.SESSION_STATUS WHERE VARIABLE_NAME RLIKE
('COM_(EXECUTE|STMT_PREPARE|STMT_EXECUTE|STMT_CLOSE) ');
+-----+-----+
| VARIABLE_NAME          | VARIABLE_VALUE |
+-----+-----+
| COM_EXECUTE_IMMEDIATE | 1              |
| COM_EXECUTE_SQL       | 0              |
| COM_STMT_CLOSE        | 1              |
| COM_STMT_EXECUTE      | 1              |
| COM_STMT_PREPARE      | 1              |
+-----+-----+
```

1.1.1.6 Programmatic & Compound Statements

Compound statements in MariaDB can be used both inside and outside of [stored programs](#).

Using Compound Statements Outside of Stored Programs

Compound statements are not just for stored programs.

BEGIN END

How to write compound statements.

CASE Statement

Conditional construct with multiple choices.

DECLARE CONDITION

For declaring a named error condition (SQLSTATE or error code).

DECLARE HANDLER

Construct to declare how errors are handled.

DECLARE Variable

Declare local variables within stored programs.

FOR

FOR loops allow code to be executed a fixed number of times.

GOTO

Jump to the given label.

IF

A basic conditional construct statement.

ITERATE

Used to repeat the execution of the current loop.

Labels

Identifiers used to identify a BEGIN ... END construct.

LEAVE

Used to exit a code block.

LOOP

Used to loop within a code block without a condition.

REPEAT LOOP

Used to repeat statements until a search condition is true.

RESIGNAL

Used to send a SIGNAL again for the previous error.

RETURN

Statement to terminate execution of a stored function and return a value.

SELECT INTO

SQL statement for inserting values into variables.

SET Variable

Used to insert a value into a variable with a code block.

SIGNAL

May be used to produce a custom error message.

WHILE

Used to repeat a block of SQL statements while a search condition is true.

Cursors

Structure for traversing and processing results, sequentially.

Diagnostics

Error conditions and statement information. [🔗](#)

There are [1 related questions](#) [🔗](#).

1.1.1.6.1 Using Compound Statements Outside of Stored Programs

Compound statements can also be used outside of [stored programs](#).

```

delimiter |
IF @have_innodb THEN
  CREATE TABLE IF NOT EXISTS innodb_index_stats (
    database_name  VARCHAR(64) NOT NULL,
    table_name     VARCHAR(64) NOT NULL,
    index_name     VARCHAR(64) NOT NULL,
    last_update    TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
    stat_name      VARCHAR(64) NOT NULL,
    stat_value     BIGINT UNSIGNED NOT NULL,
    sample_size    BIGINT UNSIGNED,
    stat_description VARCHAR(1024) NOT NULL,
    PRIMARY KEY (database_name, table_name, index_name, stat_name)
  ) ENGINE=INNODB DEFAULT CHARSET=utf8 COLLATE=utf8_bin STATS_PERSISTENT=0;
END IF|
Query OK, 0 rows affected, 2 warnings (0.00 sec)

```

Note, that using compound statements this way is subject to following limitations:

- Only [BEGIN](#), [IF](#), [CASE](#), [LOOP](#), [WHILE](#), [REPEAT](#) statements may start a compound statement outside of stored programs.
- [BEGIN](#) must use the `BEGIN NOT ATOMIC` syntax (otherwise it'll be confused with [BEGIN](#) that starts a transaction).
- A compound statement might not start with a label.
- A compound statement is parsed completely—note "2 warnings" in the above example, even if the condition was false (InnoDB was, indeed, disabled), and the [CREATE TABLE](#) statement was not executed, it was still parsed and the parser produced "Unknown storage engine" warning.

Inside a compound block first three limitations do not apply, one can use anything that can be used inside a stored program — including labels, condition handlers, variables, and so on:

```

BEGIN NOT ATOMIC
  DECLARE foo CONDITION FOR 1146;
  DECLARE x INT DEFAULT 0;
  DECLARE CONTINUE HANDLER FOR SET x=1;
  INSERT INTO test.t1 VALUES ("hndlr1", val, 2);
END|

```

Example how to use `IF`:

```

IF (1>0) THEN BEGIN NOT ATOMIC SELECT 1; END ; END IF;;

```

Example of how to use `WHILE` loop:

```

DELIMITER |
BEGIN NOT ATOMIC
  DECLARE x INT DEFAULT 0;
  WHILE x <= 10 DO
    SET x = x + 1;
    SELECT x;
  END WHILE;
END|
DELIMITER ;

```

1.1.1.6.2 BEGIN END

Syntax

```

[begin_label:] BEGIN [NOT ATOMIC]
  [statement_list]
END [end_label]

```

Contents

1. [Syntax](#)
2. [Description](#)

`NOT ATOMIC` is required when used outside of a [stored procedure](#). Inside stored procedures or within an anonymous block, `BEGIN` alone starts a new anonymous block.

Description

`BEGIN ... END` syntax is used for writing compound statements. A compound statement can contain multiple statements, enclosed by the `BEGIN` and `END` keywords. `statement_list` represents a list of one or more statements, each terminated by a semicolon (i.e., `;`) statement delimiter. `statement_list` is optional, which means that the empty compound statement (`BEGIN END`) is legal.

Note that `END` will perform a commit. If you are running in [autocommit](#) mode, every statement will be committed separately. If you are not running in `autocommit` mode, you must execute a [COMMIT](#) or [ROLLBACK](#) after `END` to get the database up to date.

Use of multiple statements requires that a client is able to send statement strings containing the `;` statement delimiter. This is handled in the [mysql](#) command-line client with the [DELIMITER](#) command. Changing the `;` end-of-statement delimiter (for example, to `//`) allows `;` to be used in a program body.

A compound statement within a [stored program](#) can be [labeled](#). `end_label` cannot be given unless `begin_label` also is present. If both are present, they must be the same.

`BEGIN ... END` constructs can be nested. Each block can define its own variables, a `CONDITION`, a `HANDLER` and a [CURSOR](#), which don't exist in the outer blocks. The most local declarations override the outer objects which use the same name (see example below).

The declarations order is the following:

- `DECLARE local variables;`
- `DECLARE CONDITION S;`
- `DECLARE CURSOR S;`
- `DECLARE HANDLER S;`

Note that `DECLARE HANDLER` contains another `BEGIN ... END` construct.

Here is an example of a very simple, anonymous block:

```
BEGIN NOT ATOMIC
SET @a=1;
CREATE TABLE test.t1(a INT);
END|
```

Below is an example of nested blocks in a stored procedure:

```
CREATE PROCEDURE t( )
BEGIN
  DECLARE x TINYINT UNSIGNED DEFAULT 1;
  BEGIN
    DECLARE x CHAR(2) DEFAULT '02';
    DECLARE y TINYINT UNSIGNED DEFAULT 10;
    SELECT x, y;
  END;
  SELECT x;
END;
```

In this example, a [TINYINT](#) variable, `x` is declared in the outer block. But in the inner block `x` is re-declared as a [CHAR](#) and an `y` variable is declared. The inner `SELECT` shows the "new" value of `x`, and the value of `y`. But when `x` is selected in the outer block, the "old" value is returned. The final `SELECT` doesn't try to read `y`, because it doesn't exist in that context.

1.1.1.6.3 CASE Statement

Syntax

```

CASE case_value
  WHEN when_value THEN statement_list
  [WHEN when_value THEN statement_list] ...
  [ELSE statement_list]
END CASE

```

Or:

```

CASE
  WHEN search_condition THEN statement_list
  [WHEN search_condition THEN statement_list] ...
  [ELSE statement_list]
END CASE

```

Description

The text on this page describes the `CASE` statement for [stored programs](#). See the [CASE OPERATOR](#) for details on the `CASE` operator outside of [stored programs](#).

The `CASE` statement for [stored programs](#) implements a complex conditional construct. If a `search_condition` evaluates to true, the corresponding SQL statement list is executed. If no search condition matches, the statement list in the `ELSE` clause is executed. Each `statement_list` consists of one or more statements.

The `CASE` statement cannot have an `ELSE NULL` clause, and it is terminated with `END CASE` instead of `END`. implements a complex conditional construct. If a `search_condition` evaluates to true, the corresponding SQL statement list is executed. If no search condition matches, the statement list in the `ELSE` clause is executed. Each `statement_list` consists of one or more statements.

If no `when_value` or `search_condition` matches the value tested and the `CASE` statement contains no `ELSE` clause, a Case not found for `CASE` statement error results.

Each `statement_list` consists of one or more statements; an empty `statement_list` is not allowed. To handle situations where no value is matched by any `WHEN` clause, use an `ELSE` containing an empty `BEGIN ... END` block, as shown in this example:

```

DELIMITER |
CREATE PROCEDURE p()
BEGIN
  DECLARE v INT DEFAULT 1;
  CASE v
    WHEN 2 THEN SELECT v;
    WHEN 3 THEN SELECT 0;
    ELSE BEGIN END;
  END CASE;
END;
|

```

The indentation used here in the `ELSE` clause is for purposes of clarity only, and is not otherwise significant. See [Delimiters in the mariadb client](#) for more on the use of the delimiter command.

Note: The syntax of the `CASE` statement used inside stored programs differs slightly from that of the SQL `CASE` expression described in [CASE OPERATOR](#). The `CASE` statement cannot have an `ELSE NULL` clause, and it is terminated with `END CASE` instead of `END`.

1.1.1.6.4 DECLARE CONDITION

Syntax

```

DECLARE condition_name CONDITION FOR condition_value

condition_value:
  SQLSTATE [VALUE] sqlstate_value
| mysql_error_code

```

Description

The `DECLARE ... CONDITION` statement defines a named error condition. It specifies a condition that needs specific handling and associates a name with that condition. Later, the name can be used in a `DECLARE ... HANDLER`, `SIGNAL` or `RESIGNAL` statement (as long as the statement is located in the same `BEGIN ... END` block).

Conditions must be declared after [local variables](#), but before [CURSORS](#) and [HANDLERS](#).

A `condition_value` for `DECLARE ... CONDITION` can be an [SQLSTATE](#) value (a 5-character string literal) or a MySQL error code (a number). You should not use SQLSTATE value '00000' or MySQL error code 0, because those indicate success rather than an error condition. If you try, or if you specify an invalid SQLSTATE value, an error like this is produced:

```
ERROR 1407 (42000): Bad SQLSTATE: '00000'
```

For a list of SQLSTATE values and MariaDB error codes, see [MariaDB Error Codes](#).

1.1.1.6.5 DECLARE HANDLER

Syntax

```
DECLARE handler_type HANDLER
  FOR condition_value [, condition_value] ...
  statement

handler_type:
  CONTINUE
  | EXIT
  | UNDO

condition_value:
  SQLSTATE [VALUE] sqlstate_value
  | condition_name
  | SQLWARNING
  | NOT FOUND
  | SQLEXCEPTION
  | mariadb_error_code
```

Description

The `DECLARE ... HANDLER` statement specifies handlers that each may deal with one or more conditions. If one of these conditions occurs, the specified statement is executed. `statement` can be a simple statement (for example, `SET var_name = value`), or it can be a compound statement written using [BEGIN and END](#).

Handlers must be declared after local variables, a `CONDITION` and a `CURSOR`.

For a `CONTINUE` handler, execution of the current program continues after execution of the handler statement. For an `EXIT` handler, execution terminates for the `BEGIN ... END` compound statement in which the handler is declared. (This is true even if the condition occurs in an inner block.) The `UNDO` handler type statement is not supported.

If a condition occurs for which no handler has been declared, the default action is `EXIT`.

A `condition_value` for `DECLARE ... HANDLER` can be any of the following values:

- An [SQLSTATE](#) value (a 5-character string literal) or a MariaDB error code (a number). You should not use `SQLSTATE` value '00000' or MariaDB error code 0, because those indicate success rather than an error condition. For a list of `SQLSTATE` values and MariaDB error codes, see [MariaDB Error Codes](#).
- A condition name previously specified with `DECLARE ... CONDITION`. It must be in the same stored program. See [DECLARE CONDITION](#).
- `SQLWARNING` is shorthand for the class of `SQLSTATE` values that begin with '01'.
- `NOT FOUND` is shorthand for the class of `SQLSTATE` values that begin with '02'. This is relevant only in the context of cursors and is used to control what happens when a cursor reaches the end of a data set. If no more rows are available, a No Data condition occurs with `SQLSTATE` value 02000. To detect this condition, you can set up a handler for it (or for a `NOT FOUND` condition). An example is shown in [Cursor Overview](#). This condition also occurs for `SELECT ... INTO var_list` statements that retrieve no rows.
- `SQLEXCEPTION` is shorthand for the class of `SQLSTATE` values that do not begin with '00', '01', or '02'.

When an error raises, in some cases it could be handled by multiple `HANDLER`s. For example, there may be an handler for 1050 error, a separate handler for the 42S01 SQLSTATE, and another separate handler for the `SQLException` class: in theory all occurrences of `HANDLER` may catch the 1050 error, but MariaDB chooses the `HANDLER` with the highest precedence. Here are the precedence rules:

- Handlers which refer to an error code have the highest precedence.
- Handlers which refer to a SQLSTATE come next.
- Handlers which refer to an error class have the lowest precedence.

In some cases, a statement could produce multiple errors. If this happens, in some cases multiple handlers could have the highest precedence. In such cases, the choice of the handler is indeterminate.

Note that if an error occurs within a `CONTINUE HANDLER` block, it can be handled by another `HANDLER`. However, a `HANDLER` which is already in the stack (that is, it has been called to handle an error and its execution didn't finish yet) cannot handle new errors—this prevents endless loops. For example, suppose that a stored procedure contains a `CONTINUE HANDLER` for `SQLWARNING` and another `CONTINUE HANDLER` for `NOT FOUND`. At some point, a `NOT FOUND` error occurs, and the execution enters the `NOT FOUND HANDLER`. But within that handler, a warning occurs, and the execution enters the `SQLWARNING HANDLER`. If another `NOT FOUND` error occurs, it cannot be handled again by the `NOT FOUND HANDLER`, because its execution is not finished.

When a `DECLARE HANDLER` block can handle more than one error condition, it may be useful to know which errors occurred. To do so, you can use the [GET DIAGNOSTICS](#) statement.

An error that is handled by a `DECLARE HANDLER` construct can be issued again using the [RESIGNAL](#) statement.

Below is an example using `DECLARE HANDLER`:

```
CREATE TABLE test.t (s1 INT, PRIMARY KEY (s1));

DELIMITER //

CREATE PROCEDURE handlerdemo ( )
BEGIN
    DECLARE CONTINUE HANDLER FOR SQLSTATE '23000' SET @x2 = 1;
    SET @x = 1;
    INSERT INTO test.t VALUES (1);
    SET @x = 2;
    INSERT INTO test.t VALUES (1);
    SET @x = 3;
END;
//

DELIMITER ;

CALL handlerdemo( );

SELECT @x;
+-----+
| @x   |
+-----+
|    3 |
+-----+
```

1.1.1.6.6 DECLARE Variable

Syntax

```
DECLARE var_name [, var_name] ... [[ROW] TYPE OF] type [DEFAULT value]
```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [TYPE OF / ROW TYPE OF](#)
3. [Examples](#)

Description

This statement is used to declare local variables within [stored programs](#). To provide a default value for the variable, include a `DEFAULT` clause. The value can be specified as an expression (even subqueries are permitted); it need not be a constant. If the `DEFAULT` clause is missing, the initial value is `NULL`.

Local variables are treated like stored routine parameters with respect to data type and overflow checking. See [CREATE PROCEDURE](#).

Local variables must be declared before `CONDITION S`, [CURSORS](#) and `HANDLER S`.

Local variable names are not case sensitive.

The scope of a local variable is within the `BEGIN ... END` block where it is declared. The variable can be referred to in blocks nested within the declaring block, except those blocks that declare a variable with the same name.

TYPE OF / ROW TYPE OF

Anchored data types allow a data type to be defined based on another object, such as a table row, rather than specifically set in the declaration. If the anchor object changes, so will the anchored data type. This can lead to routines being easier to maintain, so that if the data type in the table is changed, it will automatically be changed in the routine as well.

Variables declared with `ROW TYPE OF` will have the same features as implicit [ROW](#) variables. It is not possible to use `ROW TYPE OF` variables in a `LIMIT` clause.

The real data type of `TYPE OF` and `ROW TYPE OF table_name` will become known at the very beginning of the stored routine call. [ALTER TABLE](#) or [DROP TABLE](#) statements performed inside the current routine on the tables that appear in anchors won't affect the data type of the anchored variables, even if the variable is declared after an [ALTER TABLE](#) or [DROP TABLE](#) statement.

The real data type of a `ROW TYPE OF cursor_name` variable will become known when execution enters into the block where the variable is declared. Data type instantiation will happen only once. In a cursor `ROW TYPE OF` variable that is declared inside a loop, its data type will become known on the very first iteration and won't change on further loop iterations.

The tables referenced in `TYPE OF` and `ROW TYPE OF` declarations will be checked for existence at the beginning of the stored routine call. [CREATE PROCEDURE](#) or [CREATE FUNCTION](#) will not check the referenced tables for existence.

Examples

```
DECLARE name VARCHAR(5) DEFAULT 'monty';
DECLARE x INT DEFAULT 10;
DECLARE y SMALLINT;
```

`TYPE OF` and `ROW TYPE OF` from [MariaDB 10.3](#):

```
DECLARE tmp TYPE OF t1.a; -- Get the data type from the column {{a}} in the table {{t1}}
DECLARE rec1 ROW TYPE OF t1; -- Get the row data type from the table {{t1}}
DECLARE rec2 ROW TYPE OF cur1; -- Get the row data type from the cursor {{cur1}}
```

1.1.1.6.7 FOR

Syntax

Integer range FOR loop:

```
[begin_label:]
FOR var_name IN [ REVERSE ] lower_bound .. upper_bound
DO statement_list
END FOR [ end_label ]
```

Explicit cursor FOR loop

```
[begin_label:]
FOR record_name IN cursor_name [ ( cursor_actual_parameter_list) ]
DO statement_list
END FOR [ end_label ]
```

Explicit cursor FOR loop (Oracle mode)

```
[begin_label:]
FOR record_name IN cursor_name [ ( cursor_actual_parameter_list) ]
LOOP
  statement_list
END LOOP [ end_label ]
```

Implicit cursor FOR loop

```
[begin_label:]
FOR record_name IN ( select_statement )
DO statement_list
END FOR [ end_label ]
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

Description

FOR loops allow code to be executed a fixed number of times.

In an integer range FOR loop, MariaDB will compare the lower bound and upper bound values, and assign the lower bound value to a counter. If REVERSE is not specified, and the upper bound value is greater than or equal to the counter, the counter will be incremented and the statement will continue, after which the loop is entered again. If the upper bound value is greater than the counter, the loop will be exited.

If REVERSE is specified, the counter is decremented, and the upper bound value needs to be less than or equal for the loop to continue.

Examples

Integer range FOR loop:

```
CREATE TABLE t1 (a INT);

DELIMITER //

FOR i IN 1..3
DO
  INSERT INTO t1 VALUES (i);
END FOR;
//

DELIMITER ;

SELECT * FROM t1;
+-----+
| a     |
+-----+
| 1     |
| 2     |
| 3     |
+-----+
```

REVERSE integer range FOR loop:

```
CREATE OR REPLACE TABLE t1 (a INT);
```

```
DELIMITER //
```

```
FOR i IN REVERSE 4..12
```

```
DO
```

```
    INSERT INTO t1 VALUES (i);
```

```
END FOR;
```

```
//
```

```
Query OK, 9 rows affected (0.422 sec)
```

```
DELIMITER ;
```

```
SELECT * FROM t1;
```

```
+-----+
```

```
| a      |
```

```
+-----+
```

```
| 12     |
```

```
| 11     |
```

```
| 10     |
```

```
| 9      |
```

```
| 8      |
```

```
| 7      |
```

```
| 6      |
```

```
| 5      |
```

```
| 4      |
```

```
+-----+
```

Explicit cursor in [Oracle mode](#):

```

SET sql_mode=ORACLE;

CREATE OR REPLACE TABLE t1 (a INT, b VARCHAR(32));

INSERT INTO t1 VALUES (10,'b0');
INSERT INTO t1 VALUES (11,'b1');
INSERT INTO t1 VALUES (12,'b2');

DELIMITER //

CREATE OR REPLACE PROCEDURE p1(pa INT) AS
  CURSOR cur(va INT) IS
    SELECT a, b FROM t1 WHERE a=va;
BEGIN
  FOR rec IN cur(pa)
  LOOP
    SELECT rec.a, rec.b;
  END LOOP;
END;
//

DELIMITER ;

CALL p1(10);
+-----+-----+
| rec.a | rec.b |
+-----+-----+
|    10 | b0    |
+-----+-----+

CALL p1(11);
+-----+-----+
| rec.a | rec.b |
+-----+-----+
|    11 | b1    |
+-----+-----+

CALL p1(12);
+-----+-----+
| rec.a | rec.b |
+-----+-----+
|    12 | b2    |
+-----+-----+

CALL p1(13);
Query OK, 0 rows affected (0.000 sec)

```

1.1.1.6.8 GOTO

Syntax

```
GOTO label
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Example](#)

Description

The `GOTO` statement causes the code to jump to the specified label, and continue operating from there. It is only accepted when in [Oracle mode](#).

Example

```

SET sql_mode=ORACLE;

DELIMITER //

CREATE OR REPLACE PROCEDURE p1 AS

BEGIN

    SELECT 1;
    GOTO label;
    SELECT 2;
    <<label>>
    SELECT 3;

END;

//

DELIMITER

call p1();
+---+
| 1 |
+---+
| 1 |
+---+
1 row in set (0.000 sec)

+---+
| 3 |
+---+
| 3 |
+---+
1 row in set (0.000 sec)

```

1.1.1.6.9 IF

Syntax

```

IF search_condition THEN statement_list
  [ELSEIF search_condition THEN statement_list] ...
  [ELSE statement_list]
END IF;

```

Description

`IF` implements a basic conditional construct. If the `search_condition` evaluates to true, the corresponding SQL statement list is executed. If no `search_condition` matches, the statement list in the `ELSE` clause is executed. Each `statement_list` consists of one or more statements.

1.1.1.6.10 ITERATE

Syntax

```

ITERATE label

```

`ITERATE` can appear only within `LOOP`, `REPEAT`, and `WHILE` statements. `ITERATE` means "do the loop again", and uses the statement's `label` to determine which statements to repeat. The label must be in the same stored program, not in a caller procedure.

If you try to use `ITERATE` with a non-existing label, or if the label is associated to a construct which is not a loop, the following error will be produced:

```
ERROR 1308 (42000): ITERATE with no matching label: <label_name>
```

Below is an example of how `ITERATE` might be used:

```
CREATE PROCEDURE doiterate(p1 INT)
BEGIN
  label1: LOOP
    SET p1 = p1 + 1;
    IF p1 < 10 THEN ITERATE label1; END IF;
    LEAVE label1;
  END LOOP label1;
  SET @x = p1;
END
```

1.1.1.6.11 Labels

Syntax

```
label: <construct>
[label]
```

Labels are MariaDB [identifiers](#) which can be used to identify a `BEGIN ... END` construct or a loop. They have a maximum length of 16 characters and can be quoted with backticks (i.e., ```).

Labels have a start part and an end part. The start part must precede the portion of code it refers to, must be followed by a colon (`:`) and can be on the same or different line. The end part is optional and adds nothing, but can make the code more readable. If used, the end part must precede the construct's delimiter (`;`). Constructs identified by a label can be nested. Each construct can be identified by only one label.

Labels need not be unique in the stored program they belong to. However, a label for an inner loop cannot be identical to a label for an outer loop. In this case, the following error would be produced:

```
ERROR 1309 (42000): Redefining label <label_name>
```

`LEAVE` and `ITERATE` statements can be used to exit or repeat a portion of code identified by a label. They must be in the same [Stored Routine](#), [Trigger](#) or [Event](#) which contains the target label.

Below is an example using a simple label that is used to exit a `LOOP`:

```
CREATE PROCEDURE `test_sp`()
BEGIN
  `my_label`:
  LOOP
    SELECT 'looping';
    LEAVE `my_label`;
  END LOOP;
  SELECT 'out of loop';
END;
```

The following label is used to exit a procedure, and has an end part:

```
CREATE PROCEDURE `test_sp`()
`my_label`:
BEGIN
  IF @var = 1 THEN
    LEAVE `my_label`;
  END IF;
  DO something();
END `my_label`;
```

1.1.1.6.12 LEAVE

Syntax

```
LEAVE label
```

This statement is used to exit the flow control construct that has the given [label](#). The label must be in the same stored program, not in a caller procedure. `LEAVE` can be used within `BEGIN ... END` or loop constructs ([LOOP](#), [REPEAT](#), [WHILE](#)). In [Stored Procedures](#), [Triggers](#) and [Events](#), `LEAVE` can refer to the outmost `BEGIN ... END` construct; in that case, the program exits the procedure. In [Stored Functions](#), `RETURN` can be used instead.

Note that `LEAVE` cannot be used to exit a [DECLARE HANDLER](#) block.

If you try to `LEAVE` a non-existing label, or if you try to `LEAVE` a `HANDLER` block, the following error will be produced:

```
ERROR 1308 (42000): LEAVE with no matching label: <label_name>
```

The following example uses `LEAVE` to exit the procedure if a condition is true:

```
CREATE PROCEDURE proc(IN p TINYINT)
CONTAINS SQL
`whole_proc`:
BEGIN
  SELECT 1;
  IF p < 1 THEN
    LEAVE `whole_proc`;
  END IF;
  SELECT 2;
END;

CALL proc(0);
+---+
| 1 |
+---+
| 1 |
+---+
```

1.1.1.6.13 LOOP

Syntax

```
[begin_label:] LOOP
  statement_list
END LOOP [end_label]
```

Contents

- [Syntax](#)
- [Description](#)

Description

`LOOP` implements a simple loop construct, enabling repeated execution of the statement list, which consists of one or more statements, each terminated by a semicolon (i.e., `;`) statement delimiter. The statements within the loop are repeated until the loop is exited; usually this is accomplished with a [LEAVE](#) statement.

A `LOOP` statement can be [labeled](#). `end_label` cannot be given unless `begin_label` also is present. If both are present, they must be the same.

See [Delimiters](#) in the [mariadb](#) client for more on delimiter usage in the client.

1.1.1.6.14 REPEAT LOOP

Syntax

```
[begin_label:] REPEAT
    statement_list
UNTIL search_condition
END REPEAT [end_label]
```

The statement list within a `REPEAT` statement is repeated until the `search_condition` is true. Thus, a `REPEAT` always enters the loop at least once. `statement_list` consists of one or more statements, each terminated by a semicolon (i.e., `;`) statement delimiter.

A `REPEAT` statement can be [labeled](#). `end_label` cannot be given unless `begin_label` also is present. If both are present, they must be the same.

See [Delimiters](#) in the `mariadb` client for more on client delimiter usage.

```
DELIMITER //

CREATE PROCEDURE dorepeat(p1 INT)
BEGIN
    SET @x = 0;
    REPEAT SET @x = @x + 1; UNTIL @x > p1 END REPEAT;
END
//

CALL dorepeat(1000)//

SELECT @x//
+-----+
| @x   |
+-----+
| 1001 |
+-----+
```

1.1.1.6.15 RESIGNAL

Syntax

```
RESIGNAL [error_condition]
    [SET error_property
    [, error_property] ...]

error_condition:
    SQLSTATE [VALUE] 'sqlstate_value'
    | condition_name

error_property:
    error_property_name = <error_property_value>

error_property_name:
    CLASS_ORIGIN
    | SUBCLASS_ORIGIN
    | MESSAGE_TEXT
    | MYSQL_ERRNO
    | CONSTRAINT_CATALOG
    | CONSTRAINT_SCHEMA
    | CONSTRAINT_NAME
    | CATALOG_NAME
    | SCHEMA_NAME
    | TABLE_NAME
    | COLUMN_NAME
    | CURSOR_NAME
```

Contents

1. [Syntax](#)
2. [Description](#)

Description

The syntax of `RESIGNAL` and its semantics are very similar to `SIGNAL`. This statement can only be used within an error `HANDLER`. It produces an error, like `SIGNAL`. `RESIGNAL` clauses are the same as `SIGNAL`, except that they all are optional, even `SQLSTATE`. All the properties which are not specified in `RESIGNAL`, will be identical to the properties of the error that was received by the error `HANDLER`. For a description of the clauses, see [diagnostics area](#).

Note that `RESIGNAL` does not empty the diagnostics area: it just appends another error condition.

`RESIGNAL`, without any clauses, produces an error which is identical to the error that was received by `HANDLER`.

If used out of a `HANDLER` construct, `RESIGNAL` produces the following error:

```
ERROR 1645 (0K000): RESIGNAL when handler not active
```

In [MariaDB 5.5](#), if a `HANDLER` contained a `CALL` to another procedure, that procedure could use `RESIGNAL`. Since [MariaDB 10.0](#), trying to do this raises the above error.

For a list of `SQLSTATE` values and MariaDB error codes, see [MariaDB Error Codes](#).

The following procedure tries to query two tables which don't exist, producing a 1146 error in both cases. Those errors will trigger the `HANDLER`. The first time the error will be ignored and the client will not receive it, but the second time, the error is re-signaled, so the client will receive it.

```
CREATE PROCEDURE test_error( )
BEGIN
  DECLARE CONTINUE HANDLER
  FOR 1146
  BEGIN
    IF @hide_errors IS FALSE THEN
      RESIGNAL;
    END IF;
  END;
  SET @hide_errors = TRUE;
  SELECT 'Next error will be ignored' AS msg;
  SELECT `c` FROM `temptab_one`;
  SELECT 'Next error won't be ignored' AS msg;
  SET @hide_errors = FALSE;
  SELECT `c` FROM `temptab_two`;
END;

CALL test_error( );

+-----+
| msg                |
+-----+
| Next error will be ignored |
+-----+

+-----+
| msg                |
+-----+
| Next error won't be ignored |
+-----+

ERROR 1146 (42S02): Table 'test.temptab_two' doesn't exist
```

The following procedure re-signals an error, modifying only the error message to clarify the cause of the problem.

```
CREATE PROCEDURE test_error()
BEGIN
  DECLARE CONTINUE HANDLER
  FOR 1146
  BEGIN
    RESIGNAL SET
      MESSAGE_TEXT = '`temptab` does not exist';
  END;
  SELECT `c` FROM `temptab`;
END;

CALL test_error( );
ERROR 1146 (42S02): `temptab` does not exist
```

As explained above, this works on [MariaDB 5.5](#), but produces a 1645 error since 10.0.

```

CREATE PROCEDURE handle_error()
BEGIN
    RESIGNAL;
END;
CREATE PROCEDURE p()
BEGIN
    DECLARE EXIT HANDLER FOR SQLEXCEPTION CALL p();
    SIGNAL SQLSTATE '45000';
END;

```

1.1.1.6.16 RETURN

Syntax

```
RETURN expr
```

The `RETURN` statement terminates execution of a [stored function](#) and returns the value `expr` to the function caller. There must be at least one `RETURN` statement in a stored function. If the function has multiple exit points, all exit points must have a `RETURN`.

This statement is not used in [stored procedures](#), [triggers](#), or [events](#). `LEAVE` can be used instead.

The following example shows that `RETURN` can return the result of a [scalar subquery](#):

```

CREATE FUNCTION users_count() RETURNS BOOL
    READS SQL DATA
BEGIN
    RETURN (SELECT COUNT(DISTINCT User) FROM mysql.user);
END;

```

1.1.1.6.17 SELECT INTO

Syntax

```

SELECT col_name [, col_name] ...
    INTO var_name [, var_name] ...
    table_expr

```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

Description

`SELECT ... INTO` enables selected columns to be stored directly into variables. No resultset is produced. The query should return a single row. If the query returns no rows, a warning with error code 1329 occurs (No data), and the variable values remain unchanged. If the query returns multiple rows, error 1172 occurs (Result consisted of more than one row). If it is possible that the statement may retrieve multiple rows, you can use `LIMIT 1` to limit the result set to a single row.

The `INTO` clause can also be specified at the end of the statement.

In the context of such statements that occur as part of events executed by the Event Scheduler, diagnostics messages (not only errors, but also warnings) are written to the error log, and, on Windows, to the application event log.

This statement can be used with both [local variables](#) and [user-defined variables](#).

For the complete syntax, see [SELECT](#).

Another way to set a variable's value is the [SET](#) statement.

`SELECT ... INTO` results are not stored in the [query cache](#) even if `SQL_CACHE` is specified.

Examples

```
SELECT id, data INTO @x,@y
FROM test.t1 LIMIT 1;
SELECT * from t1 where t1.a=@x and t1.b=@y
```

If you want to use this construct with `UNION` you have to use the syntax:

```
SELECT * INTO @x FROM (SELECT t1.a FROM t1 UNION SELECT t2.a FROM t2) dt;
```

1.1.1.2.7.10 SET Variable

1.1.1.6.19 SIGNAL

Syntax

```
SIGNAL error_condition
  [SET error_property
  [, error_property] ...]

error_condition:
  SQLSTATE [VALUE] 'sqlstate_value'
  | condition_name

error_property:
  error_property_name = <error_property_value>

error_property_name:
  CLASS_ORIGIN
  | SUBCLASS_ORIGIN
  | MESSAGE_TEXT
  | MYSQL_ERRNO
  | CONSTRAINT_CATALOG
  | CONSTRAINT_SCHEMA
  | CONSTRAINT_NAME
  | CATALOG_NAME
  | SCHEMA_NAME
  | TABLE_NAME
  | COLUMN_NAME
  | CURSOR_NAME
```

Contents

1. [Syntax](#)
2. [Errors](#)
3. [Examples](#)

`SIGNAL` empties the [diagnostics area](#) and produces a custom error. This statement can be used anywhere, but is generally useful when used inside a [stored program](#). When the error is produced, it can be caught by a [HANDLER](#). If not, the current stored program, or the current statement, will terminate with the specified error.

Sometimes an error [HANDLER](#) just needs to `SIGNAL` the same error it received, optionally with some changes. Usually the `RESIGNAL` statement is the most convenient way to do this.

`error_condition` can be an `SQLSTATE` value or a named error condition defined via `DECLARE CONDITION`. `SQLSTATE` must be a constant string consisting of five characters. These codes are standard to ODBC and ANSI SQL. For customized errors, the recommended `SQLSTATE` is '45000'. For a list of `SQLSTATE` values used by MariaDB, see the [MariaDB Error Codes](#) page. The `SQLSTATE` can be read via the API method `mysql_sqlstate()`.

To specify error properties user-defined variables and [local variables](#) can be used, as well as [character set conversions](#) (but you can't set a collation).

The error properties, their type and their default values are explained in the [diagnostics area](#) page.

Errors

If the SQLSTATE is not valid, the following error like this will be produced:

```
ERROR 1407 (42000): Bad SQLSTATE: '123456'
```

If a property is specified more than once, an error like this will be produced:

```
ERROR 1641 (42000): Duplicate condition information item 'MESSAGE_TEXT'
```

If you specify a condition name which is not declared, an error like this will be produced:

```
ERROR 1319 (42000): Undefined CONDITION: cond_name
```

If MYSQL_ERRNO is out of range, you will get an error like this:

```
ERROR 1231 (42000): Variable 'MYSQL_ERRNO' can't be set to the value of '0'
```

Examples

Here's what happens if **SIGNAL** is used in the client to generate errors:

```
SIGNAL SQLSTATE '01000';
Query OK, 0 rows affected, 1 warning (0.00 sec)

SHOW WARNINGS;

+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1642 | Unhandled user-defined warning condition |
+-----+-----+-----+
1 row in set (0.06 sec)

SIGNAL SQLSTATE '02000';
ERROR 1643 (02000): Unhandled user-defined not found condition
```

How to specify MYSQL_ERRNO and MESSAGE_TEXT properties:

```
SIGNAL SQLSTATE '45000' SET MYSQL_ERRNO=30001, MESSAGE_TEXT='Hello, world!';

ERROR 30001 (45000): Hello, world!
```

The following code shows how to use user variables, local variables and character set conversion with SIGNAL:

```
CREATE PROCEDURE test_error(x INT)
BEGIN
  DECLARE errno SMALLINT UNSIGNED DEFAULT 31001;
  SET @errmsg = 'Hello, world!';
  IF x = 1 THEN
    SIGNAL SQLSTATE '45000' SET
      MYSQL_ERRNO = errno,
      MESSAGE_TEXT = @errmsg;
  ELSE
    SIGNAL SQLSTATE '45000' SET
      MYSQL_ERRNO = errno,
      MESSAGE_TEXT = _utf8'Hello, world!';
  END IF;
END;
```

How to use named error conditions:

```

CREATE PROCEDURE test_error(n INT)
BEGIN
  DECLARE `too_big` CONDITION FOR SQLSTATE '45000';
  IF n > 10 THEN
    SIGNAL `too_big`;
  END IF;
END;

```

In this example, we'll define a [HANDLER](#) for an error code. When the error occurs, we [SIGNAL](#) a more informative error which makes sense for our procedure:

```

CREATE PROCEDURE test_error()
BEGIN
  DECLARE EXIT HANDLER
  FOR 1146
  BEGIN
    SIGNAL SQLSTATE '45000' SET
    MESSAGE_TEXT = 'Temporary tables not found; did you call init() procedure?';
  END;
  -- this will produce a 1146 error
  SELECT `c` FROM `temptab`;
END;

```

1.1.1.6.20 WHILE

Syntax

```

[begin_label:] WHILE search_condition DO
  statement_list
END WHILE [end_label]

```

Description

The statement list within a `WHILE` statement is repeated as long as the `search_condition` is true. `statement_list` consists of one or more statements. If the loop must be executed at least once, `REPEAT ... LOOP` can be used instead.

A `WHILE` statement can be [labeled](#). `end_label` cannot be given unless `begin_label` also is present. If both are present, they must be the same.

Examples

```

CREATE PROCEDURE dowhile ()
BEGIN
  DECLARE v1 INT DEFAULT 5;

  WHILE v1 > 0 DO
    ...
    SET v1 = v1 - 1;
  END WHILE;
END

```

1.1.1.6.21 Cursors

A cursor is a structure that allows you to go over records sequentially, and perform processing based on the result.

Cursor Overview

Structure for traversing and processing results sequentially.

DECLARE CURSOR

Declares a cursor which can be used inside stored programs.

OPEN

Open a previously declared cursor.

FETCH

Fetch a row from a cursor.

CLOSE

Close a previously opened cursor.

There are [1 related questions](#)

1.1.1.6.21.1 Cursor Overview

Contents

- [Description](#)
- [Examples](#)

Description

A cursor is a structure that allows you to go over records sequentially, and perform processing based on the result.

MariaDB permits cursors inside [stored programs](#), and MariaDB cursors are non-scrollable, read-only and asensitive.

- Non-scrollable means that the rows can only be fetched in the order specified by the SELECT statement. Rows cannot be skipped, you cannot jump to a specific row, and you cannot fetch rows in reverse order.
- Read-only means that data cannot be updated through the cursor.
- Asensitive means that the cursor points to the actual underlying data. This kind of cursor is quicker than the alternative, an insensitive cursor, as no data is copied to a temporary table. However, changes to the data being used by the cursor will affect the cursor data.

Cursors are created with a [DECLARE CURSOR](#) statement and opened with an [OPEN](#) statement. Rows are read with a [FETCH](#) statement before the cursor is finally closed with a [CLOSE](#) statement.

When FETCH is issued and there are no more rows to extract, the following error is produced:

```
ERROR 1329 (02000): No data - zero rows fetched, selected, or processed
```

To avoid problems, a [DECLARE HANDLER](#) statement is generally used. The HANDLER should handle the 1329 error, or the '02000' [SQLSTATE](#), or the NOT FOUND error class.

Only [SELECT](#) statements are allowed for cursors, and they cannot be contained in a variable - so, they cannot be composed dynamically. However, it is possible to SELECT from a view. Since the [CREATE VIEW](#) statement can be executed as a prepared statement, it is possible to dynamically create the view that is queried by the cursor.

From [MariaDB 10.3.0](#) , cursors can have parameters. Cursor parameters can appear in any part of the [DECLARE CURSOR](#) select_statement where a stored procedure variable is allowed (select list, WHERE, HAVING, LIMIT etc). See [DECLARE CURSOR](#) and [OPEN](#) for syntax, and below for an example:

Examples

```

CREATE TABLE c1(i INT);

CREATE TABLE c2(i INT);

CREATE TABLE c3(i INT);

DELIMITER //

CREATE PROCEDURE p1()
BEGIN
    DECLARE done INT DEFAULT FALSE;
    DECLARE x, y INT;
    DECLARE cur1 CURSOR FOR SELECT i FROM test.c1;

1.1.1.6.21.2 DECLARE CURSOR

Syntax

<= [MariaDB 10.2](#)

```
DECLARE cursor_name CURSOR FOR select_statement
```

From [MariaDB 10.3](#)

```
DECLARE cursor_name CURSOR [(cursor_formal_parameter[,...])] FOR select_statement
```

```
cursor_formal_parameter:
    name type [collate clause]
```

From [MariaDB 10.8](#)

```
DECLARE cursor_name CURSOR [(cursor_formal_parameter[,...])] FOR select_statement
```

```
cursor_formal_parameter:
    [IN] name type [collate clause]
```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [Parameters](#)
 2. [IN](#)

Description

This statement declares a [cursor](#). Multiple cursors may be declared in a [stored program](#), but each cursor in a given block must have a unique name.

`select_statement` is not executed until the [OPEN](#) statement is executed. It is important to remember this if the query produces an error, or calls functions which have side effects.

A `SELECT` associated to a cursor can use variables, but the query itself cannot be a variable, and cannot be dynamically composed. The `SELECT` statement cannot have an `INTO` clause.

Cursors must be declared before [HANDLERS](#), but after local variables and [CONDITIONS](#).

Parameters

From [MariaDB 10.3.0](#), cursors can have parameters. This is a non-standard SQL extension. Cursor parameters can appear in any part of the `DECLARE CURSOR select_statement` where a stored procedure variable is allowed (`select list`, `WHERE`, `HAVING`, `LIMIT` etc).

IN

MariaDB starting with [10.8.0](#)

From [MariaDB 10.8.0](#) preview release, the `IN` qualifier is supported in the `cursor_format_parameter` part of the syntax.

See [Cursor Overview](#) for an example.

1.1.1.6.21.3 OPEN

Syntax

<= [MariaDB 10.2](#)

```
OPEN cursor_name
```

From [MariaDB 10.3](#)

```
OPEN cursor_name [expression[,...]];
```

Contents

1. [Syntax](#)
2. [Description](#)

Description

This statement opens a [cursor](#) which was previously declared with [DECLARE CURSOR](#).

The query associated to the `DECLARE CURSOR` is executed when `OPEN` is executed. It is important to remember this if the query produces an error, or calls functions which have side effects.

This is necessary in order to [FETCH](#) rows from a cursor.

See [Cursor Overview](#) for an example.

1.1.1.6.21.4 FETCH

Syntax

```
FETCH cursor_name INTO var_name [, var_name] ...
```

Contents

1. [Syntax](#)
2. [Description](#)

Description

This statement fetches the next row (if a row exists) using the specified [open cursor](#), and advances the cursor pointer.

`var_name` can be a [local variable](#), but *not* a [user-defined variable](#).

If no more rows are available, a No Data condition occurs with `SQLSTATE` value `02000`. To detect this condition, you can set up a handler for it (or for a `NOT FOUND` condition).

See [Cursor Overview](#) for an example.

1.1.1.6.21.5 CLOSE

Syntax

```
CLOSE cursor_name
```

Contents

1. [Syntax](#)
2. [Description](#)

Description

This statement closes a previously [opened](#) cursor. The cursor must have been previously opened or else an error occurs.

If not closed explicitly, a cursor is closed at the end of the compound statement in which it was declared.

See [Cursor Overview](#) for an example.

1.1.1.7 Stored Routine Statements

CALL

Invokes a stored procedure.

DO

Executes expressions without returning results.

There are [1 related questions](#) [↗](#).

1.1.1.7.1 CALL

Syntax

```
CALL sp_name([parameter[,...]])  
CALL sp_name[()]
```

Description

The `CALL` statement invokes a [stored procedure](#) that was defined previously with `CREATE PROCEDURE`.

Stored procedure names can be specified as `database_name.procedure_name`. Procedure names and database names can be quoted with backticks (```). This is necessary if they are reserved words, or contain special characters. See [identifier qualifiers](#) for details.

`CALL p()` and `CALL p` are equivalent.

If parentheses are used, any number of spaces, tab characters and newline characters are allowed between the procedure's name and the open parenthesis.

`CALL` can pass back values to its caller using parameters that are declared as `OUT` or `INOUT` parameters. If no value is assigned to an `OUT` parameter, `NULL` is assigned (and its former value is lost). To pass such values from another stored program you can use [user-defined variables](#), [local variables](#) or routine's parameters; in other contexts, you can only use user-defined variables.

`CALL` can also be executed as a prepared statement. Placeholders can be used for `IN` parameters in all versions of MariaDB; for `OUT` and `INOUT` parameters, placeholders can be used since [MariaDB 5.5](#).

When the procedure returns, a client program can also obtain the number of rows affected for the final statement executed within the routine: At the SQL level, call the `ROW_COUNT()` function; from the C API, call the `mysql_affected_rows()` function.

If the `CLIENT_MULTI_RESULTS` API flag is set, `CALL` can return any number of resultsets and the called stored procedure can execute prepared statements. If it is not set, at most one resultset can be returned and prepared statements cannot be used within procedures.

1.1.1.7.2 DO

Syntax

```
DO expr [, expr] ...
```

Description

`DO` executes the expressions but does not return any results. In most respects, `DO` is shorthand for `SELECT expr, ...`, but has the advantage that it is slightly faster when you do not care about the result.

`DO` is useful primarily with functions that have side effects, such as `RELEASE_LOCK()`.

1.1.1.2.1 Table Statements

1.1.1.9 Transactions

"An SQL-transaction (transaction) is a sequence of executions of SQL-statements that is atomic with respect to recovery. That is to say: either the execution result is completely successful, or it has no effect on any SQL-schemas or SQL-data."

— The SQL Standard

The [InnoDB](#) storage engine supports [ACID](#)-compliant transactions.

Transaction Articles

START TRANSACTION

[Basic transaction control statements.](#)

COMMIT

[Ends a transaction, making changes visible to subsequent transactions](#)

ROLLBACK

[Cancel current transaction and the changes to data](#)

SET TRANSACTION

[Sets the transaction isolation level.](#)

LOCK TABLES

5

Explicitly lock tables.

SAVEPOINT

1

SAVEPOINT for a ROLLBACK.

Metadata Locking

A lock which protects each transaction from external DDL statements.

SQL statements That Cause an Implicit Commit

List of statements which implicitly commit the current transaction

Transaction Timeouts

Timing out idle transactions

UNLOCK TABLES

Explicitly releases any table locks held by the current session.

WAIT and NOWAIT

Extended syntax so that it is possible to set lock wait timeout for certain statements.

XA Transactions

Transactions designed to allow distributed transactions.

READ COMMITTED

Each consistent read, even within the same transaction, sets and reads its own fresh snapshot.

READ UNCOMMITTED

SELECT statements are performed in a non-locking fashion, but a possible ea...

REPEATABLE READ

All consistent reads within the same transaction read the snapshot established by the first read.

SERIALIZABLE

Similar to REPEATABLE READ, with SELECT ... LOCK IN SHARE MODE if autocommit is disabled.

1.1.1.9.1 START TRANSACTION

Syntax

```
START TRANSACTION [transaction_property [, transaction_property] ...] | BEGIN [WORK]
COMMIT [WORK] [AND [NO] CHAIN] [[NO] RELEASE]
ROLLBACK [WORK] [AND [NO] CHAIN] [[NO] RELEASE]
SET autocommit = {0 | 1}
```

```
transaction_property:
    WITH CONSISTENT SNAPSHOT
    | READ WRITE
    | READ ONLY
```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [Access Mode](#)
 2. [autocommit](#)
 3. [DDL Statements](#)
 4. [in_transaction](#)
 5. [WITH CONSISTENT SNAPSHOT](#)
3. [Examples](#)

Description

The `START TRANSACTION` or `BEGIN` statement begins a new transaction. `COMMIT` commits the current transaction, making its changes permanent. `ROLLBACK` rolls back the current transaction, canceling its changes. The `SET autocommit` statement disables or enables the default autocommit mode for the current session.

`START TRANSACTION` and `SET autocommit = 1` implicitly commit the current transaction, if any.

The optional `WORK` keyword is supported for `COMMIT` and `ROLLBACK`, as are the `CHAIN` and `RELEASE` clauses. `CHAIN` and `RELEASE` can be used for additional control over transaction completion. The value of the `completion_type` system variable determines the default completion behavior.

The `AND CHAIN` clause causes a new transaction to begin as soon as the current one ends, and the new transaction has the same isolation level as the just-terminated transaction. The `RELEASE` clause causes the server to disconnect the current client session after terminating the current transaction. Including the `NO` keyword suppresses `CHAIN` or `RELEASE` completion, which can be useful if the `completion_type` system variable is set to cause chaining or release completion by default.

Access Mode

The access mode specifies whether the transaction is allowed to write data or not. By default, transactions are in `READ WRITE` mode (see the `tx_read_only` system variable). `READ ONLY` mode allows the storage engine to apply optimizations that cannot be used for transactions which write data. Note that unlike the global `read_only` mode, `READ ONLY ADMIN` (and `SUPER` before [MariaDB 10.11.0](#)) privilege doesn't allow writes and DDL statements on temporary tables are not allowed either.

It is not permitted to specify both `READ WRITE` and `READ ONLY` in the same statement.

`READ WRITE` and `READ ONLY` can also be specified in the `SET TRANSACTION` statement, in which case the specified mode is valid for all sessions, or for all subsequent transaction used by the current session.

autocommit

By default, MariaDB runs with `autocommit` mode enabled. This means that as soon as you execute a statement that updates (modifies) a table, MariaDB stores the update on disk to make it permanent. To disable autocommit mode, use the following statement:

```
SET autocommit=0;
```

After disabling autocommit mode by setting the autocommit variable to zero, changes to transaction-safe tables (such as those for InnoDB or `NDBCLUSTER`) are not made permanent immediately. You must use `COMMIT` to store your changes to disk or `ROLLBACK` to ignore the changes.

To disable autocommit mode for a single series of statements, use the `START TRANSACTION` statement.

DDL Statements

DDL statements (`CREATE`, `ALTER`, `DROP`) and administrative statements (`FLUSH`, `RESET`, `OPTIMIZE`, `ANALYZE`, `CHECK`, `REPAIR`, `CACHE INDEX`), transaction management statements (`BEGIN`, `START TRANSACTION`) and `LOAD DATA INFILE`, cause an implicit `COMMIT` and start a new transaction. An exception to this rule are the DDL that operate on temporary tables: you can `CREATE`, `ALTER` and `DROP` them without causing any `COMMIT`, but those actions cannot be rolled back. This means that if you call `ROLLBACK`, the temporary tables you created in the transaction will remain, while the rest of the transaction will be rolled back.

Transactions cannot be used in Stored Functions or Triggers. In Stored Procedures and Events `BEGIN` is not allowed, so you should use `START TRANSACTION` instead.

A transaction acquires a `metadata lock` on every table it accesses to prevent other connections from altering their structure. The lock is released at the end of the transaction. This happens even with non-transactional storage engines (like `MEMORY` or `CONNECT`), so it makes sense to use transactions with non-transactional tables.

in_transaction

The `in_transaction` system variable is a session-only, read-only variable that returns `1` inside a transaction, and `0` if not in a transaction.

WITH CONSISTENT SNAPSHOT

The `WITH CONSISTENT SNAPSHOT` option starts a consistent read for storage engines such as [InnoDB](#) that can do so, the same as if a `START TRANSACTION` followed by a `SELECT` from any InnoDB table was issued.

See [Enhancements for START TRANSACTION WITH CONSISTENT SNAPSHOT](#).

Examples

```
START TRANSACTION;
SELECT @A:=SUM(salary) FROM table1 WHERE type=1;
UPDATE table2 SET summary=@A WHERE type=1;
COMMIT;
```

1.1.1.9.2 COMMIT

The `COMMIT` statement ends a transaction, saving any changes to the data so that they become visible to subsequent transactions. Also, [unlocks metadata](#) changed by current transaction. If `autocommit` is set to 1, an implicit commit is performed after each statement. Otherwise, all transactions which don't end with an explicit `COMMIT` are implicitly rolled back and the changes are lost. The `ROLLBACK` statement can be used to do this explicitly.

The required syntax for the `COMMIT` statement is as follows:

```
COMMIT [WORK] [AND [NO] CHAIN] [[NO] RELEASE]
```

`COMMIT` is the more important transaction terminator, as well as the more interesting one. The basic form of the `COMMIT` statement is simply the keyword `COMMIT` (the keyword `WORK` is simply noise and can be omitted without changing the effect).

The optional `AND CHAIN` clause is a convenience for initiating a new transaction as soon as the old transaction terminates. If `AND CHAIN` is specified, then there is effectively nothing between the old and new transactions, although they remain separate. The characteristics of the new transaction will be the same as the characteristics of the old one — that is, the new transaction will have the same access mode, isolation level and diagnostics area size (we'll discuss all of these shortly) as the transaction just terminated.

`RELEASE` tells the server to disconnect the client immediately after the current transaction.

There are `NO RELEASE` and `AND NO CHAIN` options. By default, commits do not `RELEASE` or `CHAIN`, but it's possible to change this default behavior with the `completion_type` server system variable. In this case, the `AND NO CHAIN` and `NO RELEASE` options override the server default.

1.1.1.9.3 ROLLBACK

The `ROLLBACK` statement rolls back (ends) a transaction, destroying any changes to SQL-data so that they never become visible to subsequent transactions. The required syntax for the `ROLLBACK` statement is as follows.

```
ROLLBACK [ WORK ] [ AND [ NO ] CHAIN ]
[ TO [ SAVEPOINT ] {<savepoint name> | <simple target specification> } ]
```

The `ROLLBACK` statement will either end a transaction, destroying all data changes that happened during any of the transaction, or it will just destroy any data changes that happened since you established a savepoint. The basic form of the `ROLLBACK` statement is just the keyword `ROLLBACK` (the keyword `WORK` is simply noise and can be omitted without changing the effect).

The optional `AND CHAIN` clause is a convenience for initiating a new transaction as soon as the old transaction terminates. If `AND CHAIN` is specified, then there is effectively nothing between the old and new transactions, although they remain separate. The characteristics of the new transaction will be the same as the characteristics of the old one — that is, the new transaction will have the same access mode, isolation level and diagnostics area size (we'll discuss all of these shortly) as the transaction just terminated. The `AND NO CHAIN` option just tells your DBMS to end the transaction — that is, these four SQL statements are equivalent:

```
ROLLBACK;
ROLLBACK WORK;
ROLLBACK AND NO CHAIN;
ROLLBACK WORK AND NO CHAIN;
```

All of them end a transaction without saving any transaction characteristics. The only other options, the equivalent statements:

```
ROLLBACK AND CHAIN;  
ROLLBACK WORK AND CHAIN;
```

both tell your DBMS to end a transaction, but to save that transaction's characteristics for the next transaction.

`ROLLBACK` is much simpler than `COMMIT`: it may involve no more than a few deletions (of Cursors, locks, prepared SQL statements and log-file entries). It's usually assumed that `ROLLBACK` can't fail, although such a thing is conceivable (for example, an encompassing transaction might reject an attempt to `ROLLBACK` because it's lining up for a `COMMIT`).

`ROLLBACK` cancels all effects of a transaction. It does not cancel effects on objects outside the DBMS's control (for example the values in host program variables or the settings made by some SQL/CLI function calls). But in general, it is a convenient statement for those situations when you say "oops, this isn't working" or when you simply don't care whether your temporary work becomes permanent or not.

Here is a moot question. If all you've been doing is `SELECT` s, so that there have been no data changes, should you end the transaction with `ROLLBACK` or `COMMIT`? It shouldn't really matter because both `ROLLBACK` and `COMMIT` do the same transaction-terminating job. However, the popular conception is that `ROLLBACK` implies failure, so after a successful series of `SELECT` statements the convention is to end the transaction with `COMMIT` rather than `ROLLBACK`.

MariaDB (and most other DBMSs) supports rollback of SQL-data change statements, but not of SQL-Schema statements. This means that if you use any of `CREATE`, `ALTER`, `DROP`, `GRANT`, `REVOKE`, you are implicitly committing at execution time.

```
INSERT INTO Table_2 VALUES (5);  
DROP TABLE Table_3 CASCADE;  
ROLLBACK;
```

The result will be that both the `INSERT` and the `DROP` will go through as separate transactions so the `ROLLBACK` will have no effect.

1.1.1.9.4 SET TRANSACTION

Syntax

```
SET [GLOBAL | SESSION] TRANSACTION  
    transaction_property [, transaction_property] ...  
  
transaction_property:  
    ISOLATION LEVEL level  
    | READ WRITE  
    | READ ONLY  
  
level:  
    REPEATABLE READ  
    | READ COMMITTED  
    | READ UNCOMMITTED  
    | SERIALIZABLE
```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [Isolation Level](#)
 2. [Isolation Levels](#)
 1. [READ UNCOMMITTED](#)
 2. [READ COMMITTED](#)
 3. [REPEATABLE READ](#)
 4. [SERIALIZABLE](#)
 5. [innodb_snapshot_isolation](#)
 3. [Access Mode](#)
3. [Examples](#)

Description

This statement sets the transaction isolation level or the transaction access mode globally, for the current session, or for the next transaction:

- With the `GLOBAL` keyword, the statement sets the default transaction level globally for all subsequent sessions. Existing sessions are unaffected.
- With the `SESSION` keyword, the statement sets the default transaction level for all subsequent transactions performed within the current session.
- Without any `SESSION` or `GLOBAL` keyword, the statement sets the isolation level for only the next (not started) transaction performed within the current session. After that it reverts to using the session value.

A change to the global default isolation level requires the `SUPER` privilege. Any session is free to change its session isolation level (even in the middle of a transaction), or the isolation level for its next transaction.

Isolation Level

To set the global default isolation level at server startup, use the `--transaction-isolation=level` option on the command line or in an option file. Values of level for this option use dashes rather than spaces, so the allowable values are `READ_UNCOMMITTED`, `READ-COMMITTED`, `REPEATABLE-READ`, or `SERIALIZABLE`. For example, to set the default isolation level to `REPEATABLE READ`, use these lines in the `[mariadb]` section of an option file:

```
[mariadb]
transaction-isolation = REPEATABLE-READ
```

To determine the global and session transaction isolation levels at runtime, check the value of the `tx_isolation` system variable (note that the variable has been renamed `transaction_isolation` from `MariaDB 11.1.1` to match the option, and the old name deprecated).

```
SELECT @@GLOBAL.tx_isolation, @@tx_isolation;
```

From `MariaDB 11.1.1`:

```
SELECT @@GLOBAL.transaction_isolation, @@transaction_isolation;
```

InnoDB supports each of the transaction isolation levels described here using different locking strategies. The default level is `REPEATABLE READ`. For additional information about InnoDB record-level locks and how it uses them to execute various types of statements, see [InnoDB Lock Modes](#), and <http://dev.mysql.com/doc/refman/en/innodb-locks-set.html>.

Isolation Levels

The following sections describe how MariaDB supports the different transaction levels.

READ UNCOMMITTED

`SELECT` statements are performed in a non-locking fashion, but a possible earlier version of a row might be used. Thus, using this isolation level, such reads are not consistent. This is also called a "dirty read." Otherwise, this isolation level works like `READ COMMITTED`.

READ COMMITTED

A somewhat Oracle-like isolation level with respect to consistent (non-locking) reads: Each consistent read, even within the same transaction, sets and reads its own fresh snapshot. See <http://dev.mysql.com/doc/refman/en/innodb-consistent-read.html>.

For locking reads (`SELECT` with `FOR UPDATE` or `LOCK IN SHARE MODE`), InnoDB locks only index records, not the gaps before them, and thus allows the free insertion of new records next to locked records. For `UPDATE` and `DELETE` statements, locking depends on whether the statement uses a unique index with a unique search condition (such as `WHERE id = 100`), or a range-type search condition (such as `WHERE id > 100`). For a unique index with a unique search condition, InnoDB locks only the index record found, not the gap before it. For range-type searches, InnoDB locks the index range scanned, using gap locks or next-key (gap plus index-record) locks to block insertions by other sessions into the gaps covered by the range. This is necessary because "phantom rows" must be blocked for MariaDB replication and recovery to work.

Note: If the `READ COMMITTED` isolation level is used or the `innodb_locks_unsafe_for_binlog` system variable is enabled, there is no InnoDB gap locking except for `foreign-key` constraint checking and duplicate-key checking. Also, record locks for non-matching rows are released after MariaDB has evaluated the `WHERE` condition. If you use `READ COMMITTED` or enable `innodb_locks_unsafe_for_binlog`, you must use row-based binary logging.

REPEATABLE READ

This is the default isolation level for InnoDB. For consistent reads, there is an important difference from the `READ COMMITTED` isolation level: All consistent reads within the same transaction read the snapshot established by the first read. This convention means that if you issue several plain (non-locking) `SELECT` statements within the same transaction, these `SELECT` statements are consistent also with respect to each other. See <http://dev.mysql.com/doc/refman/en/innodb-consistent-read.html>.

For locking reads (`SELECT` with `FOR UPDATE` or `LOCK IN SHARE MODE`), `UPDATE`, and `DELETE` statements, locking depends on whether the statement uses a unique index with a unique search condition, or a range-type search condition. Prior to [MariaDB 10.3.38](#), [MariaDB 10.4.28](#), [MariaDB 10.5.19](#), [MariaDB 10.6.12](#), [MariaDB 10.7.8](#), [MariaDB 10.8.7](#), [MariaDB 10.9.5](#), [MariaDB 10.10.3](#), [MariaDB 10.11.2](#) and [MariaDB 11.0.0](#), for a unique index with a unique search condition, InnoDB locks only the index record found, not the gap before it. From these versions, MariaDB no longer relaxes the gap locking for unique indexes.

For other search conditions, InnoDB locks the index range scanned, using gap locks or next-key (gap plus index-record) locks to block insertions by other sessions into the gaps covered by the range.

This is the minimum isolation level for non-distributed [XA transactions](#).

SERIALIZABLE

This level is like `REPEATABLE READ`, but InnoDB implicitly converts all plain `SELECT` statements to `SELECT ... LOCK IN SHARE MODE` if `autocommit` is disabled. If `autocommit` is enabled, the `SELECT` is its own transaction. It therefore is known to be read only and can be serialized if performed as a consistent (non-locking) read and need not block for other transactions. (This means that to force a plain `SELECT` to block if other transactions have modified the selected rows, you should disable `autocommit`.)

Distributed [XA transactions](#) should always use this isolation level.

innodb_snapshot_isolation

If the `innodb_snapshot_isolation` system variable is not set to `ON`, strictly-speaking anything other than `READ UNCOMMITTED` is not clearly defined. `innodb_snapshot_isolation` was introduced in [MariaDB 10.6.18](#), [MariaDB 10.11.8](#), [MariaDB 11.0.6](#), [MariaDB 11.1.5](#), [MariaDB 11.2.4](#), [MariaDB 11.4.2](#) to address this, but defaults to `OFF` for backwards compatibility. Setting to `ON` will result in attempts to acquire a lock on a record that does not exist in the current read view raising an error, and the transaction being rolled back.

Access Mode

The access mode specifies whether the transaction is allowed to write data or not. By default, transactions are in `READ WRITE` mode (see the `tx_read_only` system variable). `READ ONLY` mode allows the storage engine to apply optimizations that cannot be used for transactions which write data. Note that unlike the global `read_only` mode, `READ_ONLY ADMIN` (and `SUPER` before [MariaDB 10.11.0](#)) privilege doesn't allow writes and DDL statements on temporary tables are not allowed either.

It is not permitted to specify both `READ WRITE` and `READ ONLY` in the same statement.

`READ WRITE` and `READ ONLY` can also be specified in the `START TRANSACTION` statement, in which case the specified mode is only valid for one transaction.

Examples

```
SET GLOBAL TRANSACTION ISOLATION LEVEL SERIALIZABLE;
```

Attempting to set the isolation level within an existing transaction without specifying `GLOBAL` or `SESSION`.

```
START TRANSACTION;

SET TRANSACTION ISOLATION LEVEL SERIALIZABLE;
ERROR 1568 (25001): Transaction characteristics can't be changed while a transaction is in progress
```

1.1.1.9.5 LOCK TABLES

Syntax

```
LOCK TABLE[S]
tbl_name [[AS] alias] lock_type
[, tbl_name [[AS] alias] lock_type] ...
[WAIT n|NOWAIT]

lock_type:
  READ [LOCAL]
  | [LOW_PRIORITY] WRITE
  | WRITE CONCURRENT

UNLOCK TABLES
```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [Aliases](#)
 2. [WAIT/NOWAIT](#)
3. [Limitations](#)

Description

The *lock_type* can be one of:

Option	Description
READ	Read lock, no writes allowed
READ LOCAL	Read lock, but allow concurrent inserts
WRITE	Exclusive write lock. No other connections can read or write to this table
LOW_PRIORITY WRITE	Exclusive write lock, but allow new read locks on the table until we get the write lock.
WRITE CONCURRENT	Exclusive write lock, but allow READ LOCAL locks to the table.

MariaDB enables client sessions to acquire table locks explicitly for the purpose of cooperating with other sessions for access to tables, or to prevent other sessions from modifying tables during periods when a session requires exclusive access to them. A session can acquire or release locks only for itself. One session cannot acquire locks for another session or release locks held by another session.

Locks may be used to emulate transactions or to get more speed when updating tables.

`LOCK TABLES` explicitly acquires table locks for the current client session. Table locks can be acquired for base tables or views. To use `LOCK TABLES`, you must have the `LOCK TABLES` privilege, and the `SELECT` privilege for each object to be locked. See [GRANT](#)

For view locking, `LOCK TABLES` adds all base tables used in the view to the set of tables to be locked and locks them automatically. If you lock a table explicitly with `LOCK TABLES`, any tables used in triggers are also locked implicitly, as described in [Triggers and Implicit Locks](#).

`UNLOCK TABLES` explicitly releases any table locks held by the current session.

Aliases

Aliases need to correspond to the aliases used in prior SQL statements in the session. For example:

```
LOCK TABLE t1 AS t1_alias1 READ;

SELECT * FROM t1;
ERROR 1100 (HY000): Table 't1' was not locked with LOCK TABLES

SELECT * FROM t1 AS t1_alias2;
ERROR 1100 (HY000): Table 't1_alias2' was not locked with LOCK TABLES

SELECT * FROM t1 AS t1_alias1;
```

WAIT/NOWAIT

Set the lock wait timeout. See [WAIT and NOWAIT](#).

Limitations

- `LOCK TABLES` [doesn't work when using Galera cluster](#). You may experience crashes or locks when used with Galera.
- `LOCK TABLES` works on XtraDB/InnoDB tables only if the `innodb_table_locks` system variable is set to 1 (the default) and `autocommit` is set to 0 (1 is default). Please note that no error message will be returned on `LOCK TABLES` with `innodb_table_locks = 0`.
- `LOCK TABLES` [implicitly commits](#) the active transaction, if any. Also, starting a transaction always releases all table locks acquired with `LOCK TABLES`. This means that there is no way to have table locks and an active transaction at the same time. The only exceptions are the transactions in `autocommit` mode. To preserve the data integrity between transactional and non-transactional tables, the `GET_LOCK()` function can be used.
- When using `LOCK TABLES` on a `TEMPORARY` table, it will always be locked with a `WRITE` lock.
- While a connection holds an explicit read lock on a table, it cannot modify it. If you try, the following error will be produced:

```
ERROR 1099 (HY000): Table 'tab_name' was locked with a READ lock and can't be updated
```

- While a connection holds an explicit lock on a table, it cannot access a non-locked table. If you try, the following error will be produced:

```
ERROR 1100 (HY000): Table 'tab_name' was not locked with LOCK TABLES
```

- While a connection holds an explicit lock on a table, it cannot issue the following: `INSERT DELAYED`, `CREATE TABLE`, `CREATE TABLE ... LIKE`, and DDL statements involving stored programs and views (except for triggers). If you try, the following error will be produced:

```
ERROR 1192 (HY000): Can't execute the given command because you have active locked tables or an active transaction
```

- `LOCK TABLES` can not be used in stored routines - if you try, the following error will be produced on creation:

```
ERROR 1314 (0A000): LOCK is not allowed in stored procedures
```

1.1.1.9.6 SAVEPOINT

Syntax

```
SAVEPOINT identifier  
ROLLBACK [WORK] TO [SAVEPOINT] identifier  
RELEASE SAVEPOINT identifier
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Errors](#)

Description

InnoDB supports the SQL statements `SAVEPOINT`, `ROLLBACK TO SAVEPOINT`, `RELEASE SAVEPOINT` and the optional `WORK` keyword for `ROLLBACK`.

Each savepoint must have a legal [MariaDB identifier](#). A savepoint is a named sub-transaction.

Normally `ROLLBACK` undoes the changes performed by the whole transaction. When used with the `TO` clause, it undoes the changes performed after the specified savepoint, and erases all subsequent savepoints. However, all locks that have been acquired after the save point will survive. `RELEASE SAVEPOINT` does not rollback or commit any changes, but removes the specified savepoint.

When the execution of a trigger or a stored function begins, it is not possible to use statements which reference a savepoint which was defined from out of that stored program.

When a [COMMIT](#) (including implicit commits) or a [ROLLBACK](#) statement (with no TO clause) is performed, they act on the whole transaction, and all savepoints are removed.

Errors

If COMMIT or ROLLBACK is issued and no transaction was started, no error is reported.

If SAVEPOINT is issued and no transaction was started, no error is reported but no savepoint is created. When ROLLBACK TO SAVEPOINT or RELEASE SAVEPOINT is called for a savepoint that does not exist, an error like this is issued:

```
ERROR 1305 (42000): SAVEPOINT svp_name does not exist
```

1.1.1.9.7 Metadata Locking

MariaDB supports metadata locking. This means that when a transaction (including [XA transactions](#)) uses a table, it locks its metadata until the end of transaction. Non-transactional tables are also locked, as well as views and objects which are related to locked tables/views (stored functions, triggers, etc). When a connection tries to use a DDL statement (like an [ALTER TABLE](#)) which modifies a table that is locked, that connection is queued, and has to wait until it's unlocked. Using savepoints and performing a partial rollback does not release metadata locks.

[LOCK TABLES ... WRITE](#) are also queued. Some wrong statements which produce an error may not need to wait for the lock to be freed.

The metadata lock's timeout is determined by the value of the [lock_wait_timeout](#) server system variable (in seconds). However, note that its default value is 31536000 (1 year, MariaDB <= 10.2.3), or 86400 (1 day, MariaDB >= 10.2.4). If this timeout is exceeded, the following error is returned:

```
ERROR 1205 (HY000): Lock wait timeout exceeded; try restarting transaction
```

If the [metadata_lock_info](#) plugin is installed, the [Information Schema metadata_lock_info](#) table stores information about existing metadata locks.

MariaDB starting with [10.5.2](#)

From [MariaDB 10.5](#), the [Performance Schema metadata_locks](#) table contains metadata lock information.

Example

Let's use the following MEMORY (non-transactional) table:

```
CREATE TABLE t (a INT) ENGINE = MEMORY;
```

Connection 1 starts a transaction, and INSERTs a row into t:

```
START TRANSACTION;
INSERT INTO t SET a=1;
```

t's metadata is now locked by connection 1. Connection 2 tries to alter t, but has to wait:

```
ALTER TABLE t ADD COLUMN b INT;
```

Connection 2's prompt is blocked now.

Now connection 1 ends the transaction:

```
COMMIT;
```

...and connection 2 finally gets the output of its command:

```
Query OK, 1 row affected (35.23 sec)
Records: 1 Duplicates: 0 Warnings: 0
```

1.1.1.9.8 SQL statements That Cause an Implicit Commit

Some SQL statements cause an implicit commit. As a rule of thumb, such statements are DDL statements. The same statements (except for [SHUTDOWN](#)) produce a 1400 error (`SQLSTATE 'XAE09'`) if a XA transaction is in effect.

Here is the list:

```
ALTER DATABASE ... UPGRADE DATA DIRECTORY NAME
ALTER EVENT
ALTER FUNCTION
ALTER PROCEDURE
ALTER SEQUENCE
ALTER SERVER
ALTER TABLE
ALTER VIEW
ANALYZE TABLE
BEGIN
CACHE INDEX
CHANGE MASTER TO
CHECK TABLE
CREATE DATABASE
CREATE EVENT
CREATE FUNCTION
CREATE INDEX
CREATE PROCEDURE
CREATE ROLE
CREATE SEQUENCE
CREATE SERVER
CREATE TABLE
CREATE TRIGGER
CREATE USER
CREATE VIEW
DROP DATABASE
DROP EVENT
DROP FUNCTION
DROP INDEX
DROP PROCEDURE
DROP ROLE
DROP SEQUENCE
DROP SERVER
DROP TABLE
DROP TRIGGER
DROP USER
DROP VIEW
FLUSH
GRANT
LOAD INDEX INTO CACHE
LOCK TABLES
OPTIMIZE TABLE
RENAME TABLE
RENAME USER
REPAIR TABLE
RESET
REVOKE
SET PASSWORD
SHUTDOWN
START SLAVE
START TRANSACTION
STOP SLAVE
TRUNCATE TABLE
```

`SET autocommit = 1` causes an implicit commit if the value was 0.

All these statements cause an implicit commit before execution. This means that, even if the statement fails with an error, the transaction is committed. Some of them, like `CREATE TABLE ... SELECT`, also cause a commit immediately after execution. Such statements couldn't be rolled back in any case.

If you are not sure whether a statement has implicitly committed the current transaction, you can query the [in_transaction](#) server system variable.

Note that when a transaction starts (not in autocommit mode), all locks acquired with [LOCK TABLES](#) are released. And

acquiring such locks always commits the current transaction. To preserve the data integrity between transactional and non-transactional tables, the `GET_LOCK()` function can be used.

Exceptions

These statements do not cause an implicit commit in the following cases:

- `CREATE TABLE` and `DROP TABLE`, when the `TEMPORARY` keyword is used.
 - However, `TRUNCATE TABLE` causes an implicit commit even when used on a temporary table.
- `CREATE FUNCTION` and `DROP FUNCTION`, when used to create a UDF (instead of a stored function). However, `CREATE INDEX` and `DROP INDEX` cause commits even when used with temporary tables.
- `UNLOCK TABLES` causes a commit only if a `LOCK TABLES` was used on non-transactional tables.
- `START SLAVE`, `STOP SLAVE`, `RESET SLAVE` and `CHANGE MASTER TO` did not cause implicit commits prior to MariaDB 10.0.

1.1.1.9.9 Transaction Timeouts

MariaDB has always had the `wait_timeout` and `interactive_timeout` settings, which close connections after a certain period of inactivity.

However, these are by default set to a long wait period. In situations where transactions may be started, but not committed or rolled back, more granular control and a shorter timeout may be desirable so as to avoid locks being held for too long.

MariaDB 10.3 introduced three new variables to handle this situation.

- `idle_transaction_timeout` (all transactions)
- `idle_write_transaction_timeout` (write transactions - called `idle_readwrite_transaction_timeout` until MariaDB 10.3.2 [↗](#))
- `idle_readonly_transaction_timeout` (read transactions)

These accept a time in seconds to time out, by closing the connection, transactions that are idle for longer than this period. By default all are set to zero, or no timeout.

`idle_transaction_timeout` affects all transactions, `idle_write_transaction_timeout` affects write transactions only and `idle_readonly_transaction_timeout` affects read transactions only. The latter two variables work independently. However, if either is set along with `idle_transaction_timeout`, the settings for `idle_write_transaction_timeout` or `idle_readonly_transaction_timeout` will take precedence.

Examples

```
SET SESSION idle_transaction_timeout=2;
BEGIN;
SELECT * FROM t;
Empty set (0.000 sec)
## wait 3 seconds
SELECT * FROM t;
ERROR 2006 (HY000): MySQL server has gone away
```

```
SET SESSION idle_write_transaction_timeout=2;
BEGIN;
SELECT * FROM t;
Empty set (0.000 sec)
## wait 3 seconds
SELECT * FROM t;
Empty set (0.000 sec)
INSERT INTO t VALUES(1);
## wait 3 seconds
SELECT * FROM t;
ERROR 2006 (HY000): MySQL server has gone away
```

```

SET SESSION idle_transaction_timeout=2, SESSION idle_readonly_transaction_timeout=10;
BEGIN;
SELECT * FROM t;
Empty set (0.000 sec)
## wait 3 seconds
SELECT * FROM t;
Empty set (0.000 sec)
## wait 11 seconds
SELECT * FROM t;
ERROR 2006 (HY000): MySQL server has gone away

```

1.1.1.9.10 UNLOCK TABLES

Syntax

```
UNLOCK TABLES
```

Contents

1. [Syntax](#)
2. [Description](#)

Description

`UNLOCK TABLES` explicitly releases any table locks held by the current session. See [LOCK TABLES](#) for more information.

In addition to releasing table locks acquired by the `LOCK TABLES` statement, the `UNLOCK TABLES` statement also releases the global read lock acquired by the `FLUSH TABLES WITH READ LOCK` statement. The `FLUSH TABLES WITH READ LOCK` statement is very useful for performing backups. See [FLUSH](#) for more information about `FLUSH TABLES WITH READ LOCK`.

1.1.1.9.11 WAIT and NOWAIT

Extended syntax so that it is possible to set `innodb_lock_wait_timeout` and `lock_wait_timeout` for the following statements:

Syntax

```

ALTER TABLE tbl_name [WAIT n|NOWAIT] ...
CREATE ... INDEX ON tbl_name (index_col_name, ...) [WAIT n|NOWAIT] ...
DROP INDEX ... [WAIT n|NOWAIT]
DROP TABLE tbl_name [WAIT n|NOWAIT] ...
LOCK TABLE ... [WAIT n|NOWAIT]
OPTIMIZE TABLE tbl_name [WAIT n|NOWAIT]
RENAME TABLE tbl_name [WAIT n|NOWAIT] ...
SELECT ... FOR UPDATE [WAIT n|NOWAIT]
SELECT ... LOCK IN SHARE MODE [WAIT n|NOWAIT]
TRUNCATE TABLE tbl_name [WAIT n|NOWAIT]

```

Description

The lock wait timeout can be explicitly set in the statement by using either `WAIT n` (to set the wait in seconds) or `NOWAIT`, in which case the statement will immediately fail if the lock cannot be obtained. `WAIT 0` is equivalent to `NOWAIT`.

1.1.1.9.12 XA Transactions

Contents

1. [Overview](#)
2. [Internal XA vs External XA](#)
3. [Transaction Coordinator Log](#)
4. [Syntax](#)
 1. [XA START](#)
 2. [XA END](#)
 3. [XA PREPARE](#)
 4. [XA COMMIT](#)
 5. [XA ROLLBACK](#)
 6. [XA RECOVER](#)
5. [Examples](#)
6. [Known Issues](#)
 1. [MariaDB Galera Cluster](#)
 2. [Incompatibility with 10.4 XA behaviour](#)

Overview

The MariaDB XA implementation is based on the X/Open CAE document Distributed Transaction Processing: The XA Specification. This document is published by The Open Group and available at <http://www.opengroup.org/public/pubs/catalog/c193.htm>.

XA transactions are designed to allow distributed transactions, where a transaction manager (the application) controls a transaction which involves multiple resources. Such resources are usually DBMSs, but could be resources of any type. The whole set of required transactional operations is called a global transaction. Each subset of operations which involve a single resource is called a local transaction. XA used a 2-phases commit (2PC). With the first commit, the transaction manager tells each resource to prepare an effective commit, and waits for a confirm message. The changes are not still made effective at this point. If any of the resources encountered an error, the transaction manager will rollback the global transaction. If all resources communicate that the first commit is successful, the transaction manager can require a second commit, which makes the changes effective.

In MariaDB, XA transactions can only be used with storage engines that support them. At least [InnoDB](#), [TokuDB](#), [SPIDER](#) and [MyRocks](#) support them. For InnoDB, until [MariaDB 10.2](#), XA transactions can be disabled by setting the `innodb_support_xa` server system variable to 0. From [MariaDB 10.3](#), XA transactions are always supported.

Like regular transactions, XA transactions create [metadata locks](#) on accessed tables.

XA transactions require [REPEATABLE READ](#) as a minimum isolation level. However, distributed transactions should always use [SERIALIZABLE](#).

Trying to start more than one XA transaction at the same time produces a 1400 error (`SQLSTATE 'XAE09'`). The same error is produced when attempting to start an XA transaction while a regular transaction is in effect. Trying to start a regular transaction while an XA transaction is in effect produces a 1399 error (`SQLSTATE 'XAE07'`).

The [statements that cause an implicit COMMIT](#) for regular transactions produce a 1400 error (`SQLSTATE 'XAE09'`) if a XA transaction is in effect.

Internal XA vs External XA

XA transactions are an overloaded term in MariaDB. If a [storage engine](#) is XA-capable, it can mean one or both of these:

- It supports MariaDB's internal two-phase commit API. This is transparent to the user. Sometimes this is called "internal XA", since MariaDB's internal [transaction coordinator log](#) can handle coordinating these transactions.
- It supports XA transactions, with the `XA START`, `XA PREPARE`, `XA COMMIT`, etc. statements. Sometimes this is called "external XA", since it requires the use of an external transaction coordinator to use this feature properly.

Transaction Coordinator Log

If you have two or more XA-capable storage engines enabled, then a transaction coordinator log must be available.

There are currently two implementations of the transaction coordinator log:

- Binary log-based transaction coordinator log
- Memory-mapped file-based transaction coordinator log

If the [binary log](#) is enabled on a server, then the server will use the binary log-based transaction coordinator log. Otherwise, it will use the memory-mapped file-based transaction coordinator log.

See [Transaction Coordinator Log](#) for more information.

Syntax

```
XA {START|BEGIN} xid [JOIN|RESUME]

XA END xid [SUSPEND [FOR MIGRATE]]

XA PREPARE xid

XA COMMIT xid [ONE PHASE]

XA ROLLBACK xid

XA RECOVER [FORMAT=['RAW'|'SQL']]

xid: gtrid [, bqual [, formatID ]]
```

The interface to XA transactions is a set of SQL statements starting with `XA`. Each statement changes a transaction's state, determining which actions it can perform. A transaction which does not exist is in the `NON-EXISTING` state.

When trying to execute an operation which is not allowed for the transaction's current state, an error is produced:

```
XA COMMIT 'test' ONE PHASE;
ERROR 1399 (XAE07): XAER_RMFAIL: The command cannot be executed when global transaction is in
the ACTIVE state

XA COMMIT 'test2';
ERROR 1399 (XAE07): XAER_RMFAIL: The command cannot be executed when global transaction is in
the NON-EXISTING state
```

XA START

```
XA {START|BEGIN} xid [JOIN|RESUME]
```

`XA START` (or `BEGIN`) starts a transaction and defines its `xid` (a transaction identifier). The new transaction will be in `ACTIVE` state.

The `xid` can have 3 components, though only the first one is mandatory. `gtrid` is a quoted string representing a global transaction identifier. `bqual` is a quoted string representing a local transaction identifier. `formatID` is an unsigned integer indicating the format used for the first two components; if not specified, defaults to 1. MariaDB does not interpret in any way these components, and only uses them to identify a transaction. `xid`s of transactions in effect must be unique.

Using the `JOIN` or `RESUME` keywords will currently cause an error to be returned.

```
MariaDB [test]> XA START 'test' RESUME;
ERROR 1398 (XAE05): XAER_INVALID: Invalid arguments (or unsupported command)
MariaDB [test]> XA START 'test' JOIN;
ERROR 1398 (XAE05): XAER_INVALID: Invalid arguments (or unsupported command)
```

An exception to this is that `XA START xid RESUME` will resume the transaction if the `xid` is the same as the previous `xid` used in `XA END xid`. This simply undoes the `XA END` and moves it from the `IDLE` state back into `ACTIVE`.

```
XA START 'test';
INSERT INTO t VALUES (1,2);
XA END 'test';
XA START 'test' RESUME; -- This reverts the XA END and continues the transaction
INSERT INTO t VALUES (3,4);
XA END 'test';
XA PREPARE 'test';
XA COMMIT 'test';
```

XA END

```
XA END xid [SUSPEND [FOR MIGRATE]]
```

`XA END` declares that the specified `ACTIVE` transaction is finished and it changes its state to `IDLE`. `SUSPEND [FOR`

MIGRATE] has no effect.

XA PREPARE

```
XA PREPARE xid
```

`XA PREPARE` prepares an `IDLE` transaction for commit, changing its state to `PREPARED`. Prepared transactions are stored persistently and will survive disconnects and server crashes, and must be explicitly committed or rolled back.

MariaDB until 10.5

Before [MariaDB 10.5](#), prepared transactions were automatically rolled back on client disconnect, but were not rolled back if the server was crashed or killed. This violated XA guarantees and could have caused inconsistent data, if the transaction in question was already irrevocably committed in another XA participant.

XA COMMIT

```
XA COMMIT xid [ONE PHASE]
```

`XA COMMIT` definitely commits and terminates a transaction which has already been `PREPARED`. If the `ONE PHASE` clause is specified, this statements performs a 1-phase commit on an `IDLE` transaction.

XA ROLLBACK

```
XA ROLLBACK xid
```

`XA ROLLBACK` rolls back and terminates an `IDLE` or `PREPARED` transaction.

XA RECOVER

```
XA RECOVER [FORMAT=['RAW'|'SQL']]
```

The `XA RECOVER` statement shows information about all transactions which are in the `PREPARED` state. It does not matter which connection created the transaction: if it has been `PREPARED`, it appears. But this does not mean that a connection can commit or rollback a transaction which was started by another connection. Note that transactions using a 1-phase commit are never in the `PREPARED` state, so they cannot be shown by `XA RECOVER`.

`XA RECOVER` produces four columns:

```
XA RECOVER;
+-----+-----+-----+-----+
| formatID | gtrid_length | bqual_length | data |
+-----+-----+-----+-----+
|          1 |             4 |              0 | test |
+-----+-----+-----+-----+
```

You can use `XA RECOVER FORMAT='SQL'` to get the data in a human readable form that can be directly copy-pasted into `XA COMMIT` or `XA ROLLBACK`. This is particularly useful for binary `xid` generated by some transaction coordinators.

`formatID` is the `formatID` part of `xid`.

`data` are the `gtrid` and `bqual` parts of `xid`, concatenated.

`gtrid_length` and `bqual_length` are the lengths of `gtrid` and `bqual`, respectively.

Examples

2-phases commit:

```
XA START 'test';

INSERT INTO t VALUES (1,2);

XA END 'test';

XA PREPARE 'test';

XA COMMIT 'test';
```

1-phase commit:

```
XA START 'test';

INSERT INTO t VALUES (1,2);

XA END 'test';

XA COMMIT 'test' ONE PHASE;
```

Human-readable:

```
xa start '12\r34\t67\v78', 'abc\ndef', 3;

insert t1 values (40);

xa end '12\r34\t67\v78', 'abc\ndef', 3;

xa prepare '12\r34\t67\v78', 'abc\ndef', 3;

xa recover format='RAW';
+-----+-----+-----+-----+
| formatID | gtrid_length | bqual_length | data |
+-----+-----+-----+-----+
34      67v78abc      11 |          7 | 12
def |
+-----+-----+-----+-----+

xa recover format='SQL';
+-----+-----+-----+-----+
| formatID | gtrid_length | bqual_length | data |
+-----+-----+-----+-----+
|          3 |          11 |          7 | X'31320d3334093637763738',X'6162630a646566',3 |
+-----+-----+-----+-----+

xa rollback X'31320d3334093637763738',X'6162630a646566',3;
```

Known Issues

MariaDB Galera Cluster

[MariaDB Galera Cluster](#) does not support XA transactions.

However, [MariaDB Galera Cluster](#) builds include a built-in plugin called `wsrep`. Prior to [MariaDB 10.4.3](#), this plugin was internally considered an [XA-capable storage engine](#). Consequently, these [MariaDB Galera Cluster](#) builds have multiple XA-capable storage engines by default, even if the only "real" storage engine that supports external [XA transactions](#) enabled on these builds by default is [InnoDB](#). Therefore, when using one these builds MariaDB would be forced to use a [transaction coordinator log](#) by default, which could have performance implications.

See [Transaction Coordinator Log Overview: MariaDB Galera Cluster](#) for more information.

Incompatibility with 10.4 XA behaviour

In 10.4 and earlier, an XA transaction was still tied to the connection until COMMIT, and would be rolled back on disconnect. From [MariaDB 10.5](#), `XA PREPARE` persists the XA transaction following the XA Specification. If an existing application relies on the previous behavior, upgrading to 10.5 or later can leave XA transactions in the PREPARED state indefinitely after disconnect, causing such applications to no longer function correctly.

As a work-around, the variable [legacy_xa_rollback_at_disconnect](#) can be set to TRUE to re-enable the old behavior and roll

back XA transactions in the PREPARED state at disconnect. This is non-standard behaviour, and is not recommended for new applications. If rollback-at-disconnect is desired, it is better to use a normal (non-XA) transaction.

1.1.1.9.13 READ COMMITTED

`READ COMMITTED` is one of the transaction isolation levels. Each consistent read, even within the same transaction, sets and reads its own fresh snapshot.

See [SET TRANSACTION#Isolation Levels](#) for details.

1.1.1.9.14 READ UNCOMMITTED

`READ UNCOMMITTED` is one of the transaction isolation levels. `SELECT` statements are performed in a non-locking fashion, but a possible earlier version of a row might be used

See [SET TRANSACTION#Isolation Levels](#) for details.

1.1.1.9.15 REPEATABLE READ

`REPEATABLE READ` is one of the transaction isolation levels. All consistent reads within the same transaction read the snapshot established by the first read.

See [SET TRANSACTION#Isolation Levels](#) for details.

1.1.1.9.16 SERIALIZABLE

`SERIALIZABLE` is one of the transaction isolation levels. Similar to `REPEATABLE READ`, but InnoDB implicitly converts all plain `SELECT` statements to `SELECT ... LOCK IN SHARE MODE` if autocommit is disabled.

See [SET TRANSACTION#Isolation Levels](#) for details.

1.1.1.2.15 HELP Command

1.1.1.11 Comment Syntax

There are three supported comment styles in MariaDB:

1. From a '#' to the end of a line:

```
SELECT * FROM users; # This is a comment
```

2. From a '--' to the end of a line. The space after the two dashes is required (as in MySQL).

```
SELECT * FROM users; -- This is a comment
```

3. C style comments from an opening '/*' to a closing '*/'. Comments of this form can span multiple lines:

```
SELECT * FROM users; /* This is a
multi-line
comment */
```

Nested comments are possible in some situations, but they are not supported or recommended.

Executable Comments

As an aid to portability between different databases, MariaDB supports executable comments. These special comments allow you to embed SQL code which will not execute when run on other databases, but will execute when run on MariaDB.

MariaDB supports both MySQL's executable comment format, and a slightly modified version specific to MariaDB. This way, if you have SQL code that works on MySQL and MariaDB, but not other databases, you can wrap it in a MySQL executable comment, and if you have code that specifically takes advantage of features only available in MariaDB you can use the MariaDB specific format to hide the code from MySQL.

Executable Comment Syntax

MySQL and MariaDB executable comment syntax:

```
/*! MySQL or MariaDB-specific code */
```

Code that should be executed only starting from a specific MySQL or MariaDB version:

```
/*!##### MySQL or MariaDB-specific code */
```

The numbers, represented by ' ##### ' in the syntax examples above specify the specific the minimum versions of MySQL and MariaDB that should execute the comment. The first number is the major version, the second 2 numbers are the minor version and the last 2 is the patch level.

For example, if you want to embed some code that should only execute on MySQL or MariaDB starting from 5.1.0, you would do the following:

```
/*!50100 MySQL and MariaDB 5.1.0 (and above) code goes here. */
```

MariaDB-only executable comment syntax (starting from [MariaDB 5.3.1](#)):

```
/*M! MariaDB-specific code */  
/*M!##### MariaDB-specific code */
```

MariaDB ignores MySQL-style executable comments that have a version number in the range 50700..99999. This is needed to skip features introduced in MySQL-5.7 that are not ported to MariaDB 10.x yet.

```
/*!50701 MariaDB-10.x ignores MySQL-5.7 specific code */
```

Note: comments which have a version number in the range 50700..99999 that use MariaDB-style executable comment syntax are still executed.

```
/*M!50701 MariaDB-10.x does not ignore this */
```

Statement delimiters cannot be used within executable comments.

Examples

In MySQL all the following will return 2: In MariaDB, the last 2 queries would return 3.

```
SELECT 2 /* +1 */;  
SELECT 1 /*! +1 */;  
SELECT 1 /*!50101 +1 */;  
SELECT 2 /*M! +1 */;  
SELECT 2 /*M!50301 +1 */;
```

The following executable statement will not work due to the delimiter inside the executable portion:

```
/*M!100100 select 1 ; */  
ERROR 1064 (42000): You have an error in your SQL syntax; check the manual that corresponds to your MariaDB server version for the right syntax to use near '' at line 1
```

Instead, the delimiter should be placed outside the executable portion:

```
/*M!100100 select 1 */;  
+----+  
| 1 |  
+----+  
| 1 |  
+----+
```

1.2 Built-in Functions

1.1.2 SQL Language Structure

SQL language structure rules.

Identifier Names

Naming rules for identifiers.

Identifier Case-sensitivity

Whether objects are case-sensitive or not is partly determined by the under...

Binary Literals

Binary literals can be written in one of the following formats.

Boolean Literals

True and false.

Date and Time Literals

Literals regarding date and time.

Hexadecimal Literals

Hexadecimal literals can be written using any of the following syntaxes

Identifier Qualifiers

How to reference an object and its context in an SQL statement.

Identifier to File Name Mapping

Some identifiers map to a file name on the filesystem. Databases each have ...

MariaDB Error Code Reference

MariaDB error codes reference list.

Numeric Literals

Numeric literals are written as a sequence of digits from 0 to 9

Reserved Words

List of reserved words in MariaDB.

SQLSTATE

A string which identifies a condition's class and subclass

String Literals

Strings are sequences of characters and are enclosed with quotes.

Table Value Constructors

Documents adding arbitrary values to the result-set.

User-Defined Variables

Variables which exist within a session.

- [1. Unquoted](#)
- [2. Quoted](#)
- [3. Further Rules](#)
- [4. Quote Character](#)
- [5. Maximum Length](#)
- [6. Multiple Identifiers](#)
- [7. Examples](#)

Databases, tables, indexes, columns, aliases, views, stored routines, triggers, events, variables, partitions, tablespaces, savepoints, labels, users, roles, are collectively known as identifiers, and have certain rules for naming.

Identifiers may be quoted using the backtick character - ```. Quoting is optional for identifiers that don't contain special characters, or for identifiers that are not [reserved words](#). If the `ANSI_QUOTES SQL_MODE` flag is set, double quotes (`"`) can also be used to quote identifiers. If the `MSSQL` flag is set, square brackets (`[` and `]`) can be used for quoting.

Even when using reserved words as names, [fully qualified names](#) do not need to be quoted. For example, `test.select` has only one possible meaning, so it is correctly parsed even without quotes.

Unquoted

The following characters are valid, and allow identifiers to be unquoted:

- ASCII: [0-9,a-z,A-Z\$_] (numerals 0-9, basic Latin letters, both lowercase and uppercase, dollar sign, underscore)
- Extended: U+0080 .. U+FFFF

Quoted

The following characters are valid, but identifiers using them must be quoted:

- ASCII: U+0001 .. U+007F (full Unicode Basic Multilingual Plane (BMP) except for U+0000)
- Extended: U+0080 .. U+FFFF
- Identifier quotes can themselves be used as part of an identifier, as long as they are quoted.

Further Rules

There are a number of other rules for identifiers:

- Identifiers are stored as Unicode (UTF-8)
- Identifiers may or may not be case-sensitive. See [Identifier Case-sensitivity](#).
- Database, table and column names can't end with space characters
- Identifier names may begin with a numeral, but can't only contain numerals unless quoted.
- An identifier starting with a numeral, followed by an 'e', may be parsed as a floating point number, and needs to be quoted.
- Identifiers are not permitted to contain the ASCII NUL character (U+0000) and supplementary characters (U+10000 and higher).
- Names such as 5e6, 9e are not prohibited, but it's strongly recommended not to use them, as they could lead to ambiguity in certain contexts, being treated as a number or expression.
- User variables cannot be used as part of an identifier, or as an identifier in an SQL statement.

Quote Character

The regular quote character is the backtick character - ```, but if the `ANSI_QUOTES SQL_MODE` option is specified, a regular double quote - `"` may be used as well.

The backtick character can be used as part of an identifier. In that case the identifier needs to be quoted. The quote character can be the backtick, but in that case, the backtick in the name must be escaped with another backtick.

Maximum Length

- Databases, tables, columns, indexes, constraints, stored routines, triggers, events, views, tablespaces, servers and log file groups have a maximum length of 64 characters.
- Compound statement [labels](#) have a maximum length of 16 characters
- Aliases have a maximum length of 256 characters, except for column aliases in [CREATE VIEW](#) statements, which are checked against the maximum column length of 64 characters (not the maximum alias length of 256 characters).
- Users have a maximum length of 80 characters.
- [Roles](#) have a maximum length of 128 characters.
- Multi-byte characters do not count extra towards towards the character limit.

Multiple Identifiers

MariaDB allows the column name to be used on its own if the reference will be unambiguous, or the table name to be used with the column name, or all three of the database, table and column names. A period is used to separate the identifiers, and the period can be surrounded by spaces.

Examples

Using the period to separate identifiers:

```
CREATE TABLE t1 (i int);

INSERT INTO t1(i) VALUES (10);

SELECT i FROM t1;
+-----+
| i     |
+-----+
|  10  |
+-----+

SELECT t1.i FROM t1;
+-----+
| i     |
+-----+
|  10  |
+-----+

SELECT test.t1.i FROM t1;
+-----+
| i     |
+-----+
|  10  |
+-----+
```

The period can be separated by spaces:

```
SELECT test . t1 . i FROM t1;
+-----+
| i     |
+-----+
|  10  |
+-----+
```

Resolving ambiguity:

```
CREATE TABLE t2 (i int);

SELECT i FROM t1 LEFT JOIN t2 ON t1.i=t2.i;
ERROR 1052 (23000): Column 'i' in field list is ambiguous

SELECT t1.i FROM t1 LEFT JOIN t2 ON t1.i=t2.i;
+-----+
| i     |
+-----+
|  10  |
+-----+
```

Creating a table with characters that require quoting:

```
CREATE TABLE 123% (i int);
ERROR 1064 (42000): You have an error in your SQL syntax;
  check the manual that corresponds to your MariaDB server version for the right syntax
  to use near '123% (i int)' at line 1

CREATE TABLE `123%` (i int);
Query OK, 0 rows affected (0.85 sec)

CREATE TABLE `TABLE` (i int);
Query OK, 0 rows affected (0.36 sec)
```

Using double quotes as a quoting character:

```
CREATE TABLE "SELECT" (i int);
ERROR 1064 (42000): You have an error in your SQL syntax;
  check the manual that corresponds to your MariaDB server version for the right syntax
  to use near '"SELECT" (i int)' at line 1

SET sql_mode='ANSI_QUOTES';
Query OK, 0 rows affected (0.03 sec)

CREATE TABLE "SELECT" (i int);
Query OK, 0 rows affected (0.46 sec)
```

Using an identifier quote as part of an identifier name:

```
SHOW VARIABLES LIKE 'sql_mode';
+-----+-----+
| Variable_name | Value          |
+-----+-----+
| sql_mode      | ANSI_QUOTES   |
+-----+-----+

CREATE TABLE "fg`d" (i int);
Query OK, 0 rows affected (0.34 sec)
```

Creating the table named * (Unicode number: U+002A) requires quoting.

```
CREATE TABLE `*` (a INT);
```

Floating point ambiguity:

```
CREATE TABLE 8984444cce5d (x INT);
Query OK, 0 rows affected (0.38 sec)

CREATE TABLE 8981e56cce5d (x INT);
ERROR 1064 (42000): You have an error in your SQL syntax;
  check the manual that corresponds to your MariaDB server version for the right syntax
  to use near '8981e56cce5d (x INT)' at line 1

CREATE TABLE `8981e56cce5d` (x INT);
Query OK, 0 rows affected (0.39 sec)
```

1.1.2.2 Identifier Case-sensitivity

Whether objects are case-sensitive or not is partly determined by the underlying operating system. Unix-based systems are case-sensitive, Windows is not, while Mac OS X is usually case-insensitive by default, but devices can be configured as case-sensitive using Disk Utility.

Database, table, table aliases and [trigger](#) names are affected by the systems case-sensitivity, while index, column, column aliases, [stored routine](#) and [event](#) names are never case sensitive.

Log file group name are case sensitive.

The [lower_case_table_names](#) server system variable plays a key role. It determines whether table names, aliases and database names are compared in a case-sensitive manner. If set to 0 (the default on Unix-based systems), table names and aliases and database names are compared in a case-sensitive manner. If set to 1 (the default on Windows), names are stored in lowercase and not compared in a case-sensitive manner. If set to 2 (the default on Mac OS X), names are stored as declared, but compared in lowercase.

It is thus possible to make Unix-based systems behave like Windows and ignore case-sensitivity. The reverse is not true prior to Windows 10, as the underlying Windows filesystem could not support this. It is possible since Windows 10, although case-insensitivity is still the default operating system setting.

Even on case-insensitive systems, you are required to use the same case consistently within the same statement. The following statement fails, as it refers to the table name in a different case.

```
SELECT * FROM a_table WHERE A_table.id>10;
```

For a full list of identifier naming rules, see [Identifier Names](#).

Please note that [lower_case_table_names](#) is a database initialization parameter. This means that, along with

[innodb_page_size](#), this variable must be set before running [mariadb-install-db](#), and will not change the behavior of servers unless applied before the creation of core system databases.

1.1.2.3 Binary Literals

Binary literals can be written in one of the following formats: `b'value'`, `B'value'` or `0bvalue`, where `value` is a string composed by `0` and `1` digits.

Binary literals are interpreted as binary strings, and are convenient to represent [VARBINARY](#), [BINARY](#) or [BIT](#) values.

To convert a binary literal into an integer, just add `0`.

Examples

Printing the value as a binary string:

```
SELECT 0b1000001;
+-----+
| 0b1000001 |
+-----+
| A          |
+-----+
```

Converting the same value into a number:

```
SELECT 0b1000001+0;
+-----+
| 0b1000001+0 |
+-----+
|           65 |
+-----+
```

1.1.2.4 Boolean Literals

In MariaDB, `FALSE` is a synonym of `0` and `TRUE` is a synonym of `1`. These constants are case insensitive, so `TRUE`, `True`, and `true` are equivalent.

These terms are not synonyms of `0` and `1` when used with the `IS` operator. So, for example, `10 IS TRUE` returns `1`, while `10 = TRUE` returns `0` (because `1 != 10`).

The `IS` operator accepts a third constant exists: `UNKNOWN`. It is always a synonym of `NULL`.

`TRUE` and `FALSE` are [reserved words](#), while `UNKNOWN` is not.

1.1.2.5 Date and Time Literals

Contents

1. [Standard syntaxes](#)
2. [DATE literals](#)
3. [DATETIME literals](#)
4. [TIME literals](#)
5. [2-digit years](#)
6. [Microseconds](#)
7. [Date and time literals and the SQL_MODE](#)

Standard syntaxes

MariaDB supports the SQL standard and ODBC syntaxes for [DATE](#), [TIME](#) and [TIMESTAMP](#) literals.

SQL standard syntax:

- `DATE 'string'`
- `TIME 'string'`
- `TIMESTAMP 'string'`

ODBC syntax:

- {d 'string'}
- {t 'string'}
- {ts 'string'}

The timestamp literals are treated as `DATETIME` literals, because in MariaDB the range of `DATETIME` is closer to the `TIMESTAMP` range in the SQL standard.

`string` is a string in a proper format, as explained below.

DATE literals

A `DATE` string is a string in one of the following formats: `'YYYY-MM-DD'` or `'YY-MM-DD'`. Note that any punctuation character can be used as delimiter. All delimiters must consist of 1 character. Different delimiters can be used in the same string. Delimiters are optional (but if one delimiter is used, all delimiters must be used).

A `DATE` literal can also be an integer, in one of the following formats: `YYYYMMDD` or `YYMMDD`.

All the following `DATE` literals are valid, and they all represent the same value:

```
'19940101'
'940101'
'1994-01-01'
'94/01/01'
'1994-01/01'
'94:01!01'
19940101
940101
```

DATETIME literals

A `DATETIME` string is a string in one of the following formats: `'YYYY-MM-DD HH:MM:SS'` or `'YY-MM-DD HH:MM:SS'`. Note that any punctuation character can be used as delimiter for the date part and for the time part. All delimiters must consist of 1 character. Different delimiters can be used in the same string. The hours, minutes and seconds parts can consist of one character. For this reason, delimiters are mandatory for `DATETIME` literals.

The delimiter between the date part and the time part can be a `T` or any sequence of space characters (including tabs, new lines and carriage returns).

A `DATETIME` literal can also be a number, in one of the following formats: `YYYYMMDDHHMMSS`, `YYMMDDHHMMSS`, `YYYYMMDD` or `YYMMDD`. In this case, all the time subparts must consist of 2 digits.

All the following `DATE` literals are valid, and they all represent the same value:

```
'1994-01-01T12:30:03'
'1994/01/01\n\t 12+30+03'
'1994/01\01\n\t 12+30-03'
'1994-01-01 12:30:3'
```

TIME literals

A `TIME` string is a string in one of the following formats: `'D HH:MM:SS'`, `'HH:MM:SS'`, `'D HH:MM'`, `'HH:MM'`, `'D HH'`, or `'SS'`. `D` is a value from 0 to 34 which represents days. `:` is the only allowed delimiter for `TIME` literals.

Delimiters are mandatory, with an exception: the `'HHMMSS'` format is allowed. When delimiters are used, each part of the literal can consist of one character.

A `TIME` literal can also be a number in one of the following formats: `HHMMSS`, `MMSS`, or `SS`.

The following literals are equivalent:

```
'09:05:00'
'9:05:0'
'9:5:0'
'090500'
```

- 2-digit years

The year part in `DATE` and `DATETIME` literals is determined as follows:

- 70 - 99 = 1970 - 1999
- 00 - 69 = 2000 - 2069

Microseconds

`DATETIME` and `TIME` literals can have an optional microseconds part. For both string and numeric forms, it is expressed as a decimal part. Up to 6 decimal digits are allowed. Examples:

```
'12:30:00.123456'  
123000.123456
```

See [Microseconds in MariaDB](#) for details.

Date and time literals and the `SQL_MODE`

Unless the `SQL_MODE NO_ZERO_DATE` flag is set, some special values are allowed: the `'0000-00-00'` `DATE`, the `'00:00:00'` `TIME`, and the `0000-00-00 00:00:00` `DATETIME`.

If the `ALLOW_INVALID_DATES` flag is set, the invalid dates (for example, 30th February) are allowed. If not, if the `NO_ZERO_DATE` is set, an error is produced; otherwise, a zero-date is returned.

Unless the `NO_ZERO_IN_DATE` flag is set, each subpart of a date or time value (years, hours...) can be set to 0.

1.1.2.6 Hexadecimal Literals

Contents

1. [Examples](#)
 1. [Fun with Types](#)
 2. [Differences Between MariaDB and MySQL](#)

Hexadecimal literals can be written using any of the following syntaxes:

- `x' value '`
- `X' value '` (SQL standard)
- `0x value` (ODBC)

`value` is a sequence of hexadecimal digits (from 0 to 9 and from A to F). The case of the digits does not matter. With the first two syntaxes, `value` must consist of an even number of digits. With the last syntax, digits can be even, and they are treated as if they had an extra 0 at the beginning.

Normally, hexadecimal literals are interpreted as binary string, where each pair of digits represents a character. When used in a numeric context, they are interpreted as integers. (See the example below). In no case can a hexadecimal literal be a decimal number.

The first two syntaxes; `x' value '` and `x' value`, follow the SQL standard, and behave as a string in all contexts in MariaDB since [MariaDB 10.0.3](#) and [MariaDB 5.5.31](#) (fixing [MDEV-4489](#)). The latter syntax, `0x value`, is a MySQL/MariaDB extension for hex hybrids and behaves as a string or as a number depending on context. MySQL treats all syntaxes the same, so there may be different results in MariaDB and MySQL (see below).

Examples

Representing the `a` character with the three syntaxes explained above:

```
SELECT x'61', X'61', 0x61;  
+-----+-----+-----+  
| x'61' | X'61' | 0x61 |  
+-----+-----+-----+  
| a     | a     | a     |  
+-----+-----+-----+
```

Hexadecimal literals in a numeric context:

```

SELECT 0 + 0xF, -0xF;
+-----+-----+
| 0 + 0xF | -0xF |
+-----+-----+
|      15 |  -15 |
+-----+-----+

```

Fun with Types

```

CREATE TABLE t1 (a INT, b VARCHAR(10));
INSERT INTO t1 VALUES (0x31, 0x61), (COALESCE(0x31), COALESCE(0x61));

SELECT * FROM t1;
+-----+-----+
| a     | b     |
+-----+-----+
| 49    | a     |
| 1     | a     |
+-----+-----+

```

The reason for the differing results above is that when 0x31 is inserted directly to the column, it's treated as a number, while when 0x31 is passed to `COALESCE()`, it's treated as a string, because:

- HEX values have a string data type by default.
- `COALESCE()` has the same data type as the argument.

Differences Between MariaDB and MySQL

```

SELECT x'0a'+0;
+-----+
| x'0a'+0 |
+-----+
|        0 |
+-----+
1 row in set, 1 warning (0.00 sec)

Warning (Code 1292): Truncated incorrect DOUBLE value: '\x0A'

SELECT X'0a'+0;
+-----+
| X'0a'+0 |
+-----+
|        0 |
+-----+
1 row in set, 1 warning (0.00 sec)

Warning (Code 1292): Truncated incorrect DOUBLE value: '\x0A'

SELECT 0x0a+0;
+-----+
| 0x0a+0 |
+-----+
|      10 |
+-----+

```

In MySQL (up until at least MySQL 8.0.26):

```
SELECT x'0a'+0;
```

```
+-----+  
| x'0a'+0 |  
+-----+  
|      10 |  
+-----+
```

```
SELECT X'0a'+0;
```

```
+-----+  
| X'0a'+0 |  
+-----+  
|      10 |  
+-----+
```

```
SELECT 0x0a+0;
```

```
+-----+  
| 0x0a+0 |  
+-----+  
|      10 |  
+-----+
```

1.1.2.7 Identifier Qualifiers

Contents

Qualifiers are used within SQL statements to reference data structures, such as databases, tables, or columns. For example, typically a SELECT query contains references to some columns and at least one table.

Qualifiers can be composed by one or more [identifiers](#), where the initial parts affect the context within which the final identifier is interpreted:

- For a database, only the database identifier needs to be specified.
- For objects which are contained in a database (like tables, views, functions, etc) the database identifier can be specified. If no database is specified, the current database is assumed (see [USE](#) and [DATABASE\(\)](#) for more details). If there is no default database and no database is specified, an error is issued.
- For column names, the table and the database are generally obvious from the context of the statement. It is however possible to specify the table identifier, or the database identifier plus the table identifier.
- An identifier is fully-qualified if it contains all possible qualifiers, for example, the following column is fully qualified:
`db_name.tbl_name.col_name`

If a qualifier is composed by more than one identifier, a dot (.) must be used as a separator. All identifiers can be quoted individually. Extra spacing (including new lines and tabs) is allowed.

All the following examples are valid:

- `db_name.tbl_name.col_name`
- `tbl_name`
- ``db_name`.`tbl_name`.`col_name``
- ``db_name`.`tbl_name``
- `db_name.tbl_name`

If a table identifier is prefixed with a dot (.), the default database is assumed. This syntax is supported for ODBC compliance, but has no practical effect on MariaDB. These qualifiers are equivalent:

- `tbl_name`
- `.tbl_name`
- ``.`tbl_name``
- ``.`tbl_name``

For DML statements, it is possible to specify a list of the partitions using the PARTITION clause. See [Partition Pruning and Selection](#) for details.

1.1.2.8 Identifier to File Name Mapping

Some identifiers map to a file name on the filesystem. Databases each have their own directory, while, depending on the [storage engine](#), table names and index names may map to a file name.

Not all characters that are allowed in table names can be used in file names. Every filesystem has its own rules of what characters can be used in file names. To let the user create tables using all characters allowed in the SQL Standard and to not depend on whatever particular filesystem a particular database resides, MariaDB encodes "potentially unsafe"

characters in the table name to derive the corresponding file name.

This is implemented using a special character set. MariaDB converts a table name to the "filename" character set to get the file name for this table. And it converts the file name from the "filename" character set to, for example, utf8 to get the table name for this file name.

The conversion rules are as follows: if the identifier is made up only of basic Latin numbers, letters and/or the underscore character, the encoding matches the name (see however [Identifier Case Sensitivity](#)). Otherwise they are encoded according to the following table:

Code Range	Pattern	Number	Used	Unused	Blocks
00C0..017F	[@][0..4][g..z]	5*20= 100	97	3	Latin-1 Supplement + Latin Extended-A
0370..03FF	[@][5..9][g..z]	5*20= 100	88	12	Greek and Coptic
0400..052F	[@][g..z][0..6]	20*7= 140	137	3	Cyrillic + Cyrillic Supplement
0530..058F	[@][g..z][7..8]	20*2= 40	38	2	Armenian
2160..217F	[@][g..z][9]	20*1= 20	16	4	Number Forms
0180..02AF	[@][g..z][a..k]	20*11=220	203	17	Latin Extended-B + IPA Extensions
1E00..1EFF	[@][g..z][l..r]	20*7= 140	136	4	Latin Extended Additional
1F00..1FFF	[@][g..z][s..z]	20*8= 160	144	16	Greek Extended
....	[@][a..f][g..z]	6*20= 120	0	120	RESERVED
24B6..24E9	[@][@][a..z]	26	26	0	Enclosed Alphanumerics
FF21..FF5A	[@][a..z][@]	26	26	0	Halfwidth and Fullwidth forms

Code Range values are UCS-2.

All of this encoding happens transparently at the filesystem level with one exception. Until MySQL 5.1.6, an old encoding was used. Identifiers created in a version before MySQL 5.1.6, and which haven't been updated to the new encoding, the server prefixes `mysql50` to their name.

Examples

Find the file name for a table with a non-Latin1 name:

```
select cast(convert("this_is_таблица" USING filename) as binary);
+-----+
| cast(convert("this_is_таблица" USING filename) as binary) |
+-----+
| this_is_@y0@g0@h0@r0@o0@i1@g0 |
+-----+
```

Find the table name for a file name:

```
select convert(_filename "this_is_@y0@g0@h0@r0@o0@i1@g0" USING utf8);
+-----+
| convert(_filename "this_is_@y0@g0@h0@r0@o0@i1@g0" USING utf8) |
+-----+
| this_is_таблица |
+-----+
```

An old table created before MySQL 5.1.6, with the old encoding:

```
SHOW TABLES;
+-----+
| Tables_in_test |
+-----+
| #mysql50#table@1 |
+-----+
```

The prefix needs to be supplied to reference this table:

```
SHOW COLUMNS FROM `table@1`;
ERROR 1146 (42S02): Table 'test.table@1' doesn't exist

SHOW COLUMNS FROM `#mysql50#table@1`;
+-----+-----+-----+-----+-----+
| Field | Type      | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+
| i     | int(11)   | YES  |     | NULL    |      |
+-----+-----+-----+-----+-----+
```

6.4.1.1.2.1.1 MariaDB Error Code Reference

1.1.2.10 Numeric Literals

Numeric literals are written as a sequence of digits from 0 to 9. Initial zeros are ignored. A sign can always precede the digits, but it is optional for positive numbers. In decimal numbers, the integer part and the decimal part are divided with a dot (.).

If the integer part is zero, it can be omitted, but the literal must begin with a dot.

The notation with exponent can be used. The exponent is preceded by an E or e character. The exponent can be preceded by a sign and must be an integer. A number N with an exponent part X, is calculated as $N * POW(10, X)$.

In some cases, adding zeroes at the end of a decimal number can increment the precision of the expression where the number is used. For example, `PI()` by default returns a number with 6 decimal digits. But the `PI()+0.0000000000` expression (with 10 zeroes) returns a number with 10 decimal digits.

[Hexadecimal literals](#) are interpreted as numbers when used in numeric contexts.

Examples

```
10
+10
-10
```

All these literals are equivalent:

```
0.1
.1
+0.1
+.1
```

With exponents:

```
0.2E3 -- 0.2 * POW(10, 3) = 200
.2e3
.2e+2
1.1e-10 -- 0.00000000011
-1.1e10 -- -11000000000
```

1.1.2.11 Reserved Words

Contents

1. [Reserved Words](#)
2. [Exceptions](#)
3. [Oracle Mode](#)
4. [Function Names](#)

The following is a list of all reserved words in MariaDB.

Reserved words cannot be used as [Identifiers](#), unless they are quoted.

The definitive list of reserved words for each version can be found by examining the `sql/lex.h` and `sql/sql_yacc.yy` files.

Exceptions

Some keywords are exceptions for historical reasons, and are permitted as unquoted identifiers. These include:

Keyword
ACTION
BIT
DATE
ENUM
NO
TEXT
TIME
TIMESTAMP

Oracle Mode

In [Oracle mode](#), from [MariaDB 10.3](#), there are a number of extra reserved words:

Keyword	Notes
BODY	
ELSIF	
GOTO	
HISTORY	<= MariaDB 10.3.6 only
MINUS	From MariaDB 10.6.1
OTHERS	
PACKAGE	
PERIOD	<= MariaDB 10.3.6 only
RAISE	
ROWNUM	From MariaDB 10.6.1
ROWTYPE	
SYSDATE	From MariaDB 10.6.1
SYSTEM	<= MariaDB 10.3.6 only. Note however that SYSTEM sometimes needs to be quoted to avoid confusion with System-versioned tables .
SYSTEM_TIME	<= MariaDB 10.3.6 only
VERSIONING	<= MariaDB 10.3.6 only
WITHOUT	<= MariaDB 10.3.6 only

Function Names

If the `IGNORE_SPACE SQL_MODE` flag is set, function names become reserved words.

6.4.1.1.2.1.3 SQLSTATE

1.1.2.13 String Literals

Strings are sequences of characters and are enclosed with quotes.

The syntax is:

```
[_charset_name]'string' [COLLATE collation_name]
```

For example:

```
'The MariaDB Foundation'  
_utf8 'Foundation' COLLATE utf8_unicode_ci;
```

Strings can either be enclosed in single quotes or in double quotes (the same character must be used to both open and close the string).

The ANSI SQL-standard does not permit double quotes for enclosing strings, and although MariaDB does by default, if the MariaDB server has enabled the [ANSI_QUOTES_SQL_SQL_MODE](#), double quotes will be treated as being used for [identifiers](#) instead of strings.

Strings that are next to each other are automatically concatenated. For example:

```
'The ' 'MariaDB ' 'Foundation'
```

and

```
'The MariaDB Foundation'
```

are equivalent.

The `\` (backslash character) is used to escape characters (unless the [SQL_MODE](#) hasn't been set to [NO_BACKSLASH_ESCAPES](#)). For example:

```
'MariaDB's new features'
```

is not a valid string because of the single quote in the middle of the string, which is treated as if it closes the string, but is actually meant as part of the string, an apostrophe. The backslash character helps in situations like this:

```
'MariaDB\'s new features'
```

is now a valid string, and if displayed, will appear without the backslash.

```
SELECT 'MariaDB\'s new features';  
+-----+  
| MariaDB's new features |  
+-----+  
| MariaDB's new features |  
+-----+
```

Another way to escape the quoting character is repeating it twice:

```
SELECT 'I'm here', ""Double"";  
+-----+-----+  
| I'm here | "Double" |  
+-----+-----+  
| I'm here | "Double" |  
+-----+-----+
```

Escape Sequences

There are other escape sequences also. Here is a full list:

Escape sequence	Character
<code>\0</code>	ASCII NUL (0x00).
<code>\'</code>	Single quote (``).
<code>\"</code>	Double quote (``).
<code>\b</code>	Backspace.
<code>\n</code>	Newline, or linefeed,.
<code>\r</code>	Carriage return.
<code>\t</code>	Tab.

\z	ASCII 26 (Control+Z). See note following the table.
\\	Backslash (“\”).
\%	“%” character. See note following the table.
_	A “_” character. See note following the table.

Escaping the % and _ characters can be necessary when using the [LIKE](#) operator, which treats them as special characters.

The ASCII 26 character (\z) needs to be escaped when included in a batch file which needs to be executed in Windows. The reason is that ASCII 26, in Windows, is the end of file (EOF).

Backslash (\), if not used as an escape character, must always be escaped. When followed by a character that is not in the above table, backslashes will simply be ignored.

1.1.2.14 Table Value Constructors

MariaDB starting with [10.3.3](#)

Table Value Constructors were introduced in [MariaDB 10.3.3](#)

Syntax

```
VALUES ( row_value[, row_value...]), (...)...
```

Description

Contents

- [Syntax](#)
- [Description](#)
- [Examples](#)

In Unions, Views, and sub-queries, a Table Value Constructor (TVC) allows you to inject arbitrary values into the result-set. The given values must have the same number of columns as the result-set, otherwise it returns Error 1222.

Examples

Using TVC's with [UNION](#) operations:

```
CREATE TABLE test.t1 (val1 INT, val2 INT);
INSERT INTO test.t1 VALUES(5, 8), (3, 4), (1, 2);

SELECT * FROM test.t1
UNION
VALUES (70, 90), (100, 110);

+-----+-----+
| val1 | val2 |
+-----+-----+
| 5    | 8    |
| 3    | 4    |
| 1    | 2    |
| 70   | 90   |
| 100  | 110  |
+-----+-----+
```

Using TVC's with a [CREATE VIEW](#) statement:

```
CREATE VIEW v1 AS VALUES (7, 9), (9, 10);
```

```
SELECT * FROM v1;
```

```
+---+----+
| 7 | 9 |
+---+----+
| 7 | 9 |
| 9 | 10 |
+---+----+
```

Using TVC with an `ORDER BY` clause:

```
SELECT * FROM test.t1
UNION
VALUES (10, 20), (30, 40), (50, 60), (70, 80)
ORDER BY val1 DESC;
```

Using TVC with `LIMIT` clause:

```
SELECT * FROM test.t1
UNION
VALUES (10, 20), (30, 40), (50, 60), (70, 80)
LIMIT 2 OFFSET 4;
```

```
+-----+-----+
| val1 | val2 |
+-----+-----+
| 30 | 40 |
| 50 | 60 |
+-----+-----+
```

1.1.2.15 User-Defined Variables

Contents

1. [Viewing](#)
2. [Flushing User-Defined Variables](#)
3. [Examples](#)

User-defined variables are variables which can be created by the user and exist in the session. This means that no one can access user-defined variables that have been set by another user, and when the session is closed these variables expire. However, these variables can be shared between several queries and [stored programs](#).

User-defined variables names must be preceded by a single `@` character (`@`). While it is safe to use a reserved word as a user-variable name, the only allowed characters are ASCII letters, digits, dollar sign (`$`), underscore (`_`) and dot (`.`). If other characters are used, the name can be quoted in one of the following ways:

- `@`var_name``
- `@'var_name'`
- `@"var_name"`

These characters can be escaped as usual.

User-variables names are case insensitive, though they were case sensitive in MySQL 4.1 and older versions.

User-defined variables cannot be declared. They can be read even if no value has been set yet; in that case, they are NULL. To set a value for a user-defined variable you can use:

- [SET](#) statement;
- `:=` operator within a SQL statement;
- [SELECT ... INTO](#).

Since user-defined variables type cannot be declared, the only way to force their type is using [CAST\(\)](#) or [CONVERT\(\)](#):

```
SET @str = CAST(123 AS CHAR(5));
```

If a variable has not been used yet, its value is NULL:

```

SELECT @x IS NULL;
+-----+
| @x IS NULL |
+-----+
|          1 |
+-----+

```

It is unsafe to read a user-defined variable and set its value in the same statement (unless the command is SET), because the order of these actions is undefined.

User-defined variables can be used in most MariaDB's statements and clauses which accept an SQL expression. However there are some exceptions, like the [LIMIT](#) clause.

They must be used to [PREPARE](#) a prepared statement:

```

@sql = 'DELETE FROM my_table WHERE c>1;';
PREPARE stmt FROM @sql;
EXECUTE stmt;
DEALLOCATE PREPARE stmt;

```

Another common use is to include a counter in a query:

```

SET @var = 0;
SELECT a, b, c, (@var:=@var+1) AS counter FROM my_table;

```

Viewing

User-defined variables can be viewed by either querying the [USER_VARIABLES](#), or by running `SHOW USER_VARIABLES`.

Flushing User-Defined Variables

User-defined variables are reset and the [Information Schema table](#) emptied with the [FLUSH USER_VARIABLES](#) statement.

Examples

```

SET @v1 = 0;
SET @v2 = 'abc';
SET @v3 = CAST(123 AS CHAR(5));

SHOW USER_VARIABLES;
+-----+-----+
| Variable_name | Value |
+-----+-----+
| v3            | 123   |
| v2            | abc   |
| v1            | 0     |
+-----+-----+

SELECT * FROM information_schema.USER_VARIABLES ORDER BY VARIABLE_NAME;
+-----+-----+-----+-----+
| VARIABLE_NAME | VARIABLE_VALUE | VARIABLE_TYPE | CHARACTER_SET_NAME |
+-----+-----+-----+-----+
| v1            | 0              | INT           | latin1              |
| v2            | abc            | VARCHAR      | utf8                 |
| v3            | 123            | VARCHAR      | utf8                 |
+-----+-----+-----+-----+

FLUSH USER_VARIABLES;

SELECT * FROM information_schema.USER_VARIABLES ORDER BY VARIABLE_NAME;
Empty set (0.000 sec)

```

1.1.3 Geographic & Geometric Features

MariaDB supports spatial extensions that enable the creation, storage and analysis of geographic features. These can be

used in the [Aria](#), [MyISAM](#), [InnoDB/XtraDB](#) and [ARCHIVE](#) engines in MariaDB.

[Partitioned tables](#) do not support geometric types.

1.1.3.1 GIS Resources

Here are a few resources for those interested in GIS in MariaDB.

- [OGC Simple Feature Access](#) - the Open Geospatial Consortium's OpenGIS Simple Features Specifications For SQL.
- [Geo/Spatial Search with MySQL](#) - a presentation by Alexander Rubin, from the MySQL Conference in 2006.

There are currently no differences between GIS in stable versions of MariaDB and GIS in MySQL. There are, however, some extensions and enhancements being worked on. See "[MariaDB Plans - GIS](#)" for more information.

1.1.3.2 GIS features in 5.3.3

Basic information about the existing spatial features can be found in the [Geographic Features](#) section of the Knowledgebase. The [Spatial Extensions page of the MySQL manual](#) also applies to MariaDB.

The [MariaDB 5.3.3](#) release, contains code improving the spatial functionality in MariaDB.

MySQL operates on spatial data based on the OpenGIS standards, particularly the [OpenGIS SFS](#) (Simple feature access, SQL option).

Initial support was based on version 05-134 of the standard. MariaDB implements a subset of the 'SQL with Geometry Types' environment proposed by the OGC. And the SQL environment was extended with a set of geometry types.

MariaDB supports spatial extensions to operate on spatial features. These features are available for [Aria](#), [MyISAM](#), [InnoDB](#), [NDB](#), and [ARCHIVE](#) tables.

For spatial columns, Aria and MyISAM supports both [SPATIAL](#) and non-SPATIAL indexes. Other storage engines support non-SPATIAL indexes.

The most recent changes in the code are aimed at meeting the OpenGIS requirements. One thing missed in previous versions is that the functions which check spatial relations didn't consider the actual shape of an object, instead they operate only on their bounding rectangles. These legacy functions have been left as they are and new, properly-working functions are named with an 'ST_' prefix, in accordance with the latest OpenGIS requirements. Also, operations over geometry features were added.

The list of new functions:

Spatial operators. They produce new geometries.

Name	Description
ST_UNION(A, B)	union of A and B
ST_INTERSECTION(A, B)	intersection of A and B
ST_SYMDIFFERENCE(A, B)	symdifference, notintersecting parts of A and B
ST_BUFFER(A, radius)	returns the shape of the area that lies in 'radius' distance from the shape A.

Predicates, return boolean result of the relationship

Name	Description
ST_INTERSECTS(A, B)	if A and B have an intersection
ST_CROSSES(A, B)	if A and B cross
ST_EQUALS(A, B)	if A and B are equal
ST_WITHIN(A, B)	if A lies within B
ST_CONTAINS(A,B)	if B lies within A
ST_DISJOINT(A,B)	if A and B have no intersection
ST_TOUCHES(A,B)	if A touches B

1.1.3.3 Geometry Types

Contents

1. Description
2. Examples
 1. POINT
 2. LINESTRING
 3. POLYGON
 4. MULTIPOINT
 5. MULTILINESTRING
 6. MULTIPOLYGON
 7. GEOMETRYCOLLECTION
 8. GEOMETRY

Description

MariaDB provides a standard way of creating spatial columns for geometry types, for example, with [CREATE TABLE](#) or [ALTER TABLE](#). Currently, spatial columns are supported for [MyISAM](#), [InnoDB](#) and [ARCHIVE](#) tables. See also [SPATIAL INDEX](#) [↗](#).

The basic geometry type is `GEOMETRY`. But the type can be more specific. The following types are supported:

Geometry Types
POINT
LINESTRING
POLYGON
MULTIPOINT
MULTILINESTRING
MULTIPOLYGON
GEOMETRYCOLLECTION
GEOMETRY

Examples

Note: For clarity, only one type is listed per table in the examples below, but a table row can contain multiple types. For example:

```
CREATE TABLE object (shapeA POLYGON, shapeB LINESTRING);
```

POINT

```
CREATE TABLE gis_point (g POINT);
SHOW FIELDS FROM gis_point;
INSERT INTO gis_point VALUES
  (PointFromText('POINT(10 10)'),
   (PointFromText('POINT(20 10)'),
   (PointFromText('POINT(20 20)'),
   (PointFromWKB(AsWKB(PointFromText('POINT(10 20)')))));
```

LINESTRING

```
CREATE TABLE gis_line (g LINESTRING);
SHOW FIELDS FROM gis_line;
INSERT INTO gis_line VALUES
  (LineFromText('LINESTRING(0 0,0 10,10 0)'),
   (LineStringFromText('LINESTRING(10 10,20 10,20 20,10 20,10 10)'),
   (LineStringFromWKB(AsWKB(LineString(Point(10, 10), Point(40, 10)))));
```

POLYGON

```

CREATE TABLE gis_polygon (g POLYGON);
SHOW FIELDS FROM gis_polygon;
INSERT INTO gis_polygon VALUES
  (PolygonFromText('POLYGON((10 10,20 10,20 20,10 20,10 10))')),
  (PolyFromText('POLYGON((0 0,50 0,50 50,0 50,0 0), (10 10,20 10,20 20,10 20,10 10))')),
  (PolyFromWKB(AsWKB(Polygon(LineString(Point(0, 0), Point(30, 0), Point(30, 30), Point(0,
0))))));

```

MULTIPOINT

```

CREATE TABLE gis_multi_point (g MULTIPOINT);
SHOW FIELDS FROM gis_multi_point;
INSERT INTO gis_multi_point VALUES
  (MultiPointFromText('MULTIPOINT(0 0,10 10,20 20 20)')),
  (MPointFromText('MULTIPOINT(1 1,11 11,21,21 21)')),
  (MPointFromWKB(AsWKB(MultiPoint(Point(3, 6), Point(4, 10))))));

```

MULTILINESTRING

```

CREATE TABLE gis_multi_line (g MULTILINESTRING);
SHOW FIELDS FROM gis_multi_line;
INSERT INTO gis_multi_line VALUES
  (MultiLineStringFromText('MULTILINESTRING((10 48,10 21,10 0), (16 0,16 23,16 48))')),
  (MLineFromText('MULTILINESTRING((10 48,10 21,10 0))')),
  (MLineFromWKB(AsWKB(MultiLineString(LineString(Point(1, 2), Point(3, 5)),
LineString(Point(2, 5), Point(5, 8), Point(21, 7))))));

```

MULTIPOLYGON

```

CREATE TABLE gis_multi_polygon (g MULTIPOLYGON);
SHOW FIELDS FROM gis_multi_polygon;
INSERT INTO gis_multi_polygon VALUES
  (MultiPolygonFromText('MULTIPOLYGON(((28 26,28 0,84 0,84 42,28 26), (52 18,66 23,73 9,48
6,52 18)), ((59 18,67 18,67 13,59 13,59 18)))')),
  (MPolyFromText('MULTIPOLYGON(((28 26,28 0,84 0,84 42,28 26), (52 18,66 23,73 9,48 6,52 18)),
((59 18,67 18,67 13,59 13,59 18)))')),
  (MPolyFromWKB(AsWKB(MultiPolygon(Polygon(LineString(Point(0, 3), Point(3, 3), Point(3, 0),
Point(0, 3))))));

```

GEOMETRYCOLLECTION

```

CREATE TABLE gis_geometrycollection (g GEOMETRYCOLLECTION);
SHOW FIELDS FROM gis_geometrycollection;
INSERT INTO gis_geometrycollection VALUES
  (GeomCollFromText('GEOMETRYCOLLECTION(POINT(0 0), LINESTRING(0 0,10 10))')),
  (GeometryFromWKB(AsWKB(GeometryCollection(Point(44, 6), LineString(Point(3, 6), Point(7,
9)))))),
  (GeomFromText('GeometryCollection()')),
  (GeomFromText('GeometryCollection EMPTY'));

```

GEOMETRY

```

CREATE TABLE gis_geometry (g GEOMETRY);
SHOW FIELDS FROM gis_geometry;
INSERT into gis_geometry SELECT * FROM gis_point;
INSERT into gis_geometry SELECT * FROM gis_line;
INSERT into gis_geometry SELECT * FROM gis_polygon;
INSERT into gis_geometry SELECT * FROM gis_multi_point;
INSERT into gis_geometry SELECT * FROM gis_multi_line;
INSERT into gis_geometry SELECT * FROM gis_multi_polygon;
INSERT into gis_geometry SELECT * FROM gis_geometrycollection;

```

1.1.3.4 Geometry Hierarchy

Description

Geometry is the base class. It is an abstract class. The instantiable subclasses of Geometry are restricted to zero-, one-, and two-dimensional geometric objects that exist in two-dimensional coordinate space. All instantiable geometry classes are defined so that valid instances of a geometry class are topologically closed (that is, all defined geometries include their boundary).

The base Geometry class has subclasses for Point, Curve, Surface, and GeometryCollection:

- [Point](#) represents zero-dimensional objects.
- Curve represents one-dimensional objects, and has subclass [LineString](#), with sub-subclasses Line and LinearRing.
- Surface is designed for two-dimensional objects and has subclass [Polygon](#).
- [GeometryCollection](#) has specialized zero-, one-, and two-dimensional collection classes named [MultiPoint](#), [MultiLineString](#), and [MultiPolygon](#) for modeling geometries corresponding to collections of Points, LineStrings, and Polygons, respectively. MultiCurve and MultiSurface are introduced as abstract superclasses that generalize the collection interfaces to handle Curves and Surfaces.

Geometry, Curve, Surface, MultiCurve, and MultiSurface are defined as non-instantiable classes. They define a common set of methods for their subclasses and are included for extensibility.

[Point](#), [LineString](#), [Polygon](#), [GeometryCollection](#), [MultiPoint](#), [MultiLineString](#), and [MultiPolygon](#) are instantiable classes.

1.1.3.15 SPATIAL INDEX

Contents

1. [Description](#)
 1. [Data-at-Rest Encryption](#)

Description

On [MyISAM](#), [Aria](#) and [InnoDB](#) tables, MariaDB can create spatial indexes (an R-tree index) using syntax similar to that for creating regular indexes, but extended with the `SPATIAL` keyword. Currently, columns in spatial indexes must be declared `NOT NULL`.

Spatial indexes can be created when the table is created, or added after the fact like so:

- with [CREATE TABLE](#):

```
CREATE TABLE geom (g GEOMETRY NOT NULL, SPATIAL INDEX(g));
```

- with [ALTER TABLE](#):

```
ALTER TABLE geom ADD SPATIAL INDEX(g);
```

- with [CREATE INDEX](#):

```
CREATE SPATIAL INDEX sp_index ON geom (g);
```

`SPATIAL INDEX` creates an `R-tree` index. For storage engines that support non-spatial indexing of spatial columns, the engine creates a `B-tree` index. A `B-tree` index on spatial values is useful for exact-value lookups, but not for range scans.

For more information on indexing spatial columns, see [CREATE INDEX](#).

To drop spatial indexes, use [ALTER TABLE](#) or [DROP INDEX](#):

- with [ALTER TABLE](#):

```
ALTER TABLE geom DROP INDEX g;
```

- with [DROP INDEX](#):

```
DROP INDEX sp_index ON geom;
```

Data-at-Rest Encryption

Before [MariaDB 10.4.3](#), InnoDB's spatial indexes could not be [encrypted](#). If an InnoDB table was encrypted and if it contained spatial indexes, then those indexes would be unencrypted.

In [MariaDB 10.4.3](#) and later, if `innodb_checksum_algorithm` is set to `full_crc32` or `strict_full_crc32`, and if the table does not use `ROW_FORMAT=COMPRESSED`, then InnoDB spatial indexes will be encrypted if the table is encrypted.

See [MDEV-12026](#) for more information.

1.1.3.16 GeoJSON

GeoJSON is a format for encoding various geographic data structures.

ST_AsGeoJSON

Returns the given geometry as a GeoJSON element.

ST_GeomFromGeoJSON

Given a GeoJSON input, returns a geometry object

1.1.3.16.1 ST_AsGeoJSON

Syntax

```
ST_AsGeoJSON(g[, max_decimals[, options]])
```

Description

Returns the given geometry *g* as a GeoJSON element. The optional *max_decimals* limits the maximum number of decimals displayed.

The optional *options* flag can be set to `1` to add a bounding box to the output.

Examples

```
SELECT ST_AsGeoJSON(ST_GeomFromText('POINT(5.3 7.2)'));
+-----+
| ST_AsGeoJSON(ST_GeomFromText('POINT(5.3 7.2)')) |
+-----+
| {"type": "Point", "coordinates": [5.3, 7.2]}      |
+-----+
```

1.1.3.16.2 ST_GeomFromGeoJSON

Syntax

```
ST_GeomFromGeoJSON(g[, option])
```

Description

Given a GeoJSON input *g*, returns a geometry object. The *option* specifies what to do if *g* contains geometries with coordinate dimensions higher than 2.

Option	Description
1	Return an error (the default)
2 - 4	The document is accepted, but the coordinates for higher coordinate dimensions are stripped off.

Note that this function did not work correctly before [MariaDB 10.2.8](#) - see [MDEV-12180](#).

Examples

```
SET @j = '{"type": "Point", "coordinates": [5.3, 15.0]}';

SELECT ST_AsText(ST_GeomFromGeoJSON(@j));
+-----+
| ST_AsText(ST_GeomFromGeoJSON(@j)) |
+-----+
| POINT(5.3 15)                       |
+-----+
```

1.1.3.17 Miscellaneous GIS functions

ST_Collect

Given multiple geometries, returns the aggregation of the distinct geometry arguments.

ST_GeoHash

Returns the geohash corresponding to the input values.

ST_IsValid

Returns 1 if the argument is geometrically valid, 0 if not.

ST_LatFromGeoHash

Decodes a given geohash and returns the latitude.

ST_LongFromGeoHash

Decodes a given geohash string and returns the longitude in the interval [180, -180].

ST_PointFromGeoHash

From a geohash, returns a point where the x is the longitude and the y is the latitude.

ST_Simplify

Applies the Ramer–Douglas–Peucker algorithm to provide generalized simplifications.

ST_Validate

Checks that a given geometry is valid.

1.1.3.17.1 ST_Collect

MariaDB starting with [11.8](#)

ST_Collect was added in [MariaDB 11.8](#).

Syntax

```
ST_Collect (g)
```

Description

ST_Collect is an aggregate function that can also be used as a window function.

Given multiple geometries, returns the aggregation of the distinct geometry arguments. This function also supports the DISTINCT option. If DISTINCT is used, it returns the aggregation of the distinct geometry arguments.

The resulting value type is chosen using the following policy:

- If all arguments are [Point](#) values, the result is a [MultiPoint](#) value.
- If all arguments are [LineString](#) values, the result is a [MultiLineString](#) value.
- If all arguments are [Polygon](#) values, the result is a [MultiPolygon](#) value.
- Otherwise, the result is a [GeometryCollection](#) value.

If there are multiple geometry arguments and those arguments are in the same spatial reference system (SRS), the return value is in that SRS. If those arguments are not in the same SRS, an `ER_GIS_DIFFERENT_SRIDS_AGGREGATION` error occurs.

Examples

Multiple [Point](#) geometries aggregated into a [MultiPoint](#) geometry:

```

CREATE OR REPLACE TABLE t1 ( running_number INTEGER NOT NULL
    AUTO_INCREMENT, grouping_condition INTEGER, location GEOMETRY , PRIMARY KEY (
    running_number));

INSERT INTO t1 ( grouping_condition, location ) VALUES
    ( 0,ST_GEOFROMTEXT('POINT(0 0)',4326)),
    ( 1,ST_GEOFROMTEXT('POINT(0 0)',4326)),
    ( 0,ST_GEOFROMTEXT('POINT(1 0)',4326)),
    ( 1,ST_GEOFROMTEXT('POINT(2 0)',4326)),
    ( 0,ST_GEOFROMTEXT('POINT(3 0)',4326));

SELECT ST_EQUALS( (SELECT ST_COLLECT( location ) AS t FROM t1),
    ST_GEOFROMTEXT('MULTIPOINT(0 0,0 0,1 0,2 0,3 0) ',4326)) AS equals;
+-----+
| equals |
+-----+
|      1 |
+-----+

```

1.1.3.17.2 ST_GeoHash

MariaDB starting with [11.8](#)
 ST_GeoHash was added in [MariaDB 11.8](#).

Syntax

```

ST_GeoHash(longitude, latitude, max_length)
ST_GeoHash(point, max_length)

```

Description

Returns the geohash corresponding to the input values, or NULL if any argument is NULL. Geohashes encode latitude and longitude coordinates into a text string made up only of numeric and lowercase latin letter characters.

The `longitude` parameter is a numeric value in the interval [180, -180]. `latitude` is a numeric value in the interval [90, -90].

In the case of `point`, the x coordinate is treated as the latitude and the y coordinate is treated as the longitude. The same constraints apply.

The `max_length` parameter is the upper limit on the resulting string size and cannot exceed 100.

The [ST_LatFromGeoHash](#) function decodes a given geohash and returns the latitude.

Examples

```

SELECT ST_GeoHash(ST_GeomFromText('POINT(1 1)'),15), ST_GeoHash(0,30,15);
+-----+-----+
| ST_GeoHash(ST_GeomFromText('POINT(1 1)'),15) | ST_GeoHash(0,30,15) |
+-----+-----+
| s00twy01mtw037m                               | sj248j248j248j2     |
+-----+-----+

```

1.1.3.17.3 ST_IsValid

MariaDB starting with [11.8](#)
 ST_IsValid was added in [MariaDB 11.8](#).

Syntax

```
ST_IsValid(g)
```

Description

Given a geometry input, returns 1 if the argument is geometrically valid according to the OGC specifications, 0 if the argument is not geometrically valid.

Unlike [ST_Validate](#), requires valid GIS data, or `ERROR 3037 (22023): Invalid GIS data provided to function st_isvalid` is returned.

Examples

```
SELECT ST_IsValid(ST_GeomFromText('LINESTRING (0 0, 1 1)'));
+-----+
| ST_IsValid(ST_GeomFromText('LINESTRING (0 0, 1 1)')) |
+-----+
|                                     1 |
+-----+

SELECT ST_IsValid(ST_GeomFromText('LINESTRING (0 0, 0 0)'));
+-----+
| ST_IsValid(ST_GeomFromText('LINESTRING (0 0, 0 0)')) |
+-----+
|                                     0 |
+-----+
```

A [POINT](#) requires both x and y co-ordinates:

```
SELECT ST_IsValid(ST_GeomFromText('POINT (0)'));
ERROR 3037 (22023): Invalid GIS data provided to function st_isvalid.
```

1.1.3.17.4 ST_LatFromGeoHash

MariaDB starting with [11.8](#)
ST_LatFromGeoHash was added in [MariaDB 11.8](#).

Syntax

```
ST_LatFromGeoHash(geohash)
```

Description

Decodes a given `geohash` string and returns the latitude in the interval [90, -90].

If the argument is NULL, the return value is NULL. If the argument is invalid, an `ER_INCORRECT_TYPE` error is thrown.

The [ST_GeoHash](#) function can be used to generate geohashes.

Examples

```
SELECT ST_LatFromGeoHash('zzzzzzzz'), ST_LatFromGeoHash('xvrfxvrfxvrfxvr');
+-----+-----+
| ST_LatFromGeoHash('zzzzzzzz') | ST_LatFromGeoHash('xvrfxvrfxvrfxvr') |
+-----+-----+
|                               90 |                               30 |
+-----+-----+
```

1.1.3.17.5 ST_LongFromGeoHash

MariaDB starting with [11.8](#)
ST_LongFromGeoHash was added in [MariaDB 11.8](#).

Syntax

```
ST_LongFromGeoHash(geohash)
```

Description

Decodes a given `geohash` string and returns the longitude in the interval [180, -180].

If the argument is NULL, the return value is NULL. If the argument is invalid, an `ER_INCORRECT_TYPE` error is thrown.

The `ST_GeoHash` function can be used to generate geohashes.

Examples

```
SELECT ST_LongFromGeoHash('zzzzzzzz'), ST_LongFromGeoHash('sj248j248j248j2');
+-----+-----+
| ST_LongFromGeoHash('zzzzzzzz') | ST_LongFromGeoHash('sj248j248j248j2') |
+-----+-----+
|                               | 0 |
+-----+-----+
```

1.1.3.17.6 ST_PointFromGeoHash

MariaDB starting with [11.8](#)
ST_PointFromGeoHash was added in [MariaDB 11.8](#).

Syntax

```
ST_PointFromGeoHash(geohash, srid)
```

Description

Takes a given `geohash` string and returns a point where the x is the longitude and the y is the latitude.

The latitude is returned as a numeric value in the interval [180, -180]. The longitude is returned as a numeric value in the interval [90, -90]. If the argument is NULL, the return value is NULL. If the argument is invalid, an `ER_GIS_INVALID_DATA` is thrown.

Examples

```
SELECT ST_ASTEXT(ST_POINTFROMGEOHASH("s00twy01mtw037m",0));
+-----+-----+
| ST_ASTEXT(ST_POINTFROMGEOHASH("s00twy01mtw037m",0)) |
+-----+-----+
| POINT(1 1) |
+-----+-----+

SELECT ST_ASTEXT(ST_POINTFROMGEOHASH(ST_GEOHASH(180,90,20),0));
+-----+-----+
| ST_ASTEXT(ST_POINTFROMGEOHASH(ST_GEOHASH(180,90,20),0)) |
+-----+-----+
| POINT(180 90) |
+-----+-----+
```

1.1.3.17.7 ST_Simplify

MariaDB starting with [11.8](#)
ST_Simplify was added in [MariaDB 11.8](#).

Syntax

```
ST_Simplify(g, max_distance)
```

Description

Takes as input a geometry (*g*) and a double (*max_distance*). It applies the [Ramer–Douglas–Peucker algorithm](#) on *g* and returns the resulting geometry.

The goal of the Douglas-Peucker algorithm is to provide generalized simplifications by returning a geometry that is similar to *g* but uses only a subset of points. To perform the simplification, all the vertices that are shorter than *max_distance* are removed.

The algorithm may produce self-intersections and therefore result in invalid geometries. [ST_IsValid](#) can be used to test validity of the result.

If the *max_distance* is not positive or is NULL, an ER_WRONG_ARGUMENT will occur.

Examples

```
SELECT ST_AsText(ST_Simplify(ST_GeomFromText('LINESTRING(0 0,0 2,2 2,2 4,4 4,4 6,6 6)'), 0.5));
+-----+
| ST_AsText(ST_Simplify(ST_GeomFromText('LINESTRING(0 0,0 2,2 2,2 4,4 4,4 6,6 6)'), 0.5)) |
+-----+
| LINESTRING(0 0,0 2,2 2,2 4,4 4,4 6,6 6) |
+-----+

SELECT ST_AsText(ST_Simplify(ST_GeomFromText('LINESTRING(0 0,0 2,2 2,2 4,4 4,4 6,6 6)'), 1));
+-----+
| ST_AsText(ST_Simplify(ST_GeomFromText('LINESTRING(0 0,0 2,2 2,2 4,4 4,4 6,6 6)'), 1)) |
+-----+
| LINESTRING(0 0,0 2,2 2,2 4,6 6) |
+-----+
```

1.1.3.17.8 ST_Validate

MariaDB starting with [11.8](#)
ST_Validate was added in [MariaDB 11.8](#).

Syntax

```
ST_Validate(g)
```

Description

The function checks that a given geometry is compliant with the Well-Known Binary (WKB) format and Spatial Reference System Identifier (SRID) syntax, and is geometrically valid.

It returns the geometry if it's valid, or NULL if not.

The function is useful to filter out invalid geometry data.

Examples

A **POINT** requires both x and y co-ordinates:

```
SELECT ST_ASTEXT(ST_VALIDATE(ST_GeomFromText('POINT(1 0)')));
+-----+
| ST_ASTEXT(ST_VALIDATE(ST_GeomFromText('POINT(1 0)')) |
+-----+
| POINT(1 0) |
+-----+

SELECT ST_ASTEXT(ST_VALIDATE(ST_GeomFromText('POINT(1)')));
+-----+
| ST_ASTEXT(ST_VALIDATE(ST_GeomFromText('POINT(1)')) |
+-----+
| NULL |
+-----+
```

1.1.4 NoSQL

MariaDB supports a lot of commands and interfaces that are closer to NoSQL than to SQL.

CONNECT

*The **CONNECT** storage engine enables MariaDB to access external local or remote data.*

HANDLER

Direct access to reading rows from the storage engine.

HandlerSocket

A NoSQL plugin giving you direct access to InnoDB and SPIDER.

Dynamic Columns

Dynamic columns allow one to store different sets of columns for each row in a table

Dynamic Columns from MariaDB 10

Improvements to Dynamic Columns from MariaDB 10.

Dynamic Column API

Client-side API for reading and writing Dynamic Columns blobs

Dynamic Columns API

MariaDB 10.0 API for reading and writing dynamic-columns blobs [↗](#)

JSON Functions

Built-in functions related to JSON.

LOAD_FILE

Returns file contents as a string.

Cassandra Storage Engine

A storage engine interface to Cassandra. [↗](#)

There are [1 related questions](#) [↗](#).

5.3.7 CONNECT

1.1.4.2 HANDLER

The **HANDLER** statements give you direct access to reading rows from the storage engine. This is much faster than normal access through **SELECT** as there is less parsing involved and no optimizer involved.

You can use [prepared statements](#) for **HANDLER READ**, which should give you a speed comparable to [HandlerSocket](#). Also see Yoshinori Matsunobu's blog post [Using MySQL as a NoSQL - A story for exceeding 750,000 qps on a commodity server](#) [↗](#).

HANDLER Commands

Direct access to table storage engine interfaces for key lookups and key or table scans.

HANDLER for MEMORY Tables

Using HANDLER commands efficiently with MEMORY/HEAP tables

1.1.4.2.1 HANDLER Commands

Syntax

```

HANDLER tbl_name OPEN [ [AS] alias]
HANDLER tbl_name READ index_name { = | >= | <= | < } (value1,value2,...)
  [ WHERE where_condition ] [LIMIT ... ]
HANDLER tbl_name READ index_name { FIRST | NEXT | PREV | LAST }
  [ WHERE where_condition ] [LIMIT ... ]
HANDLER tbl_name READ { FIRST | NEXT }
  [ WHERE where_condition ] [LIMIT ... ]
HANDLER tbl_name CLOSE

```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Key Lookup](#)
4. [Key Scans](#)
5. [Table Scans](#)
6. [Limitations](#)
 1. [Finding 'Old Rows'](#)
 2. [Invisible Columns](#)
 3. [System-Versioned Tables](#)
 4. [Other Limitations](#)
7. [Error Codes](#)
8. [Examples](#)

Description

The `HANDLER` statement provides direct access to table storage engine interfaces for key lookups and key or table scans. It is available for at least [Aria](#), [Memory](#), [MyISAM](#) and [InnoDB](#) tables (and should work with most 'normal' storage engines, but not with system tables, [MERGE](#) or [views](#)).

`HANDLER ... OPEN` opens a table, allowing it to be accessible to subsequent `HANDLER ... READ` statements. The table can either be opened using an alias, or a table name. If opened with an alias, references to this table by further `HANDLER` statements must use this alias, and not the table name. If opened with a table name qualified by database name, further references to this table must use the unqualified table name. For example, if a table is opened with `db1.t1`, further references must use `t1`.

The table object is only closed when `HANDLER ... CLOSE` is called by the session, or the session closes, and is not shared by other sessions.

[Prepared statements](#) work with `HANDLER READ`, which gives a much higher performance (50% speedup) as there is no parsing and all data is transformed in binary (without conversions to text, as with the normal protocol).

The `HANDLER` command does not work with [partitioned tables](#).

Key Lookup

A key lookup is started with:

```

HANDLER tbl_name READ index_name { = | >= | <= | < } (value,value) [LIMIT...]

```

The values stands for the value of each of the key columns. For most key types (except for HASH keys in MEMORY storage engine) you can use a prefix subset of it's columns.

If you are using `LIMIT`, then in case of `>=` or `>` then there is an implicit `NEXT` implied, while if you are using `<=` or `<` then there is an implicit `PREV` implied.

After the initial read, you can use

```
HANDLER tbl_name READ index_name NEXT [ LIMIT ... ]  
or  
HANDLER tbl_name READ index_name PREV [ LIMIT ... ]
```

to scan the rows in key order.

Note that the row order is not defined for keys with duplicated values and will vary from engine to engine.

Key Scans

You can scan a table in key order by doing:

```
HANDLER tbl_name READ index_name FIRST [ LIMIT ... ]  
HANDLER tbl_name READ index_name NEXT [ LIMIT ... ]
```

or, if the handler supports backwards key scans (most do):

```
HANDLER tbl_name READ index_name LAST [ LIMIT ... ]  
HANDLER tbl_name READ index_name PREV [ LIMIT ... ]
```

Table Scans

You can scan a table in row order by doing:

```
HANDLER tbl_name READ FIRST [ LIMIT ... ]  
HANDLER tbl_name READ NEXT [ LIMIT ... ]
```

Limitations

As this is a direct interface to the storage engine, some limitations may apply for what you can do and what happens if the table changes. Here follows some of the common limitations:

Finding 'Old Rows'

HANDLER READ is not transaction safe, consistent or atomic. It's ok for the storage engine to return rows that existed when you started the scan but that were later deleted. This can happen as the storage engine may cache rows as part of the scan from a previous read.

You may also find rows committed since the scan originally started.

Invisible Columns

HANDLER ... READ also reads the data of [invisible-columns](#).

System-Versioned Tables

HANDLER ... READ reads everything from [system-versioned tables](#), and so includes `row_start` and `row_end` fields, as well as all rows that have since been deleted or changed, including when history partitions are used.

Other Limitations

- If you do an [ALTER TABLE](#), all your HANDLERs for that table are automatically closed.
- If you do an ALTER TABLE for a table that is used by some other connection with HANDLER, the ALTER TABLE will wait for the HANDLER to be closed.
- For HASH keys, you must use all key parts when searching for a row.
- For HASH keys, you can't do a key scan of all values. You can only find all rows with the same key value.
- While each HANDLER READ command is atomic, if you do a scan in many steps, then some engines may give you [error 1020](#) if the table changed between the commands. Please refer to the [specific engine handler page](#) if this happens.

Error Codes

- [Error 1031](#) (ER_ILLEGAL_HA) Table storage engine for 't1' doesn't have this option
 - If you get this for HANDLER OPEN it means the storage engine doesn't support HANDLER calls.
 - If you get this for HANDLER READ it means you are trying to use an incomplete HASH key.
- [Error 1020](#) (ER_CHECKREAD) Record has changed since last read in table '...'
 - This means that the table changed between two reads and the handler can't handle this case for the given scan.

Examples

```
CREATE TABLE t1 (f1 INT);

INSERT INTO t1 VALUES (1), (2), (3);

HANDLER t1 OPEN;

HANDLER t1 READ NEXT;
+-----+
| f1  |
+-----+
|  1  |
+-----+

HANDLER t1 READ NEXT;
+-----+
| f1  |
+-----+
|  2  |
+-----+
```

In the previous example, the HANDLER was opened with the t1 table name. Since HANDLERS use unqualified table names, trying to access another table with this same name, even though it's in another database, will result in ambiguity. An alias needs to be used to avoid the ambiguity, resulting in [Error 1066: Not unique table/alias](#).

```
CREATE DATABASE db_new;

CREATE TABLE db_new.t1 (id INT);

INSERT INTO db_new.t1 VALUES (4), (5), (6);

HANDLER db_new.t1 OPEN;
ERROR 1066 (42000): Not unique table/alias: 't1'

HANDLER db_new.t1 OPEN AS db_new_t1;

HANDLER db_new_t1 READ NEXT LIMIT 3;
+-----+
| id  |
+-----+
|  4  |
|  5  |
|  6  |
+-----+
```

1.1.4.2.2 HANDLER for MEMORY Tables

This article explains how to use [HANDLER commands](#) efficiently with [MEMORY/HEAP](#) tables.

If you want to scan a table for over different key values, not just search for exact key values, you should create your keys with 'USING BTREE':

```
CREATE TABLE t1 (a INT, b INT, KEY(a), KEY b USING BTREE (b)) engine=memory;
```

In the above table, `a` is a [HASH](#) key that only supports exact matches (=) while `b` is a [BTREE](#) key that you can use to scan the table in key order, starting from start or from a given key value.

The limitations for HANDLER READ with Memory|HEAP tables are:

Limitations for HASH keys

- You must use all key parts when searching for a row.
- You can't do a key scan of all values. You can only find all rows with the same key value.
- READ NEXT gives error 1031 if the tables changed since last read.

Limitations for BTREE keys

- READ NEXT gives error 1031 if the tables changed since last read. This limitation can be lifted in the future.

Limitations for table scans

- READ NEXT gives error 1031 if the table was truncated since last READ call.

1.1.4.3 HandlerSocket

HandlerSocket gives you direct access to [InnoDB](#) and [SPIDER](#). It is included in MariaDB as a ready-to use plugin.

HandlerSocket is a NoSQL plugin for MariaDB. It works as a daemon inside the mariadb process, accepting TCP connections, and executing requests from clients. HandlerSocket does not support SQL queries. Instead, it supports simple CRUD operations on tables.

HandlerSocket can be much faster than mysqld/libmysql in some cases because it has lower CPU, disk, and network overhead:

1. To lower CPU usage it does not parse SQL.
2. Next, it batch-processes requests where possible, which further reduces CPU usage and lowers disk usage.
3. Lastly, the client/server protocol is very compact compared to mysql/libmysql, which reduces network usage.

HandlerSocket Installation

[Installing the HandlerSocket plugin.](#)

HandlerSocket Configuration Options

[HandlerSocket configuration options.](#)

HandlerSocket Client Libraries

[Available HandlerSocket Client Libraries](#)

Testing HandlerSocket in a Source Distribution

[Testing HandlerSocket in a source distribution.](#)

HandlerSocket External Resources

[HandlerSocket external resources and documentation](#)

1.1.4.3.1 HandlerSocket Installation

After MariaDB is installed, use the [INSTALL PLUGIN](#) command (as the root user) to install the HandlerSocket plugin. This command only needs to be run once, like so:

```
INSTALL PLUGIN handlersocket SONAME 'handlersocket.so';
```

After installing the plugin, [SHOW PROCESSLIST](#) you first need to configure some settings. All [HandlerSocket configuration options](#) are placed in the [mysqld] section of your my.cnf file.

At least the [handlersocket_address](#), [handlersocket_port](#) and [handlersocket_port_wr](#) options need to be set. For example:

```
handlersocket_address="127.0.0.1"  
handlersocket_port="9998"  
handlersocket_port_wr="9999"
```

After updating the configuration options, restart MariaDB.

On the client side, to make use of the plugin you will need to install the appropriate client library (i.e. libhsclient for C++ applications and perl-Net-HandlerSocket for perl applications).

1.1.4.3.2 HandlerSocket Configuration Options

Contents

1. [handlersocket_accept_balance](#)
2. [handlersocket_address](#)
3. [handlersocket_backlog](#)
4. [handlersocket_epoll](#)
5. [handlersocket_plain_secret](#)
6. [handlersocket_plain_secret_wr](#)
7. [handlersocket_port](#)
8. [handlersocket_port_wr](#)
9. [handlersocket_rcvbuf](#)
10. [handlersocket_readsize](#)
11. [handlersocket_sndbuf](#)
12. [handlersocket_threads](#)
13. [handlersocket_threads_wr](#)
14. [handlersocket_timeout](#)
15. [handlersocket_verbose](#)
16. [handlersocket_wrlsock_timeout](#)

The [HandlerSocket](#) plugin has the following options.

See also the [Full list of MariaDB options, system and status variables](#).

Add the options to the `[mysqld]` section of your `my.cnf` file.

`handlersocket_accept_balance`

- **Description:** When set to a value other than zero ('0'), handlersocket will try to balance accepted connections among threads. Default is 0 but if you use persistent connections (for example if you use client-side connection pooling) then a non-zero value is recommended.
- **Commandline:** `--handlersocket-accept-balance="value"`
- **Scope:** Global
- **Dynamic:** No
- **Type:** number
- **Range:** 0 to 10000
- **Default Value:** 0

`handlersocket_address`

- **Description:** Specify the IP address to bind to.
- **Commandline:** `--handlersocket-address="value"`
- **Scope:** Global
- **Dynamic:** No
- **Type:** IP Address
- **Default Value:** Empty, previously 0.0.0.0

`handlersocket_backlog`

- **Description:** Specify the listen backlog length.
 - **Commandline:** `--handlersocket-backlog="value"`
 - **Scope:** Global
 - **Dynamic:** No
 - **Type:** number
 - **Range:** 5 to 1000000
 - **Default Value:** 32768
-

handlersocket_epoll

- **Description:** Specify whether to use epoll for I/O multiplexing.
 - **Commandline:** `--handlersocket-epoll="value"`
 - **Scope:** Global
 - **Dynamic:** No
 - **Type:** number
 - **Valid values:**
 - **Min:** 0
 - **Max:** 1
 - **Default Value:** 1
-

handlersocket_plain_secret

- **Description:** When set, enables plain-text authentication for the listener for read requests, with the value of the option specifying the secret authentication key.
 - **Commandline:** `--handlersocket-plain-secret="value"`
 - **Dynamic:** No
 - **Type:** string
 - **Default Value:** Empty
-

handlersocket_plain_secret_wr

- **Description:** When set, enables plain-text authentication for the listener for write requests, with the value of the option specifying the secret authentication key.
 - **Commandline:** `--handlersocket-plain-secret-wr="value"`
 - **Dynamic:** No
 - **Type:** string
 - **Default Value:** Empty
-

handlersocket_port

- **Description:** Specify the port to bind to for reads. An empty value disables the listener.
 - **Commandline:** `--handlersocket-port="value"`
 - **Scope:** Global
 - **Dynamic:** No
 - **Type:** number
 - **Default Value:** Empty, previously 9998
-

handlersocket_port_wr

- **Description:** Specify the port to bind to for writes. An empty value disables the listener.
 - **Commandline:** `--handlersocket-port-wr="value"`
 - **Scope:** Global
 - **Dynamic:** No
 - **Type:** number
 - **Default Value:** Empty, previously 9999
-

handlersocket_rcvbuf

- **Description:** Specify the maximum socket receive buffer (in bytes). If '0' then the system default is used.
 - **Commandline:** `--handlersocket-rcvbuf="value"`
 - **Scope:** Global
 - **Dynamic:** No
 - **Type:** number
 - **Range:** 0 to 1677216
 - **Default Value:** 0
-

handlersocket_readsize

- **Description:** Specify the minimum length of the request buffer. Larger values consume available memory but can make handlersocket faster for large requests.
 - **Commandline:** `--handlersocket-readsize="value"`
 - **Scope:** Global
 - **Dynamic:** No
 - **Type:** number
 - **Range:** 0 to 1677216
 - **Default Value:** 0 (possibly 4096)
-

handlersocket_sndbuf

- **Description:** Specify the maximum socket send buffer (in bytes). If '0' then the system default is used.
 - **Commandline:** `--handlersocket-sndbuf="value"`
 - **Scope:** Global
 - **Dynamic:** No
 - **Type:** number
 - **Range:** 0 to 1677216
 - **Default Value:** 0
-

handlersocket_threads

- **Description:** Specify the number of worker threads for reads. Recommended value = ((# CPU cores) * 2).
 - **Commandline:** `--handlersocket-threads="value"`
 - **Scope:** Global
 - **Dynamic:** No
 - **Type:** number
 - **Range:** 1 to 3000
 - **Default Value:** 16
-

handlersocket_threads_wr

- **Description:** Specify the number of worker threads for writes. Recommended value = 1.
 - **Commandline:** `--handlersocket-threads-wr="value"`
 - **Scope:** Global
 - **Dynamic:** No
 - **Type:** number
 - **Range:** 1 to 3000
 - **Default Value:** 1
-

handlersocket_timeout

- **Description:** Specify the socket timeout in seconds.
 - **Commandline:** `--handlersocket-timeout="value"`
 - **Scope:** Global
 - **Dynamic:** No
 - **Type:** number
 - **Range:** 30 to 3600
 - **Default Value:** 300
-

handlersocket_verbose

- **Description:** Specify the logging verbosity.
- **Commandline:** `--handlersocket-verbose="value"`
- **Scope:** Global
- **Dynamic:** No
- **Type:** number

- **Valid values:**
 - **Min:** 0
 - **Max:** 10000
- **Default Value:** 10

handlersocket_wrlock_timeout

- **Description:** The write lock timeout in seconds. When acting on write requests, handlersocket locks an advisory lock named 'handlersocket_wr' and this option sets the timeout for it.
- **Commandline:** `--handlersocket-wrlock-timeout="value"`
- **Scope:** Global
- **Dynamic:** No
- **Type:** number
- **Range:** 0 to 3600

1.1.4.3.3 HandlerSocket Client Libraries

In order to make use of the [HandlerSocket](#) plugin in your applications, you will need to use the appropriate client library. The following client libraries are available:

- C++
 - `libhsclient` *(included with the HandlerSocket plugin source)*
- Perl
 - `perl-Net-HandlerSocket` *(included with the HandlerSocket plugin source)*
- PHP
 - [Net_HandlerSocket](#)
 - [HSPHP](#)
 - [php-ext-handlersocketi](#)
- Java
 - [hs4j](#)
 - [handlersocketforjava](#)
- Python
 - [python-handler-socket](#)
 - [pyhandlersocket](#)
- Ruby
 - [ruby-handlersocket](#)
 - [handlersocket](#)
- JavaScript
 - `node-handlersocket`
- Scala
 - [hs2client](#)
- Haskell
 - `HandlerSocket-Haskell-Client`

1.1.4.3.4 Testing HandlerSocket in a Source Distribution

Contents

1. [MariaDB 5.5](#)
2. [MariaDB 5.3](#)

MariaDB 5.5

In [MariaDB 5.5](#), which is built using `cmake`, `Makefile.PL` is not generated automatically. If you want to run the perl tests, you will need to create it manually from `Makefile.PL.in`. It is fairly easy to do by replacing `LIB` and `INC` values with the correct ones. Also, `libhsclient.so` is not built by default; `libhsclient.a` can be found in `plugin/handler_socket` folder.

MariaDB 5.3

If you want to test or use handlersocket with a source installation of [MariaDB 5.3](#), here is one way to do this:

1. Compile with one of the build scripts that has the `-max` option, like `BUILD/compile-pentium64-max` or `BUILD/compile-pentium64-debug-max`
2. Start mysqld with the test framework

```
cd mysql-test
LD_LIBRARY_PATH=../plugin/handler_socket/libhsclient/.libs \
MTR_VERSION=1 perl mysql-test-run.pl --start-and-exit 1st \
--mysqld=--plugin-dir=../plugin/handler_socket/handlersocket/.libs \
--mysqld=--loose-handlersocket_port=9998 \
--mysqld=--loose-handlersocket_port_wr=9999 \
--master_port=9306 --mysqld=--innodb
```

3. This will end with:

```
Servers started, exiting
```

4. Load handlersocket

```
client/mysql -uroot --protocol=tcp --port=9306 \
-e 'INSTALL PLUGIN handlersocket soname "handlersocket.so"'
```

5. Configure and compile the handlersocket perl module

```
cd plugin/handler_socket/perl-Net-HandlerSocket
perl Makefile.PL
make
```

6. If you would like to install the handlersocket perl module permanently, you should do:

```
make install
```

If you do this, you don't have to set `PERL5LIB` below.

7. Run the handlersocket test suite

```
cd plugin/handler_socket/regtest/test_01_lib
MYHOST=127.0.0.1 MYPOR=9306 LD_LIBRARY_PATH=../../libhsclient/.libs/ \
PERL5LIB=../common:../../perl-Net-HandlerSocket/lib:../../perl-Net-
HandlerSocket/blib/arch/auto/Net/HandlerSocket/ ./run.sh
```

1.1.4.3.5 HandlerSocket External Resources

Some resources and documentation about HandlerSocket.

 4. [MariaDB 5.3 vs MariaDB 10.0](#)
 5. [Client-side API](#)
 6. [Limitations](#)

Dynamic columns allow one to store different sets of columns for each row in a table. It works by storing a set of columns in a blob and having a small set of functions to manipulate it.

Dynamic columns should be used when it is not possible to use regular columns.

A typical use case is when one needs to store items that may have many different attributes (like size, color, weight, etc), and the set of possible attributes is very large and/or unknown in advance. In that case, attributes can be put into dynamic columns.

Dynamic Columns Basics

The table should have a blob column which will be used as storage for dynamic columns:

```
create table assets (  
  item_name varchar(32) primary key, -- A common attribute for all items  
  dynamic_cols blob -- Dynamic columns will be stored here  
);
```

Once created, one can access dynamic columns via dynamic column functions:

Insert a row with two dynamic columns: color=blue, size=XL

```
INSERT INTO assets VALUES  
('MariaDB T-shirt', COLUMN_CREATE('color', 'blue', 'size', 'XL'));
```

Insert another row with dynamic columns: color=black, price=500

```
INSERT INTO assets VALUES  
('Thinkpad Laptop', COLUMN_CREATE('color', 'black', 'price', 500));
```

Select dynamic column 'color' for all items:

```
SELECT item_name, COLUMN_GET(dynamic_cols, 'color' as char)  
AS color FROM assets;  
+-----+-----+  
| item_name      | color |  
+-----+-----+  
| MariaDB T-shirt | blue  |  
| Thinkpad Laptop | black |  
+-----+-----+
```

It is possible to add and remove dynamic columns from a row:

```

-- Remove a column:
UPDATE assets SET dynamic_cols=COLUMN_DELETE(dynamic_cols, "price")
WHERE COLUMN_GET(dynamic_cols, 'color' AS CHAR)='black';

-- Add a column:
UPDATE assets SET dynamic_cols=COLUMN_ADD(dynamic_cols, 'warranty', '3 years')
WHERE item_name='Thinkpad Laptop';

```

You can also list all columns, or get them together with their values in JSON format:

```

SELECT item_name, column_list(dynamic_cols) FROM assets;
+-----+-----+
| item_name      | column_list(dynamic_cols) |
+-----+-----+
| MariaDB T-shirt | `size`,`color`           |
| Thinkpad Laptop | `color`,`warranty`       |
+-----+-----+

SELECT item_name, COLUMN_JSON(dynamic_cols) FROM assets;
+-----+-----+
| item_name      | COLUMN_JSON(dynamic_cols) |
+-----+-----+
| MariaDB T-shirt | {"size":"XL","color":"blue"} |
| Thinkpad Laptop | {"color":"black","warranty":"3 years"} |
+-----+-----+

```

Dynamic Columns Reference

The rest of this page is a complete reference of dynamic columns in MariaDB

Dynamic Columns Functions

COLUMN_CREATE

```

COLUMN_CREATE(column_nr, value [as type], [column_nr, value
[as type]]...);
COLUMN_CREATE(column_name, value [as type], [column_name, value
[as type]]...);

```

Return a dynamic columns blob that stores the specified columns with values.

The return value is suitable for

- storing in a table
- further modification with other dynamic columns functions

The **as type** part allows one to specify the value type. In most cases, this is redundant because MariaDB will be able to deduce the type of the value. Explicit type specification may be needed when the type of the value is not apparent. For example, a literal '2012-12-01' has a CHAR type by default, one will need to specify '2012-12-01' AS DATE to have it stored as a date. See the [Datatypes](#) section for further details. Note also [MDEV-597](#).

Typical usage:

```

-- MariaDB 5.3+:
INSERT INTO tbl SET dyncol_blob=COLUMN_CREATE(1 /*column id*/, "value");
-- MariaDB 10.0.1+:
INSERT INTO tbl SET dyncol_blob=COLUMN_CREATE("column_name", "value");

```

COLUMN_ADD

```

COLUMN_ADD(dyncol_blob, column_nr, value [as type],
[column_nr, value [as type]]...);
COLUMN_ADD(dyncol_blob, column_name, value [as type],
[column_name, value [as type]]...);

```

Adds or updates dynamic columns.

- `dyncol_blob` must be either a valid dynamic columns blob (for example, `COLUMN_CREATE` returns such blob), or an empty string.
- `column_name` specifies the name of the column to be added. If `dyncol_blob` already has a column with this name, it will be overwritten.
- `value` specifies the new value for the column. Passing a `NULL` value will cause the column to be deleted.
- `as type` is optional. See [#datatypes](#) section for a discussion about types.

The return value is a dynamic column blob after the modifications.

Typical usage:

```
-- MariaDB 5.3+:
UPDATE tbl SET dyncol_blob=COLUMN_ADD(dyncol_blob, 1 /*column id*/, "value")
WHERE id=1;
-- MariaDB 10.0.1+:
UPDATE t1 SET dyncol_blob=COLUMN_ADD(dyncol_blob, "column_name", "value")
WHERE id=1;
```

Note: `COLUMN_ADD()` is a regular function (just like `CONCAT()`), hence, in order to update the value in the table you have to use the `UPDATE ... SET dynamic_col=COLUMN_ADD(dynamic_col, ...,)` pattern.

COLUMN_GET

```
COLUMN_GET(dyncol_blob, column_nr as type);
COLUMN_GET(dyncol_blob, column_name as type);
```

Get the value of a dynamic column by its name. If no column with the given name exists, `NULL` will be returned.

`column_name as type` requires that one specify the datatype of the dynamic column they are reading.

This may seem counter-intuitive: why would one need to specify which datatype they're retrieving? Can't the dynamic columns system figure the datatype from the data being stored?

The answer is: SQL is a statically-typed language. The SQL interpreter needs to know the datatypes of all expressions before the query is run (for example, when one is using prepared statements and runs `"select COLUMN_GET(...)"`, the prepared statement API requires the server to inform the client about the datatype of the column being read before the query is executed and the server can see what datatype the column actually has).

See the [Datatypes](#) section for more information about datatypes.

COLUMN_DELETE

```
COLUMN_DELETE(dyncol_blob, column_nr, column_nr...);
COLUMN_DELETE(dyncol_blob, column_name, column_name...);
```

Delete a dynamic column with the specified name. Multiple names can be given.

The return value is a dynamic column blob after the modification.

COLUMN_EXISTS

```
COLUMN_EXISTS(dyncol_blob, column_nr);
COLUMN_EXISTS(dyncol_blob, column_name);
```

Check if a column with name `column_name` exists in `dyncol_blob`. If yes, return `1`, otherwise return `0`.

COLUMN_LIST

```
COLUMN_LIST(dyncol_blob);
```

Return a comma-separated list of column names. The names are quoted with backticks.

```

SELECT column_list(column_create('col1','val1','col2','val2'));
+-----+
| column_list(column_create('col1','val1','col2','val2')) |
+-----+
| `col1`,`col2` |
+-----+

```

COLUMN_CHECK

```
COLUMN_CHECK(dyncol_blob);
```

Check if `dyncol_blob` is a valid packed dynamic columns blob. Return value of 1 means the blob is valid, return value of 0 means it is not.

Rationale: Normally, one works with valid dynamic column blobs. Functions like `COLUMN_CREATE`, `COLUMN_ADD`, `COLUMN_DELETE` always return valid dynamic column blobs. However, if a dynamic column blob is accidentally truncated, or transcoded from one character set to another, it will be corrupted. This function can be used to check if a value in a blob field is a valid dynamic column blob.

Note: It is possible that a truncation cut a Dynamic Column "clearly" so that `COLUMN_CHECK` will not notice the corruption, but in any case of truncation a warning is issued during value storing.

COLUMN_JSON

```
COLUMN_JSON(dyncol_blob);
```

Return a JSON representation of data in `dyncol_blob`.

Example:

```

SELECT item_name, COLUMN_JSON(dynamic_cols) FROM assets;
+-----+-----+
| item_name      | COLUMN_JSON(dynamic_cols) |
+-----+-----+
| MariaDB T-shirt | {"size":"XL","color":"blue"} |
| Thinkpad Laptop | {"color":"black","warranty":"3 years"} |
+-----+-----+

```

Limitation: `COLUMN_JSON` will decode nested dynamic columns at a nesting level of not more than 10 levels deep. Dynamic columns that are nested deeper than 10 levels will be shown as BINARY string, without encoding.

Nesting Dynamic Columns

It is possible to use nested dynamic columns by putting one dynamic column blob inside another. The `COLUMN_JSON` function will display nested columns.

```

SET @tmp= column_create('parent_column',
  column_create('child_column', 12345));
Query OK, 0 rows affected (0.00 sec)

SELECT column_json(@tmp);
+-----+
| column_json(@tmp) |
+-----+
| {"parent_column":{"child_column":12345}} |
+-----+

SELECT column_get(column_get(@tmp, 'parent_column' AS char),
  'child_column' AS int);
+-----+-----+
| column_get(column_get(@tmp, 'parent_column' as char), 'child_column' as int) |
+-----+-----+
| | 12345 |
+-----+-----+

```

If you are trying to get a nested dynamic column as a string use 'as BINARY' as the last argument of `COLUMN_GET` (otherwise problems with character set conversion and illegal symbols are possible):

```
select column_json( column_get(
  column_create('test1',
    column_create('key1','value1','key2','value2','key3','value3')),
  'test1' as BINARY));
```

Datatypes

In SQL, one needs to define the type of each column in a table. Dynamic columns do not provide any way to declare a type in advance ("whenever there is a column 'weight', it should be integer" is not possible). However, each particular dynamic column value is stored together with its datatype.

The set of possible datatypes is mostly the same as that used by the SQL `CAST` and `CONVERT` functions. However, note that there are currently some differences - see [MDEV-597](#).

type	dynamic column internal type	description
BINARY [(N)]	DYN_COL_STRING	(variable length string with binary charset)
CHAR [(N)]	DYN_COL_STRING	(variable length string with charset)
DATE	DYN_COL_DATE	(date - 3 bytes)
DATETIME [(D)]	DYN_COL_DATETIME	(date and time (with microseconds) - 9 bytes)
DECIMAL [(M[, D])]	DYN_COL_DECIMAL	(variable length binary decimal representation with MariaDB limitation)
DOUBLE [(M, D)]	DYN_COL_DOUBLE	(64 bit double-precision floating point)
INTEGER	DYN_COL_INT	(variable length, up to 64 bit signed integer)
SIGNED [INTEGER]	DYN_COL_INT	(variable length, up to 64 bit signed integer)
TIME [(D)]	DYN_COL_TIME	(time (with microseconds , may be negative) - 6 bytes)
UNSIGNED [INTEGER]	DYN_COL_UINT	(variable length, up to 64bit unsigned integer)

A Note About Lengths

If you're running queries like

```
SELECT COLUMN_GET(blob, 'colname' as CHAR) ...
```

without specifying a maximum length (i.e. using `#as CHAR#`, not `as CHAR(n)`), MariaDB will report the maximum length of the resultset column to be `53,6870,911` (bytes or characters?) for [MariaDB 5.3-10.0.0](#) and `16,777,216` for [MariaDB 10.0.1](#)+. This may cause excessive memory usage in some client libraries, because they try to pre-allocate a buffer of maximum resultset width. If you suspect you're hitting this problem, use `CHAR(n)` whenever you're using `COLUMN_GET` in the select list.

MariaDB 5.3 vs MariaDB 10.0

The dynamic columns feature was introduced into MariaDB in two steps:

1. [MariaDB 5.3](#) was the first version to support dynamic columns. Only numbers could be used as column names in this version.
2. In [MariaDB 10.0.1](#), column names can be either numbers or strings. Also, the `COLUMN_JSON` and `COLUMN_CHECK` functions were added.

See also [Dynamic Columns in MariaDB 10](#).

Client-side API

It is also possible to create or parse dynamic columns blobs on the client side. `libmysql` client library now includes an API for writing/reading dynamic column blobs. See [dynamic-columns-api](#) for details.

Limitations

Description	Limit
Max number of columns	65535
Max total length of packed dynamic column	max_allowed_packet (1G)

1.1.4.5 Dynamic Columns from MariaDB 10

Contents

1. [Column Name Support](#)
2. [Changes in Behavior](#)
3. [New Functions](#)
 1. [COLUMN_CHECK](#)
 2. [COLUMN_JSON](#)
4. [Other Changes](#)
5. [Interface with Cassandra](#)

MariaDB starting with [10.0.1](#) [↗](#)

[MariaDB 10.0.1](#) [↗](#) introduced the following improvements to the [dynamic columns](#) feature.

Column Name Support

It is possible to refer to column by names. Names can be used everywhere where in [MariaDB 5.3](#) one could use only strings:

- Create a dynamic column blob:

```
COLUMN_CREATE('int_col', 123 as int, 'double_col', 3.14 as double, 'string_col', 'text-data' as char);
```

- Set a column value:

```
COLUMN_ADD(dyncol_blob, 'intcol', 1234);
```

- Get a column value:

```
COLUMN_GET(dynstr, 'column1' as char(10));
```

- Check whether a column exists

```
COLUMN_EXISTS(dyncol_blob, 'column_name');
```

Changes in Behavior

- Column list output now includes quoting:

```
select column_list(column_create(1, 22, 2, 23));
+-----+
| column_list(column_create(1, 22, 2, 23)) |
+-----+
| `1`,`2` |
+-----+
select column_list(column_create('column1', 22, 'column2', 23));
+-----+
| column_list(column_create('column1', 22, 'column2', 23)) |
+-----+
| `column1`,`column2` |
+-----+
```

- Column name interpretation has been changed so that the string now is not converted to a number. So some "magic" tricks will not work any more, for example, "1test" and "1" now become different column names:

```

select column_list(column_add(column_create('1a', 22), '1b', 23));
+-----+
| column_list(column_add(column_create('1a', 22), '1b', 23)) |
+-----+
| `1a`,`1b` |
+-----+

```

Old behavior:

```

select column_list(column_add(column_create('1a', 22), '1b', 23));
+-----+
| column_list(column_add(column_create('1a', 22), '1b', 23)) |
+-----+
| 1 |
+-----+

```

New Functions

The following new functions have been added to dynamic columns in MariaDB 10

COLUMN_CHECK

COLUMN_CHECK is used to check a column's integrity. When it encounters an error it does not return illegal format errors but returns false instead. It also checks integrity more thoroughly and finds errors in the dynamic column internal structures which might not be found by other functions.

```

select column_check(column_create('column1', 22));
+-----+
| column_check(column_create('column1', 22)) |
+-----+
| 1 |
+-----+

select column_check('abracadabra');
+-----+
| column_check('abracadabra') |
+-----+
| 0 |
+-----+

```

COLUMN_JSON

COLUMN_JSON converts all dynamic column record content to a JSON object.

```

select column_json(column_create('column1', 1, 'column2', "two"));
+-----+
| column_json(column_create('column1', 1, 'column2', "two")) |
+-----+
| {"column1":1,"column2":"two"} |
+-----+

```

Other Changes

- All API functions have the prefix `mariadb_dyncol_` (the old prefix `dynamic_column_` is deprecated)
- API changed to be able to work with the new format (`*_named` functions).
- Removed 'delete' function because deleting could be done by adding NULL value.
- 'Time' and 'datetime' in the new format are stored without microseconds if they are 0.
- New function added to API (except that two which are representing SQL level functions):
 - 'Unpack' the dynamic columns content to an arrays of values and names.
 - 3 functions to get any column value as string, integer (long long) or floating point (double).
- New type of "dynamic column" row added on the API level (in SQL level output it is a string but if you use dynamic column functions to construct object it will be added as dynamic column value) which allow to add dynamic columns inside dynamic columns. JSON function represent such recursive constructions correctly but limit depth of representation as current implementation limit (internally depth of dynamic columns embedding is not limited).

Interface with Cassandra

CassandraSE is no longer actively being developed and has been removed in [MariaDB 10.6](#). See [MDEV-23024](#).

Some internal changes were added to dynamic columns to allow them to serve as an interface to Apache Cassandra dynamic columns. The [Cassandra engine](#) may pack all columns which were not mentioned in the MariaDB interface table definition and even bring changes in the dynamic column contents back to the cassandra columns family (the table analog in cassandra).

1.1.4.6 Dynamic Column API

This page describes the client-side API for reading and writing [Dynamic Columns](#) blobs.

Normally, you should use [Dynamic column functions](#) which are run inside the MariaDB server and allow one to access Dynamic Columns content without any client-side libraries.

If you need to read/write dynamic column blobs **on the client** for some reason, this API enables that.

 14. [mariadb_dyncol_column_cmp_named](#)

Where to get it

The API is a part of `libmysql` C client library. In order to use it, you need to include this header file

```
#include <mysql/ma_dyncol.h>
```

and link against `libmysql`.

Data structures

DYNAMIC_COLUMN

`DYNAMIC_COLUMN` represents a packed dynamic column blob. It is essentially a string-with-length and is defined as follows:

```

/* A generic-purpose arbitrary-length string defined in MySQL Client API */
typedef struct st_dynamic_string
{
    char *str;
    size_t length,max_length,alloc_increment;
} DYNAMIC_STRING;

...

typedef DYNAMIC_STRING DYNAMIC_COLUMN;

```

DYNAMIC_COLUMN_VALUE

Dynamic columns blob stores {name, value} pairs. `DYNAMIC_COLUMN_VALUE` structure is used to represent the value in accessible form.

```

struct st_dynamic_column_value
{
    DYNAMIC_COLUMN_TYPE type;
    union
    {
        long long long_value;
        unsigned long long ulong_value;
        double double_value;
        struct {
            MYSQL_LEX_STRING value;
            CHARSET_INFO *charset;
        } string;
        struct {
            decimal_digit_t buffer[DECIMAL_BUFF_LENGTH];
            decimal_t value;
        } decimal;
        MYSQL_TIME time_value;
    } x;
};
typedef struct st_dynamic_column_value DYNAMIC_COLUMN_VALUE;

```

Every value has a type, which is determined by the `type` member.

type	structure field
DYN_COL_NULL	-
DYN_COL_INT	value.x.long_value
DYN_COL_UINT	value.x.ulong_value
DYN_COL_DOUBLE	value.x.double_value
DYN_COL_STRING	value.x.string.value, value.x.string.charset
DYN_COL_DECIMAL	value.x.decimal.value
DYN_COL_DATETIME	value.x.time_value
DYN_COL_DATE	value.x.time_value
DYN_COL_TIME	value.x.time_value
DYN_COL_DYNCOL	value.x.string.value

Notes

- Values with type `DYN_COL_NULL` do not ever occur in dynamic columns blobs.
- Type `DYN_COL_DYNCOL` means that the value is a packed dynamic blob. This is how nested dynamic columns are done.
- Before storing a value to `value.x.decimal.value`, one must call `mariadb_dyncol_prepare_decimal()` to initialize the space for storage.

enum_dyncol_func_result

enum `enum_dyncol_func_result` is used as return value.

value	name	meaning
0	ER_DYNCOL_OK	OK
0	ER_DYNCOL_NO	(the same as ER_DYNCOL_OK but for functions which return a YES/NO)
1	ER_DYNCOL_YES	YES response or success
2	ER_DYNCOL_TRUNCATED	Operation succeeded but the data was truncated
-1	ER_DYNCOL_FORMAT	Wrong format of the encoded string
-2	ER_DYNCOL_LIMIT	A limit of implementation reached
-3	ER_DYNCOL_RESOURCE	Out of resources
-4	ER_DYNCOL_DATA	Incorrect input data
-5	ER_DYNCOL_UNKNOWN_CHARSET	Unknown character set

Result codes that are less than zero represent error conditions.

Function reference

Functions come in pairs:

- `xxx()` operates on the old (pre-MariaDB-10.0.1) dynamic column blob format where columns were identified by numbers.
- `xxx_named()` can operate on both old or new data format. If it modifies the blob, it will convert it to the new data format.

You should use `xxx_named()` functions, unless you need to keep the data compatible with MariaDB versions before 10.0.1.

mariadb_dyncol_create_many

Create a packed dynamic blob from arrays of values and names.

```
enum enum_dyncol_func_result
mariadb_dyncol_create_many(DYNAMIC_COLUMN *str,
                           uint column_count,
                           uint *column_numbers,
                           DYNAMIC_COLUMN_VALUE *values,
                           my_bool new_string);

enum enum_dyncol_func_result
mariadb_dyncol_create_many_named(DYNAMIC_COLUMN *str,
                                  uint column_count,
                                  MYSQL_LEX_STRING *column_keys,
                                  DYNAMIC_COLUMN_VALUE *values,
                                  my_bool new_string);
```

where

```
str           OUT  Packed dynamic blob will be put here
column_count  IN   Number of columns
column_numbers IN   Column numbers array (old format)
column_keys   IN   Column names array (new format)
values        IN   Column values array
new_string    IN   If TRUE then the str will be reinitialized (not freed) before usage
```

mariadb_dyncol_update_many

Add or update columns in a dynamic columns blob. To delete a column, update its value to a "non-value" of type

```
DYN_COL_NULL
```

```

enum enum_dyncol_func_result
mariadb_dyncol_update_many(DYNAMIC_COLUMN *str,
                           uint column_count,
                           uint *column_numbers,
                           DYNAMIC_COLUMN_VALUE *values);

enum enum_dyncol_func_result
mariadb_dyncol_update_many_named(DYNAMIC_COLUMN *str,
                                 uint column_count,
                                 MYSQL_LEX_STRING *column_keys,
                                 DYNAMIC_COLUMN_VALUE *values);

```

str	IN/OUT	Dynamic columns blob to be modified.
column_count	IN	Number of columns in following arrays
column_numbers	IN	Column numbers array (old format)
column_keys	IN	Column names array (new format)
values	IN	Column values array

mariadb_dyncol_exists

Check if column with given name exists in the blob

```

enum enum_dyncol_func_result
mariadb_dyncol_exists(DYNAMIC_COLUMN *str, uint column_number);
enum enum_dyncol_func_result
mariadb_dyncol_exists_named(DYNAMIC_COLUMN *str, MYSQL_LEX_STRING *column_key);

```

str	IN	Packed dynamic columns string.
column_number	IN	Column number (old format)
column_key	IN	Column name (new format)

The function returns YES/NO or Error code

mariadb_dyncol_column_count

Get number of columns in a dynamic column blob

```

enum enum_dyncol_func_result
mariadb_dyncol_column_count(DYNAMIC_COLUMN *str, uint *column_count);

```

str	IN	Packed dynamic columns string.
column_count	OUT	Number of not NULL columns in the dynamic columns string

mariadb_dyncol_list

List columns in a dynamic column blob.

```

enum enum_dyncol_func_result
mariadb_dyncol_list(DYNAMIC_COLUMN *str, uint *column_count, uint **column_numbers);
enum enum_dyncol_func_result
mariadb_dyncol_list_named(DYNAMIC_COLUMN *str, uint *column_count,
                          MYSQL_LEX_STRING **column_keys);

```

str	IN	Packed dynamic columns string.
column_count	OUT	Number of columns in following arrays
column_numbers	OUT	Column numbers array (old format). Caller should free this array.
column_keys	OUT	Column names array (new format). Caller should free this array.

mariadb_dyncol_get

Get a value of one column

```
enum enum_dyncol_func_result
mariadb_dyncol_get(DYNAMIC_COLUMN *org, uint column_number,
                  DYNAMIC_COLUMN_VALUE *value);
enum enum_dyncol_func_result
mariadb_dyncol_get_named(DYNAMIC_COLUMN *str, MYSQL_LEX_STRING *column_key,
                        DYNAMIC_COLUMN_VALUE *value);
```

str IN Packed dynamic columns string.

column_number IN Column numbers array (old format)

column_key IN Column names array (new format)

value OUT Value of the column

If the column is not found NULL returned as a value of the column.

mariadb_dyncol_unpack

Get value of all columns

```
enum enum_dyncol_func_result
mariadb_dyncol_unpack(DYNAMIC_COLUMN *str,
                     uint *column_count,
                     MYSQL_LEX_STRING **column_keys,
                     DYNAMIC_COLUMN_VALUE **values);
```

str IN Packed dynamic columns string to unpack.

column_count OUT Number of columns in following arrays

column_keys OUT Column names array (should be free by caller)

values OUT Values of the columns array (should be free by caller)

mariadb_dyncol_has_names

Check whether the dynamic columns blob uses new data format (the one where columns are identified by names)

```
my_bool mariadb_dyncol_has_names(DYNAMIC_COLUMN *str);
```

str IN Packed dynamic columns string.

mariadb_dyncol_check

Check whether dynamic column blob has correct data format.

```
enum enum_dyncol_func_result
mariadb_dyncol_check(DYNAMIC_COLUMN *str);
```

str IN Packed dynamic columns string.

mariadb_dyncol_json

Get contents of a dynamic columns blob in a JSON form

```
enum enum_dyncol_func_result
mariadb_dyncol_json(DYNAMIC_COLUMN *str, DYNAMIC_STRING *json);
```

str IN Packed dynamic columns string.

mariadb_dyncol_val_TYPE

Get dynamic column value as one of the base types

```
enum enum_dyncol_func_result
mariadb_dyncol_val_str(DYNAMIC_STRING *str, DYNAMIC_COLUMN_VALUE *val,
                      CHARSET_INFO *cs, my_bool quote);
enum enum_dyncol_func_result
mariadb_dyncol_val_long(longlong *ll, DYNAMIC_COLUMN_VALUE *val);
enum enum_dyncol_func_result
mariadb_dyncol_val_double(double *dbl, DYNAMIC_COLUMN_VALUE *val);
```

str or ll or dbl OUT value of the column

val IN Value

mariadb_dyncol_prepare_decimal

Initialize DYNAMIC_COLUMN_VALUE before value of value.x.decimal.value can be set

```
void mariadb_dyncol_prepare_decimal(DYNAMIC_COLUMN_VALUE *value);
```

value OUT Value of the column

This function links value.x.decimal.value to value.x.decimal.buffer.

mariadb_dyncol_value_init

Initialize a DYNAMIC_COLUMN_VALUE structure to a safe default.

```
#define mariadb_dyncol_value_init(V) (V)->type= DYN_COL_NULL
```

mariadb_dyncol_column_cmp_named

Compare two column names (currently, column names are compared with memcmp())

```
int mariadb_dyncol_column_cmp_named(const MYSQL_LEX_STRING *s1,
                                   const MYSQL_LEX_STRING *s2);
```

1.1.4.7 Dynamic Columns from MariaDB 10

Contents

1. [Column Name Support](#)
2. [Changes in Behavior](#)
3. [New Functions](#)
 1. [COLUMN_CHECK](#)
 2. [COLUMN_JSON](#)
4. [Other Changes](#)
5. [Interface with Cassandra](#)

MariaDB starting with [10.0.1](#) 

[MariaDB 10.0.1](#)  introduced the following improvements to the [dynamic columns](#) feature.

Column Name Support

It is possible to refer to column by names. Names can be used everywhere where in [MariaDB 5.3](#) one could use only strings:

- Create a dynamic column blob:

```
COLUMN_CREATE('int_col', 123 as int, 'double_col', 3.14 as double, 'string_col', 'text-
data' as char);
```

- Set a column value:

```
COLUMN_ADD(dyncol_blob, 'intcol', 1234);
```

- Get a column value:

```
COLUMN_GET(dynstr, 'column1' as char(10));
```

- Check whether a column exists

```
COLUMN_EXISTS(dyncol_blob, 'column_name');
```

Changes in Behavior

- Column list output now includes quoting:

```
select column_list(column_create(1, 22, 2, 23));
+-----+
| column_list(column_create(1, 22, 2, 23)) |
+-----+
| `1`, `2`                                |
+-----+
select column_list(column_create('column1', 22, 'column2', 23));
+-----+
| column_list(column_create('column1', 22, 'column2', 23)) |
+-----+
| `column1`, `column2`                                |
+-----+
```

- Column name interpretation has been changed so that the string now is not converted to a number. So some "magic" tricks will not work any more, for example, "1test" and "1" now become different column names:

```
select column_list(column_add(column_create('1a', 22), '1b', 23));
+-----+
| column_list(column_add(column_create('1a', 22), '1b', 23)) |
+-----+
| `1a`, `1b`                                |
+-----+
```

Old behavior:

```
select column_list(column_add(column_create('1a', 22), '1b', 23));
+-----+
| column_list(column_add(column_create('1a', 22), '1b', 23)) |
+-----+
| 1                                |
+-----+
```

New Functions

The following new functions have been added to dynamic columns in MariaDB 10

COLUMN_CHECK

COLUMN_CHECK is used to check a column's integrity. When it encounters an error it does not return illegal format errors but returns false instead. It also checks integrity more thoroughly and finds errors in the dynamic column internal structures which might not be found by other functions.

```

select column_check(column_create('column1', 22));
+-----+
| column_check(column_create('column1', 22)) |
+-----+
|                                     1 |
+-----+

select column_check('abracadabra');
+-----+
| column_check('abracadabra') |
+-----+
|                               0 |
+-----+

```

COLUMN_JSON

COLUMN_JSON converts all dynamic column record content to a JSON object.

```

select column_json(column_create('column1', 1, 'column2', "two"));
+-----+
| column_json(column_create('column1', 1, 'column2', "two")) |
+-----+
| {"column1":1,"column2":"two"} |
+-----+

```

Other Changes

- All API functions have the prefix `mariadb_dyncol_` (the old prefix `dynamic_column_` is deprecated)
- API changed to be able to work with the new format (`*_named` functions).
- Removed 'delete' function because deleting could be done by adding NULL value.
- 'Time' and 'datetime' in the new format are stored without microseconds if they are 0.
- New function added to API (except that two which are representing SQL level functions):
 - 'Unpack' the dynamic columns content to an arrays of values and names.
 - 3 functions to get any column value as string, integer (long long) or floating point (double).
- New type of "dynamic column" row added on the API level (in SQL level output it is a string but if you use dynamic column functions to construct object it will be added as dynamic column value) which allow to add dynamic columns inside dynamic columns. JSON function represent such recursive constructions correctly but limit depth of representation as current implementation limit (internally depth of dynamic columns embedding is not limited).

Interface with Cassandra

CassandraSE is no longer actively being developed and has been removed in [MariaDB 10.6](#). See [MDEV-23024](#).

Some internal changes were added to dynamic columns to allow them to serve as an interface to Apache Cassandra dynamic columns. The [Cassandra engine](#) may pack all columns which were not mentioned in the MariaDB interface table definition and even bring changes in the dynamic column contents back to the cassandra columns family (the table analog in cassandra).

1.2.9.4 JSON Functions

1.1.1.4.2.4.4 LOAD_FILE

1.1.5 Operators

Operators can be used for comparing values or for assigning values. There are several operators and they may be used in different SQL statements and clauses. Some can be used somewhat on their own, not within an SQL statement clause.

For comparing values—string or numeric—you can use symbols such as the equal-sign (i.e., `=`) or the exclamation point and the equal-sign together (i.e., `!=`). You might use these in `WHERE` clauses or within a flow-control statement or function (e.g., `IF()`). You can also use basic regular expressions with the `LIKE` operator.

For assigning values, you can also use the equal-sign or other arithmetic symbols (e.g. plus-sign). You might do this with the `SET` statement or in a `SET` clause in an `UPDATE` statement.

Arithmetic Operators

Addition Operator (+)

Addition.

DIV

Integer division.

Division Operator (/)

Division.

MOD

Modulo operation. Remainder of N divided by M.

Modulo Operator (%)

Modulo operator. Returns the remainder of N divided by M.

Multiplication Operator (*)

Multiplication.

Subtraction Operator (-)

Subtraction and unary minus.

Assignment Operators

Assignment Operator (:=)

Assignment operator for assigning a value.

Assignment Operator (=)

The equal sign as an assignment operator.

Bit Functions and Operators

Operator Precedence

Precedence of SQL operators

&

Bitwise AND

<<

Left shift

>>

Shift right.

BIT_COUNT

Returns the number of set bits

^

Bitwise XOR

|

Bitwise OR

~

Bitwise NOT

Parentheses

Parentheses modify the precedence of other operators in an expression

TRUE FALSE

TRUE and FALSE evaluate to 1 and 0

Comparison Operators

!=

Not equal operator.

<

Less than operator.

<=

Less than or equal operator.

<=>

NULL-safe equal operator.

=

Equal operator.

>

Greater than operator.

>=

Greater than or equal operator.

BETWEEN AND

True if expression between two values.

COALESCE

Returns the first non-NULL parameter

GREATEST

Returns the largest argument.

IN

True if expression equals any of the values in the list.

INTERVAL

Index of the argument that is less than the first argument

IS

Tests whether a boolean is TRUE, FALSE, or UNKNOWN.

IS NOT

Tests whether a boolean value is not TRUE, FALSE, or UNKNOWN

IS NOT NULL

Tests whether a value is not NULL

IS NULL

Tests whether a value is NULL

ISNULL

Checks if an expression is NULL

LEAST

Returns the smallest argument.

NOT BETWEEN

Same as NOT (expr BETWEEN min AND max)

NOT IN

Same as NOT (expr IN (value,...))

Logical Operators

!
Logical NOT.

&&
Logical AND.

XOR
Logical XOR.

||
Logical OR.

Other Operators Articles

Operator Precedence
Precedence of SQL operators

There are [3 related questions](#) .

1.1.5.1 Arithmetic Operators

Arithmetic operators for addition, subtraction, multiplication, division and the modulo operator

Addition Operator (+)
Addition.

DIV
Integer division.

Division Operator (/)
Division.

MOD
Modulo operation. Remainder of N divided by M.

Modulo Operator (%)
Modulo operator. Returns the remainder of N divided by M.

Multiplication Operator (*)
Multiplication.

Subtraction Operator (-)
Subtraction and unary minus.

1.1.5.1.1 Addition Operator (+)

Syntax

+

Contents

- [Syntax](#)
- [Description](#)
- [Examples](#)

Description

Addition.

If both operands are integers, the result is calculated with [BIGINT](#) precision. If either integer is unsigned, the result is also an unsigned integer.

For real or string operands, the operand with the highest precision determines the result precision.

Examples

```
SELECT 3+5;
+-----+
| 3+5 |
+-----+
| 8 |
+-----+
```

1.2.5.6 DIV

1.1.5.1.3 Division Operator (/)

Syntax

```
/
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

Description

Division operator. Dividing by zero will return NULL. By default, returns four digits after the decimal. This is determined by the server system variable [div_precision_increment](#) which by default is four. It can be set from 0 to 30.

Dividing by zero returns NULL. If the [ERROR_ON_DIVISION_BY_ZERO SQL_MODE](#) is used (the default since [MariaDB 10.2.4](#)), a division by zero also produces a warning.

Examples

```
SELECT 4/5;
+-----+
| 4/5 |
+-----+
| 0.8000 |
+-----+

SELECT 300/(2-2);
+-----+
| 300/(2-2) |
+-----+
| NULL |
+-----+

SELECT 300/7;
+-----+
| 300/7 |
+-----+
| 42.8571 |
+-----+
```

Changing [div_precision_increment](#) for the session from the default of four to six:

```
SET div_precision_increment = 6;
```

```
SELECT 300/7;
```

```
+-----+  
| 300/7 |  
+-----+  
| 42.857143 |  
+-----+
```

```
SELECT 300/7;
```

```
+-----+  
| 300/7 |  
+-----+  
| 42.857143 |  
+-----+
```

1.2.5.28 MOD

1.1.5.1.5 Modulo Operator (%)

Syntax

```
N % M
```

Description

Modulo operator. Returns the remainder of *N* divided by *M*. See also [MOD](#).

Examples

```
SELECT 1042 % 50;
```

```
+-----+  
| 1042 % 50 |  
+-----+  
|          42 |  
+-----+
```

1.1.5.1.6 Multiplication Operator (*)

Syntax

```
*
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

Description

Multiplication operator.

Examples

```

SELECT 7*6;
+-----+
| 7*6 |
+-----+
| 42 |
+-----+

SELECT 1234567890*9876543210;
+-----+
| 1234567890*9876543210 |
+-----+
| -6253480962446024716 |
+-----+

SELECT 18014398509481984*18014398509481984.0;
+-----+
| 18014398509481984*18014398509481984.0 |
+-----+
| 324518553658426726783156020576256.0 |
+-----+

SELECT 18014398509481984*18014398509481984;
+-----+
| 18014398509481984*18014398509481984 |
+-----+
| 0 |
+-----+

```

1.1.5.1.7 Subtraction Operator (-)

Syntax

```
-
```

Description

Subtraction. The operator is also used as the unary minus for changing sign.

If both operands are integers, the result is calculated with [BIGINT](#) precision. If either integer is unsigned, the result is also an unsigned integer, unless the `NO_UNSIGNED_SUBTRACTION` [SQL_MODE](#) is enabled, in which case the result is always signed.

For real or string operands, the operand with the highest precision determines the result precision.

Examples

```

SELECT 96-9;
+-----+
| 96-9 |
+-----+
| 87 |
+-----+

SELECT 15-17;
+-----+
| 15-17 |
+-----+
| -2 |
+-----+

SELECT 3.66 + 1.333;
+-----+
| 3.66 + 1.333 |
+-----+
| 4.993 |
+-----+

```

Unary minus:

```

SELECT - (3+5);
+-----+
| - (3+5) |
+-----+
| -8 |
+-----+

```

1.1.5.2 Assignment Operators

Operators for assigning a value

Assignment Operator (:=)

Assignment operator for assigning a value.

Assignment Operator (=)

The equal sign as an assignment operator.

1.1.5.2.1 Assignment Operator (:=)

Syntax

```
var_name := expr
```

Description

Assignment operator for assigning a value. The value on the right is assigned to the variable on left.

Unlike the [= operator](#), := can always be used to assign a value to a variable.

This operator works with both [user-defined variables](#) and [local variables](#).

When assigning the same value to several variables, [LAST_VALUE\(\)](#) can be useful.

Examples

```

SELECT @x := 10;
+-----+
| @x := 10 |
+-----+
|      10 |
+-----+

SELECT @x, @y := @x;
+-----+-----+
| @x | @y := @x |
+-----+-----+
|  10 |      10 |
+-----+-----+

```

1.1.5.2.2 Assignment Operator (=)

Syntax

```
identifier = expr
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

Description

The equal sign is used as both an assignment operator in certain contexts, and as a [comparison operator](#). When used as assignment operator, the value on the right is assigned to the variable (or column, in some contexts) on the left.

Since its use can be ambiguous, unlike the [:= assignment operator](#), the = assignment operator cannot be used in all contexts, and is only valid as part of a [SET](#) statement, or the SET clause of an [UPDATE](#) statement

This operator works with both [user-defined variables](#) and [local variables](#).

Examples

```
UPDATE table_name SET x = 2 WHERE x > 100;
```

```
SET @x = 1, @y := 2;
```

1.2.8.1 Bit Functions and Operators

1.1.5.4 Comparison Operators

The comparison operators include: !=, <, <=, <=>, >=, >, etc...

!=

Not equal operator.

<

Less than operator.

<=

Less than or equal operator.

<=>

NULL-safe equal operator.

=

Equal operator.

>

Greater than operator.

>=

Greater than or equal operator.

BETWEEN AND

True if expression between two values.

COALESCE

Returns the first non-NULL parameter

GREATEST

Returns the largest argument.

IN

True if expression equals any of the values in the list.

INTERVAL

Index of the argument that is less than the first argument

IS

Tests whether a boolean is TRUE, FALSE, or UNKNOWN.

IS NOT

Tests whether a boolean value is not TRUE, FALSE, or UNKNOWN

IS NOT NULL

Tests whether a value is not NULL

IS NULL

Tests whether a value is NULL

ISNULL

Checks if an expression is NULL

LEAST

Returns the smallest argument.

NOT BETWEEN

Same as NOT (expr BETWEEN min AND max)

NOT IN

Same as NOT (expr IN (value,...))

1.1.5.4.1 Not Equal Operator: !=

Syntax

```
<>, !=
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

Description

Not equal operator. Evaluates both SQL expressions and returns 1 if they are not equal and 0 if they are equal, or `NULL` if either expression is `NULL`. If the expressions return different data types, (for instance, a number and a string), performs type conversion.

When used in row comparisons these two queries return the same results:

```
SELECT (t1.a, t1.b) != (t2.x, t2.y)
FROM t1 INNER JOIN t2;

SELECT (t1.a != t2.x) OR (t1.b != t2.y)
FROM t1 INNER JOIN t2;
```

Examples

```
SELECT '.01' <> '0.01';
+-----+
| '.01' <> '0.01' |
+-----+
|                1 |
+-----+

SELECT .01 <> '0.01';
+-----+
| .01 <> '0.01' |
+-----+
|                0 |
+-----+

SELECT 'zapp' <> 'zappp';
+-----+
| 'zapp' <> 'zappp' |
+-----+
|                1 |
+-----+
```

1.1.5.4.2 <

Syntax

<

Contents

- [1. Syntax](#)
- [2. Description](#)
- [3. Examples](#)

Description

Less than operator. Evaluates both SQL expressions and returns 1 if the left value is less than the right value and 0 if it is not, or `NULL` if either expression is `NULL`. If the expressions return different data types, (for instance, a number and a string), performs type conversion.

When used in row comparisons these two queries return the same results:

```
SELECT (t1.a, t1.b) < (t2.x, t2.y)
FROM t1 INNER JOIN t2;

SELECT (t1.a < t2.x) OR ((t1.a = t2.x) AND (t1.b < t2.y))
FROM t1 INNER JOIN t2;
```

Examples

```
SELECT 2 < 2;
+-----+
| 2 < 2 |
+-----+
|      0 |
+-----+
```

Type conversion:

```
SELECT 3 < '4';
+-----+
| 3 < '4' |
+-----+
|       1 |
+-----+
```

Case insensitivity - see [Character Sets and Collations](#):

```
SELECT 'a' < 'A';
+-----+
| 'a' < 'A' |
+-----+
|          0 |
+-----+
```

1.1.5.4.3 <=

Syntax

```
<=
```

Contents

- [Syntax](#)
- [Description](#)
- [Examples](#)

Description

Less than or equal operator. Evaluates both SQL expressions and returns 1 if the left value is less than or equal to the right value and 0 if it is not, or `NULL` if either expression is `NULL`. If the expressions return different data types, (for instance, a number and a string), performs type conversion.

When used in row comparisons these two queries return the same results:

```
SELECT (t1.a, t1.b) <= (t2.x, t2.y)
FROM t1 INNER JOIN t2;

SELECT (t1.a < t2.x) OR ((t1.a = t2.x) AND (t1.b <= t2.y))
FROM t1 INNER JOIN t2;
```

Examples

```
SELECT 0.1 <= 2;
+-----+
| 0.1 <= 2 |
+-----+
|         1 |
+-----+
```

```

SELECT 'a'<='A';
+-----+
| 'a'<='A' |
+-----+
|          1 |
+-----+

```

1.1.5.4.4 <=>

Syntax

```
<=>
```

Description

NULL-safe equal operator. It performs an equality comparison like the [= operator](#), but returns 1 rather than NULL if both operands are NULL, and 0 rather than NULL if one operand is NULL.

`a <=> b` is equivalent to `a = b OR (a IS NULL AND b IS NULL)`.

When used in row comparisons these two queries return the same results:

```

SELECT (t1.a, t1.b) <=> (t2.x, t2.y)
FROM t1 INNER JOIN t2;

SELECT (t1.a <=> t2.x) AND (t1.b <=> t2.y)
FROM t1 INNER JOIN t2;

```

See also [NULL Values in MariaDB](#).

Examples

```

SELECT 1 <=> 1, NULL <=> NULL, 1 <=> NULL;
+-----+-----+-----+
| 1 <=> 1 | NULL <=> NULL | 1 <=> NULL |
+-----+-----+-----+
|          1 |          1 |          0 |
+-----+-----+-----+

SELECT 1 = 1, NULL = NULL, 1 = NULL;
+-----+-----+-----+
| 1 = 1 | NULL = NULL | 1 = NULL |
+-----+-----+-----+
|          1 |          NULL |          NULL |
+-----+-----+-----+

```

1.1.5.4.5 =

Syntax

```
left_expr = right_expr
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

Description

Equal operator. Evaluates both SQL expressions and returns 1 if they are equal, 0 if they are not equal, or `NULL` if either expression is `NULL`. If the expressions return different data types (for example, a number and a string), a type conversion is performed.

When used in row comparisons these two queries are synonymous and return the same results:

```
SELECT (t1.a, t1.b) = (t2.x, t2.y) FROM t1 INNER JOIN t2;

SELECT (t1.a = t2.x) AND (t1.b = t2.y) FROM t1 INNER JOIN t2;
```

To perform a `NULL`-safe comparison, use the `<=>` operator.

`=` can also be used as an [assignment operator](#).

Examples

```
SELECT 1 = 0;
+-----+
| 1 = 0 |
+-----+
|      0 |
+-----+

SELECT '0' = 0;
+-----+
| '0' = 0 |
+-----+
|        1 |
+-----+

SELECT '0.0' = 0;
+-----+
| '0.0' = 0 |
+-----+
|          1 |
+-----+

SELECT '0.01' = 0;
+-----+
| '0.01' = 0 |
+-----+
|           0 |
+-----+

SELECT '.01' = 0.01;
+-----+
| '.01' = 0.01 |
+-----+
|              1 |
+-----+

SELECT (5 * 2) = CONCAT('1', '0');
+-----+
| (5 * 2) = CONCAT('1', '0') |
+-----+
|                             1 |
+-----+

SELECT 1 = NULL;
+-----+
| 1 = NULL |
+-----+
|      NULL |
+-----+

SELECT NULL = NULL;
+-----+
| NULL = NULL |
+-----+
|           NULL |
+-----+
```

1.1.5.4.6 >

Syntax

>

Contents

- [1. Syntax](#)
- [2. Description](#)
- [3. Examples](#)

Description

Greater than operator. Evaluates both SQL expressions and returns 1 if the left value is greater than the right value and 0 if it is not, or `NULL` if either expression is `NULL`. If the expressions return different data types, (for instance, a number and a string), performs type conversion.

When used in row comparisons these two queries return the same results:

```
SELECT (t1.a, t1.b) > (t2.x, t2.y)
FROM t1 INNER JOIN t2;

SELECT (t1.a > t2.x) OR ((t1.a = t2.x) AND (t1.b > t2.y))
FROM t1 INNER JOIN t2;
```

Examples

```
SELECT 2 > 2;
+-----+
| 2 > 2 |
+-----+
|    0 |
+-----+

SELECT 'b' > 'a';
+-----+
| 'b' > 'a' |
+-----+
|          1 |
+-----+
```

1.1.5.4.7 >=

Syntax

>=

Contents

- [1. Syntax](#)
- [2. Description](#)
- [3. Examples](#)

Description

Greater than or equal operator. Evaluates both SQL expressions and returns 1 if the left value is greater than or equal to the right value and 0 if it is not, or `NULL` if either expression is `NULL`. If the expressions return different data types, (for instance, a number and a string), performs type conversion.

When used in row comparisons these two queries return the same results:

```
SELECT (t1.a, t1.b) >= (t2.x, t2.y)
FROM t1 INNER JOIN t2;
```

```
SELECT (t1.a > t2.x) OR ((t1.a = t2.x) AND (t1.b >= t2.y))
FROM t1 INNER JOIN t2;
```

Examples

```
SELECT 2 >= 2;
```

```
+-----+
| 2 >= 2 |
+-----+
|      1 |
+-----+
```

```
SELECT 'A' >= 'a';
```

```
+-----+
| 'A' >= 'a' |
+-----+
|          1 |
+-----+
```

1.1.5.4.8 BETWEEN AND

Syntax

```
expr BETWEEN min AND max
```

Contents

- [1. Syntax](#)
- [2. Description](#)
- [3. Examples](#)

Description

If expr is greater than or equal to min and expr is less than or equal to max, BETWEEN returns 1, otherwise it returns 0. This is equivalent to the expression (min <= expr AND expr <= max) if all the arguments are of the same type. Otherwise type conversion takes place according to the rules described at [Type Conversion](#), but applied to all the three arguments.

Examples

```
SELECT 1 BETWEEN 2 AND 3;
```

```
+-----+
| 1 BETWEEN 2 AND 3 |
+-----+
|                  0 |
+-----+
```

```
SELECT 'b' BETWEEN 'a' AND 'c';
```

```
+-----+
| 'b' BETWEEN 'a' AND 'c' |
+-----+
|                          1 |
+-----+
```

```
SELECT 2 BETWEEN 2 AND '3';
```

```
+-----+
| 2 BETWEEN 2 AND '3' |
+-----+
|                      1 |
+-----+
```

```
SELECT 2 BETWEEN 2 AND 'x-3';
```

```
+-----+
| 2 BETWEEN 2 AND 'x-3' |
+-----+
|                      0 |
+-----+
1 row in set, 1 warning (0.00 sec)
```

```
Warning (Code 1292): Truncated incorrect DOUBLE value: 'x-3'
```

NULL:

```
SELECT 1 BETWEEN 1 AND NULL;
```

```
+-----+
| 1 BETWEEN 1 AND NULL |
+-----+
|                      NULL |
+-----+
```

DATE, DATETIME and TIMESTAMP examples. Omitting the time component compares against 00:00, so later times on the same date are not returned:

```
CREATE TABLE `x` (
  a date ,
  b datetime,
  c timestamp
)
```

```
INSERT INTO x VALUES
```

```
('2018-11-11', '2018-11-11 05:15', '2018-11-11 05:15'),
('2018-11-12', '2018-11-12 05:15', '2018-11-12 05:15');
```

```
SELECT * FROM x WHERE a BETWEEN '2018-11-11' AND '2018-11-12';
```

```
+-----+-----+
| a          | b          | c          |
+-----+-----+
| 2018-11-11 | 2018-11-11 05:15:00 | 2018-11-11 05:15:00 |
| 2018-11-12 | 2018-11-12 05:15:00 | 2018-11-12 05:15:00 |
+-----+-----+
```

```
SELECT * FROM x WHERE b BETWEEN '2018-11-11' AND '2018-11-12';
```

```
+-----+-----+
| a          | b          | c          |
+-----+-----+
| 2018-11-11 | 2018-11-11 05:15:00 | 2018-11-11 05:15:00 |
+-----+-----+
```

```
SELECT * FROM x WHERE c BETWEEN '2018-11-11' AND '2018-11-12';
```

```
+-----+-----+
| a          | b          | c          |
+-----+-----+
| 2018-11-11 | 2018-11-11 05:15:00 | 2018-11-11 05:15:00 |
+-----+-----+
```

1.1.5.4.9 COALESCE

Syntax

```
COALESCE(value,...)
```

Description

Returns the first non-NULL value in the list, or NULL if there are no non-NULL values. At least one parameter must be passed.

The function is useful when substituting a default value for null values when displaying data.

See also [NULL Values in MariaDB](#).

Examples

```
SELECT COALESCE(NULL, 1);
+-----+
| COALESCE(NULL, 1) |
+-----+
|                1 |
+-----+
```

```
SELECT COALESCE(NULL, NULL, NULL);
+-----+
| COALESCE(NULL, NULL, NULL) |
+-----+
|                NULL |
+-----+
```

When two arguments are given, COALESCE() is the same as IFNULL():

```
SET @a=NULL, @b=1;

SELECT COALESCE(@a, @b), IFNULL(@a, @b);
+-----+-----+
| COALESCE(@a, @b) | IFNULL(@a, @b) |
+-----+-----+
|                1 |                1 |
+-----+-----+
```

Hex type confusion:

```
CREATE TABLE t1 (a INT, b VARCHAR(10));
INSERT INTO t1 VALUES (0x31, 0x61), (COALESCE(0x31), COALESCE(0x61));

SELECT * FROM t1;
+-----+-----+
| a     | b     |
+-----+-----+
| 49   | a     |
| 1    | a     |
+-----+-----+
```

The reason for the differing results above is that when 0x31 is inserted directly to the column, it's treated as a number (see [Hexadecimal Literals](#)), while when 0x31 is passed to COALESCE(), it's treated as a string, because:

- HEX values have a string data type by default.
- COALESCE() has the same data type as the argument.

Substituting zero for NULL (in this case when the aggregate function returns NULL after finding no rows):

```

SELECT SUM(score) FROM student;
+-----+
| SUM(score) |
+-----+
|      NULL  |
+-----+

SELECT COALESCE(SUM(score),0) FROM student;
+-----+
| COALESCE(SUM(score),0) |
+-----+
|                0      |
+-----+

```

1.1.5.4.10 GREATEST

Syntax

```
GREATEST (value1, value2, ...)
```

Description

With two or more arguments, returns the largest (maximum-valued) argument. The arguments are compared using the same rules as for [LEAST\(\)](#).

Examples

```

SELECT GREATEST(2,0);
+-----+
| GREATEST(2,0) |
+-----+
|              2 |
+-----+

```

```

SELECT GREATEST(34.0,3.0,5.0,767.0);
+-----+
| GREATEST(34.0,3.0,5.0,767.0) |
+-----+
|                          767.0 |
+-----+

```

```

SELECT GREATEST('B','A','C');
+-----+
| GREATEST('B','A','C') |
+-----+
| C                      |
+-----+

```

1.1.5.4.11 IN

Syntax

```
expr IN (value,...)
```

Description

Returns 1 if *expr* is equal to any of the values in the IN list, else returns 0. If all values are constants, they are evaluated according to the type of *expr* and sorted. The search for the item then is done using a binary search. This means IN is very quick if the IN value list consists entirely of constants. Otherwise, type conversion takes place according to the rules described at [Type Conversion](#), but applied to all the arguments.

If *expr* is NULL, IN always returns NULL. If at least one of the values in the list is NULL, and one of the comparisons is true, the result is 1. If at least one of the values in the list is NULL and none of the comparisons is true, the result is NULL.

Examples

```
SELECT 2 IN (0,3,5,7);
+-----+
| 2 IN (0,3,5,7) |
+-----+
|                0 |
+-----+
```

```
SELECT 'wefwf' IN ('wee','wefwf','weg');
+-----+
| 'wefwf' IN ('wee','wefwf','weg') |
+-----+
|                                   1 |
+-----+
```

Type conversion:

```
SELECT 1 IN ('1', '2', '3');
+-----+
| 1 IN ('1', '2', '3') |
+-----+
|                       1 |
+-----+
```

```
SELECT NULL IN (1, 2, 3);
+-----+
| NULL IN (1, 2, 3) |
+-----+
|                 NULL |
+-----+
```

```
SELECT 1 IN (1, 2, NULL);
+-----+
| 1 IN (1, 2, NULL) |
+-----+
|                   1 |
+-----+
```

```
SELECT 5 IN (1, 2, NULL);
+-----+
| 5 IN (1, 2, NULL) |
+-----+
|                 NULL |
+-----+
```

1.1.5.4.12 INTERVAL

Syntax

```
INTERVAL (N,N1,N2,N3,...)
```

Description

Returns the index of the last argument that is less than the first argument or is NULL.

Returns 0 if $N < N_1$, 1 if $N < N_2$, 2 if $N < N_3$ and so on or -1 if N is NULL. All arguments are treated as integers. It is required that $N_1 < N_2 < N_3 < \dots < N_n$ for this function to work correctly. This is because a fast binary search is used.

Examples

```
SELECT INTERVAL(23, 1, 15, 17, 30, 44, 200);
+-----+
| INTERVAL(23, 1, 15, 17, 30, 44, 200) |
+-----+
|                                     3 |
+-----+

SELECT INTERVAL(10, 1, 10, 100, 1000);
+-----+
| INTERVAL(10, 1, 10, 100, 1000) |
+-----+
|                                     2 |
+-----+

SELECT INTERVAL(22, 23, 30, 44, 200);
+-----+
| INTERVAL(22, 23, 30, 44, 200) |
+-----+
|                                     0 |
+-----+

SELECT INTERVAL(10, 2, NULL);
+-----+
| INTERVAL(10, 2, NULL) |
+-----+
|                         2 |
+-----+
```

1.1.5.4.13 IS

Syntax

```
IS boolean_value
```

Description

Tests a value against a boolean value, where `boolean_value` can be TRUE, FALSE, or UNKNOWN.

There is an important difference between using IS TRUE or comparing a value with TRUE using =. When using =, only 1 equals to TRUE. But when using IS TRUE, all values which are logically true (like a number > 1) return TRUE.

Examples

```
SELECT 1 IS TRUE, 0 IS FALSE, NULL IS UNKNOWN;
+-----+-----+-----+
| 1 IS TRUE | 0 IS FALSE | NULL IS UNKNOWN |
+-----+-----+-----+
|         1 |         1 |         1 |
+-----+-----+-----+
```

Difference between = and IS TRUE :

```
SELECT 2 = TRUE, 2 IS TRUE;
```

```
+-----+-----+
| 2 = TRUE | 2 IS TRUE |
+-----+-----+
|         0 |         1 |
+-----+-----+
```

1.1.5.4.14 IS NOT

Syntax

```
IS NOT boolean_value
```

Description

Tests a value against a boolean value, where `boolean_value` can be TRUE, FALSE, or UNKNOWN.

Examples

```
SELECT 1 IS NOT UNKNOWN, 0 IS NOT UNKNOWN, NULL IS NOT UNKNOWN;
```

```
+-----+-----+-----+
| 1 IS NOT UNKNOWN | 0 IS NOT UNKNOWN | NULL IS NOT UNKNOWN |
+-----+-----+-----+
|           1 |           1 |           0 |
+-----+-----+-----+
```

```
SELECT NULL IS NOT TRUE, NULL IS NOT FALSE;
```

```
+-----+-----+
| NULL IS NOT TRUE | NULL IS NOT FALSE |
+-----+-----+
|           1 |           1 |
+-----+-----+
```

1.1.5.4.15 IS NOT NULL

Syntax

```
IS NOT NULL
```

Description

Tests whether a value is not NULL. See also [NULL Values in MariaDB](#).

Examples

```
SELECT 1 IS NOT NULL, 0 IS NOT NULL, NULL IS NOT NULL;
```

```
+-----+-----+-----+
| 1 IS NOT NULL | 0 IS NOT NULL | NULL IS NOT NULL |
+-----+-----+-----+
|           1 |           1 |           0 |
+-----+-----+-----+
```

1.1.5.4.16 IS NULL

Syntax

```
IS NULL
```

Description

Tests whether a value is NULL. See also [NULL Values in MariaDB](#).

Examples

```
SELECT 1 IS NULL, 0 IS NULL, NULL IS NULL;
+-----+-----+-----+
| 1 IS NULL | 0 IS NULL | NULL IS NULL |
+-----+-----+-----+
|          0 |          0 |          1 |
+-----+-----+-----+
```

Compatibility

Some ODBC applications use the syntax `auto_increment_field IS NOT NULL` to find the latest row that was inserted with an autogenerated key value. If your applications need this, you can set the `sql_auto_is_null` variable to 1.

```
SET @@sql_auto_is_null=1;
CREATE TABLE t1 (auto_increment_column INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
INSERT INTO t1 VALUES (NULL);
SELECT * FROM t1 WHERE auto_increment_column IS NULL;

+-----+
| auto_increment_column |
+-----+
|          1 |
+-----+
```

1.1.5.4.17 ISNULL

Syntax

```
ISNULL(expr)
```

Description

If `expr` is NULL, ISNULL() returns 1, otherwise it returns 0.

See also [NULL Values in MariaDB](#).

Examples

```

SELECT ISNULL(1+1);
+-----+
| ISNULL(1+1) |
+-----+
|           0 |
+-----+

SELECT ISNULL(1/0);
+-----+
| ISNULL(1/0) |
+-----+
|           1 |
+-----+

```

1.1.5.4.18 LEAST

Syntax

```
LEAST(value1,value2,...)
```

Description

With two or more arguments, returns the smallest (minimum-valued) argument. The arguments are compared using the following rules:

- If the return value is used in an INTEGER context or all arguments are integer-valued, they are compared as integers.
- If the return value is used in a REAL context or all arguments are real-valued, they are compared as reals.
- If any argument is a case-sensitive string, the arguments are compared as case-sensitive strings.
- In all other cases, the arguments are compared as case-insensitive strings.

LEAST() returns NULL if any argument is NULL.

Examples

```

SELECT LEAST(2,0);
+-----+
| LEAST(2,0) |
+-----+
|           0 |
+-----+

```

```

SELECT LEAST(34.0,3.0,5.0,767.0);
+-----+
| LEAST(34.0,3.0,5.0,767.0) |
+-----+
|                   3.0 |
+-----+

```

```

SELECT LEAST('B','A','C');
+-----+
| LEAST('B','A','C') |
+-----+
| A |
+-----+

```

1.1.5.4.19 NOT BETWEEN

Syntax

```
expr NOT BETWEEN min AND max
```

Description

This is the same as NOT (expr [BETWEEN](#) min AND max).

Note that the meaning of the alternative form NOT expr [BETWEEN](#) min AND max is affected by the `HIGH_NOT_PRECEDENCE` [SQL_MODE](#) flag.

Examples

```
SELECT 1 NOT BETWEEN 2 AND 3;
+-----+
| 1 NOT BETWEEN 2 AND 3 |
+-----+
|                        1 |
+-----+
```

```
SELECT 'b' NOT BETWEEN 'a' AND 'c';
+-----+
| 'b' NOT BETWEEN 'a' AND 'c' |
+-----+
|                                0 |
+-----+
```

NULL:

```
SELECT 1 NOT BETWEEN 1 AND NULL;
+-----+
| 1 NOT BETWEEN 1 AND NULL |
+-----+
|                            NULL |
+-----+
```

1.1.5.4.20 NOT IN

Syntax

```
expr NOT IN (value,...)
```

Description

This is the same as NOT (expr [IN](#) (value,...)).

Examples

```
SELECT 2 NOT IN (0,3,5,7);
+-----+
| 2 NOT IN (0,3,5,7) |
+-----+
|                        1 |
+-----+
```

```

SELECT 'wefwf' NOT IN ('wee', 'wefwf', 'weg');
+-----+
| 'wefwf' NOT IN ('wee', 'wefwf', 'weg') |
+-----+
|                                     0 |
+-----+

```

```

SELECT 1 NOT IN ('1', '2', '3');
+-----+
| 1 NOT IN ('1', '2', '3') |
+-----+
|                               0 |
+-----+

```

NULL:

```

SELECT NULL NOT IN (1, 2, 3);
+-----+
| NULL NOT IN (1, 2, 3) |
+-----+
|                NULL |
+-----+

```

```

SELECT 1 NOT IN (1, 2, NULL);
+-----+
| 1 NOT IN (1, 2, NULL) |
+-----+
|                               0 |
+-----+

```

```

SELECT 5 NOT IN (1, 2, NULL);
+-----+
| 5 NOT IN (1, 2, NULL) |
+-----+
|                NULL |
+-----+

```

1.1.5.5 Logical Operators

NOT, AND, Exclusive OR and OR

!

Logical NOT.

&&

Logical AND.

XOR

Logical XOR.

||

Logical OR.

1.1.5.5.1 !

Syntax

```
NOT, !
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

Description

Logical NOT. Evaluates to 1 if the operand is 0, to 0 if the operand is non-zero, and NOT NULL returns NULL.

By default, the `!` operator has a [higher precedence](#). If the `HIGH_NOT_PRECEDENCE SQL_MODE` flag is set, `NOT` and `!` have the same precedence.

Examples

```
SELECT NOT 10;
```

```
+-----+
| NOT 10 |
+-----+
|      0 |
+-----+
```

```
SELECT NOT 0;
```

```
+-----+
| NOT 0 |
+-----+
|      1 |
+-----+
```

```
SELECT NOT NULL;
```

```
+-----+
| NOT NULL |
+-----+
|      NULL |
+-----+
```

```
SELECT ! (1+1);
```

```
+-----+
| ! (1+1) |
+-----+
|        0 |
+-----+
```

```
SELECT ! 1+1;
```

```
+-----+
| ! 1+1 |
+-----+
|      1 |
+-----+
```

1.1.5.5.2 &&

Syntax

```
AND, &&
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

Description

Logical AND. Evaluates to 1 if all operands are non-zero and not NULL, to 0 if one or more operands are 0, otherwise NULL is returned.

For this operator, [short-circuit evaluation](#) can be used.

Examples

```
SELECT 1 && 1;
```

```
+-----+
| 1 && 1 |
+-----+
|      1 |
+-----+
```

```
SELECT 1 && 0;
```

```
+-----+
| 1 && 0 |
+-----+
|      0 |
+-----+
```

```
SELECT 1 && NULL;
```

```
+-----+
| 1 && NULL |
+-----+
|      NULL |
+-----+
```

```
SELECT 0 && NULL;
```

```
+-----+
| 0 && NULL |
+-----+
|          0 |
+-----+
```

```
SELECT NULL && 0;
```

```
+-----+
| NULL && 0 |
+-----+
|          0 |
+-----+
```

1.1.5.5.3 XOR

Syntax

```
XOR
```

Contents

- [Syntax](#)
- [Description](#)
- [Examples](#)

Description

XOR stands for eXclusive OR. Returns NULL if either operand is NULL. For non-NULL operands, evaluates to 1 if an odd number of operands is non-zero, otherwise 0 is returned.

Examples

```

SELECT 1 XOR 1;
+-----+
| 1 XOR 1 |
+-----+
|         0 |
+-----+

SELECT 1 XOR 0;
+-----+
| 1 XOR 0 |
+-----+
|         1 |
+-----+

SELECT 1 XOR NULL;
+-----+
| 1 XOR NULL |
+-----+
|         NULL |
+-----+

```

In the following example, the right `1 XOR 1` is evaluated first, and returns `0`. Then, `1 XOR 0` is evaluated, and `1` is returned.

```

SELECT 1 XOR 1 XOR 1;
+-----+
| 1 XOR 1 XOR 1 |
+-----+
|               1 |
+-----+

```

1.1.5.5.4 ||

Syntax

```
OR, ||
```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [Oracle Mode](#)
3. [Examples](#)

Description

Logical OR. When both operands are non-NULL, the result is 1 if any operand is non-zero, and 0 otherwise. With a NULL operand, the result is 1 if the other operand is non-zero, and NULL otherwise. If both operands are NULL, the result is NULL.

For this operator, [short-circuit evaluation](#) can be used.

Note that, if the `PIPES_AS_CONCAT SQL_MODE` is set, `||` is used as a string concatenation operator. This means that `a || b` is the same as `CONCAT(a,b)`. See [CONCAT\(\)](#) for details.

Oracle Mode

In [Oracle mode](#), `||` ignores `NULL`.

Examples

```

SELECT 1 || 1;
+-----+
| 1 || 1 |
+-----+
|      1 |
+-----+

SELECT 1 || 0;
+-----+
| 1 || 0 |
+-----+
|      1 |
+-----+

SELECT 0 || 0;
+-----+
| 0 || 0 |
+-----+
|      0 |
+-----+

SELECT 0 || NULL;
+-----+
| 0 || NULL |
+-----+
|      NULL |
+-----+

SELECT 1 || NULL;
+-----+
| 1 || NULL |
+-----+
|          1 |
+-----+

```

In Oracle mode:

```

SELECT 0 || NULL;
+-----+
| 0 || NULL |
+-----+
| 0          |
+-----+

```

1.1.5.6 Operator Precedence

The precedence is the order in which the SQL operators are evaluated.

The following list shows the SQL operator precedence. Operators that appear first in the list have a higher precedence. Operators which are listed together have the same precedence.

- INTERVAL
- BINARY , COLLATE
- !
- - (unary minus), bitwise not () (unary bit inversion)
- || (string concatenation)
- ^
- * , / , DIV , %, MOD
- - , +
- << , >>
- &
- |
- LIKE , REGEXP , IN
- BETWEEN
- = (comparison), <=> , >= , > , <= , < , <> , != , IS
- NOT
- && , AND
- XOR

- `||` (logical or), `OR`
- `=` (assignment), `:=`

Functions precedence is always higher than operators precedence.

In this page `CASE` refers to the [CASE operator](#), not to the [CASE statement](#) .

If the `HIGH_NOT_PRECEDENCE SQL_MODE` is set, `NOT` has the same precedence as `!` .

The `||` operator's precedence, as well as its meaning, depends on the `PIPES_AS_CONCAT SQL_MODE` flag: if it is on, `||` can be used to concatenate strings (like the [CONCAT\(\)](#) function) and has a higher precedence.

The `=` operator's precedence depends on the context - it is higher when `=` is used as a comparison operator.

[Parenthesis](#)  can be used to modify the operators precedence in an expression.

Short-circuit evaluation

The `AND` , `OR` , `&&` and `||` operators support short-circuit evaluation. This means that, in some cases, the expression on the right of those operators is not evaluated, because its result cannot affect the result. In the following cases, short-circuit evaluation is used and `x()` is not evaluated:

- `FALSE AND x()`
- `FALSE && x()`
- `TRUE OR x()`
- `TRUE || x()`
- `NULL BETWEEN x() AND x()`

Note however that the short-circuit evaluation does *not* apply to `NULL AND x()` . Also, `BETWEEN` 's right operands are not evaluated if the left operand is `NULL` , but in all other cases all the operands are evaluated.

This is a speed optimization. Also, since functions can have side-effects, this behavior can be used to choose whether execute them or not using a concise syntax:

```
SELECT some_function() OR log_error();
```

1.1.6 Sequences

This section is about sequence objects. For details about the storage engine, see [Sequence Storage Engine](#) .

A sequence is an object that generates a sequence of numeric values, as specified by the [CREATE SEQUENCE](#) statement. Sequences are an alternative to [AUTO_INCREMENT](#) when you want more control over how sequence numbers are generated.

Since a `SEQUENCE` caches values, it can sometimes be faster. Also, you can access the last value generated by all used sequences; it's not subjected to limitations of [LAST_INSERT_ID\(\)](#) .

See also [Sequence Storage Engine](#) .

Sequence Overview

Object that generates a sequence of numeric values.

CREATE SEQUENCE

Creates a sequence that generates new values when called with NEXT VALUE FOR.

SHOW CREATE SEQUENCE

Shows the CREATE SEQUENCE statement that creates the sequence.

ALTER SEQUENCE

Change options for a SEQUENCE.

DROP SEQUENCE

Deleting a SEQUENCE.

SEQUENCE Functions

Functions that can be used on SEQUENCES.

Information Schema SEQUENCES Table

Information about sequences on the server.

SHOW TABLES

List of non-temporary tables, views or sequences.

Error 4084: Sequence has run out

Error 4084: Sequence '%-.64s%.64s' has run out [↗](#)

1.1.6.1 Sequence Overview

This page is about sequence objects. For details about the storage engine, see [Sequence Storage Engine](#).

Introduction

A sequence is an object that generates a sequence of numeric values, as specified by the [CREATE SEQUENCE](#) statement.

CREATE SEQUENCE will create a sequence that generates new values when called with NEXT VALUE FOR sequence_name. It's an alternative to [AUTO INCREMENT](#) when one wants to have more control of how the numbers are generated. As the SEQUENCE caches values (up to the CACHE value in the [CREATE SEQUENCE](#) statement, by default 1000) it can in some cases be much faster than AUTO INCREMENT. Another benefit is that one can access the last value generated by all used sequences, which solves one of the limitations with [LAST_INSERT_ID\(\)](#).

Creating a Sequence

The [CREATE SEQUENCE](#) statement is used to create a sequence. Here is an example of a sequence starting at 100, incrementing by 10 each time:

```
CREATE SEQUENCE s START WITH 100 INCREMENT BY 10;
```

The CREATE SEQUENCE statement, along with defaults, can be viewed with the [SHOW CREATE SEQUENCE STATEMENT](#), for example:

```
SHOW CREATE SEQUENCE s\G
***** 1. row *****
      Table: s
Create Table: CREATE SEQUENCE `s` start with 100 minvalue 1 maxvalue 9223372036854775806
            increment by 10 cache 1000 nocycle ENGINE=InnoDB
```

Using Sequence Objects

To get the [next value from a sequence](#), use

```
NEXT VALUE FOR sequence_name
```

or

```
NEXTVAL(sequence_name)
```

or in Oracle mode ([SQL_MODE=ORACLE](#))

```
sequence_name.nextval
```

For [retrieving the last value](#) used by the current connection from a sequence use:

```
PREVIOUS VALUE FOR sequence_name
```

or

```
LASTVAL(sequence_name)
```

or in Oracle mode ([SQL_MODE=ORACLE](#))

```
sequence_name.currval
```

For example:

```
SELECT NEXTVAL(s);
+-----+
| NEXTVAL(s) |
+-----+
|          100 |
+-----+

SELECT NEXTVAL(s);
+-----+
| NEXTVAL(s) |
+-----+
|          110 |
+-----+

SELECT LASTVAL(s);
+-----+
| LASTVAL(s) |
+-----+
|          110 |
+-----+
```

Using Sequences in DEFAULT

Sequences can be used in DEFAULT:

```
create sequence s1;
create table t1 (a int primary key default (next value for s1), b int);
insert into t1 (b) values (1), (2);
select * from t1;
+---+-----+
| a | b |
+---+-----+
| 1 | 1 |
| 2 | 2 |
+---+-----+
```

Changing a Sequence

The [ALTER SEQUENCE](#) statement is used for changing sequences. For example, to restart the sequence at another value:

```
ALTER SEQUENCE s RESTART 50;

SELECT NEXTVAL(s);
+-----+
| NEXTVAL(s) |
+-----+
|          50 |
+-----+
```

The [SETVAL](#) function can also be used to set the next value to be returned for a SEQUENCE, for example:

```
SELECT SETVAL(s, 100);
+-----+
| SETVAL(s, 100) |
+-----+
|          100 |
+-----+
```

[SETVAL](#) can only be used to increase the sequence value. Attempting to set a lower value will fail, returning NULL:

```
SELECT SETVAL (s, 50);
+-----+
| SETVAL (s, 50) |
+-----+
|           NULL |
+-----+
```

Dropping a Sequence

The [DROP SEQUENCE](#) statement is used to drop a sequence, for example:

```
DROP SEQUENCE s;
```

Replication

If one wants to use Sequences in a master-master setup or with Galera one should use `INCREMENT=0`. This will tell the Sequence to use `auto_increment_increment` and `auto_increment_offset` to generate unique values for each server.

Standards Compliance

MariaDB supports both ANSI SQL and Oracle syntax for sequences.

However as `SEQUENCE` is implemented as a special kind of table, it uses the same namespace as tables. The benefits are that sequences show up in [SHOW TABLES](#), and one can also create a sequence with [CREATE TABLE](#) and drop it with [DROP TABLE](#). One can [SELECT](#) from it as from any other table. This ensures that all old tools that work with tables should work with sequences.

Since sequence objects act as regular tables in many contexts, they will be affected by [LOCK TABLES](#). This is not the case in other DBMS, such as Oracle, where `LOCK TABLE` does not affect sequences.

Notes

One of the goals with the Sequence implementation is that all old tools, such as [mariadb-dump](#) (previously `mysqldump`), should work unchanged, while still keeping the normal usage of sequence standard compatibly.

To make this possible, `sequence` is currently implemented as a table with a few exclusive properties.

The special properties for sequence tables are:

- A sequence table has always one row.
- When one creates a sequence, either with [CREATE TABLE](#) or [CREATE SEQUENCE](#), one row will be inserted.
- If one tries to insert into a sequence table, the single row will be updated. This allows [mariadb-dump](#) to work but also gives the additional benefit that one can change all properties of a sequence with a single insert. New applications should of course also use `ALTER SEQUENCE`.
- [UPDATE](#) or [DELETE](#) can't be performed on Sequence objects.
- Doing a select on the sequence shows the current state of the sequence, except the values that are reserved in the cache. The `next_value` column shows the next value not reserved by the cache.
- [FLUSH TABLES](#) will close the sequence and the next sequence number generated will be according to what's stored in the Sequence object. In effect, this will discard the cached values.
- A number of normal table operations work on Sequence tables. See next section.

Table Operations that Work with Sequences

- [SHOW CREATE TABLE sequence_name](#). This shows the table structure that is behind the `SEQUENCE` including the field names that can be used with [SELECT](#) or even [CREATE TABLE](#).
- [CREATE TABLE sequence-structure ... SEQUENCE=1](#)
- [ALTER TABLE sequence RENAME TO sequence2](#)
- [RENAME TABLE sequence_name TO new_sequence_name](#)
- [DROP TABLE sequence_name](#). This is allowed mainly to get old tools like [mariadb-dump](#) to work with sequence tables.
- [SHOW TABLES](#)

Implementation

Internally, sequence tables are created as a normal table without rollback (the [InnoDB](#), [Aria](#) and [MySAM](#) engines support this), wrapped by a sequence engine object. This allowed us to create sequences with almost no performance impact for normal tables. (The cost is one 'if' per insert if the [binary log](#) is enabled).

Underlying Table Structure

The following example shows the table structure of sequences and how it can be used as a table. (Output of results are slightly edited to make them easier to read)

```
create sequence t1;
show create sequence t1\G
***** 1. row *****
CREATE SEQUENCE `t1` start with 1 minvalue 1 maxvalue 9223372036854775806
increment by 1 cache 1000 nocycle ENGINE=InnoDB

show create table t1\G
***** 1. row *****
Create Table: CREATE TABLE `t1` (
  `next_not_cached_value` bigint(21) NOT NULL,
  `minimum_value` bigint(21) NOT NULL,
  `maximum_value` bigint(21) NOT NULL,
  `start_value` bigint(21) NOT NULL COMMENT 'start value when sequences is created or value if
RESTART is used',
  `increment` bigint(21) NOT NULL COMMENT 'increment value',
  `cache_size` bigint(21) unsigned NOT NULL,
  `cycle_option` tinyint(1) unsigned NOT NULL COMMENT '0 if no cycles are allowed, 1 if the
sequence should begin a new cycle when maximum_value is passed',
  `cycle_count` bigint(21) NOT NULL COMMENT 'How many cycles have been done'
) ENGINE=InnoDB SEQUENCE=1

select * from t1\G
next_not_cached_value: 1
minimum_value: 1
maximum_value: 9223372036854775806
start_value: 1
increment: 1
cache_size: 1000
cycle_option: 0
cycle_count: 0
```

The `cycle_count` column is incremented every time the sequence wraps around.

Credits

- Thanks to Jianwe Zhao from Aliyun for his work on SEQUENCE in AliSQL, which gave ideas and inspiration for this work.
- Thanks to Peter Gulutzan, who helped test and gave useful comments about the implementation.

1.1.6.2 CREATE SEQUENCE

Syntax

```
CREATE [OR REPLACE] [TEMPORARY] SEQUENCE [IF NOT EXISTS] sequence_name
[AS { TINYINT | SMALLINT | MEDIUMINT | INT | INTEGER | BIGINT } [SIGNED | UNSIGNED]]
[ INCREMENT [ BY | = ] number ]
[ MINVALUE [=] number | NO MINVALUE | NOMINVALUE ]
[ MAXVALUE [=] number | NO MAXVALUE | NOMAXVALUE ]
[ START [ WITH | = ] number ]
[ CACHE [=] number | NOCACHE ] [ CYCLE | NOCYCLE]
table\_options
```

First value that the sequence will generate. Default MINVALUE if INCREMENT > 0, and MAX_VALUE if INCREMENT < 0.

CACHE / NOCACHE

Number of values that should be cached. 0 if no CACHE. The underlying table will be updated first time a new sequence number is generated and each time the cache runs out. Default 1000. [FLUSH TABLES](#), shutting down the server, etc. will discard the cached values, and the next sequence number generated will be according to what's stored in the Sequence object. In effect, this will discard the cached values. Note that setting the cache to 1 from 1000, can make inserts to tables using sequences for default values 2x slower and increase the binary log sizes up to 7x.

CYCLE / NOCYCLE

If `CYCLE` is used, then the sequence should start again from `MINVALUE` after it has run out of values. Default value is `NOCYCLE`.

Constraints on Create Arguments

To be able to create a legal sequence, the following must hold:

- `MAXVALUE >= start`
- `MAXVALUE > MINVALUE`
- `START >= MINVALUE`
- `MAXVALUE <= 9223372036854775806 (LONGLONG_MAX-1)`. From [MariaDB 11.5](#), the parser accepts values beyond this, and converts based on the int type.
- `MINVALUE >= -9223372036854775807 (LONGLONG_MIN+1)`. From [MariaDB 11.5](#), the parser accepts values beyond this, and converts based on the int type.

Note that sequences can't generate the maximum/minimum 64 bit number because of the constraint of `MINVALUE` and `MAXVALUE`.

Atomic DDL

MariaDB starting with [10.6.1](#)
[MariaDB 10.6.1](#) supports [Atomic DDL](#) and `CREATE SEQUENCE` is atomic.

Examples

```
CREATE SEQUENCE s START WITH 100 INCREMENT BY 10;

CREATE SEQUENCE s2 START WITH -100 INCREMENT BY -10;
```

The following statement fails, as the increment conflicts with the defaults

```
CREATE SEQUENCE s3 START WITH -100 INCREMENT BY 10;
ERROR 4082 (HY000): Sequence 'test.s3' values are conflicting
```

The sequence can be created by specifying workable minimum and maximum values:

```
CREATE SEQUENCE s3 START WITH -100 INCREMENT BY 10 MINVALUE=-100 MAXVALUE=1000;
```

From [MariaDB 11.5](#):

```
CREATE SEQUENCE s3 AS BIGINT UNSIGNED START WITH 10;
```

Parser accepting larger or smaller values:

```

create sequence s1;
create table t1 (a int primary key default nextval(s1), b int);
insert into t1 (b) values(1);
select * from t1;
+---+-----+
| a | b   |
+---+-----+
| 1 | 1   |
+---+-----+

```

1.1.1.2.8.18 SHOW CREATE SEQUENCE

1.1.6.4 ALTER SEQUENCE

Syntax

```

ALTER SEQUENCE [IF EXISTS] sequence_name
[ INCREMENT [ BY | = ] number ]
[ MINVALUE [=] number | NO MINVALUE | NOMINVALUE ]
[ MAXVALUE [=] number | NO MAXVALUE | NOMAXVALUE ]
[ START [ WITH | = ] number ] [ CACHE [=] number ] [ [ NO ] CYCLE ]
[ RESTART [[WITH | =] number]

```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [Arguments to ALTER SEQUENCE](#)
 2. [INSERT](#)
 3. [Notes](#)

`ALTER SEQUENCE` allows one to change any values for a `SEQUENCE` created with [CREATE SEQUENCE](#).

The options for `ALTER SEQUENCE` can be given in any order.

Description

`ALTER SEQUENCE` changes the parameters of an existing sequence generator. Any parameters not specifically set in the `ALTER SEQUENCE` command retain their prior settings.

`ALTER SEQUENCE` requires the [ALTER privilege](#).

Arguments to ALTER SEQUENCE

The following options may be used:

Option	Default value	Description
INCREMENT	1	Increment to use for values. May be negative.
MINVALUE	1 if INCREMENT > 0 and -9223372036854775807 if INCREMENT < 0	Minimum value for the sequence.
MAXVALUE	9223372036854775806 if INCREMENT > 0 and -1 if INCREMENT < 0	Max value for sequence.
START	MINVALUE if INCREMENT > 0 and MAX_VALUE if INCREMENT < 0	First value that the sequence will generate.

CACHE	1000	Number of values that should be cached. 0 if no <code>CACHE</code> . The underlying table will be updated first time a new sequence number is generated and each time the cache runs out.
CYCLE	0 (= NO CYCLE)	1 if the sequence should start again from <code>MINVALUE #</code> after it has run out of values.
RESTART	START if restart value not is given	If <code>RESTART</code> option is used, <code>NEXT VALUE</code> will return the restart value.

The optional clause `RESTART [WITH restart]` sets the next value for the sequence. This is equivalent to calling the `SETVAL()` function with the `is_used` argument as 0. The specified value will be returned by the next call of `nextval`. Using `RESTART` with no restart value is equivalent to supplying the start value that was recorded by `CREATE SEQUENCE` or last set by `ALTER SEQUENCE START WITH`.

`ALTER SEQUENCE` will not allow you to change the sequence so that it's inconsistent. For example:

```
CREATE SEQUENCE s1;
ALTER SEQUENCE s1 MINVALUE 10;
ERROR 4061 (HY000): Sequence 'test.t1' values are conflicting

ALTER SEQUENCE s1 MINVALUE 10 RESTART 10;
ERROR 4061 (HY000): Sequence 'test.t1' values are conflicting

ALTER SEQUENCE s1 MINVALUE 10 START 10 RESTART 10;
```

INSERT

To allow `SEQUENCE` objects to be backed up by old tools, like `mariadb-dump`, one can use `SELECT` to read the current state of a `SEQUENCE` object and use an `INSERT` to update the `SEQUENCE` object. `INSERT` is only allowed if all fields are specified:

```
CREATE SEQUENCE s1;
INSERT INTO s1 VALUES(1000,10,2000,1005,1,1000,0,0);
SELECT * FROM s1;
```

```
+-----+-----+-----+-----+-----+-----+-----+-----+
| next_value | min_value | max_value | start | increment | cache | cycle | round |
+-----+-----+-----+-----+-----+-----+-----+-----+
|      1000 |         10 |        2000 | 1005 |          1 | 1000 |    0 |    0 |
+-----+-----+-----+-----+-----+-----+-----+-----+
```

```
SHOW CREATE SEQUENCE s1;
+-----+-----+-----+-----+-----+-----+-----+-----+
| Table | Create Table
|
+-----+-----+-----+-----+-----+-----+-----+-----+
| s1    | CREATE SEQUENCE `s1` start with 1005 minvalue 10 maxvalue 2000 increment by 1 cache 1000 nocycle ENGINE=Aria |
+-----+-----+-----+-----+-----+-----+-----+-----+
```

Notes

`ALTER SEQUENCE` will instantly affect all future `SEQUENCE` operations. This is in contrast to some other databases where the changes requested by `ALTER SEQUENCE` will not be seen until the sequence cache has run out.

`ALTER SEQUENCE` will take a full table lock of the sequence object during its (brief) operation. This ensures that `ALTER SEQUENCE` is replicated correctly. If you only want to set the next sequence value to a higher value than current, then you should use `SETVAL()` instead, as this is not blocking.

If you want to change storage engine, sequence comment or rename the sequence, you can use `ALTER TABLE` for this.

1.1.6.5 DROP SEQUENCE

Syntax

```
DROP [TEMPORARY] SEQUENCE [IF EXISTS] [/*COMMENT TO SAVE*/]
sequence_name [, sequence_name] ...
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Notes](#)

Description

`DROP SEQUENCE` removes one or more [sequences](#) created with [CREATE SEQUENCE](#). You must have the `DROP` privilege for each sequence. MariaDB returns an error indicating by name which non-existing tables it was unable to drop, but it also drops all of the tables in the list that do exist.

Important: When a table is dropped, user privileges on the table are not automatically dropped. See [GRANT](#).

If another connection is using the sequence, a metadata lock is active, and this statement will wait until the lock is released. This is also true for non-transactional tables.

For each referenced sequence, `DROP SEQUENCE` drops a temporary sequence with that name, if it exists. If it does not exist, and the `TEMPORARY` keyword is not used, it drops a non-temporary sequence with the same name, if it exists. The `TEMPORARY` keyword ensures that a non-temporary sequence will not accidentally be dropped.

Use `IF EXISTS` to prevent an error from occurring for sequences that do not exist. A NOTE is generated for each non-existent sequence when using `IF EXISTS`. See [SHOW WARNINGS](#).

`DROP SEQUENCE` requires the [DROP privilege](#).

Notes

`DROP SEQUENCE` only removes sequences, not tables. However, [DROP TABLE](#) can remove both sequences and tables.

1.1.6.6 SEQUENCE Functions

Functions that can be used on SEQUENCES

LASTVAL

Synonym for PREVIOUS VALUE for sequence_name.

NEXT VALUE for sequence_name

Generate next value for a SEQUENCE. Same as NEXTVAL().

NEXTVAL

Synonym for NEXT VALUE for sequence_name.

PREVIOUS VALUE FOR sequence_name

Get last value generated from a SEQUENCE. Same as LASTVAL().

SETVAL

Set the next value to be returned from a SEQUENCE.

1.1.6.6.1 LASTVAL

`LASTVAL` is a synonym for [PREVIOUS VALUE for sequence_name](#).

1.1.6.6.2 NEXT VALUE for sequence_name

Syntax

```
NEXT VALUE FOR sequence
```

or

```
NEXTVAL(sequence_name)
```

or in Oracle mode ([SQL_MODE=ORACLE](#))

```
sequence_name.nextval
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

`NEXT VALUE FOR` is ANSI SQL syntax while `NEXTVAL()` is PostgreSQL syntax.

Description

Generate next value for a `SEQUENCE` .

- You can greatly speed up `NEXT VALUE` by creating the sequence with the `CACHE` option. If not, every `NEXT VALUE` usage will cause changes in the stored `SEQUENCE` table.
- When using `NEXT VALUE` the value will be reserved at once and will not be reused, except if the `SEQUENCE` was created with `CYCLE` . This means that when you are using `SEQUENCE` s you have to expect gaps in the generated sequence numbers.
- If one updates the `SEQUENCE` with [SETVAL\(\)](#) or [ALTER SEQUENCE ... RESTART](#) , `NEXT VALUE FOR` will notice this and start from the next requested value.
- [FLUSH TABLES](#) will close the sequence and the next sequence number generated will be according to what's stored in the `SEQUENCE` object. In effect, this will discard the cached values.
- A server restart (or closing the current connection) also causes a drop of all cached values. The cached sequence numbers are reserved only for the current connection.
- `NEXT VALUE` requires the `INSERT` [privilege](#).
- You can also use `NEXT VALUE FOR sequence` for column `DEFAULT` .

Once the sequence is complete, unless the sequence has been created with the `CYCLE` attribute (not the default), calling the function will result in [Error 4084: Sequence has run out](#) [↗](#).

Examples

```

CREATE OR REPLACE SEQUENCE s MAXVALUE=2;

SELECT NEXTVAL (s);
+-----+
| NEXTVAL (s) |
+-----+
|          1 |
+-----+

SELECT NEXTVAL (s);
+-----+
| NEXTVAL (s) |
+-----+
|          2 |
+-----+

SELECT NEXTVAL (s);
ERROR 4084 (HY000): Sequence 'test.s' has run out

ALTER SEQUENCE s MAXVALUE=2 CYCLE;

SELECT NEXTVAL (s);
+-----+
| NEXTVAL (s) |
+-----+
|          1 |
+-----+

```

1.1.6.6.3 NEXTVAL

`NEXTVAL` is a synonym for [NEXT VALUE for sequence_name](#).

1.1.6.6.4 PREVIOUS VALUE FOR sequence_name

Syntax

```
PREVIOUS VALUE FOR sequence_name
```

or

```
LASTVAL(sequence_name)
```

or in Oracle mode ([SQL_MODE=ORACLE](#))

```
sequence_name.currval
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

`PREVIOUS VALUE FOR` is IBM DB2 syntax while `LASTVAL()` is PostgreSQL syntax.

Description

Gets the most recent value in the current connection generated from a sequence.

- If the sequence has not yet been used by the connection, `PREVIOUS VALUE FOR` returns `NULL` (the same thing applies with a new connection which doesn't see a last value for an existing sequence).
- If a `SEQUENCE` has been dropped and re-created then it's treated as a new `SEQUENCE` and `PREVIOUS VALUE FOR` will return `NULL`.

- Returns `NULL` if the sequence is complete
- `FLUSH TABLES` has no effect on `PREVIOUS VALUE FOR`.
- Previous values for all used sequences are stored per connection until connection ends.
- `PREVIOUS VALUE FOR` requires the [SELECT privilege](#).

Examples

```
CREATE SEQUENCE s START WITH 100 INCREMENT BY 10;

SELECT PREVIOUS VALUE FOR s;
+-----+
| PREVIOUS VALUE FOR s |
+-----+
|           NULL      |
+-----+

# The function works for sequences only, if the table is used an error is generated
SELECT PREVIOUS VALUE FOR t;
ERROR 4089 (42S02): 'test.t' is not a SEQUENCE

# Call the NEXT VALUE FOR s:
SELECT NEXT VALUE FOR s;
+-----+
| NEXT VALUE FOR s |
+-----+
|           100    |
+-----+

SELECT PREVIOUS VALUE FOR s;
+-----+
| PREVIOUS VALUE FOR s |
+-----+
|           100    |
+-----+
```

Now try to start the new connection and check that the last value is still `NULL`, before updating the value in the new connection after the output of the new connection gets current value (110 in the example below). Note that first connection cannot see this change and the result of last value still remains the same (100 in the example above).

```
$ .mysql -uroot test -e"SELECT PREVIOUS VALUE FOR s; SELECT NEXT VALUE FOR s; SELECT PREVIOUS
VALUE FOR s;"
+-----+
| PREVIOUS VALUE FOR s |
+-----+
|           NULL      |
+-----+
+-----+
| NEXT VALUE FOR s |
+-----+
|           110    |
+-----+
+-----+
| PREVIOUS VALUE FOR s |
+-----+
|           110    |
+-----+
```

Returns `NULL` if the sequence has run out:

```

CREATE OR REPLACE SEQUENCE s MAXVALUE=2;

SELECT NEXTVAL(s), LASTVAL(s);
+-----+-----+
| NEXTVAL(s) | LASTVAL(s) |
+-----+-----+
|          1 |          1 |
+-----+-----+

SELECT NEXTVAL(s), LASTVAL(s);
+-----+-----+
| NEXTVAL(s) | LASTVAL(s) |
+-----+-----+
|          2 |          2 |
+-----+-----+

SELECT NEXTVAL(s), LASTVAL(s);
ERROR 4084 (HY000): Sequence 'test.s' has run out

SELECT LASTVAL(s);
+-----+
| LASTVAL(s) |
+-----+
|        NULL |
+-----+

```

1.1.6.6.5 SETVAL

Syntax

```
SETVAL(sequence_name, next_value, [is_used, [round]])
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

Description

Set the next value to be returned for a `SEQUENCE`.

This function is compatible with PostgreSQL syntax, extended with the `round` argument.

If the `is_used` argument is not given or is `1` or `true`, then the next used value will one after the given value. If `is_used` is `0` or `false` then the next generated value will be the given value.

If `round` is used then it will set the `round` value (or the internal cycle count, starting at zero) for the sequence. If `round` is not used, it's assumed to be 0.

`next_value` must be an integer literal.

For `SEQUENCE` tables defined with `CYCLE` (see [CREATE SEQUENCE](#)) one should use both `next_value` and `round` to define the next value. In this case the current sequence value is defined to be `round, next_value`.

The result returned by `SETVAL()` is `next_value` or `NULL` if the given `next_value` and `round` is smaller than the current value.

`SETVAL()` will not set the `SEQUENCE` value to a something that is less than its current value. This is needed to ensure that `SETVAL()` is replication safe. If you want to set the `SEQUENCE` to a smaller number use [ALTER SEQUENCE](#).

If `CYCLE` is used, first `round` and then `next_value` are compared to see if the value is bigger than the current value.

Internally, in the MariaDB server, `SETVAL()` is used to inform replicas that a `SEQUENCE` has changed value. The replica may get `SETVAL()` statements out of order, but this is ok as only the biggest one will have an effect.

`SETVAL` requires the [INSERT privilege](#).

Examples

```
SELECT setval(foo, 42);           -- Next nextval will return 43
SELECT setval(foo, 42, true);    -- Same as above
SELECT setval(foo, 42, false);   -- Next nextval will return 42
```

SETVAL setting higher and lower values on a sequence with an increment of 10:

```
SELECT NEXTVAL(s);
+-----+
| NEXTVAL(s) |
+-----+
|          50 |
+-----+

SELECT SETVAL(s, 100);
+-----+
| SETVAL(s, 100) |
+-----+
|           100 |
+-----+

SELECT NEXTVAL(s);
+-----+
| NEXTVAL(s) |
+-----+
|          110 |
+-----+

SELECT SETVAL(s, 50);
+-----+
| SETVAL(s, 50) |
+-----+
|           NULL |
+-----+

SELECT NEXTVAL(s);
+-----+
| NEXTVAL(s) |
+-----+
|          120 |
+-----+
```

Example demonstrating `round`:

```
CREATE OR REPLACE SEQUENCE s1
  START WITH 1
  MINVALUE 1
  MAXVALUE 99
  INCREMENT BY 1
  CACHE 20
  CYCLE;

SELECT SETVAL(s1, 99, 1, 0);
+-----+
| SETVAL(s1, 99, 1, 0) |
+-----+
|                99 |
+-----+

SELECT NEXTVAL(s1);
+-----+
| NEXTVAL(s1) |
+-----+
|             1 |
+-----+
```

The following statement returns NULL, as the given `next_value` and `round` is smaller than the current value.

```

SELECT SETVAL(s1, 99, 1, 0);
+-----+
| SETVAL(s1, 99, 1, 0) |
+-----+
|                NULL |
+-----+

SELECT NEXTVAL(s1);
+-----+
| NEXTVAL(s1) |
+-----+
|           2 |
+-----+

```

Increasing the round from zero to 1 will allow `next_value` to be returned.

```

SELECT SETVAL(s1, 99, 1, 1);
+-----+
| SETVAL(s1, 99, 1, 1) |
+-----+
|                99 |
+-----+

SELECT NEXTVAL(s1);
+-----+
| NEXTVAL(s1) |
+-----+
|           1 |
+-----+

```

1.1.1.2.8.54 SHOW TABLES

1.1.7 Temporal Tables

MariaDB supports temporal data tables in the form of system-versioned tables (allowing you to query and operate on historic data), application-time periods (allow you to query and operate on a temporal range of data), and bitemporal tables (which combine both system-versioning and application-time periods).

System-Versioned Tables

System-versioned tables record the history of all changes to table data.

Application-Time Periods

Application-time period tables, defined by a range between two temporal columns.

Bitemporal Tables

Bitemporal tables use versioning both at the system and application-time period levels.

1.1.7.1 System-Versioned Tables

Contents

1. System-Versioned Tables
 1. Creating a System-Versioned Table
 2. Adding or Removing System Versioning To/From a Table
 3. Inserting Data
 4. Querying Historical Data
 1. SELECT
 2. Views and Subqueries
 3. Use in Replication and Binary Logs
 5. Transaction-Precise History in InnoDB
 6. Storing the History Separately
 1. Default Partitions
 2. Automatically Creating Partitions
 7. Removing Old History
 8. Excluding Columns From Versioning
2. System Variables

 2. `system_versioning_asof`
 3. `system_versioning_innodb_algorithm_simple`
 4. `system_versioning_insert_history`
3. Limitations

MariaDB supports temporal data tables in the form of system-versioning tables (allowing you to query and operate on historic data, discussed below), [application-time periods](#) (allow you to query and operate on a temporal range of data), and [bitemporal tables](#) (which combine both system-versioning and [application-time periods](#)).

System-Versioned Tables

System-versioned tables store the history of all changes, not only data which is currently applicable. This allows data analysis for any point in time, auditing of changes and comparison of data from different points in time. Typical uses cases are:

- Forensic analysis & legal requirements to store data for N years.
- Data analytics (retrospective, trends etc.), e.g. to get your staff information as of one year ago.
- Point-in-time recovery - recover a table state as of particular point in time.

System-versioned tables were first introduced in the SQL:2011 standard.

Creating a System-Versioned Table

The `CREATE TABLE` syntax has been extended to permit creating a system-versioned table. To be system-versioned, according to SQL:2011, a table must have two generated columns, a period, and a special table option clause:

```
CREATE TABLE t (  
  x INT,  
  start_timestamp TIMESTAMP(6) GENERATED ALWAYS AS ROW START,  
  end_timestamp TIMESTAMP(6) GENERATED ALWAYS AS ROW END,  
  PERIOD FOR SYSTEM_TIME(start_timestamp, end_timestamp)  
) WITH SYSTEM VERSIONING;
```

In MariaDB one can also use a simplified syntax:

```
CREATE TABLE t (  
  x INT  
) WITH SYSTEM VERSIONING;
```

In the latter case no extra columns will be created and they won't clutter the output of, say, `SELECT * FROM t`. The versioning information will still be stored, and it can be accessed via the pseudo-columns `ROW_START` and `ROW_END`:

```
SELECT x, ROW_START, ROW_END FROM t;
```

Adding or Removing System Versioning To/From a Table

An existing table can be [altered](#) to enable system versioning for it.

```
CREATE TABLE t(  
  x INT  
);
```

```
ALTER TABLE t ADD SYSTEM VERSIONING;
```

```
SHOW CREATE TABLE t\G  
***** 1. row *****  
      Table: t  
Create Table: CREATE TABLE `t` (  
  `x` int(11) DEFAULT NULL  
) ENGINE=InnoDB DEFAULT CHARSET=latin1 WITH SYSTEM VERSIONING
```

Similarly, system versioning can be removed from a table:

```
ALTER TABLE t DROP SYSTEM VERSIONING;
```

```
SHOW CREATE TABLE t\G  
***** 1. row *****  
      Table: t  
Create Table: CREATE TABLE `t` (  
  `x` int(11) DEFAULT NULL  
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

One can also add system versioning with all columns created explicitly:

```
ALTER TABLE t ADD COLUMN ts TIMESTAMP(6) GENERATED ALWAYS AS ROW START,  
               ADD COLUMN te TIMESTAMP(6) GENERATED ALWAYS AS ROW END,  
               ADD PERIOD FOR SYSTEM_TIME(ts, te),  
               ADD SYSTEM VERSIONING;
```

```
SHOW CREATE TABLE t\G  
***** 1. row *****  
      Table: t  
Create Table: CREATE TABLE `t` (  
  `x` int(11) DEFAULT NULL,  
  `ts` timestamp(6) GENERATED ALWAYS AS ROW START,  
  `te` timestamp(6) GENERATED ALWAYS AS ROW END,  
  PERIOD FOR SYSTEM_TIME (`ts`, `te`)  
) ENGINE=InnoDB DEFAULT CHARSET=latin1 WITH SYSTEM VERSIONING
```

MariaDB starting with 11.7

From [MariaDB 11.7](#), it is possible to convert a versioned table from implicit to explicit row_start/row_end columns. Note that in order to do any ALTER on a system versioned table, [system_versioning_alter_history](#) must be set to `KEEP`.

```
CREATE OR REPLACE TABLE t1 (x INT) WITH SYSTEM VERSIONING;  
  
SET system_versioning_alter_history = keep;  
  
ALTER TABLE t1 ADD COLUMN rs TIMESTAMP(6) AS ROW START,  
                ADD COLUMN re TIMESTAMP(6) AS ROW END, ADD PERIOD FOR SYSTEM_TIME (rs,re)
```

Prior to [MariaDB 11.7](#), this would result in a duplicate row error:

```
CREATE OR REPLACE TABLE t1 (x INT) WITH SYSTEM VERSIONING;  
  
SET system_versioning_alter_history = keep;  
  
ALTER TABLE t1 ADD COLUMN rs TIMESTAMP(6) AS ROW START,  
                ADD COLUMN re TIMESTAMP(6) AS ROW END, ADD PERIOD FOR SYSTEM_TIME (rs,re);  
  
ERROR 4134 (HY000): Duplicate ROW START column `rs`
```

Inserting Data

When data is inserted into a system-versioned table, it is given a *row_start* value of the current timestamp, and a *row_end* value of `FROM_UNIXTIME(2147483647.999999)`. The current timestamp can be adjusted by setting the `timestamp system variable`, for example:

```
SELECT NOW();
+-----+
| NOW()          |
+-----+
| 2022-10-24 23:09:38 |
+-----+

INSERT INTO t VALUES(1);

SET @@timestamp = UNIX_TIMESTAMP('2033-10-24');

INSERT INTO t VALUES(2);

SET @@timestamp = default;

INSERT INTO t VALUES(3);

SELECT a,row_start,row_end FROM t;
+-----+-----+-----+
| a      | row_start                               | row_end                               |
+-----+-----+-----+
| 1      | 2022-10-24 23:09:38.951347            | 2038-01-19 05:14:07.999999          |
| 2      | 2033-10-24 00:00:00.000000            | 2038-01-19 05:14:07.999999          |
| 3      | 2022-10-24 23:09:38.961857            | 2038-01-19 05:14:07.999999          |
+-----+-----+-----+
```

Querying Historical Data

SELECT

To query the historical data one uses the clause `FOR SYSTEM_TIME` directly after the table name (before the table alias, if any). SQL:2011 provides three syntactic extensions:

- `AS OF` is used to see the table as it was at a specific point in time in the past:

```
SELECT * FROM t FOR SYSTEM_TIME AS OF TIMESTAMP '2016-10-09 08:07:06';
```

- `BETWEEN start AND end` will show all rows that were visible at any point between two specified points in time. It works inclusively, a row visible exactly at *start* or exactly at *end* will be shown too.

```
SELECT * FROM t FOR SYSTEM_TIME BETWEEN (NOW() - INTERVAL 1 YEAR) AND NOW();
```

- `FROM start TO end` will also show all rows that were visible at any point between two specified points in time, including *start*, but **excluding** *end*.

```
SELECT * FROM t FOR SYSTEM_TIME FROM '2016-01-01 00:00:00' TO '2017-01-01 00:00:00';
```

Additionally MariaDB implements a non-standard extension:

- `ALL` will show all rows, historical and current.

```
SELECT * FROM t FOR SYSTEM_TIME ALL;
```

If the `FOR SYSTEM_TIME` clause is not used, the table will show the *current* data. This is usually the same as if one had specified `FOR SYSTEM_TIME AS OF CURRENT_TIMESTAMP`, unless one has adjusted the *row_start* value (until [MariaDB 10.11](#), only possible by setting the `secure_timestamp` variable). For example:

```

CREATE OR REPLACE TABLE t (a int) WITH SYSTEM VERSIONING;

SELECT NOW();
+-----+
| NOW() |
+-----+
| 2022-10-24 23:43:37 |
+-----+

INSERT INTO t VALUES (1);

SET @@timestamp = UNIX_TIMESTAMP('2033-03-03');

INSERT INTO t VALUES (2);

DELETE FROM t;

SET @@timestamp = default;

SELECT a, row_start, row_end FROM t FOR SYSTEM_TIME ALL;
+-----+-----+-----+
| a | row_start | row_end |
+-----+-----+-----+
| 1 | 2022-10-24 23:43:37.192725 | 2033-03-03 00:00:00.000000 |
| 2 | 2033-03-03 00:00:00.000000 | 2033-03-03 00:00:00.000000 |
+-----+-----+-----+
2 rows in set (0.000 sec)

SELECT a, row_start, row_end FROM t FOR SYSTEM_TIME AS OF CURRENT_TIMESTAMP;
+-----+-----+-----+
| a | row_start | row_end |
+-----+-----+-----+
| 1 | 2022-10-24 23:43:37.192725 | 2033-03-03 00:00:00.000000 |
+-----+-----+-----+
1 row in set (0.000 sec)

SELECT a, row_start, row_end FROM t;
Empty set (0.001 sec)

```

Views and Subqueries

When a system-versioned table is used in a view or in a subquery in the from clause, `FOR SYSTEM_TIME` can be used directly in the view or subquery body, or (non-standard) applied to the whole view when it's being used in a `SELECT`:

```
CREATE VIEW v1 AS SELECT * FROM t FOR SYSTEM_TIME AS OF TIMESTAMP'2016-10-09 08:07:06';
```

Or

```
CREATE VIEW v1 AS SELECT * FROM t;
SELECT * FROM v1 FOR SYSTEM_TIME AS OF TIMESTAMP'2016-10-09 08:07:06';
```

Use in Replication and Binary Logs

Tables that use system-versioning implicitly add the `row_end` column to the Primary Key. While this is generally not an issue for most use cases, it can lead to problems when re-applying write statements from the binary log or in replication environments, where a primary retries an SQL statement on the replica.

Specifically, these writes include a value on the `row_end` column containing the timestamp from when the write was initially made. The re-occurrence of the Primary Key with the old system-versioning columns raises an error due to the duplication.

To mitigate this with MariaDB Replication, set the `secure_timestamp` system variable to `YES` on the replica. When set, the replica uses its own system clock when applying to the row log, meaning that the primary can retry as many times as needed without causing a conflict. The retries generate new historical rows with new values for the `row_start` and `row_end` columns.

Transaction-Precise History in InnoDB

A point in time when a row was inserted or deleted does not necessarily mean that a change became visible at the same moment. With transactional tables, a row might have been inserted in a long transaction, and became visible hours after it was inserted.

For some applications — for example, when doing data analytics on one-year-old data — this distinction does not matter much. For others — forensic analysis — it might be crucial.

MariaDB supports transaction-precise history (only for the [InnoDB storage engine](#)) that allows seeing the data exactly as it would've been seen by a new connection doing a `SELECT` at the specified point in time — rows inserted *before* that point, but committed *after* will not be shown.

To use transaction-precise history, InnoDB needs to remember not timestamps, but transaction identifier per row. This is done by creating generated columns as `BIGINT UNSIGNED`, not `TIMESTAMP(6)`:

```
CREATE TABLE t (
  x INT,
  start_trxid BIGINT UNSIGNED GENERATED ALWAYS AS ROW START,
  end_trxid BIGINT UNSIGNED GENERATED ALWAYS AS ROW END,
  PERIOD FOR SYSTEM_TIME(start_trxid, end_trxid)
) WITH SYSTEM VERSIONING;
```

These columns must be specified explicitly, but they can be made [INVISIBLE](#) to avoid cluttering `SELECT *` output.

Note that if you are using an engine that does not support system versioning with transaction ids, you will get an error like `"start_trxid" must be of type TIMESTAMP(6) for system-versioned table "t"`.

When one uses transaction-precise history, one can optionally use transaction identifiers in the `FOR SYSTEM_TIME` clause:

```
SELECT * FROM t FOR SYSTEM_TIME AS OF TRANSACTION 12345;
```

This will show the data, exactly as it was seen by the transaction with the identifier 12345.

Data for this feature is stored in the [mysql.transaction_registry](#) table.

Storing the History Separately

When the history is stored together with the current data, it increases the size of the table, so current data queries — table scans and index searches — will take more time, because they will need to skip over historical data. If most queries on that table use only current data, it might make sense to store the history separately, to reduce the overhead from versioning.

This is done by partitioning the table by `SYSTEM_TIME`. Because of the [partition pruning](#) optimization, all current data queries will only access one partition, the one that stores current data.

This example shows how to create such a partitioned table:

```
CREATE TABLE t (x INT) WITH SYSTEM VERSIONING
PARTITION BY SYSTEM_TIME (
  PARTITION p_hist HISTORY,
  PARTITION p_cur CURRENT
);
```

In this example all history will be stored in the partition `p_hist` while all current data will be in the partition `p_cur`. The table must have exactly one current partition and at least one historical partition.

Partitioning by `SYSTEM_TIME` also supports automatic partition rotation. One can rotate historical partitions by time or by size. This example shows how to rotate partitions by size:

```
CREATE TABLE t (x INT) WITH SYSTEM VERSIONING
PARTITION BY SYSTEM_TIME LIMIT 100000 (
  PARTITION p0 HISTORY,
  PARTITION p1 HISTORY,
  PARTITION pcur CURRENT
);
```

MariaDB will start writing history rows into partition `p0`, and at the end of the statement that wrote the 100000th row, MariaDB will switch to partition `p1`. There are only two historical partitions, so when `p1` overflows, MariaDB will issue a warning, but will continue writing into it.

Similarly, one can rotate partitions by time:

```
CREATE TABLE t (x INT) WITH SYSTEM VERSIONING
PARTITION BY SYSTEM_TIME INTERVAL 1 WEEK (
  PARTITION p0 HISTORY,
  PARTITION p1 HISTORY,
  PARTITION p2 HISTORY,
  PARTITION pcur CURRENT
);
```

This means that the history for the first week after the table was created will be stored in `p0`. The history for the second week — in `p1`, and all later history will go into `p2`. One can see the exact rotation time for each partition in the `INFORMATION_SCHEMA.PARTITIONS` table.

It is possible to combine partitioning by `SYSTEM_TIME` and subpartitions:

```
CREATE TABLE t (x INT) WITH SYSTEM VERSIONING
PARTITION BY SYSTEM_TIME
SUBPARTITION BY KEY (x)
SUBPARTITIONS 4 (
  PARTITION ph HISTORY,
  PARTITION pc CURRENT
);
```

Default Partitions

MariaDB starting with 10.5.0

Since partitioning by current and historical data is such a typical usecase, from [MariaDB 10.5](#), it is possible to use a simplified statement to do so. For example, instead of

```
CREATE TABLE t (x INT) WITH SYSTEM VERSIONING
PARTITION BY SYSTEM_TIME (
  PARTITION p0 HISTORY,
  PARTITION pn CURRENT
);
```

you can use

```
CREATE TABLE t (x INT) WITH SYSTEM VERSIONING
PARTITION BY SYSTEM_TIME;
```

You can also specify the number of partitions, which is useful if you want to rotate history by time, for example:

```
CREATE TABLE t (x INT) WITH SYSTEM VERSIONING
PARTITION BY SYSTEM_TIME
INTERVAL 1 MONTH
PARTITIONS 12;
```

Specifying the number of partitions without specifying a rotation condition will result in a warning:

```
CREATE OR REPLACE TABLE t (x INT) WITH SYSTEM VERSIONING
PARTITION BY SYSTEM_TIME PARTITIONS 12;
Query OK, 0 rows affected, 1 warning (0.518 sec)

Warning (Code 4115): Maybe missing parameters: no rotation condition for multiple HISTORY partitions.
```

while specifying only 1 partition will result in an error:

```
CREATE OR REPLACE TABLE t (x INT) WITH SYSTEM VERSIONING
PARTITION BY SYSTEM_TIME PARTITIONS 1;
ERROR 4128 (HY000): Wrong partitions for `t`: must have at least one HISTORY and exactly one last CURRENT
```

Automatically Creating Partitions

MariaDB starting with 10.9.1 [↗](#)

From [MariaDB 10.9.1](#) [↗](#), the `AUTO` keyword can be used to automatically create history partitions.

For example

```
CREATE TABLE t1 (x int) WITH SYSTEM VERSIONING
PARTITION BY SYSTEM_TIME INTERVAL 1 HOUR AUTO;

CREATE TABLE t1 (x int) WITH SYSTEM VERSIONING
PARTITION BY SYSTEM_TIME INTERVAL 1 MONTH
STARTS '2021-01-01 00:00:00' AUTO PARTITIONS 12;

CREATE TABLE t1 (x int) WITH SYSTEM VERSIONING
PARTITION BY SYSTEM_TIME LIMIT 1000 AUTO;
```

Or with explicit partitions:

```
CREATE TABLE t1 (x int) WITH SYSTEM VERSIONING
PARTITION BY SYSTEM_TIME INTERVAL 1 HOUR AUTO
(PARTITION p0 HISTORY, PARTITION pn CURRENT);
```

To disable or enable auto-creation one can use ALTER TABLE by adding or removing AUTO from the partitioning specification:

```
CREATE TABLE t1 (x int) WITH SYSTEM VERSIONING
PARTITION BY SYSTEM_TIME INTERVAL 1 HOUR AUTO;

# Disables auto-creation:
ALTER TABLE t1 PARTITION BY SYSTEM_TIME INTERVAL 1 HOUR;

# Enables auto-creation:
ALTER TABLE t1 PARTITION BY SYSTEM_TIME INTERVAL 1 HOUR AUTO;
```

If the rest of the partitioning specification is identical to CREATE TABLE, no repartitioning will be done (for details see [MDEV-27328](#)).

Removing Old History

Because it stores all the history, a system-versioned table might grow very large over time. There are many options to trim down the space and remove the old history.

One can completely drop the versioning from the table and add it back again, this will delete all the history:

```
ALTER TABLE t DROP SYSTEM VERSIONING;
ALTER TABLE t ADD SYSTEM VERSIONING;
```

It might be a rather time-consuming operation, though, as the table will need to be rebuilt, possibly twice (depending on the storage engine).

Another option would be to use partitioning and drop some of historical partitions:

```
ALTER TABLE t DROP PARTITION p0;
```

Note, that one cannot drop a current partition or the only historical partition.

And the third option; one can use a variant of the [DELETE](#) statement to prune the history:

```
DELETE HISTORY FROM t;
```

or only old history up to a specific point in time:

```
DELETE HISTORY FROM t BEFORE SYSTEM_TIME '2016-10-09 08:07:06';
```

or to a specific transaction (with `BEFORE SYSTEM_TIME TRANSACTION xxx`).

To protect the integrity of the history, this statement requires a special [DELETE HISTORY](#) privilege.

Currently, using the DELETE HISTORY statement with a BEFORE SYSTEM_TIME greater than the ROW_END of the active records (as a [TIMESTAMP](#), this has a maximum value of '2038-01-19 03:14:07' [UTC](#)) will result in the historical records being dropped, and the active records being deleted and moved to history. See [MDEV-25468](#).

Prior to [MariaDB 10.4.5](#), the `TRUNCATE TABLE` statement drops all historical records from a system-versioned-table.

From [MariaDB 10.4.5](#), historic data is protected from `TRUNCATE` statements, as per the SQL standard, and an Error 4137 is instead raised:

```
TRUNCATE t;  
ERROR 4137 (HY000): System-versioned tables do not support TRUNCATE TABLE
```

Excluding Columns From Versioning

Another MariaDB extension allows one to version only a subset of columns in a table. This is useful, for example, if you have a table with user information that should be versioned, but one column is, let's say, a login counter that is incremented often and is not interesting to version. Such a column can be excluded from versioning by declaring it `WITHOUT`

`VERSIONING`

```
CREATE TABLE t (  
  x INT,  
  y INT WITHOUT SYSTEM VERSIONING  
) WITH SYSTEM VERSIONING;
```

A column can also be declared `WITH VERSIONING`, that will automatically make the table versioned. The statement below is equivalent to the one above:

```
CREATE TABLE t (  
  x INT WITH SYSTEM VERSIONING,  
  y INT  
);
```

System Variables

There are a number of system variables related to system-versioned tables:

system_versioning_alter_history

- **Description:** SQL:2011 does not allow `ALTER TABLE` on system-versioned tables. When this variable is set to `ERROR`, an attempt to alter a system-versioned table will result in an error. When this variable is set to `KEEP`, `ALTER TABLE` will be allowed, but the history will become incorrect — querying historical data will show the new table structure. This mode is still useful, for example, when adding new columns to a table. Note that if historical data contains or would contain nulls, attempting to `ALTER` these columns to be `NOT NULL` will return an error (or warning if `strict_mode` is not set).
- **Commandline:** `--system-versioning-alter-history=value`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Type:** Enum
- **Default Value:** `ERROR`
- **Valid Values:** `ERROR`, `KEEP`

system_versioning_asof

- **Description:** If set to a specific timestamp value, an implicit `FOR SYSTEM_TIME AS OF` clause will be applied to all queries. This is useful if one wants to do many queries for history at the specific point in time. Set it to `'DEFAULT'` to restore the default behavior. Has no effect on DML, so queries such as `INSERT .. SELECT` and `REPLACE .. SELECT` need to state `AS OF` explicitly.

Note: You need to use quotes around the name `'DEFAULT'` when setting the session value, unquoted literal `DEFAULT` will restore the current global value instead.

- **Commandline:** None
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Type:** Varchar
- **Default Value:** `DEFAULT`

system_versioning_innodb_algorithm_simple

- **Description:** Never fully implemented and removed in the following release.
- **Commandline:** `--system-versioning-innodb-algorithm-simple[={0|1}]`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Type:** Boolean
- **Default Value:** ON
- **Introduced:** [MariaDB 10.3.4](#)
- **Removed:** [MariaDB 10.3.5](#)

system_versioning_insert_history

- **Description:** Allows direct inserts into ROW_START and ROW_END columns if [secure_timestamp](#) allows changing [timestamp](#).
- **Commandline:** `--system-versioning-insert-history[={0|1}]`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Type:** Boolean
- **Default Value:** OFF
- **Introduced:** [MariaDB 10.11.0](#)

Limitations

- Versioning clauses can not be applied to [generated \(virtual and persistent\) columns](#).
- Before [MariaDB 10.11](#), [mariadb-dump](#) did not read historical rows from versioned tables, and so historical data would not be backed up. Also, a restore of the timestamps would not be possible as they cannot be defined by an insert/a user. From [MariaDB 10.11](#), use the `-H` or `--dump-history` options to include the history.

1.1.7.2 Application-Time Periods

Contents

1. [Creating Tables with Time Periods](#)
2. [Adding and Removing Time Periods](#)
3. [Deletion by Portion](#)
4. [Updating by Portion](#)
5. [WITHOUT OVERLAPS](#)
6. [Information Schema](#)
7. [Further Examples](#)

Extending [system-versioned tables](#), MariaDB supports application-time period tables. Time periods are defined by a range between two temporal columns. The columns must be of the same [temporal data type](#), i.e. [DATE](#), [TIMESTAMP](#) or [DATETIME](#) ([TIME](#) and [YEAR](#) are not supported), and of the same width.

Using time periods implicitly defines the two columns as `NOT NULL`. It also adds a constraint to check whether the first value is less than the second value. The constraint is invisible to [SHOW CREATE TABLE](#) statements. The name of this constraint is prefixed by the time period name, to avoid conflict with other constraints.

Creating Tables with Time Periods

To create a table with a time period, use a [CREATE TABLE](#) statement with the `PERIOD` table option.

```
CREATE TABLE t1 (  
  name VARCHAR(50),  
  date_1 DATE,  
  date_2 DATE,  
  PERIOD FOR date_period(date_1, date_2));
```

This creates a table with a `time_period` period and populates the table with some basic temporal values.

Examples are available in the MariaDB Server source code, at `mysql-test/suite/period/r/create.result`.

Adding and Removing Time Periods

The `ALTER TABLE` statement now supports syntax for adding and removing time periods from a table. To add a period, use the `ADD PERIOD` clause.

For example:

```
CREATE OR REPLACE TABLE rooms (  
  room_number INT,  
  guest_name VARCHAR(255),  
  checkin DATE,  
  checkout DATE  
);  
  
ALTER TABLE rooms ADD PERIOD FOR p(checkin, checkout);
```

To remove a period, use the `DROP PERIOD` clause:

```
ALTER TABLE rooms DROP PERIOD FOR p;
```

Both `ADD PERIOD` and `DROP PERIOD` clauses include an option to handle whether the period already exists:

```
ALTER TABLE rooms ADD PERIOD IF NOT EXISTS FOR p(checkin, checkout);  
  
ALTER TABLE rooms DROP PERIOD IF EXISTS FOR p;
```

Deletion by Portion

You can also remove rows that fall within certain time periods.

When MariaDB executes a `DELETE FOR PORTION` statement, it removes the row:

- When the row period falls completely within the delete period, it removes the row.
- When the row period overlaps the delete period, it shrinks the row, removing the overlap from the first or second row period value.
- When the delete period falls completely within the row period, it splits the row into two rows. The first row runs from the starting row period to the starting delete period. The second runs from the ending delete period to the ending row period.

To test this, first populate the table with some data to operate on:

```
CREATE TABLE t1 (  
  name VARCHAR(50),  
  date_1 DATE,  
  date_2 DATE,  
  PERIOD FOR date_period(date_1, date_2));  
  
INSERT INTO t1 (name, date_1, date_2) VALUES  
  ('a', '1999-01-01', '2000-01-01'),  
  ('b', '1999-01-01', '2018-12-12'),  
  ('c', '1999-01-01', '2017-01-01'),  
  ('d', '2017-01-01', '2019-01-01');  
  
SELECT * FROM t1;  
+-----+-----+-----+  
| name | date_1 | date_2 |  
+-----+-----+-----+  
| a    | 1999-01-01 | 2000-01-01 |  
| b    | 1999-01-01 | 2018-12-12 |  
| c    | 1999-01-01 | 2017-01-01 |  
| d    | 2017-01-01 | 2019-01-01 |  
+-----+-----+-----+
```

Then, run the `DELETE FOR PORTION` statement:

```
DELETE FROM t1
FOR PORTION OF date_period
FROM '2001-01-01' TO '2018-01-01';
Query OK, 3 rows affected (0.028 sec)
```

```
SELECT * FROM t1 ORDER BY name;
+-----+-----+-----+
| name | date_1 | date_2 |
+-----+-----+-----+
| a    | 1999-01-01 | 2000-01-01 |
| b    | 1999-01-01 | 2001-01-01 |
| b    | 2018-01-01 | 2018-12-12 |
| c    | 1999-01-01 | 2001-01-01 |
| d    | 2018-01-01 | 2019-01-01 |
+-----+-----+-----+
```

Here:

- a is **unchanged**, as the range falls entirely out of the specified portion to be deleted.
- b, with values ranging from 1999 to 2018, is **split** into two rows, 1999 to 2000 and 2018-01 to 2018-12 (i.e. one extra row has been inserted).
- c, with values ranging from 1999 to 2017, where only the upper value falls within the portion to be deleted, has been **shrunk** to 1999 to 2001.
- d, with values ranging from 2017 to 2019, where only the lower value falls within the portion to be deleted, has been **shrunk** to 2018 to 2019.

The `DELETE FOR PORTION` statement has the following restrictions

- The `FROM...TO` clause must be constant
- Multi-delete is not supported

If there are `DELETE` or `INSERT` triggers, it works as follows: any matched row is deleted, and then one or two rows are inserted. If the record is deleted completely, nothing is inserted.

Updating by Portion

The `UPDATE` syntax now supports `UPDATE FOR PORTION`, which modifies rows based on their occurrence in a range:

To test it, first populate the table with some data:

```
TRUNCATE t1;

INSERT INTO t1 (name, date_1, date_2) VALUES
('a', '1999-01-01', '2000-01-01'),
('b', '1999-01-01', '2018-12-12'),
('c', '1999-01-01', '2017-01-01'),
('d', '2017-01-01', '2019-01-01');

SELECT * FROM t1;
+-----+-----+-----+
| name | date_1 | date_2 |
+-----+-----+-----+
| a    | 1999-01-01 | 2000-01-01 |
| b    | 1999-01-01 | 2018-12-12 |
| c    | 1999-01-01 | 2017-01-01 |
| d    | 2017-01-01 | 2019-01-01 |
+-----+-----+-----+
```

Then run the update:

```

UPDATE t1 FOR PORTION OF date_period
  FROM '2000-01-01' TO '2018-01-01'
SET name = CONCAT(name, '_original');

SELECT * FROM t1 ORDER BY name;
+-----+-----+-----+
| name      | date_1    | date_2    |
+-----+-----+-----+
| a         | 1999-01-01 | 2000-01-01 |
| b         | 1999-01-01 | 2000-01-01 |
| b         | 2018-01-01 | 2018-12-12 |
| b_original | 2000-01-01 | 2018-01-01 |
| c         | 1999-01-01 | 2000-01-01 |
| c_original | 2000-01-01 | 2017-01-01 |
| d         | 2018-01-01 | 2019-01-01 |
| d_original | 2017-01-01 | 2018-01-01 |
+-----+-----+-----+

```

- a is **unchanged**, as the range falls entirely out of the specified portion to be updated.
- For b, with years ranging from 1999 to 2018, two extra rows are **inserted**, with ranges 1999-01 to 2000-01 and 2018-01 to 2018-12. The original row's period has been **shrunk** to years 2000 and 2018, and the name field has got "_original" appended.
- c, with values ranging from 1999 to 2017, where only the upper value falls within the portion to be updated, has been **shrunk** to 1999 to 2001.
- d, with values ranging from 2017 to 2019, where only the lower value falls within the portion to be updated, has been **shrunk** to 2018 to 2019.
- Original rows affected by the update have "_original" appended to the name.

The `UPDATE FOR PORTION` statement has the following limitations:

- The operation cannot modify the two temporal columns used by the time period
- The operation cannot reference period values in the `SET` expression
- `FROM...TO` expressions must be constant

WITHOUT OVERLAPS

MariaDB starting with [10.5.3](#)

MariaDB 10.5 introduced a new clause, `WITHOUT OVERLAPS`, which allows one to create an index specifying that application time periods should not overlap.

An index constrained by `WITHOUT OVERLAPS` is required to be either a primary key or a unique index.

Take the following example, an application time period table for a booking system:

```

CREATE OR REPLACE TABLE rooms (
  room_number INT,
  guest_name VARCHAR(255),
  checkin DATE,
  checkout DATE,
  PERIOD FOR p(checkin, checkout)
);

INSERT INTO rooms VALUES
(1, 'Regina', '2020-10-01', '2020-10-03'),
(2, 'Cochise', '2020-10-02', '2020-10-05'),
(1, 'Nowell', '2020-10-03', '2020-10-07'),
(2, 'Eusebius', '2020-10-04', '2020-10-06');

```

Our system is not intended to permit overlapping bookings, so the fourth record above should not have been inserted. Using `WITHOUT OVERLAPS` in a unique index (in this case based on a combination of room number and the application time period) allows us to specify this constraint in the table definition.

```

CREATE OR REPLACE TABLE rooms (
  room_number INT,
  guest_name VARCHAR(255),
  checkin DATE,
  checkout DATE,
  PERIOD FOR p(checkin,checkout),
  UNIQUE (room_number, p WITHOUT OVERLAPS)
);

INSERT INTO rooms VALUES
(1, 'Regina', '2020-10-01', '2020-10-03'),
(2, 'Cochise', '2020-10-02', '2020-10-05'),
(1, 'Nowell', '2020-10-03', '2020-10-07'),
(2, 'Eusebius', '2020-10-04', '2020-10-06');
ERROR 1062 (23000): Duplicate entry '2-2020-10-06-2020-10-04' for key 'room_number'

```

Information Schema

MariaDB starting with 11.4

From MariaDB 11.4, the Information Schema contains the following support for application time period tables.

- [INFORMATION_SCHEMA.PERIODS](#) view.
- [INFORMATION_SCHEMA.KEY_PERIOD_USAGE](#) view.
- Additional columns `IS_SYSTEM_TIME_PERIOD_START` and `IS_SYSTEM_TIME_PERIOD_END` in the [INFORMATION_SCHEMA.COLUMNS](#) view.

Further Examples

The implicit change from NULL to NOT NULL:

```

CREATE TABLE `t2` (
  `id` int(11) DEFAULT NULL,
  `d1` datetime DEFAULT NULL,
  `d2` datetime DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1;

ALTER TABLE t2 ADD PERIOD FOR p(d1,d2);

SHOW CREATE TABLE t2\G
***** 1. row *****
      Table: t2
Create Table: CREATE TABLE `t2` (
* //a// is *unchanged*, as the range falls entirely out of the specified portion to be updated.
* For //b//, with years ranging from 1999 to 2018, two extra rows are *inserted*, with ranges 199
* //c//, with values ranging from 1999 to 2017, where only the upper value falls within the porti
* //d//, with values ranging from 2017 to 2019, where only the lower value falls within the porti
* Original rows affected by the update have "_original" appended to the ##name## field.
  `id` int(11) DEFAULT NULL,
  `d1` datetime NOT NULL,
  `d2` datetime NOT NULL,
  PERIOD FOR `p` (`d1`, `d2`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1

```

Due to this constraint, trying to add a time period where null data already exists will fail.

```

CREATE OR REPLACE TABLE `t2` (
  `id` int(11) DEFAULT NULL,
  `d1` datetime DEFAULT NULL,
  `d2` datetime DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1;

INSERT INTO t2(id) VALUES(1);

ALTER TABLE t2 ADD PERIOD FOR p(d1,d2);
ERROR 1265 (01000): Data truncated for column 'd1' at row 1

```

1.1.7.3 Bitemporal Tables

MariaDB starting with [10.4.3](#)

Bitemporal tables are tables that use versioning both at the [system](#) and [application-time period](#) levels.

Contents

- [Using Bitemporal Tables](#)

Using Bitemporal Tables

To create a bitemporal table, use:

```
CREATE TABLE test.t3 (  
  date_1 DATE,  
  date_2 DATE,  
  row_start TIMESTAMP(6) AS ROW START INVISIBLE,  
  row_end TIMESTAMP(6) AS ROW END INVISIBLE,  
  PERIOD FOR application_time(date_1, date_2),  
  PERIOD FOR system_time(row_start, row_end)  
WITH SYSTEM VERSIONING;
```

Note that, while `system_time` here is also a time period, it cannot be used in `DELETE FOR PORTION` or `UPDATE FOR PORTION` statements.

```
DELETE FROM test.t3  
FOR PORTION OF system_time  
  FROM '2000-01-01' TO '2018-01-01';  
ERROR 42000: You have an error in your SQL syntax; check the manual that corresponds  
  to your MariaDB server version for the right syntax to use near  
  'of system_time from '2000-01-01' to '2018-01-01'' at line 1
```

1.1.8 Vectors

The Next Generation of MariaDB: Powered by Vector Search

Watch the Webinar [↗](#)

MariaDB starting with [11.7](#)

Vectors were introduced in [MariaDB 11.7](#)

Vectors are a feature that allow MariaDB Server to perform as a relational vector database.

Vector Overview

Overview of vectors, a feature that allows MariaDB to perform as a relational vector database.

CREATE TABLE with Vectors

MariaDB has a dedicated VECTOR(N) data type with a built-in data validation.

Vector System Variables

List and description of vector-related server system variables.

Vector Functions

Built-in functions related to Vectors.

VECTOR

Vector data type.

1.1.8.1 Vector Overview

The Next Generation of MariaDB: Powered by Vector Search

Watch the Webinar [↗](#)

MariaDB starting with [11.7](#)
Vectors were introduced in [MariaDB 11.7](#)

MariaDB Vector is a feature that allows MariaDB Server to perform as a relational vector database. Vectors generated by your favourite AI model can be stored and searched for in MariaDB.

The initial implementation uses the modified HNSW algorithm for searching in the vector index (to solve the so-called Approximate Nearest Neighbor problem), and defaults to Euclidean distance. Concurrent reads/writes and all [transaction isolation levels](#) are supported.

MariaDB uses int16 for indexes, which gives 15 bits to store the value, rather than 10 bits for float16.

Creating

Vectors can be defined using `VECTOR INDEX` for the index definition, and using the [VECTOR data type](#) in the `CREATE TABLE` statement.

```
CREATE TABLE v (  
  id INT PRIMARY KEY,  
  v VECTOR(5) NOT NULL,  
  VECTOR INDEX (v)  
);
```

The distance function used to build the vector index can be `euclidean` (the default), or `cosine`. An additional option, `M`, can also be used to configure the vector index. Larger values mean slower SELECTs and INSERTs, larger index size and higher memory consumption but more accurate results. The valid range is from 3 to 200.

```
CREATE TABLE embeddings (  
  doc_id BIGINT UNSIGNED PRIMARY KEY,  
  embedding VECTOR(1536) NOT NULL,  
  VECTOR INDEX (embedding) M=8 DISTANCE=cosine  
);
```

Inserting

Vector columns store [32-bit IEEE 754 floating point numbers](#) [↗](#).

```
INSERT INTO v VALUES  
(1, x'e360d63ebe554f3fcd523f4522193f5236083d'),  
(2, x'f511303f72224a3fdd05fe3eb22a133ffae86a3f'),  
(3, x'f09baa3ea172763f123def3e0c7fe53e288bf33e'),  
(4, x'b97a523f2a193e3eb4f62e3f2d23583e9dd60d3f'),  
(5, x'f7c5df3e984b2b3e65e59d3d7376db3eac63773e'),  
(6, x'de01453ffa486d3f10aa4d3fdd66813c71cb163f'),  
(7, x'76edfc3e4b57243f10f8423fb158713f020bda3e'),  
(8, x'56926c3fd098d3e2c8c5e3d1ad4953daa9d0b3e'),  
(9, x'7b713f3e5258323f80d1113d673b2b3f66e3583f'),  
(10, x'6ca1d43e9df91b3fe580da3e1c247d3f147cf33e');
```

Alternatively one can use `VEC_FromText()` function:

INSERT INTO v VALUES

```
(1,Vec_FromText ('[0.418708,0.809902,0.823193,0.598179,0.0332549]')),
(2,Vec_FromText ('[0.687774,0.789588,0.496138,0.57487,0.917617]')),
(3,Vec_FromText ('[0.333221,0.962687,0.467263,0.448235,0.475671]')),
(4,Vec_FromText ('[0.822185,0.185643,0.683452,0.211072,0.554056]')),
(5,Vec_FromText ('[0.437057,0.167281,0.0770977,0.428638,0.241591]')),
(6,Vec_FromText ('[0.76956,0.926895,0.803376,0.0157961,0.589042]')),
(7,Vec_FromText ('[0.493999,0.641957,0.761598,0.94276,0.425865]')),
(8,Vec_FromText ('[0.924108,0.275466,0.0543329,0.0731585,0.136344]')),
(9,Vec_FromText ('[0.186956,0.69666,0.0356002,0.668875,0.84722]')),
(10,Vec_FromText ('[0.415294,0.609278,0.426765,0.988832,0.475556]'));
```

Querying

For vector indexes built with the `euclidean` function, `VEC_DISTANCE_EUCLIDEAN` can be used. It calculates a Euclidean (L2) distance between two points.

```
SELECT id FROM v ORDER BY
  VEC_DISTANCE_EUCLIDEAN(v, x'6ca1d43e9df91b3fe580da3e1c247d3f147cf33e');
+----+
| id |
+----+
| 10 |
| 7  |
| 3  |
| 9  |
| 2  |
| 1  |
| 5  |
| 4  |
| 6  |
| 8  |
+----+
```

Most commonly, this kind of query is done with a limit, for example to return vectors that are closest to a given vector, such as from a user search query, image or a song fragment.

```
SELECT id FROM v
  ORDER BY VEC_DISTANCE_EUCLIDEAN(v, x'6ca1d43e9df91b3fe580da3e1c247d3f147cf33e') LIMIT 2;
+----+
| id |
+----+
| 10 |
| 7  |
+----+
```

For vector indexes built with the `cosine` function, `VEC_DISTANCE_COSINE` can be used. It calculates a [Cosine distance](#)  between two vectors

```
SELECT VEC_DISTANCE_COSINE(VEC_FROMTEXT ('[1,2,3]'), VEC_FROMTEXT ('[3,5,7]'));
```

The `VEC_DISTANCE` function is a generic function that behaves either as `VEC_DISTANCE_EUCLIDEAN` or `VEC_DISTANCE_COSINE`, depending on the underlying index type.

```

SELECT id FROM v
ORDER BY VEC_DISTANCE(v, x'6cald43e9df91b3fe580da3e1c247d3f147cf33e');
+-----+
| id |
+-----+
| 10 |
| 7 |
| 3 |
| 9 |
| 2 |
| 1 |
| 5 |
| 4 |
| 6 |
| 8 |
+-----+

```

System Variables

There are a number of system variables used for vectors. See [Vector System Variables](#).

1.1.8.2 CREATE TABLE with Vectors

The Next Generation of MariaDB: Powered by Vector Search

Watch the Webinar [↗](#)

MariaDB starting with [11.7](#)

[Vector search](#) was added in [MariaDB 11.7](#).

MariaDB has a dedicated [VECTOR\(N\)](#) data type with a built-in data validation. N is the number of dimensions that all vector values in the column will have. For example,

```

CREATE TABLE embeddings (
  doc_id BIGINT UNSIGNED PRIMARY KEY,
  embedding VECTOR(1536)
);

```

To have a fast vector search one needs to index the vector column, creating a [VECTOR](#) index:

```

CREATE TABLE embeddings (
  doc_id BIGINT UNSIGNED PRIMARY KEY,
  embedding VECTOR(1536) NOT NULL,
  VECTOR INDEX (embedding)
);

```

Note that there can be only one vector index in the table and the indexed vector column must be `NOT NULL`.

There are two options that can be used to configure the vector index.

- `M` — Larger values mean slower SELECTs and INSERTs, larger index size and higher memory consumption but more accurate results. The valid range is from `3` to `200`.
- `DISTANCE` — Distance function to build the vector index for. Searches using a different distance function will not be able to use a vector index. Valid values are `cosine` and `euclidean` (the default). For example,

```

CREATE TABLE embeddings (
  doc_id BIGINT UNSIGNED PRIMARY KEY,
  embedding VECTOR(1536) NOT NULL,
  VECTOR INDEX (embedding) M=8 DISTANCE=cosine
);

```

1.1.8.3 Vector Functions

The Next Generation of MariaDB: Powered by Vector Search

Watch the Webinar [↗](#)

The following functions are for use with [Vectors](#).

VEC_DISTANCE

Behaves either as [VEC_DISTANCE_EUCLIDEAN](#) or [VEC_DISTANCE_COSINE](#), depending ...

VEC_DISTANCE_COSINE

Calculates a Cosine distance between two vectors.

VEC_DISTANCE_EUCLIDEAN

Calculates a Euclidean (L2) distance between two points.

VEC_FromText

Converts a text representation of the vector to a vector.

VEC_ToText

Converts a binary vector into a json array of numbers (floats).

1.1.8.3.1 VEC_DISTANCE

The Next Generation of MariaDB: Powered by Vector Search

Watch the Webinar [↗](#)

MariaDB starting with [11.8](#)

[VEC_DISTANCE](#) was introduced in [MariaDB 11.8](#).

Syntax

```
VEC_DISTANCE(v, s)
```

Description

`VEC_DISTANCE` is a generic function that will behave either as [VEC_DISTANCE_EUCLIDEAN](#), calculating the Euclidean (L2) distance between two points. or [VEC_DISTANCE_COSINE](#), calculating the Cosine distance between two vectors, depending on the underlying index type.

If the underlying index cannot be determined, an [error 4206](#) [↗](#) is returned:

```
ERROR 4206 (HY000): Cannot determine distance type for VEC_DISTANCE, index is not found
```

Example

```

INSERT INTO v VALUES
  (1, x'e360d63ebe554f3fcdabc523f4522193f5236083d'),
  (2, x'f511303f72224a3fdd05fe3eb22a133ffae86a3f'),
  (3, x'f09baa3ea172763f123def3e0c7fe53e288bf33e'),
  (4, x'b97a523f2a193e3eb4f62e3f2d23583e9dd60d3f'),
  (5, x'f7c5df3e984b2b3e65e59d3d7376db3eac63773e'),
  (6, x'de01453ffa486d3f10aa4d3fdd66813c71cb163f'),
  (7, x'76edfc3e4b57243f10f8423fb158713f020bda3e'),
  (8, x'56926c3fdf098d3e2c8c5e3d1ad4953daa9d0b3e'),
  (9, x'7b713f3e5258323f80d1113d673b2b3f66e3583f'),
  (10, x'6ca1d43e9df91b3fe580da3e1c247d3f147cf33e');

SELECT id FROM v
ORDER BY VEC_DISTANCE (v, x'6ca1d43e9df91b3fe580da3e1c247d3f147cf33e');
+----+
| id |
+----+
| 10 |
| 7  |
| 3  |
| 9  |
| 2  |
| 1  |
| 5  |
| 4  |
| 6  |
| 8  |
+----+

```

1.1.8.3.2 VEC_DISTANCE_COSINE

The Next Generation of MariaDB: Powered by Vector Search

Watch the Webinar [↗](#)

MariaDB starting with [11.7](#)
 Vectors were introduced in [MariaDB 11.7](#)

Syntax

```
VEC_DISTANCE_COSINE (v, s)
```

Description

`VEC_Distance_Cosine` is an SQL function that calculates a [Cosine distance](#) [↗](#) between two vectors.

If the vector index was not built for the cosine function (see [CREATE TABLE with Vectors](#)), the index will not be used, and a full table scan performed instead. The `VEC_DISTANCE` function is a generic function that behaves either as `VEC_DISTANCE_EUCLIDEAN` or `VEC_DISTANCE_COSINE`, depending on the underlying index type.

Example

```

select vec_distance_cosine(vec_fromtext('[1,2,3]'), vec_fromtext('[3,5,7]'));
+-----+
| vec_distance_cosine(vec_fromtext('[1,2,3]'), vec_fromtext('[3,5,7]')) |
+-----+
| 0.00258509695694209 |
+-----+

```

1.1.8.3.3 VEC_DISTANCE_EUCLIDEAN

The Next Generation of MariaDB: Powered by Vector Search

Watch the Webinar [↗](#)

MariaDB starting with [11.7](#)
Vectors were introduced in [MariaDB 11.7](#).

Syntax

```
VEC_DISTANCE_EUCLIDEAN(v, s)
```

Description

`VEC_Distance_Euclidean` is an SQL function that calculates a Euclidean (L2) distance between two points.

If the vector index was not built for the euclidean function (see [CREATE TABLE with Vectors](#)), the index will not be used, and a full table scan performed instead. The `VEC_DISTANCE` function is a generic function that behaves either as `VEC_DISTANCE_EUCLIDEAN` or `VEC_DISTANCE_COSINE`, depending on the underlying index type.

Example

```
INSERT INTO v VALUES
(1, x'e360d63ebe554f3fcdbc523f4522193f5236083d'),
(2, x'f511303f72224a3fdd05fe3eb22a133ffae86a3f'),
(3, x'f09baa3ea172763f123def3e0c7fe53e288bf33e'),
(4, x'b97a523f2a193e3eb4f62e3f2d23583e9dd60d3f'),
(5, x'f7c5df3e984b2b3e65e59d3d7376db3eac63773e'),
(6, x'de01453ffa486d3f10aa4d3fdd66813c71cb163f'),
(7, x'76edfc3e4b57243f10f8423fb158713f020bda3e'),
(8, x'56926c3fdf098d3e2c8c5e3d1ad4953daa9d0b3e'),
(9, x'7b713f3e5258323f80d1113d673b2b3f66e3583f'),
(10, x'6ca1d43e9df91b3fe580da3e1c247d3f147cf33e');

SELECT id FROM v
ORDER BY VEC_Distance_Euclidean(v, x'6ca1d43e9df91b3fe580da3e1c247d3f147cf33e');
+----+
| id |
+----+
| 10 |
| 7  |
| 3  |
| 9  |
| 2  |
| 1  |
| 5  |
| 4  |
| 6  |
| 8  |
+----+
```

1.1.8.3.4 VEC_FromText

The Next Generation of MariaDB: Powered by Vector Search

[Watch the Webinar](#)

MariaDB starting with [11.6](#)

[Vectors](#) were introduced in [MariaDB 11.7](#).

Syntax

```
VEC_FromText(s)
```

Description

`VEC_FromText` converts a text representation of the vector (json array of numbers) to a vector (little-endian IEEE float sequence of bytes, 4 bytes per float).

Example

```
select hex(vec_fromtext('[1,2,3]'));
+-----+
| hex(vec_fromtext('[1,2,3]')) |
+-----+
| 0000803F0000004000004040      |
+-----+
```

1.1.8.3.5 VEC_ToText

The Next Generation of MariaDB: Powered by Vector Search

[Watch the Webinar](#)

MariaDB starting with [11.7](#)

[Vectors](#) were introduced in [MariaDB 11.7](#).

Syntax

```
VEC_ToText(v)
```

Description

`VEC_ToText` converts a binary vector into a json array of numbers (floats). Returns NULL and throws a warning [4201](#) if given an invalid vector.

Example

```

SELECT VEC_ToText(x'e360d63ebe554f3fcdbc523f4522193f5236083d');
+-----+
| VEC_ToText(x'e360d63ebe554f3fcdbc523f4522193f5236083d') |
+-----+
| [0.418708,0.809902,0.823193,0.598179,0.033255] |
+-----+

```

Invalid vector:

```

SELECT VEC_ToText(x'aabbcc');
+-----+
| VEC_ToText(x'aabbcc') |
+-----+
| NULL |
+-----+
1 row in set, 1 warning (0.000 sec)

```

Warning (Code 4201): Invalid binary vector format. Must use IEEE standard float representation in little-endian format. Use VEC_FromText() to generate it.

1.1.8.4 Vector System Variables

The Next Generation of MariaDB: Powered by Vector Search

Watch the Webinar [↗](#)

MariaDB starting with [11.7.1](#) [↗](#)

Vectors were introduced in [MariaDB 11.7.1](#)

Contents

1. [mhsw_default_distance](#)
2. [mhsw_default_m](#)
3. [mhsw_ef_search](#)
4. [mhsw_max_cache_size](#)

This page documents system variables related to [Vectors](#).

See [Server System Variables](#) for a complete list of system variables and instructions on setting them.

Also see the [Full list of MariaDB options, system and status variables](#).

`mhsw_default_distance`

- **Description:** Specifies the default distance metric for MHNSW vector indexing. This is used when the `DISTANCE` option is not explicitly defined during index creation.
- **Commandline:** `--mhsw-default-distance=val`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `enum`
- **Default Value:** `euclidean`
- **Valid Values:**
 - `euclidean` Calculates straight-line distance between vectors. Best for spatial data, images, etc, when absolute magnitude matters.
 - `cosine` Measures directional similarity between vectors. Ideal for text embeddings, semantic search, and when vector magnitude is less important.
- **Introduced:** [MariaDB 11.7.1](#)

`mhsw_default_m`

- **Description:** Defines the default value for the M parameter in MHNSW vector indexing. The `M` parameter controls the number of connections per layer in the graph structure, influencing the balance between search performance and index size.
 - Larger `M` → Better search accuracy, but larger index size and slower updates and searches.
 - Smaller `M` → Faster updates and searches, smaller index, but potentially less accurate search.
 - **Commandline:** `--mhnsw-default-m=#`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `int unsigned`
 - **Default Value:** 6
 - **Range:** 3 to 200
 - **Introduced:** [MariaDB 11.7.1](#)
-

`mhnsw_ef_search`

- **Description:** Defines the minimal number of result candidates to look for in the vector index for `ORDER BY ... LIMIT N` queries. The search will never search for less rows than that, even if `LIMIT` is smaller. This notably improves the search quality at low `LIMIT` values, at the expense of search time. Higher values may increase search quality but will also impact query performance.
 - **Commandline:** `--mhnsw-ef-search=#`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `int unsigned`
 - **Default Value:** 20
 - **Range:** 1 to 10000
 - **Introduced:** [MariaDB 11.7.1](#)
-

`mhnsw_max_cache_size`

- **Description:** Upper limit for one MHNSW vector index cache. This limits the amount of memory that can be used for caching the index, ensuring efficient memory utilization.
 - **Commandline:** `--mhnsw-max-cache-size=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `bigint unsigned`
 - **Default Value:** 16777216 (16 MB)
 - **Range:** 1048576 to 18446744073709551615
 - **Introduced:** [MariaDB 11.7.1](#)
-

1.2 Built-in Functions

Functions and procedures in MariaDB

Function and Operator Reference

A complete list of MariaDB functions and operators in alphabetical order.

String Functions

Built-In functions for the handling of strings and columns containing string values.

Date & Time Functions

Built-In functions for the handling of dates and times.

Aggregate Functions

Aggregate functions used with `GROUP BY` clauses.

Numeric Functions

Numeric and arithmetic related functions in MariaDB.

Control Flow Functions

Built-In functions for assessing data to determine what results to return.

Pseudo Columns

MariaDB has pseudo columns that can be used for different purposes.

Secondary Functions

Bit Functions and Operators

Operators for comparison and setting of values, and related functions.

Encryption, Hashing and Compression Functions

Functions used for encryption, hashing and compression.

Information Functions

Functions which return information on the server, the user, or a given query.

Miscellaneous Functions

Functions for very singular and specific needs.

Special Functions

Dynamic Columns Functions

Functions for storing key/value pairs of data within a column.

Galera Functions

Built-in functions related to Galera.

Geographic Functions

Geographic, as well as geometric functions.

JSON Functions

Built-in functions related to JSON.

SEQUENCE Functions

Functions that can be used on SEQUENCES.

Spider Functions

User-defined functions available with the Spider storage engine.

Vector Functions

Built-in functions related to Vectors.

Window Functions

Window functions for performing calculations on a set of rows related to the current row.

There are [12 related questions](#)

1.2.1 Function and Operator Reference

Name	Description	Added
+	Addition operator	
/	Division operator	
*	Multiplication operator	
%	Modulo operator. Returns the remainder of N divided by M	
-	Subtraction operator	
!=	Not equals	
<	Less than	
<=	Less than or equal	

<=>	NULL-safe equal	
=	Equal	
>	Greater than	
>=	Greater than or equal	
&	Bitwise AND	
<<	Shift left	
>>	Shift right	
^	Bitwise XOR	
!	Logical NOT	
&&	Logical AND	
XOR	Logical XOR	
	Logical OR	
	Bitwise OR	
:=	Assignment operator	
=	Assignment and comparison operator	
~	Bitwise NOT	
ABS	Returns an absolute value	
ACOS	Returns an arc cosine	
ADD_MONTHS	Add months to a date	
ADDDATE	Add days or another interval to a date	
ADDTIME	Adds a time to a time or datetime	
AES_DECRYPT	Decryption data encrypted with AES_ENCRYPT	
AES_ENCRYPT	Encrypts a string with the AES algorithm	
AREA	Synonym for ST_AREA	
AsBinary	Synonym for ST_AsBinary	
ASCII	Numeric ASCII value of leftmost character	
ASIN	Returns the arc sine	
AsText	Synonym for ST_AsText	
AsWKB	Synonym for ST_AsBinary	
AsWKT	Synonym for ST_AsText	
ATAN	Returns the arc tangent	
ATAN2	Returns the arc tangent of two variables	
AVG	Returns the average value	
BENCHMARK	Executes an expression repeatedly	
BETWEEN AND	True if expression between two values	
BIN	Returns binary value	
BINARY OPERATOR	Casts to a binary string	
BINLOG_GTID_POS	Returns a string representation of the corresponding GTID position	
BIT_AND	Bitwise AND	
BIT_COUNT	Returns the number of set bits	
BIT_LENGTH	Returns the length of a string in bits	
BIT_OR	Bitwise OR	
BIT_XOR	Bitwise XOR	
BOUNDARY	Synonym for ST_BOUNDARY	

BUFFER	Synonym for ST_BUFFER	
CASE	Returns the result where value=compare_value or for the first condition that is true	
CAST	Casts a value of one type to another type	
CEIL	Synonym for CEILING()	
CEILING	Returns the smallest integer not less than X	
CENTROID	Synonym for ST_CENTROID	
CHAR Function	Returns string based on the integer values for the individual characters	
CHARACTER_LENGTH	Synonym for CHAR_LENGTH()	
CHAR_LENGTH	Length of the string in characters	
CHARSET	Returns the character set	
CHR	Returns a string consisting of the character given by the code values of the integer	
COALESCE	Returns the first non-NULL parameter	
COERCIBILITY	Returns the collation coercibility value	
COLLATION	Collation of the string argument	
COLUMN_ADD	Adds or updates dynamic columns	
COLUMN_CHECK	Checks if a dynamic column blob is valid	
COLUMN_CREATE	Returns a dynamic columns blob	
COLUMN_DELETE	Deletes a dynamic column	
COLUMN_EXISTS	Checks is a column exists	
COLUMN_GET	Gets a dynamic column value by name	
COLUMN_JSON	Returns a JSON representation of dynamic column blob data	
COLUMN_LIST	Returns comma-separated list	
COMPRESS	Returns a binary, compressed string	
CONCAT	Returns concatenated string	
CONCAT_WS	Concatenate with separator	
CONNECTION_ID	Connection thread ID	
CONTAINS	Whether one geometry contains another	
CONVERT	Convert a value from one type to another type	
CONV	Converts numbers between different number bases	
CONVERT_TZ	Converts a datetime from on time zone to another	
CONVEXHULL	Synonym for ST_CONVEXHULL	
COS	Returns the cosine	
COT	Returns the cotangent	
COUNT	Returns count of non-null values	
COUNT DISTINCT	Returns count of number of different non-NULL values	
CRC32	Computes a cyclic redundancy check value	
CRC32C	Computes a cyclic redundancy check value	MariaDB 10.8
CROSSES	Whether two geometries spatially cross	

CUME_DIST	Window function that returns the cumulative distribution of a given row	
CURDATE	Returns the current date	
CURRENT_DATE	Synonym for CURDATE()	
CURRENT_ROLE	Current role name	
CURRENT_TIME	Synonym for CURTIME()	
CURRENT_TIMESTAMP	Synonym for NOW()	
CURRENT_USER	Username/host that authenticated the current client	
CURTIME	Returns the current time	
DATABASE	Current default database	
DATE FUNCTION	Extracts the date portion of a datetime	
DATEDIFF	Difference in days between two date/time values	
DATE_ADD	Date arithmetic - addition	
DATE_FORMAT	Formats the date value according to the format string	
DATE_SUB	Date arithmetic - subtraction	
DAY	Synonym for DAYOFMONTH()	
DAYNAME	Return the name of the weekday	
DAYOFMONTH	Returns the day of the month	
DAYOFWEEK	Returns the day of the week index	
DAYOFYEAR	Returns the day of the year	
DECODE	Decrypts a string encoded with ENCODE()	
DECODE_HISTOGRAM	Returns comma separated numerics corresponding to a probability distribution represented by a histogram	
DEFAULT	Returns column default	
DEGREES	Converts from radians to degrees	
DENSE_RANK	Rank of a given row with identical values receiving the same result, no skipping	
DES_DECRYPT	Decrypts a string encrypted with DES_ENCRYPT()	
DES_ENCRYPT	Encrypts a string using the Triple-DES algorithm	
DIMENSION	Synonym for ST_DIMENSION	
DISJOINT	Whether the two elements do not intersect	
DIV	Integer division	
ELT	Returns the N'th element from a set of strings	
ENCODE	Encrypts a string	
ENCRYPT	Encrypts a string with Unix crypt()	
ENDPOINT	Synonym for ST_ENDPOINT	
ENVELOPE	Synonym for ST_ENVELOPE	
EQUALS	Indicates whether two geometries are spatially equal	
EXP	e raised to the power of the argument	
EXPORT_SET	Returns an on string for every bit set, an off string for every bit not set	
ExteriorRing	Synonym for ST_ExteriorRing	

EXTRACT	Extracts a portion of the date	
EXTRACTVALUE	Returns the text of the first text node matched by the XPath expression	
FIELD	Returns the index position of a string in a list	
FIND_IN_SET	Returns the position of a string in a set of strings	
FLOOR	Largest integer value not greater than the argument	
FORMAT	Formats a number	
FORMAT_BYTES	Given a byte count, returns a string consisting of a value and the units in a human-readable format.	MariaDB 11.8
FORMAT_PICO_TIME	Given a time in picoseconds, returns a human-readable time value and unit indicator	MariaDB 11.0.2 
FOUND_ROWS	Number of (potentially) returned rows	
FROM_BASE64	Given a base-64 encoded string, returns the decoded result as a binary string	
FROM_DAYS	Returns a date given a day	
FROM_UNIXTIME	Returns a datetime from a Unix timestamp	
GeomCollFromText	Synonym for ST_GeomCollFromText	
GeomCollFromWKB	Synonym for ST_GeomCollFromWKB	
GEOMETRYCOLLECTION	Constructs a WKB GeometryCollection	
GeometryCollectionFromText	Synonym for ST_GeomCollFromText	
GeometryCollectionFromWKB	Synonym for ST_GeomCollFromWKB	
GeometryFromText	Synonym for ST_GeomFromText	
GeometryFromWKB	Synonym for ST_GeomFromWKB	
GeomFromText	Synonym for ST_GeomFromText	
GeomFromWKB	Synonym for ST_GeomFromWKB	
GeometryN	Synonym for ST_GeometryN	
GeometryType	Synonym for ST_GeometryType	
GET_FORMAT	Returns a format string	
GET_LOCK	Obtain LOCK	
GLENGTH	Length of a LineString value	
GREATEST	Returns the largest argument	
GROUP_CONCAT	Returns string with concatenated values from a group	
HEX	Returns hexadecimal value	
HOUR	Returns the hour	
IF	If expr1 is TRUE, returns expr2; otherwise returns expr3	
IFNULL	Check whether an expression is NULL	
IN	True if expression equals any of the values in the list	
INTERVAL	Index of the argument that is less than the first argument	
INET6_ATON	Given an IPv6 or IPv4 network address, returns a VARBINARY numeric value	
INET6_NTOA	Given an IPv6 or IPv4 network address, returns the address as a nonbinary string	

INET_ATON	Returns numeric value of IPv4 address	
INET_NTOA	Returns dotted-quad representation of IPv4 address	
INSERT Function	Replaces a part of a string with another string	
INSTR	Returns the position of a string within a string	
InteriorRingN	Synonym for ST_InteriorRingN	
INTERSECTS	Indicates whether two geometries spatially intersect	
IS	Tests whether a boolean is TRUE, FALSE, or UNKNOWN	
IsClosed	Synonym for ST_IsClosed	
IsEmpty	Synonym for ST_IsEmpty	
IS_FREE_LOCK	Checks whether lock is free to use	
IS_IPV4	Whether or not an expression is a valid IPv4 address	
IS_IPV4_COMPAT	Whether or not an IPv6 address is IPv4-compatible	
IS_IPV4_MAPPED	Whether an IPv6 address is a valid IPv4-mapped address	
IS_IPV6	Whether or not an expression is a valid IPv6 address	
IS NOT	Tests whether a boolean value is not TRUE, FALSE, or UNKNOWN	
IS NOT NULL	Tests whether a value is not NULL	
IS NULL	Tests whether a value is NULL	
ISNULL	Checks if an expression is NULL	
IsRing	Synonym for ST_IsRing	
IsSimple	Synonym for ST_IsSimple	
IS_USED_LOCK	Check if lock is in use	
JSON_ARRAY	Returns a JSON array containing the listed values	
JSON_ARRAYAGG	Returns a JSON array containing an element for each value in a given set of JSON or SQL values.	
JSON_ARRAY_INTERSECT		MariaDB 11.2.0
JSON_ARRAY_APPEND	Appends values to the end of the given arrays within a JSON document	
JSON_ARRAY_INSERT	Inserts a value into a JSON document	
JSON_COMPACT	Removes all unnecessary spaces so the json document is as short as possible	
JSON_CONTAINS	Whether a value is found in a given JSON document or at a specified path within the document	
JSON_CONTAINS_PATH	Indicates whether the given JSON document contains data at the specified path or paths	
JSON_DEPTH	Maximum depth of a JSON document	
JSON_DETAILED	Represents JSON in the most understandable way emphasizing nested structures	
JSON_EQUALS	Check for equality between JSON objects.	MariaDB 10.7

JSON_EXISTS	Determines whether a specified JSON value exists in the given data	
JSON_EXTRACT	Extracts data from a JSON document.	
JSON_INSERT	Inserts data into a JSON document	
JSON_KEY_VALUE	Extracts key/value pairs from a JSON object	MariaDB 11.2
JSON_KEYS	Returns keys from top-level value of a JSON object or top-level keys from the path	
JSON_LENGTH	Returns the length of a JSON document, or the length of a value within the document	
JSON_LOOSE	Adds spaces to a JSON document to make it look more readable	
JSON_MERGE	Merges the given JSON documents	
JSON_MERGE_PATCH	RFC 7396-compliant merge of the given JSON documents	
JSON_MERGE_PRESERVE	Synonym for JSON_MERGE_PATCH .	
JSON_NORMALIZE	Recursively sorts keys and removes spaces, allowing comparison of json documents for equality	
JSON_OBJECT	Returns a JSON object containing the given key/value pairs	
JSON_OBJECT_FILTER_KEYS		MariaDB 11.2.0 
JSON_OBJECT_TO_ARRAY		MariaDB 11.2.0 
JSON_OBJECTAGG	Returns a JSON object containing key-value pairs	
JSON_OVERLAPS	Compares two json documents for overlaps	MariaDB 10.9
JSON_PRETTY	Alias for json_detailed	MariaDB 10.10.3  , MariaDB 10.9.5  , MariaDB 10.8.7  , MariaDB 10.7.8  , MariaDB 10.6.12
JSON_QUERY	Given a JSON document, returns an object or array specified by the path	
JSON_QUOTE	Quotes a string as a JSON value	
JSON_REMOVE	Removes data from a JSON document	
JSON_REPLACE	Replaces existing values in a JSON document	
JSON_SCHEMA_VALID	Validates a JSON schema	MariaDB 11.1.0 
JSON_SEARCH	Returns the path to the given string within a JSON document	
JSON_SET	Updates or inserts data into a JSON document	
JSON_TABLE	Returns a representation of a JSON document as a relational table	MariaDB 10.6
JSON_TYPE	Returns the type of a JSON value	
JSON_UNQUOTE	Unquotes a JSON value, returning a string	
JSON_VALID	Whether a value is a valid JSON document or not	
JSON_VALUE	Given a JSON document, returns the specified scalar	
KDF	Key derivation function	MariaDB 11.3.0 
LAST_DAY	Returns the last day of the month	
LAST_INSERT_ID	Last inserted autoinc value	

LAST_VALUE	Returns the last value in a list	
LASTVAL	Get last value generated from a sequence	
LCASE	Synonym for [LOWER()]	
LEAST	Returns the smallest argument	
LEFT	Returns the leftmost characters from a string	
LENGTH	Length of the string in bytes	
LIKE	Whether expression matches a pattern	
LineFromText	Synonym for ST_LineFromText	
LineFromWKB	Synonym for ST_LineFromWKB	
LINestring	Constructs a WKB LineString value from a number of WKB Point arguments	
LineStringFromText	Synonym for ST_LineFromText	
LineStringFromWKB	Synonym for ST_LineFromWKB	
LN	Returns natural logarithm	
LOAD_FILE	Returns file contents as a string	
LOCALTIME	Synonym for NOW()	
LOCALTIMESTAMP	Synonym for NOW()	
LOCATE	Returns the position of a substring in a string	
LOG	Returns the natural logarithm	
LOG10	Returns the base-10 logarithm	
LOG2	Returns the base-2 logarithm	
LOWER	Returns a string with all characters changed to lowercase	
LPAD	Returns the string left-padded with another string to a given length	
LTRIM	Returns the string with leading space characters removed	
MAKE_SET	Make a set of strings that matches a bitmask	
MAKEDATE	Returns a date given a year and day	
MAKETIME	Returns a time	
MASTER_GTID_WAIT	Wait until slave reaches the GTID position	
MASTER_POS_WAIT	Blocks until the slave has applied all specified updates	
MATCH AGAINST	Perform a fulltext search on a fulltext index	
MAX	Returns the maximum value	
MBRContains	Whether one Minimum Bounding Rectangle contains another.	
MBRCoveredBy	Whether one Minimum Bounding Rectangle is covered by another.	MariaDB 11.8
MBRDisjoint	Whether the Minimum Bounding Rectangles of two geometries are disjoint	
MBREqual	Whether the Minimum Bounding Rectangles of two geometries are the same.	
MBREquals	Synonym for MBREqual.	
MBRIntersects	Indicates whether the Minimum Bounding Rectangles of the two geometries intersect	
MBROverlaps	Whether the Minimum Bounding Rectangles of two geometries overlap	

MBRTouches	Whether the Minimum Bounding Rectangles of two geometries touch.	
MBRWithin	Indicates whether one Minimum Bounding Rectangle is within another	
MD5	MD5 checksum	
MEDIAN	Window function that returns the median value of a range of values	
MICROSECOND	Returns microseconds from a date or datetime	
MID	Synonym for SUBSTRING(str,pos,len)	
MIN	Returns the minimum value	
MINUTE	Returns a minute from 0 to 59	
MLineFromText	Constructs MULTILINESTRING using its WKT representation and SRID	
MLineFromWKB	Constructs a MULTILINESTRING	
MOD	Modulo operation. Remainder of N divided by M	
MONTH	Returns a month from 1 to 12	
MONTHNAME	Returns the full name of the month	
MPointFromText	Constructs a MULTIPOINT value using its WKT and SRID	
MPointFromWKB	Constructs a MULTIPOINT value using its WKB representation and SRID	
MPolyFromText	Constructs a MULTIPOLYGON value	
MPolyFromWKB	Constructs a MULTIPOLYGON value using its WKB representation and SRID	
MULTILINESTRING	Constructs a MultiLineString value	
MultiLineStringFromText	Synonym for MLineFromText	
MultiLineStringFromWKB	A synonym for MLineFromWKB	
MULTIPOINT	Constructs a WKB MultiPoint value	
MultiPointFromText	Synonym for MPointFromText	
MultiPointFromWKB	Synonym for MPointFromWKB	
MULTIPOLYGON	Constructs a WKB MultiPolygon	
MultiPolygonFromText	Synonym for MPolyFromText	
MultiPolygonFromWKB	Synonym for MPolyFromWKB	
NAME_CONST	Returns the given value	
NATURAL_SORT_KEY	Sorting that is more more similar to natural human sorting	
NOT LIKE	Same as NOT(expr LIKE pat [ESCAPE 'escape_char'])	
NOT REGEXP	Same as NOT (expr REGEXP pat)	
NULLIF	Returns NULL if expr1 = expr2	
NEXTVAL	Generate next value for sequence	
NOT BETWEEN	Same as NOT (expr BETWEEN min AND max)	
NOT IN	Same as NOT (expr IN (value,...))	
NOW	Returns the current date and time	
NTILE	Returns an integer indicating which group a given row falls into	
NumGeometries	Synonym for ST_NumGeometries	
NumInteriorRings	Synonym for NumInteriorRings	

NumPoints	Synonym for ST_NumPoints	
OCT	Returns octal value	
OCTET_LENGTH	Synonym for LENGTH()	
OLD_PASSWORD	Pre MySQL 4.1 password implementation	
ORD	Return ASCII or character code	
OVERLAPS	Indicates whether two elements spatially overlap	
PASSWORD	Calculates a password string	
PERCENT_RANK	Window function that returns the relative percent rank of a given row	
PERCENTILE_CONT	Returns a value which corresponds to the given fraction in the sort order.	
PERCENTILE_DISC	Returns the first value in the set whose ordered position is the same or more than the specified fraction.	
PERIOD_ADD	Add months to a period	
PERIOD_DIFF	Number of months between two periods	
PI	Returns the value of π (pi)	
POINT	Constructs a WKB Point	
PointFromText	Synonym for ST_PointFromText	
PointFromWKB	Synonym for PointFromWKB	
PointN	Synonym for PointN	
PointOnSurface	Synonym for ST_PointOnSurface	
POLYGON	Constructs a WKB Polygon value from a number of WKB LineString arguments	
PolyFromText	Synonym for ST_PolyFromText	
PolyFromWKB	Synonym for ST_PolyFromWKB	
PolygonFromText	Synonym for ST_PolyFromText	
PolygonFromWKB	Synonym for ST_PolyFromWKB	
POSITION	Returns the position of a substring in a string	
POW	Returns X raised to the power of Y	
POWER	Synonym for POW()	
QUARTER	Returns year quarter from 1 to 4	
QUOTE	Returns quoted, properly escaped string	
RADIANS	Converts from degrees to radians	
RAND	Random floating-point value	
RANK	Rank of a given row with identical values receiving the same result	
REGEXP	Performs pattern matching	
REGEXP_INSTR	Position of the first appearance of a regex	
REGEXP_REPLACE	Replaces all occurrences of a pattern	
REGEXP_SUBSTR	Returns the matching part of a string	
RELEASE_LOCK	Releases lock obtained with GET_LOCK()	
REPEAT Function	Returns a string repeated a number of times	
REPLACE Function	Replace occurrences of a string	
REVERSE	Reverses the order of a string	

RIGHT	Returns the rightmost N characters from a string	
RLIKE	Synonym for REGEXP()	
RPAD	Returns the string right-padded with another string to a given length	
ROUND	Rounds a number	
ROW_COUNT	Number of rows affected by previous statement	
ROW_NUMBER	Row number of a given row with identical values receiving a different result	
RTRIM	Returns the string with trailing space characters removed	
SCHEMA	Synonym for DATABASE()	
SECOND	Returns the second of a time	
SEC_TO_TIME	Converts a second to a time	
SETVAL	Set the next value to be returned by a sequence	
SESSION_USER	Synonym for USER()	
SHA	Synonym for SHA1()	
SHA1	Calculates an SHA-1 checksum	
SHA2	Calculates an SHA-2 checksum	
SIGN	Returns 1, 0 or -1	
SIN	Returns the sine	
SLEEP	Pauses for the given number of seconds	
SOUNDEX	Returns a string based on how the string sounds	
SOUNDS LIKE	SOUNDEX(expr1) = SOUNDEX(expr2)	
SPACE	Returns a string of space characters	
SPIDER_BG_DIRECT_SQL	Background SQL execution	
SPIDER_COPY_TABLES	Copy table data	
SPIDER_DIRECT_SQL	Execute SQL on the remote server	
SPIDER_FLUSH_TABLE_MON_CACHE	Refreshing Spider monitoring server information	
SQRT	Square root	
SRID	Synonym for ST_SRID	
ST_AREA	Area of a Polygon	
ST_AsBinary	Converts a value to its WKB representation	
ST_AsGeoJson	Returns a GeoJSON element from a given geometry.	
ST_AsText	Converts a value to its WKT-Definition	
ST_AsWKB	Synonym for ST_AsBinary	
ST_ASWKT	Synonym for ST_ASTEXT()	
ST_BOUNDARY	Returns a geometry that is the closure of a combinatorial boundary	
ST_BUFFER	A new geometry with a buffer added to the original geometry	
ST_CENTROID	The mathematical centroid (geometric center) for a MultiPolygon	
ST_Collect	Returns the aggregation of the distinct geometry arguments	MariaDB 11.8

ST_CONTAINS	Whether one geometry is contained by another	
ST_CONVEXHULL	The minimum convex geometry enclosing all geometries within the set	
ST_CROSSES	Whether two geometries spatially cross	
ST_DIFFERENCE	Point set difference	
ST_DIMENSION	Inherent dimension of a geometry value	
ST_DISJOINT	Whether one geometry is spatially disjoint from another	
ST_DISTANCE	The distance between two geometries	
ST_DISTANCE_SPHERE	The spherical distance between two geometries	
ST_ENDPOINT	Returns the endpoint of a LineString	
ST_ENVELOPE	Returns the Minimum Bounding Rectangle for a geometry value	
ST_EQUALS	Whether two geometries are spatioially equal	
ST_ExteriorRing	Returns the exterior ring of a Polygon as a LineString	
ST_GeoHash	Returns a geohash.	MariaDB 11.8
ST_GeomCollFromText	Constructs a GEOMETRYCOLLECTION value	
ST_GeomCollFromWKB	Constructs a GEOMETRYCOLLECTION value from a WKB	
ST_GeometryCollectionFromText	Synonym for ST_GeomCollFromText	
ST_GeometryCollectionFromWKB	Synonym for ST_GeomCollFromWKB	
ST_GeometryFromText	Synonym for ST_GeomFromText	
ST_GeometryFromWKB	Synonym for ST_GeomFromWKB	
ST_GEOMETRYN	Returns the N-th geometry in a GeometryCollection	
ST_GEOMETRYTYPE	Returns name of the geometry type of which a given geometry instance is a member	
ST_GeomFromGeoJSON	Returns a geometry object from a GeoJSON input	
ST_GeomFromText	Constructs a geometry value using its WKT and SRID	
ST_GeomFromWKB	Constructs a geometry value using its WKB representation and SRID	
ST_InteriorRingN	Returns the N-th interior ring for a Polygon	
ST_INTERSECTION	The intersection, or shared portion, of two geometries	
ST_INTERSECTS	Whether two geometries spatially intersect	
ST_ISCLOSED	Returns true if a given LINESTRING's start and end points are the same	
ST_ISEMPTY	Indicated validity of geometry value	
ST_IsRing	Returns true if a given LINESTRING is both ST_IsClosed and ST_IsSimple	
ST_IsSimple	Returns true if the given Geometry has no anomalous geometric points	
ST_IsValid	Returns 1 if the argument is geometrically valid, 0 if not.	MariaDB 11.8
ST_LatFromGeoHash	Returns a latitude from the given geohash.	MariaDB 11.8

ST_LongFromGeoHash	Returns a longitude from the given geohash.	MariaDB 11.8
ST_LENGTH	Length of a LineString value	
ST_LineFromText	Creates a linestring value	
ST_LineFromWKB	Constructs a LINESTRING using its WKB and SRID	
ST_LineStringFromText	Synonym for ST_LineFromText	
ST_LineStringFromWKB	Synonym for ST_LineFromWKB	
ST_MLineFromText	Synonym for ST_GeomFromText	
ST_MLineFromWKB	Synonym for ST_GeomFromWKB	
ST_MPointFromText	Synonym for ST_GeomFromText	
ST_MPointFromWKB	Synonym for ST_GeomFromWKB	
ST_MPolyFromText	Synonym for ST_GeomFromText	
ST_MPolyFromWKB	Synonym for ST_GeomFromWKB	
ST_MultiLineStringFromText	Synonym for ST_GeomFromText	
ST_MultiLineStringFromWKB	Synonym for ST_GeomFromWKB	
ST_MultiPointFromText	Synonym for ST_GeomFromText	
ST_MultiPolygonFromText	Synonym for ST_GeomFromText	
ST_MultiPolygonFromWKB	Synonym for ST_GeomFromWKB	
ST_MultiPointFromWKB	Synonym for ST_GeomFromWKB	
ST_NUMGEOMETRIES	Number of geometries in a GeometryCollection	
ST_NumInteriorRings	Number of interior rings in a Polygon	
ST_NUMPOINTS	Returns the number of Point objects in a LineString	
ST_OVERLAPS	Whether two geometries overlap	
ST_PointFromGeoHash	Returns a point from the given geohash.	MariaDB 11.8
ST_PointFromText	Constructs a POINT value	
ST_PointFromWKB	Constructs POINT using its WKB and SRID	
ST_POINTN	Returns the N-th Point in the LineString	
ST_POINTONSURFACE	Returns a POINT guaranteed to intersect a surface	
ST_PolyFromText	Constructs a POLYGON value	
ST_PolyFromWKB	Constructs POLYGON value using its WKB representation and SRID	
ST_PolygonFromText	Synonym for ST_PolyFromText	
ST_PolygonFromWKB	Synonym for ST_PolyFromWKB	
ST_RELATE	Returns true if two geometries are related	
ST_Simplify	Applies the Ramer–Douglas–Peucker algorithm to provide generalized simplifications.	MariaDB 11.8
ST_SRID	Returns a Spatial Reference System ID	
ST_STARTPOINT	Returns the start point of a LineString	
ST_SYMDIFFERENCE	Portions of two geometries that don't intersect	
ST_TOUCHES	Whether one geometry g1 spatially touches another	
ST_UNION	Union of two geometries	

ST_Validate	Whether a geometry is compliant with the WKB format and SRID syntax, and is geometrically valid.	MariaDB 11.8
ST_WITHIN	Whether one geometry is within another	
ST_X	X-coordinate value for a point	
ST_Y	Y-coordinate for a point	
STARTPOINT	Synonym for ST_StartPoint	
STD	Population standard deviation	
STDDEV	Population standard deviation	
STDDEV_POP	Returns the population standard deviation	
STDDEV_SAMP	Standard deviation	
STR_TO_DATE	Converts a string to date	
STRCMP	Compares two strings in sort order	
SUBDATE	Subtract a date unit or number of days	
SUBSTR	Returns a substring from string starting at a given position	
SUBSTRING	Returns a substring from string starting at a given position	
SUBSTRING_INDEX	Returns the substring from string before count occurrences of a delimiter	
SUBTIME	Subtracts a time from a date/time	
SUM	Sum total	
SYS.EXTRACT_SCHEMA_FROM_FILE_NAME	Given a file path, returns the schema (database) name	MariaDB 10.6
SYS.EXTRACT_TABLE_FROM_FILE_NAME	Given a file path, returns the table name	MariaDB 10.6
SYS.FORMAT_BYTES	Returns a string consisting of a value and the units in a human-readable format	MariaDB 10.6
SYS.FORMAT_PATH	Returns a modified path after replacing subpaths matching the values of various system variables with the variable name	MariaDB 10.6
SYS.FORMAT_STATEMENT	Returns a reduced length string	MariaDB 10.6
SYS.FORMAT_TIME	Returns a human-readable time value and unit indicator	MariaDB 10.6
SYS.LIST_ADD	Adds a value to a given list	MariaDB 10.6
SYS.LIST_DROP	Drops a value from a given list	MariaDB 10.6
SYS.PS_IS_ACCOUNT_ENABLED	Whether Performance Schema instrumentation for the given account is enabled	MariaDB 10.6
SYS.PS_IS_CONSUMER_ENABLED	Whether Performance Schema instrumentation for the given consumer is enabled	MariaDB 10.6
SYS.PS_IS_INSTRUMENT_DEFAULT_ENABLED	Whether a given Performance Schema instrument is enabled by default	MariaDB 10.6
SYS.PS_IS_INSTRUMENT_DEFAULT_TIMED	Returns whether a given Performance Schema instrument is timed by default	MariaDB 10.6
SYS.PS_IS_THREAD_INSTRUMENTED	Returns whether or not Performance Schema instrumentation for the given connection_id is enabled	MariaDB 10.6
SYS.PS_THREAD_ACCOUNT	Returns the account (username@hostname) associated with the given thread_id	MariaDB 10.6
SYS.PS_THREAD_ID	Returns the thread_id associated with the given connection_id	MariaDB 10.6

SYS.PS_THREAD_STACK	Returns all statements, stages, and events within the Performance Schema for a given thread_id	MariaDB 10.6
SYS.PS_THREAD_TRX_INFO	Returns a JSON object with information about the thread specified by the given thread_id	MariaDB 10.6
SYS.QUOTE_IDENTIFIER	Quotes a string to produce a result that can be used as an identifier in an SQL statement	MariaDB 10.6
SYS.SYS_GET_CONFIG	Returns a configuration option value from the sys_config table	MariaDB 10.6
SYS.VERSION_MAJOR	Returns the MariaDB Server major release version	MariaDB 10.6
SYS.VERSION_MINOR	Returns the MariaDB Server minor release version	MariaDB 10.6
SYS.VERSION_PATCH	Returns the MariaDB Server patch release version	MariaDB 10.6
SYS_GUID	Generates a globally unique identifier	
SYSDATE	Returns the current date and time	
SYSTEM_USER	Synonym for USER()	
TAN	Returns the tangent	
TIME function	Extracts the time	
TIMEDIFF	Returns the difference between two date/times	
TIMESTAMP FUNCTION	Return the datetime, or add a time to a date/time	
TIMESTAMPADD	Add interval to a date or datetime	
TIMESTAMPDIFF	Difference between two datetimes	
TIME_FORMAT	Formats the time value according to the format string	
TIME_TO_SEC	Returns the time argument, converted to seconds	
TO_BASE64	Converts a string to its base-64 encoded form	
TO_CHAR	Converts a date/time type to a char	
TO_DAYS	Number of days since year 0	
TO_SECONDS	Number of seconds since year 0	
TOUCHES	Whether two geometries spatially touch	
TRIM	Returns a string with all given prefixes or suffixes removed	
TRUNCATE	Truncates X to D decimal places	
UCASE	Synonym for UPPER]]()	
UNHEX	Interprets pairs of hex digits as a number and converts to the character represented by the number	
UNCOMPRESS	Uncompresses string compressed with COMPRESS()	
UNCOMPRESSED_LENGTH	Returns length of a string before being compressed with COMPRESS()	
UNIX_TIMESTAMP	Returns a Unix timestamp	
UPDATEXML	Replace XML	
UPPER	Changes string to uppercase	
USER	Current user/host	
UTC_DATE	Returns the current UTC date	

UTC_TIME	Returns the current UTC time	
UTC_TIMESTAMP	Returns the current UTC date and time	
UUID	Returns a Universal Unique Identifier v1	
UUIDv4	Returns a Universal Unique Identifier v4	MariaDB 11.7
UUIDv7	Returns a Universal Unique Identifier v7	MariaDB 11.7
UUID_SHORT	Return short universal identifier	
VALUES or VALUE	Refer to columns in INSERT ... ON DUPLICATE KEY UPDATE	
VAR_POP	Population standard variance	
VAR_SAMP	Returns the sample variance	
VARIANCE	Population standard variance	
VEC_DISTANCE	Calculates either a Euclidean or Cosine distance between two vectors.	MariaDB 11.8
VEC_DISTANCE_COSINE	Calculates a Cosine distance between two vectors.	MariaDB 11.7
VEC_DISTANCE_EUCLIDEAN	Calculates a Euclidean (L2) distance between two points.	MariaDB 11.7
VEC_FromText	Converts a text representation of the vector to a vector.	MariaDB 11.6.0  Vector
VEC_ToText	Converts a binary vector into a json array of numbers (floats).	MariaDB 11.6.0  Vector
VERSION	MariaDB server version	
WEEK	Returns the week number	
WEEKDAY	Returns the weekday index	
WEEKOFYEAR	Returns the calendar week of the date as a number in the range from 1 to 53	
WEIGHT_STRING	Weight of the input string	
WITHIN	Indicate whether a geographic element is spatially within another	
WSREP_LAST_SEEN_GTID	Returns the Global Transaction ID of the most recent write transaction observed by the client.	
WSREP_LAST_WRITTEN_GTID	Returns the Global Transaction ID of the most recent write transaction performed by the client.	
WSREP_SYNC_WAIT_UPTO_GTID	Blocks the client until the transaction specified by the given Global Transaction ID is applied and committed by the node	
X	Synonym for ST_X	
Y	Synonym for ST_Y	
YEAR	Returns the year for the given date	
YEARWEEK	Returns year and week for a date	

1.2.2 String Functions

MariaDB 101: Learning the Basics of MariaDB

Watch the Webinar 

Regular Expressions Functions

Functions for dealing with regular expressions

Dynamic Columns Functions

Functions for storing key/value pairs of data within a column.

ASCII
Numeric ASCII value of leftmost character.

BIN
Returns binary value.

BINARY Operator
Casts to a binary string.

BIT_LENGTH
Returns the length of a string in bits.

CAST
Casts a value of one type to another type.

CHAR Function
Returns string based on the integer values for the individual characters.

CHARACTER_LENGTH
Synonym for CHAR_LENGTH().

CHAR_LENGTH
Length of the string in characters.

CHR
Returns string based on integer values of the individual characters.

CONCAT
Returns concatenated string.

CONCAT_WS
Concatenate with separator.

CONVERT
Convert a value from one type to another type.

ELT
Returns the N'th element from a set of strings.

EXPORT_SET
Returns an on string for every bit set, an off string for every bit not set.

EXTRACTVALUE
Returns the text of the first text node matched by the XPath expression.

FIELD
Returns the index position of a string in a list.

FIND_IN_SET
Returns the position of a string in a set of strings.

FORMAT
Formats a number.

FROM_BASE64
Given a base-64 encoded string, returns the decoded result as a binary string.

HEX

Returns hexadecimal value.

INSERT Function

Replaces a part of a string with another string.

INSTR

Returns the position of a string within a string.

LCASE

Synonym for LOWER().

LEFT

Returns the leftmost characters from a string.

LENGTH

Length of the string in bytes.

LENGTHB

Length of the given string, in bytes.

LIKE

Whether expression matches a pattern.

LOAD_FILE

Returns file contents as a string.

LOCATE

Returns the position of a substring in a string.

LOWER

Returns a string with all characters changed to lowercase.

LPAD

Returns the string left-padded with another string to a given length.

LTRIM

Returns the string with leading space characters removed.

MAKE_SET

Make a set of strings that matches a bitmask.

MATCH AGAINST

Perform a fulltext search on a fulltext index.

Full-Text Index Stopwords

Default list of full-text stopwords used by MATCH...AGAINST.

MID

Synonym for SUBSTRING(str,pos,len).

NATURAL_SORT_KEY

Sorting that is closer to natural human sorting.

NOT LIKE

Same as NOT(expr LIKE pat [ESCAPE 'escape_char']).

NOT REGEXP

Same as NOT (expr REGEXP pat).

OCTET_LENGTH

Returns the length of the given string, in bytes.

**ORD**

Return ASCII or character code.

**POSITION**

Returns the position of a substring in a string.

**QUOTE**

Returns quoted, properly escaped string.

**REPEAT Function**

Returns a string repeated a number of times.

**REPLACE Function**

Replace occurrences of a string.

**REVERSE**

Reverses the order of a string.

**RIGHT**

Returns the rightmost N characters from a string.

**RPAD**

Returns the string right-padded with another string to a given length.

**RTRIM**

Returns the string with trailing space characters removed.

**SFORMAT**

Given a string and a formatting specification, returns a formatted string.

**SOUNDEX**

Returns a string based on how the string sounds.

**SOUNDS LIKE**

SOUNDEX(expr1) = SOUNDEX(expr2).

**SPACE**

Returns a string of space characters.

**STRCMP**

Compares two strings in sort order.

**SUBSTR**

Returns a substring from string starting at a given position.

**SUBSTRING**

Returns a substring from string starting at a given position.

**SUBSTRING_INDEX**

Returns the substring from string before count occurrences of a delimiter.

**TO_BASE64**

Converts a string to its base-64 encoded form.

**TO_CHAR**

Converts a date/time/timestamp type expression to a string.

**TRIM**

Returns a string with all given prefixes or suffixes removed.

**TRIM_ORACLE**

Synonym for the Oracle mode version of TRIM().

UCASE

Synonym for UPPER().

UNCOMPRESS

Uncompresses string compressed with COMPRESS().

UNCOMPRESSED_LENGTH

Returns length of a string before being compressed with COMPRESS().

UNHEX

Interprets pairs of hex digits as numbers and converts to the character represented by the number.

UPDATEXML

Replace XML.

UPPER

Changes string to uppercase.

WEIGHT_STRING

Weight of the input string.

Type Conversion

When implicit type conversion takes place.

There are [3 related questions](#).

1.2.2.1 Regular Expressions Functions

MariaDB 101: Learning the Basics of MariaDB

[Watch the Webinar](#)

MariaDB includes a number of functions for dealing with regular expressions.

Regular Expressions Overview

Regular Expressions allow MariaDB to perform complex pattern matching on a string.

PCRE - Perl Compatible Regular Expressions

PCRE (Perl Compatible Regular Expressions) for enhanced regular expressions.

NOT REGEXP

Same as NOT (expr REGEXP pat).

REGEXP

Performs pattern matching

REGEXP_INSTR

Position of the first appearance of a regex.

REGEXP_REPLACE

Replaces all occurrences of a pattern.

REGEXP_SUBSTR

Returns the matching part of a string.

RLIKE

Synonym for REGEXP

1.2.2.1.1 Regular Expressions Overview

Contents

1. [Special Characters](#)
 1. [^](#)
 2. [\\$](#)
 3. [.](#)
 4. [*](#)
 5. [+](#)
 6. [?](#)
 7. [\(\)](#)
 8. [{ }](#)
 9. [\[\]](#)
 1. [^](#)
 2. [Word boundaries](#)
 3. [Character Classes](#)
 4. [Character Names](#)
10. [Combining](#)
11. [Escaping](#)

Regular Expressions allow MariaDB to perform complex pattern matching on a string. In many cases, the simple pattern matching provided by [LIKE](#) is sufficient. [LIKE](#) performs two kinds of matches:

- `_` - the underscore, matching a single character
- `%` - the percentage sign, matching any number of characters.

In other cases you may need more control over the returned matches, and will need to use regular expressions.

Until [MariaDB 10.0.5](#), MariaDB used the POSIX 1003.2 compliant regular expression library. The current PCRE library is mostly backwards compatible with what is described below - see the [PCRE Regular Expressions](#) article for the enhancements made in 10.0.5.

Regular expression matches are performed with the [REGEXP](#) function. [RLIKE](#) is a synonym for [REGEXP](#).

Comparisons are performed on the byte value, so characters that are treated as equivalent by a collation, but do not have the same byte-value, such as accented characters, could evaluate as unequal.

Without any special characters, a regular expression match is true if the characters match. The match is case-insensitive, except in the case of `BINARY` strings.

```
SELECT 'Maria' REGEXP 'Maria';
+-----+
| 'Maria' REGEXP 'Maria' |
+-----+
|                        1 |
+-----+

SELECT 'Maria' REGEXP 'maria';
+-----+
| 'Maria' REGEXP 'maria' |
+-----+
|                        1 |
+-----+

SELECT BINARY 'Maria' REGEXP 'maria';
+-----+
| BINARY 'Maria' REGEXP 'maria' |
+-----+
|                                0 |
+-----+
```

Note that the word being matched must match the whole pattern:

```

SELECT 'Maria' REGEXP 'Mari';
+-----+
| 'Maria' REGEXP 'Mari' |
+-----+
|                        1 |
+-----+

SELECT 'Mari' REGEXP 'Maria';
+-----+
| 'Mari' REGEXP 'Maria' |
+-----+
|                        0 |
+-----+

```

The first returns true because the pattern "Mari" exists in the expression "Maria". When the order is reversed, the result is false, as the pattern "Maria" does not exist in the expression "Mari"

A match can be performed against more than one word with the | character. For example:

```

SELECT 'Maria' REGEXP 'Monty|Maria';
+-----+
| 'Maria' REGEXP 'Monty|Maria' |
+-----+
|                        1 |
+-----+

```

Special Characters

The above examples introduce the syntax, but are not very useful on their own. It's the special characters that give regular expressions their power.

^

^ matches the beginning of a string (inside square brackets it can also mean NOT - see below):

```

SELECT 'Maria' REGEXP '^Ma';
+-----+
| 'Maria' REGEXP '^Ma' |
+-----+
|                        1 |
+-----+

```

\$

\$ matches the end of a string:

```

SELECT 'Maria' REGEXP 'ia$';
+-----+
| 'Maria' REGEXP 'ia$' |
+-----+
|                        1 |
+-----+

```

.

. matches any single character:

```

SELECT 'Maria' REGEXP 'Ma.ia';
+-----+
| 'Maria' REGEXP 'Ma.ia' |
+-----+
|                          1 |
+-----+

SELECT 'Maria' REGEXP 'Ma..ia';
+-----+
| 'Maria' REGEXP 'Ma..ia' |
+-----+
|                          0 |
+-----+

```

*

x* matches zero or more of a character x. In the examples below, it's the r character.

```

SELECT 'Maria' REGEXP 'Mar*ia';
+-----+
| 'Maria' REGEXP 'Mar*ia' |
+-----+
|                          1 |
+-----+

SELECT 'Maia' REGEXP 'Mar*ia';
+-----+
| 'Maia' REGEXP 'Mar*ia' |
+-----+
|                          1 |
+-----+

SELECT 'Marrria' REGEXP 'Mar*ia';
+-----+
| 'Marrria' REGEXP 'Mar*ia' |
+-----+
|                          1 |
+-----+

```

+

x+ matches one or more of a character x. In the examples below, it's the r character.

```

SELECT 'Maria' REGEXP 'Mar+ia';
+-----+
| 'Maria' REGEXP 'Mar+ia' |
+-----+
|                          1 |
+-----+

SELECT 'Maia' REGEXP 'Mar+ia';
+-----+
| 'Maia' REGEXP 'Mar+ia' |
+-----+
|                          0 |
+-----+

SELECT 'Marrria' REGEXP 'Mar+ia';
+-----+
| 'Marrria' REGEXP 'Mar+ia' |
+-----+
|                          1 |
+-----+

```

?

x? matches zero or one of a character x. In the examples below, it's the r character.

```

SELECT 'Maria' REGEXP 'Mar?ia';
+-----+
| 'Maria' REGEXP 'Mar?ia' |
+-----+
|                          1 |
+-----+

SELECT 'Maia' REGEXP 'Mar?ia';
+-----+
| 'Maia' REGEXP 'Mar?ia' |
+-----+
|                          1 |
+-----+

SELECT 'Marrria' REGEXP 'Mar?ia';
+-----+
| 'Marrria' REGEXP 'Mar?ia' |
+-----+
|                          0 |
+-----+

```

()

(xyz) - combine a sequence, for example (xyz)+ or (xyz)*

```

SELECT 'Maria' REGEXP '(ari)+';
+-----+
| 'Maria' REGEXP '(ari)+' |
+-----+
|                          1 |
+-----+

```

{}

x{n} and x{m,n} This notation is used to match many instances of the x. In the case of x{n} the match must be exactly that many times. In the case of x{m,n}, the match can occur from m to n times. For example, to match zero or one instance of the string ari (which is identical to (ari)?), the following can be used:

```

SELECT 'Maria' REGEXP '(ari){0,1}';
+-----+
| 'Maria' REGEXP '(ari){0,1}' |
+-----+
|                          1 |
+-----+

```

[]

[xy] groups characters for matching purposes. For example, to match either the p or the r character:

```

SELECT 'Maria' REGEXP 'Ma[pr]ia';
+-----+
| 'Maria' REGEXP 'Ma[pr]ia' |
+-----+
|                          1 |
+-----+

```

The square brackets also permit a range match, for example, to match any character from a-z, [a-z] is used. Numeric ranges are also permitted.

```

SELECT 'Maria' REGEXP 'Ma[a-z]ia';
+-----+
| 'Maria' REGEXP 'Ma[a-z]ia' |
+-----+
|                          1 |
+-----+

```

The following does not match, as r falls outside of the range a-p.

```

SELECT 'Maria' REGEXP 'Ma[a-p]ia';
+-----+
| 'Maria' REGEXP 'Ma[a-p]ia' |
+-----+
|                               0 |
+-----+

```

^

The ^ character means does NOT match, for example:

```

SELECT 'Maria' REGEXP 'Ma[^p]ia';
+-----+
| 'Maria' REGEXP 'Ma[^p]ia' |
+-----+
|                               1 |
+-----+

SELECT 'Maria' REGEXP 'Ma[^r]ia';
+-----+
| 'Maria' REGEXP 'Ma[^r]ia' |
+-----+
|                               0 |
+-----+

```

The [and] characters on their own can be literally matched inside a [] block, without escaping, as long as they immediately match the opening bracket:

```

SELECT '[Maria' REGEXP ' [[]';
+-----+
| '[Maria' REGEXP ' [[]' |
+-----+
|                               1 |
+-----+

SELECT '[Maria' REGEXP ' []]';
+-----+
| '[Maria' REGEXP ' []]' |
+-----+
|                               0 |
+-----+

SELECT ']Maria' REGEXP ' []]';
+-----+
| ']Maria' REGEXP ' []]' |
+-----+
|                               1 |
+-----+

SELECT ']Maria' REGEXP ' [a]';
+-----+
| ']Maria' REGEXP ' [a]' |
+-----+
|                               1 |
+-----+

```

Incorrect order, so no match:

```

SELECT ']Maria' REGEXP '[a] ]';
+-----+
| ']Maria' REGEXP '[a] ]' |
+-----+
|                               0 |
+-----+

```

The - character can also be matched in the same way:

```
SELECT '-Maria' REGEXP '[1-10]';
+-----+
| '-Maria' REGEXP '[1-10]' |
+-----+
|                               0 |
+-----+
```

```
SELECT '-Maria' REGEXP '[-1-10]';
+-----+
| '-Maria' REGEXP '[-1-10]' |
+-----+
|                               1 |
+-----+
```

Word boundaries

The `:<` and `:>` patterns match the beginning and the end of a word respectively. For example:

```
SELECT 'How do I upgrade MariaDB?' REGEXP '[:<:]MariaDB[:>:]';
+-----+
| 'How do I upgrade MariaDB?' REGEXP '[:<:]MariaDB[:>:]' |
+-----+
|                               1 |
+-----+
```

```
SELECT 'How do I upgrade MariaDB?' REGEXP '[:<:]Maria[:>:]';
+-----+
| 'How do I upgrade MariaDB?' REGEXP '[:<:]Maria[:>:]' |
+-----+
|                               0 |
+-----+
```

Character Classes

There are a number of shortcuts to match particular preset character classes. These are matched with the `[:character_class:]` pattern (inside a `[]` set). The following character classes exist:

Character Class	Description
alnum	Alphanumeric
alpha	Alphabetic
blank	Whitespace
cntrl	Control characters
digit	Digits
graph	Graphic characters
lower	Lowercase alphabetic
print	Graphic or space characters
punct	Punctuation
space	Space, tab, newline, and carriage return
upper	Uppercase alphabetic
xdigit	Hexadecimal digit

For example:

```
SELECT 'Maria' REGEXP 'Mar[:alnum:]*';
+-----+
| 'Maria' REGEXP 'Mar[:alnum:]*' |
+-----+
