Before [MariaDB 11.8](#), one had to use `vcol1` in the WHERE clause. Now, one can use the virtual column expression, too:

```
-- This will use the index before 11.8:
explain select * from t1 where vcol1=100;
-- Starting from 11.8, this will use the index, too:
explain select * from t1
where cast(json_value(json_data, '$.column1') as integer)=100;
```

```
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| id   | select_type | table | type | possible_keys | key   | key_len | ref   | rows | Extra |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| 1   | SIMPLE     | t1   | ref  | vcol1         | vcol1 | 5       | const | 1   |      |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
```

General Considerations

- In MariaDB, one has to create a virtual column and then create an index over it. Other databases allow to create an index directly over expression: `create index on t1((col1+col2))`. This is not yet supported in MariaDB ([MDEV-35853](#)).
- The `WHERE` clause must use the exact same expression as in the virtual column definition.
- The optimization is implemented in a similar way to MySQL: the optimizer finds potentially useful occurrences of `vcol_expr` in the `WHERE` clause and replaces them with `vcol_name`.
- In the optimizer trace, the rewrites are shown like so:

```
"virtual_column_substitution": {
  "condition": "WHERE",
  "resulting_condition": "t1.vcol1 = 100"
}
```

Accessing JSON fields

Cast the value to the desired type

SQL is strongly-typed language while JSON is weakly-typed. This means one must specify the desired datatype when accessing JSON data from SQL. In the above example, we declared `vcol1` as `INT` and then used `(CAST ... AS INTEGER)` (both in the `ALTER TABLE` and in the `WHERE` clause in `SELECT` query):

```
alter table t1
  add column vcol1 INT as (CAST(json_value(json_data, '$.column1') AS INTEGER)) ...
```

```
select ... where ... CAST(json_value(json_data, '$.column1') AS INTEGER) ...;
```

Specify collation for strings

When extracting string values, `CAST` is not necessary, as `JSON_VALUE` returns strings.

However, one must take into account collations. If one declares the column as `JSON`:

```
create table t1 (  
  json_data JSON  
  ...  
);
```

the collation of `json_data` will be `utf8mb4_bin`. The collation of `JSON_VALUE(json_data, ...)` will also be `utf8mb4_bin`.

Most use cases require a more commonly-used collation. It is possible to achieve that using the `COLLATE` clause:

```
alter table t1  
  add coll varchar(100) collate utf8mb4_uca1400_ai_ci as  
  (json_value(js1, '$.string_column') collate utf8mb4_uca1400_ai_ci),  
  add index(coll);  
...  
select ...  
where  
  json_value(js1, '$.string_column') collate utf8mb4_uca1400_ai_ci='string-value';
```

Contents

1. Overview
2. InnoDB Defragmentation
 1. System Variables
 2. Status Variables
3. Example

Overview

When rows are deleted from an [InnoDB](#) table, the rows are simply marked as deleted and not physically deleted. The free space is not returned to the operating system for re-use.

The purge thread will physically delete index keys and rows, but the free space introduced is still not returned to operating system. This can lead to gaps in the pages. If you have variable length rows, new rows may be larger than old rows and cannot make use of the available space.

You can run [OPTIMIZE TABLE](#) or [ALTER TABLE <table> ENGINE=InnoDB](#) to reconstruct the table. Unfortunately running [OPTIMIZE TABLE](#) against an InnoDB table stored in the shared table-space file `ibdata1` does two things:

- Makes the table's data and indexes contiguous inside `ibdata1`.
- Increases the size of `ibdata1` because the contiguous data and index pages are appended to `ibdata1`.

InnoDB Defragmentation

The feature described below has been deprecated in [MariaDB 11.0](#) and was removed in [MariaDB 11.1.0](#). See [MDEV-30544](#) and [MDEV-30545](#).

[MariaDB 10.1](#) merged Facebook's defragmentation code prepared for MariaDB by Matt, Seong Uck Lee from Kakao. The only major difference to Facebook's code and Matt's patch is that MariaDB does not introduce new literals to SQL and makes no changes to the server code. Instead, [OPTIMIZE TABLE](#) is used and all code changes are inside the InnoDB/XtraDB storage engines.

The behaviour of [OPTIMIZE TABLE](#) is unchanged by default, and to enable this new feature, you need to set the [innodb_defragment](#) system variable to `1`.

```
[mysqld]
...
innodb-defragment=1
```

No new tables are created and there is no need to copy data from old tables to new tables. Instead, this feature loads `n` pages (determined by [innodb-defragment-n-pages](#)) and tries to move records so that pages would be full of records and then frees pages that are fully empty after the operation.

Note that tablespace files (including `ibdata1`) will not shrink as the result of defragmentation, but one will get better memory utilization in the InnoDB buffer pool as there are fewer data pages in use.

A number of new system and status variables for controlling and monitoring the feature are introduced.

System Variables

- [innodb_defragment](#): Enable InnoDB defragmentation.
- [innodb_defragment_n_pages](#): Number of pages considered at once when merging multiple pages to defragment.

- `innodb_defragment_stats_accuracy`: Number of defragment stats changes there are before the stats are written to persistent storage.
- `innodb_defragment_fill_factor_n_recs`: Number of records of space that defragmentation should leave on the page.
- `innodb_defragment_fill_factor`: Indicates how full defragmentation should fill a page.
- `innodb_defragment_frequency`: Maximum times per second for defragmenting a single index.

Status Variables

- `InnoDB_defragment_compression_failures`: Number of defragment re-compression failures
- `InnoDB_defragment_failures`: Number of defragment failures.
- `InnoDB_defragment_count`: Number of defragment operations.

Example

```

set @@global.innodb_file_per_table = 1;
set @@global.innodb_defragment_n_pages = 32;
set @@global.innodb_defragment_fill_factor = 0.95;
CREATE TABLE tb_defragment (
pk1 bigint(20) NOT NULL,
pk2 bigint(20) NOT NULL,
fd4 text,
fd5 varchar(50) DEFAULT NULL,
PRIMARY KEY (pk1),
KEY ix1 (pk2)
) ENGINE=InnoDB;

delimiter //
create procedure innodb_insert_proc (repeat_count int)
begin
declare current_num int;
set current_num = 0;
while current_num < repeat_count do
INSERT INTO tb_defragment VALUES (current_num, 1, REPEAT('Abcdefg', 20),
REPEAT('12345',5));
INSERT INTO tb_defragment VALUES (current_num+1, 2, REPEAT('HIJKLM', 20),
REPEAT('67890',5));
INSERT INTO tb_defragment VALUES (current_num+2, 3, REPEAT('HIJKLM', 20),
REPEAT('67890',5));
INSERT INTO tb_defragment VALUES (current_num+3, 4, REPEAT('HIJKLM', 20),
REPEAT('67890',5));
set current_num = current_num + 4;
end while;
end//
delimiter ;
commit;

set autocommit=0;
call innodb_insert_proc(50000);
commit;
set autocommit=1;

```

After these CREATE and INSERT operations, the following information can be seen from the INFORMATION SCHEMA:

```

select count(*) as Value from information_schema.innodb_buffer_page
  where table_name like '%tb_defragment%' and index_name = 'PRIMARY';
Value
313

select count(*) as Value from information_schema.innodb_buffer_page
  where table_name like '%tb_defragment%' and index_name = 'ix1';
Value
72

select count(stat_value) from mysql.innodb_index_stats
  where table_name like '%tb_defragment%' and stat_name in ('n_pages_freed');
count(stat_value)
0

select count(stat_value) from mysql.innodb_index_stats
  where table_name like '%tb_defragment%' and stat_name in ('n_page_split');
count(stat_value)
0

select count(stat_value) from mysql.innodb_index_stats
  where table_name like '%tb_defragment%' and stat_name in ('n_leaf_pages_defrag');
count(stat_value)
0

SELECT table_name, data_free/1024/1024 AS data_free_MB, table_rows FROM
information_schema.tables
  WHERE engine LIKE 'InnoDB' and table_name like '%tb_defragment%';
table_name data_free_MB table_rows
tb_defragment 4.00000000 50051

SELECT table_name, index_name, sum(number_records), sum(data_size) FROM
information_schema.innodb_buffer_page
  where table_name like '%tb_defragment%' and index_name like 'PRIMARY';
table_name index_name sum(number_records) sum(data_size)
`test`.`tb_defragment` PRIMARY 25873 4739939

SELECT table_name, index_name, sum(number_records), sum(data_size) FROM
information_schema.innodb_buffer_page
  where table_name like '%tb_defragment%' and index_name like 'ix1';
table_name index_name sum(number_records) sum(data_size)
`test`.`tb_defragment` ix1 50071 1051775

```

Deleting three-quarters of the records, leaving gaps, and then optimizing:

```

delete from tb_defragment where pk2 between 2 and 4;

optimize table tb_defragment;
Table Op Msg_type Msg_text
test.tb_defragment optimize status OK
show status like '%innodb_def%';
Variable_name Value
Innodb_defragment_compression_failures 0
Innodb_defragment_failures 1
Innodb_defragment_count 4

```

Now some pages have been freed, and some merged:

```

select count(*) as Value from information_schema.innodb_buffer_page
  where table_name like '%tb_defragment%' and index_name = 'PRIMARY';
Value
0

select count(*) as Value from information_schema.innodb_buffer_page
  where table_name like '%tb_defragment%' and index_name = 'ix1';
Value
0

select count(stat_value) from mysql.innodb_index_stats
  where table_name like '%tb_defragment%' and stat_name in ('n_pages_freed');
count(stat_value)
2

select count(stat_value) from mysql.innodb_index_stats
  where table_name like '%tb_defragment%' and stat_name in ('n_page_split');
count(stat_value)
2

select count(stat_value) from mysql.innodb_index_stats
  where table_name like '%tb_defragment%' and stat_name in ('n_leaf_pages_defrag');
count(stat_value)
2

SELECT table_name, data_free/1024/1024 AS data_free_MB, table_rows FROM
information_schema.tables
  WHERE engine LIKE 'InnoDB';
table_name data_free_MB table_rows
innodb_index_stats 0.00000000 8
innodb_table_stats 0.00000000 0
tb_defragment 4.00000000 12431

SELECT table_name, index_name, sum(number_records), sum(data_size) FROM
information_schema.innodb_buffer_page
  where table_name like '%tb_defragment%' and index_name like 'PRIMARY';
table_name index_name sum(number_records) sum(data_size)
`test`.`tb_defragment` PRIMARY 690 102145

SELECT table_name, index_name, sum(number_records), sum(data_size) FROM
information_schema.innodb_buffer_page
  where table_name like '%tb_defragment%' and index_name like 'ix1';
table_name index_name sum(number_records) sum(data_size)
`test`.`tb_defragment` ix1 5295 111263

```

See [Defragmenting unused space on InnoDB tablespace](#) on the Mariadb.org blog for more details.

3.3.5.7 Entity-Attribute-Value Implementation

Contents

1. [The desires](#)
2. [Bad solution](#)
3. [The problems](#)
4. [A solution](#)
5. [But what about the ad hoc queries?](#)
6. [Why it works](#)
7. [Details on the BLOB/JSON](#)
8. [Conclusions](#)
9. [Postlog](#)

The desires

- Open-ended set of "attributes" (key=value) for each "entity". That is, the list of attributes is not known at development time, and will grow in the future. (This makes one column per attribute impractical.)
- "ad hoc" queries testing attributes.
- Attribute values come in different types (numbers, strings, dates, etc.)
- Scale to lots of entities, yet perform well.

It goes by various names

- EAV -- Entity - Attribute - Value
- key-value
- RDF -- This is a flavor of EAV
- MariaDB has dynamic columns that look something like the solution below, with the added advantage of being able to index the columns otherwise hidden in the blob. (There are caveats.)
- MySQL 5.7 Has JSON datatype, plus functions to access parts
- MongoDB, CouchDB -- and others -- Not SQL-based.

Bad solution

- Table with 3 columns: entity_id, key, value
- The "value" is a string, or maybe multiple columns depending on datatype or other kludges.
- a JOIN b ON a.entity=b.entity AND b.key='x' JOIN c ON ... WHERE a.value=... AND b.value=...

The problems

- The SELECTs get messy -- multiple JOINS
- Datatype issues -- It's clumsy to be putting numbers into strings
- Numbers stored in [VARCHAR](#) do not compare 'correctly', especially for range tests.
- Bulky.
- Dedupping the values is clumsy.

A solution

Decide which columns need to be searched/sorted by SQL queries. No, you don't need all the columns to be searchable or sortable. Certain columns are frequently used for selection; identify these. You probably won't use all of them in all queries, but you will use some of them in every query.

The solution uses one table for all the EAV stuff. The columns include the searchable fields plus one [BLOB](#). Searchable fields are declared appropriately ([INT](#), [TIMESTAMP](#), etc). The BLOB contains JSON-encoding of all the extra fields.

The table should be [InnoDB](#), hence it should have a PRIMARY KEY. The entity_id is the 'natural' PK. Add a small number of other indexes (often 'composite') on the searchable fields. [PARTITIONing](#) is unlikely to be of any use, unless the Entities should be purged after some time. (Example: News Articles)

But what about the ad hoc queries?

You have included the most important fields to search on -- date, category, etc. These should filter the data down significantly. When you also need to filter on something more obscure, that will be handled differently. The application code will look at the BLOB for that; more on this later.

Why it works

- You are not really going to search on more than a few fields.
- The disk footprint is smaller; Smaller --> More cacheable --> Faster
- It needs no JOINS
- The indexes are useful
- The one table has one row per entity, and can grow as needed. (EAV needs many rows per entity.)
- Performance is as good as the indexes you have on the 'searchable fields'.
- Optionally, you can duplicate the indexed fields in the BLOB.
- Values missing from 'searchable fields' would need to be NULL (or whatever), and the code would need to deal with such.

Details on the BLOB/JSON

- Build the extra (or all) key-value pairs in a hash (associative array) in your application. Encode it. COMPRESS it. Insert that string into the [BLOB](#).
- JSON is recommended, but not mandatory; it is simpler than XML. Other serializations (eg, YAML) could be used.
- COMPRESS the JSON and put it into a [BLOB](#) (or [MEDIUMBLOB](#)) instead of a [TEXT](#) field. Compression gives about 3x shrinkage.
- When SELECTing, UNCOMPRESS the blob. Decode the string into a hash. You are now ready to interrogate/display any of the extra fields.
- If you choose to use the JSON features of MariaDB or 5.7, you will have to forgo the compression feature described.

- MySQL 5.7.8's JSON native JSON datatype uses a binary format for more efficient access.

Conclusions

- Schema is reasonably compact (compression, real datatypes, less redundancy, etc, than EAV)
- Queries are fast (since you have picked 'good' indexes)
- Expandable (JSON is happy to have new fields)
- Compatible (No 3rd party products, just supported products)
- Range tests work (unlike storing INTs in VARCHARs)
- (Drawback) Cannot use the non-indexed attributes in WHERE or ORDER BY clauses, must deal with that in the app. (MySQL 5.7 partially alleviates this.)

Postlog

Posted Jan, 2014; Refreshed Feb, 2016.

- MariaDB's [Dynamic Columns](#)
- [MySQL 5.7's JSON](#)

This looks very promising; I will need to do more research to see how much of this article is obviated by it: [Using MySQL as a Document Store in 5.7](#), [more DocStore discussion](#)

If you insist on EAV, set `optimizer_search_depth=1`.

3.3.5.8 IP Range Table Performance

Contents

1. [The situation](#)
2. [The problem](#)
3. [The solution](#)
4. [Performance](#)
5. [Design decisions](#)
6. [Details](#)
7. [Reference implementation of IPv4](#)
8. [Reference implementation of IPv6](#)
9. [Postlog](#)

The situation

Your data includes a large set of non-overlapping 'ranges'. These could be IP addresses, datetimes (show times for a single station), zipcodes, etc.

You have pairs of start and end values; one 'item' belongs to each such 'range'. So, instinctively, you create a table with start and end of the range, plus info about the item. Your queries involve a WHERE clause that compares for being between the start and end values.

The problem

Once you get a large set of items, performance degrades. You play with the indexes, but find nothing that works well. The indexes fail to lead to optimal functioning because the database does not understand that the ranges are non-overlapping.

The solution

I will present a solution that enforces the fact that items cannot have overlapping ranges. The solution builds a table to take advantage of that, then uses Stored Routines to get around the clumsiness imposed by it.

Performance

The instinctive solution often leads to scanning half the table to do just about anything, such as finding the item containing an 'address'. In complexity terms, this is Order(N).

The solution here can usually get the desired information by fetching a single row, or a small number of rows. It is Order(1).

In a large table, "counting the disk hits" is the important part of performance. Since InnoDB is used, and the PRIMARY KEY (clustered) is used, most operations hit only 1 block.

Finding the 'block' where a given IP address lives:

- For start of block: One single-row fetch using the PRIMARY KEY
- For end of block: Ditto. The record containing this will be 'adjacent' to the other record.

For allocating or freeing a block:

- 2-7 SQL statements, hitting the clustered PRIMARY KEY for the rows containing and immediately adjacent to the block.
- One SQL statement is a DELETE; if hits as many rows as are needed for the block.
- The other statements hit one row each.

Design decisions

This is crucial to the design and its performance:

- Having just one address in the row. These were alternative designs; they seemed to be no better, and possibly worse:
- That one address could have been the 'end' address.
- The routine parameters for a 'block' could have been start of this block and start of next block.
- The IPv4 parameters could have been dotted quads; I chose to keep the reference implementation simpler instead.
- The IPv6 parameters are 32-digit hex because it was simpler than BINARY(16) or IPV5 for a reference implementation.

The interesting work is in the Ips, not the second table, so I focus on it. The inconvenience of JOINing to the second table is small compared to the performance gains.

Details

Two, not one, tables will be used. The first table (`Ips` in the reference implementations) is carefully designed to be optimal for all the basic operations needed. The second table contains other information about the 'owner' of each 'item'. In the reference implementations `owner` is an id used to JOIN the two tables. This discussion centers around `Ips` and how to efficiently map IP(s) to/from owner(s). The second table has "PRIMARY KEY(owner)".

In addition to the two-table schema, there are a set of Stored Routines to encapsulate the necessary code.

One row of Ips represents one 'item' by specifying the starting IP address and the 'owner'. The next row gives the starting IP address of the next "address block", thereby indirectly providing the ending address for the current block.

This lack of explicitly stating the "end address" leads to some clumsiness. The stored routines hide it from the user.

A special owner (indicated by '0') is reserved for "free" or "not-owned" blocks. Hence, sparse allocation of address blocks is no problem. Also, the 'free' owner is handled no differently than real owners, so there are no extra Stored Routines for such.

Links below give "reference" implementations for IPv4 and IPv6. You will need to make changes for non-IP situations, and may need to make changes even for IP situations.

These are the main stored routines provided:

- IpIncr, IpDecr -- for adding/subtracting 1
- IpStore -- for allocating/freeing a range
- IpOwner, IpRangeOwners, IpFindRanges, Owner2IpStarts, Owner2IpRanges -- for lookups
- IpNext, IpEnd -- IP of start of next block, or end of current block

None of the provided routines JOIN to the other table; you may wish to develop custom queries based on the given reference Stored Procedures.

The Ips table's size is proportional to the number of blocks. A million 'owned' blocks may be 20-50MB. This varies due to

- number of 'free' gaps (between zero and the number of owned blocks)
- datatypes used for `ip` and `owner`
- InnoDB overhead Even 100M blocks is quite manageable in today's hardware. Once things are cached, most operations would take only a few milliseconds. A trillion blocks would work, but most operations would hit the disk a few times -- only a few times.

Reference implementation of IPv4

This specific to IPv4 (32 bit, a la '196.168.1.255'). It can handle anywhere from 'nothing assigned' (1 row) to 'everything assigned' (4B rows) 'equally' well. That is, to ask the question "who owns '11.22.33.44'" is equally efficient regardless of how many blocks of IP addresses exist in the table. (OK, caching, disk hits, etc may make a slight difference.) The one function that can vary is the one that reassigns a range to a new owner. Its speed is a function of how many existing ranges need to be consumed, since those rows will be DELETED. (It helps that they are, by schema design, 'clustered'.)

Notes on the [Reference implementation for IPv4](#) 

- Externally, the user may use the dotted quad notation (11.22.33.44), but needs to convert to INT UNSIGNED for calling the Stored Procs.
- The user is responsible for converting to/from the calling datatype (INT UNSIGNED) when accessing the stored routine; suggest [INET_ATON/INET_NTOA](#).
- The internal datatype for addresses is the same as the calling datatype (INT UNSIGNED).
- Adding and subtracting 1 (simple arithmetic).
- The datatype of an 'owner' (MEDIUMINT UNSIGNED: 0..16M) -- adjust if needed.
- The address "Off the end" (255.255.255.255+1 - represented as NULL).
- The table is initialized to one row: (ip=0, owner=0), meaning "all addresses are free See the comments in the code for more details.

(The reference implementation does not handle CDRs. Such should be easy to add on, by first turning it into an IP range.)

Reference implementation of IPv6

The code for handling IP address is more complex, but the overall structure is the same as for IPv4. Launch into it only if you need IPv6.

Notes on the [reference implementation for IPv6](#):

- Externally, IPv6 has a complex string, VARCHAR(39) CHARACTER SET ASCII. The Stored Procedure IpStr2Hex() is provided.
- The user is responsible for converting to/from the calling datatype (BINARY(16)) when accessing the stored routine; suggest [INET6_ATON/INET6_NTOA](#).
- The internal datatype for addresses is the same as the calling datatype (BINARY(16)).
- Communication with the Stored routines is via 32-char hex strings.
- Inside the Procedures, and in the Ips table, an address is stored as BINARY(16) for efficiency. HEX() and UNHEX() are used at the boundaries.
- Adding/subtracting 1 is rather complex (see the code).
- The datatype of an 'owner' (MEDIUMINT UNSIGNED: 0..16M); 'free' is represented by 0. You may need a bigger datatype.
- The address "Off the end" (ffff.ffff.ffff.ffff.ffff.ffff.ffff.ffff+1 is represented by NULL).
- The table is initialized to one row: (UNHEX('00000000000000000000000000000000'), 0), meaning "all addresses are free.
- You may need to decide on a canonical representation of IPv4 in IPv6. See the comments in the code for more details.

The INET6* functions were first available in MySQL 5.6.3 and [MariaDB 10.0.3](#)

Adapting to a different non-IP 'address range' data

- The external datatype for an 'address' should be whatever is convenient for the application.
- The datatype for the 'address' in the table must be ordered, and should be as compact as possible.
- You must write the Stored functions (IpIncr, IpDecr) for incrementing/decrementing an 'address'.
- An 'owner' is an id of your choosing, but smaller is better.
- A special value (such as 0 or "") must be provided for 'free'.
- The table must be initialized to one row: (SmallestAddress, Free)

"Owner" needs a special value to represent "not owned". The reference implementations use "=" and "!=" to compare two 'owners'. Numeric values and strings work nicely with those operators; NULL does not. Hence, please do not use NULL for "not owned".

Since the datatypes are pervasive in the stored routines, adapting a reference implementation to a different concept of 'address' would require multiple minor changes.

The code enforces that consecutive blocks never have the same 'owner', so the table is of 'minimal' size. Your application can assume that such is always the case.

Allocating RAM for MariaDB - The Short Answer

If only using [MyISAM](#), set [key_buffer_size](#) to 20% of **available** RAM. (Plus [innodb_buffer_pool_size=0](#))

If only using InnoDB, set [innodb_buffer_pool_size](#) to 70% of **available** RAM. (Plus [key_buffer_size](#) = 10M, small, but not zero.)

Rule of thumb for tuning:

- Start with released copy of my.cnf / my.ini.
- Change [key_buffer_size](#) and [innodb_buffer_pool_size](#) according to engine usage and RAM.
- Slow queries can usually be 'fixed' via indexes, schema changes, or SELECT changes, not by tuning.
- Don't get carried away with the [query cache](#) until you understand what it can and cannot do.
- Don't change anything else unless you run into trouble (eg, max connections).
- Be sure the changes are under the [mysqld] section, not some other section.

The 20%/70% assumes you have at least 4GB of RAM. If you have less total available RAM, then those percentages are too high and can lead to OOM events or swapping.

Now for the gory details.

How to troubleshoot out-of-memory issues

If the MariaDB server is crashing because of 'out-of-memory' then it is probably wrongly configured.

There are two kind of buffers in MariaDB:

- Global ones that are only allocated once during the lifetime of the server:
 - Storage engine buffers ([innodb_buffer_pool_size](#), [key_buffer_size](#), [aria_pagecache_buffer_size](#), etc)
 - Query cache [query_cache_size](#).
- Global caches ones that grow and shrink dynamically on demand up to max limit:
 - [max_user_connections](#)
 - [table_open_cache](#)
 - [table_definition_cache](#)
 - [thread_cache_size](#)
- Local buffers that are allocated on demand whenever needed
 - Internal ones used during engine index creation ([myisam_sort_buffer_size](#), [aria_sort_buffer_size](#)).
 - Internal buffers for storing blobs.

- Some storage engine will keep a temporary cache to store the largest blob seen so far when scanning a table. This will be freed at end of query. Note that temporary blob storage is **not** included in the memory information in [information_schema.processlist](#) but only in the total memory used (`show global status like "memory_used"`).
- Buffers and caches used during query execution:

Variable	Description
join_buffer_size	Used when no keys can be used to find a row in next table
mrr_buffer_size	Size of buffer to use when using multi-range read with range access
net_buffer_length	Max size of network packet
read_buffer_size	Used by some storage engines when doing bulk insert
sort_buffer_size	When doing ORDER BY or GROUP BY
max_heap_table_size	Used to store temporary tables in memory. See Optimizing memory tables

If any variables in the last group is very large and you have a lot of simultaneous users that are executing queries that are using these buffers then you can run into trouble.

In a default MariaDB installation the default of most of the above variables are quite small to ensure that one does not run out of memory.

You can check which variables that have been changed in your setup by executing the following sql statement. If you are running into out-of-memory issues, it is very likely that the problematic variable is in this list!

```
select information_schema.system_variables.variable_name,
information_schema.system_variables.default_value,
global_variables.variable_value from
information_schema.system_variables,information_schema.global_variables where
system_variables.variable_name=global_variables.variable_name and
system_variables.default_value <> global_variables.variable_value and
system_variables.default_value <> 0
```

What is the Key Buffer?

[MyISAM](#) does two different things for caching.

- Index blocks (1KB each, BTree structured, from .MYI file) live in the "key buffer".
- Data block caching (from .MYD file) is left to the OS, so be sure to leave a bunch of free space for this. Caveat: Some flavors of OS always claim to be using over 90%, even when there is really lots of free space.

```
SHOW GLOBAL STATUS LIKE 'Key%';
```

then calculate [Key_read_requests](#) / [Key_reads](#). If it is high (say, over 10), then the key buffer is big enough, otherwise you should adjust the [key_buffer_size](#) value.

What is the Buffer Pool?

InnoDB does all its caching in a the [buffer pool](#), whose size is controlled by [innodb_buffer_pool_size](#). By default it contains 16KB data and index blocks from the open tables (see [innodb_page_size](#)), plus some maintenance overhead.

From [MariaDB 5.5](#), multiple buffer pools are permitted; this can help because there is one mutex per pool, thereby relieving some of the mutex bottleneck.

[More on InnoDB tuning](#) [↗](#)

Another Algorithm

This will set the main cache settings to the minimum; it could be important to systems with lots of other processes and/or RAM is 2GB or smaller.

Do [SHOW TABLE STATUS](#) for all the tables in all the databases.

Add up `Index_length` for all the MyISAM tables. Set [key_buffer_size](#) no larger than that size.

Add up `Data_length` + `Index_length` for all the InnoDB tables. Set [innodb_buffer_pool_size](#) to no more than 110% of that total.

If that leads to swapping, cut both settings back. Suggest cutting them down proportionately.

Run this to see the values for your system. (If you have a lot of tables, it can take minute(s).)

```
SELECT ENGINE,
ROUND(SUM(data_length) /1024/1024, 1) AS "Data MB",
ROUND(SUM(index_length)/1024/1024, 1) AS "Index MB",
ROUND(SUM(data_length + index_length)/1024/1024, 1) AS "Total MB",
COUNT(*) "Num Tables"
FROM INFORMATION_SCHEMA.TABLES
WHERE table_schema not in ("information_schema", "PERFORMANCE_SCHEMA", "SYS_SCHEMA", "ndbinfo")
GROUP BY ENGINE;
```

Query Memory Allocation

There are two variables that dictates how memory are allocated by MariaDB while parsing and executing a query. [query_prealloc_size](#) defines the standard buffer for memory used for query execution and [query_alloc_block_size](#) that is size of memory blocks if [query_prealloc_size](#) was not big enough. Getting these variables right will reduce memory fragmentation in the server.

Mutex Bottleneck

MySQL was designed in the days of single-CPU machines, and designed to be easily ported to many different architectures. Unfortunately, that lead to some sloppiness in how to interlock actions. There are a small number (too small) of "mutexes" to gain access to several critical processes. Of note:

- MyISAM's `key_buffer`
- The Query Cache
- InnoDB's `buffer_pool` With multi-core boxes, the mutex problem is causing performance problems. In general, past 4-8 cores, MySQL gets slower, not faster. MySQL 5.5 and Percona's XtraDB made that somewhat better in InnoDB; the practical limit for cores is more like 32, and performance tends plateaus after that rather than declining. 5.6 claims to scale up to about 48 cores.

- 32-bit OS and MariaDB

First, the OS (and the hardware?) may conspire to not let you use all 4GB, if that is what you have. If you have more than 4GB of RAM, the excess beyond 4GB is `_totally_` inaccessible and unusable on a 32-bit OS.

Secondly, the OS probably has a limit on how much RAM it will allow any process to use.

Example: FreeBSD's `maxdsiz`, which defaults to 512MB.

Example:

```
$ ulimit -a
...
max memory size (kbytes, -m) 524288
```

So, once you have determined how much RAM is available to `mysqld`, then apply the 20%/70%, but round down some.

If you get an error like `[ERROR] /usr/libexec/mysqld: Out of memory (Needed xxx bytes)`, it probably means that MySQL exceeded what the OS is willing to give it. Decrease the cache settings.

- 64-bit OS with 32-bit MariaDB

The OS is not limited by 4GB, but MariaDB is.

If you have at least 4GB of RAM, then maybe these would be good:

- `key_buffer_size` = 20% of `_all_` of RAM, but not more than 3G
- `innodb_buffer_pool_size` = 3G

You should probably upgrade MariaDB to 64-bit.

- 64-bit OS and MariaDB

MyISAM only: `key_buffer_size`: Use about 20% of RAM. Set (in `my.cnf` / `my.ini`) `innodb_buffer_pool_size=0` = 0.

InnoDB only: `innodb_buffer_pool_size=0` = 70% of RAM. If you have lots of RAM and are using 5.5 (or later), then consider

having multiple pools. Recommend 1-16 [innodb_buffer_pool_instances](#), such that each one is no smaller than 1GB. (Sorry, no metric on how much this will help; probably not a lot.)

Meanwhile, set [key_buffer_size](#) = 20M (tiny, but non-zero)

If you have a mixture of engines, lower both numbers.

[max_connections](#), [thread_stack](#) Each "thread" takes some amount of RAM. This used to be about 200KB; 100 threads would be 20MB, not a significant size. If you have [max_connections](#) = 1000, then you are talking about 200MB, maybe more. Having that many connections probably implies other issues that should be addressed.

In 5.6 (or [MariaDB 5.5](#)), optional thread pooling interacts with [max_connections](#). This is a more advanced topic.

Thread stack overrun rarely happens. If it does, do something like [thread_stack=256K](#)

[More on max_connections, wait_timeout, connection pooling, etc](#)

table_open_cache

(In older versions this was called [table_cache](#))

The OS has some limit on the number of open files it will let a process have. Each table needs 1 to 3 open files. Each PARTITION is effectively a table. Most operations on a partitioned table open [_all_ partitions](#).

In *nix, [ulimit](#) tells you what the file limit is. The maximum value is in the tens of thousands, but sometimes it is set to only 1024. This limits you to about 300 tables. More discussion on [ulimit](#)

(This paragraph is in disputed.) On the other side, the table cache is (was) inefficiently implemented -- lookups were done with a linear scan. Hence, setting [table_cache](#) in the thousands could actually slow down mysql. (Benchmarks have shown this.)

You can see how well your system is performing via [SHOW GLOBAL STATUS](#); and computing the opens/second via [Opened_files / Uptime](#) If this is more than, say, 5, [table_open_cache](#) should be increased. If it is less than, say, 1, you might get improvement by decreasing [table_open_cache](#).

From [MariaDB 10.1](#), [table_open_cache](#) defaults to 2000.

Query Cache

Short answer: [query_cache_type](#) = OFF and [query_cache_size](#) = 0

The [Query Cache](#) (QC) is effectively a hash mapping SELECT statements to resultsets.

Long answer... There are many aspects of the "Query cache"; many are negative.

- Novice Alert! The QC is totally unrelated to the [key_buffer](#) and [buffer_pool](#).
- When it is useful, the QC is blazingly fast. It would not be hard to create a benchmark that runs 1000x faster.
- There is a single mutex controlling the QC.
- The QC, unless it is OFF & 0, is consulted for [_every_ SELECT](#).
- Yes, the mutex is hit even if [query_cache_type](#) = DEMAND (2).
- Any change to a query (even adding a space) leads (potentially) to a different entry in the QC.
- If my.cnf says type=ON and you later turn it OFF, it is not fully OFF. Ref: <https://bugs.mysql.com/bug.php?id=60696>

"Pruning" is costly and frequent:

- When [_any_ write](#) happens on a table, [_all_ entries](#) in the QC for [_that_ table](#) are removed.
- It happens even on a readonly Slave.
- Purges are performed with a linear algorithm, so a large QC (even 200MB) can be noticeably slow.

To see how well your QC is performing, SHOW GLOBAL STATUS LIKE 'Qc%'; then compute the read hit rate: [Qcache_hits](#) / [Qcache_inserts](#) If it is over, say, 5, the QC might be worth keeping.

If you decide the QC is right for you, then I recommend

- [query_cache_size](#) = no more than 50M
- [query_cache_type](#) = DEMAND
- [SQL_CACHE](#) or [SQL_NO_CACHE](#) in all SELECTs, based on which queries are likely to benefit from caching.
- [Why to turn off the QC](#)
- [Discussion about size](#)

thread_cache_size

It is not necessary to tune [thread_cache_size](#) from [MariaDB 10.2.0](#). Previously, it was minor tunable variable. Zero will slow down thread (connection) creation. A small (say, 10), non-zero number is good. The setting has essentially no impact

on RAM usage.

It is the number of extra processes to hang onto. It does not restrict the number of threads; [max_connections](#) does.

Binary Logs

If you have turned on [binary logging](#) (via [log_bin](#)) for replication and/or point-in-time recovery, the system will create binary logs forever. That is, they can slowly fill up the disk. Suggest setting [expire_logs_days](#) = 14 to keep only 14 days' worth of logs.

Swappiness

RHEL, in its infinite wisdom, decided to let you control how aggressively the OS will pre-emptively swap RAM. This is good in general, but lousy for MariaDB.

MariaDB would love for RAM allocations to be reasonably stable -- the caches are (mostly) pre-allocated; the threads, etc, are (mostly) of limited scope. ANY swapping is likely to severely hurt performance of MariaDB.

With a high value for swappiness, you lose some RAM because the OS is trying to keep a lot of space free for future allocations (that MySQL is not likely to need).

With swappiness = 0, the OS will probably crash rather than swap. I would rather have MariaDB limping than die. The latest recommendation is swappiness = 1. (2015)

[More confirmation](#) [↗](#)

Somewhere in between (say, 5?) might be a good value for a MariaDB-only server.

NUMA

OK, it's time to complicate the architecture of how a CPU talks to RAM. NUMA (Non-Uniform Memory Access) enters the picture. Each CPU (or maybe socket with several cores) has a part of the RAM hanging off each. This leads to memory access being faster for local RAM, but slower (tens of cycles slower) for RAM hanging off other CPUs.

Then the OS enters the picture. In at least one case (RHEL?), two things seem to be done:

- OS allocations are pinned to the 'first' CPU's RAM.]
- Other allocations go by default to the first CPU until it is full.

Now for the problem.

- The OS and MariaDB have allocated all the 'first' RAM.
- MariaDB has allocated some of the second RAM.
- The OS needs to allocate something. Ouch -- it is out of room in the one CPU where it is willing to allocate its stuff, so it swaps out some of MariaDB. Bad.

`dmesg | grep -i numa #` to see if you have numa

Probable solution: Configure the BIOS to "interleave" the RAM allocations. This should prevent the premature swapping, at the cost of off-CPU RAM accesses half the time. Well, you have the costly accesses anyway, since you really want to use all of RAM. Older MySQL versions: `numactl --interleave=all`. Or: [innodb_numa_interleave=1](#)

Another possible solution: Turn numa off (if the OS has a way of doing that)

Overall performance loss/gain: A few percent.

Huge Pages

MariaDB 10.6.17 (and other releases after 19 Jan 2024) have transparent huge pages automatically disabled. See [MDEV-33279](#) [↗](#) "Disable transparent huge pages after page buffers has been allocated" for more information.

This is another hardware performance gimmick.

For a CPU to access RAM, especially mapping a 64-bit address to somewhere in, say, 128GB or 'real' RAM, the TLB is used. (TLB = Translation Lookup Buffer.) Think of the TLB as a hardware associative memory lookup table; given a 64-bit virtual address, what is the real address.

Because it is an associative memory of finite size, sometimes there will be "misses" that require reaching into real RAM to resolve the lookup. This is costly, so should be avoided.

Normally, RAM is 'paged' in 4KB pieces; the TLB actually maps the top (64-12) bits into a specific page. Then the bottom 12

bits of the virtual address are carried over intact.

For example, 128GB of RAM broken 4KB pages means 32M page-table entries. This is a lot, and probably far exceeds the capacity of the TLB. So, enter the "Huge page" trick.

With the help of both the hardware and the OS, it is possible to have some of RAM in huge pages, of say 4MB (instead of 4KB). This leads to far fewer TLB entries, but it means the unit of paging is 4MB for such parts of RAM. Hence, huge pages tend to be non-pagable.

Now RAM is broken into pagable and non pagable parts; what parts can reasonably be non pagable? In MariaDB, the [InnoDB Buffer Pool](#) is a perfect candidate. So, by correctly configuring these, InnoDB can run a little faster:

- Huge pages enabled
- Tell the OS to allocate the right amount (namely to match the `buffer_pool`)
- Tell MariaDB to use huge pages
- [innodb memory usage vs swap](#) 

That thread has more details on what to look for and what to set.

Overall performance gain: A few percent. Yawn. Too much hassle for too little benefit.

Jumbo Pages? Turn off.

ENGINE=MEMORY

The [Memory Storage Engine](#) is a little-used alternative to [MyISAM](#) and [InnoDB](#). The data is not persistent, so it has limited uses. The size of a MEMORY table is limited to `max_heap_table_size`, which defaults to 16MB. I mention it in case you have changed the value to something huge; this would stealing from other possible uses of RAM.

How to Set Variables

In the text file `my.cnf` (`my.ini` on Windows), add or modify a line to say something like

```
innodb_buffer_pool_size = 5G
```

That is, VARIABLE name, "=", and a value. Some abbreviations are allowed, such as M for million (1048576), G for billion.

For the server to see it, the settings must be in the "[mysqld]" section of the file.

The settings in `my.cnf` or `my.ini` will not take effect until you restart the server.

Most settings can be changed on the live system by connecting as user `root` (or other user with SUPER privilege) and doing something like

```
SET @@global.key_buffer_size = 77000000;
```

Note: No M or G suffix is allowed here.

To see the setting a global VARIABLE do something like

```
SHOW GLOBAL VARIABLES LIKE "key_buffer_size";
+-----+-----+
| Variable_name | Value |
+-----+-----+
| key_buffer_size | 76996608 |
+-----+-----+
```

Note that this particular setting was rounded down to some multiple that MariaDB liked.

You may want to do both (SET, and modify `my.cnf`) in order to make the change immediately and have it so that the next restart (for whatever reason) will again get the value.

Web Server

A web server like Apache runs multiple threads. If each thread opens a connection to MariaDB, you could run out of connections. Make sure `MaxClients` (or equivalent) is set to some civilized number (under 50).

Tools

- MySQLTuner

- TUNING-PRIMER

There are several tools that advise on memory. One misleading entry they come up with

Maximum possible memory usage: 31.3G (266% of installed RAM)

Don't let it scare you -- the formulas used are excessively conservative. They assume all of [max_connections](#) are in use and active, and doing something memory-intensive.

Total fragmented tables: 23 This implies that OPTIMIZE TABLE _might_ help. I suggest it for tables with either a high percentage of "free space" (see SHOW TABLE STATUS) or where you know you do a lot of DELETES and/or UPDATES. Still, don't bother to OPTIMIZE too often. Once a month might suffice.

MySQL 5.7

5.7 stores a lot more information in RAM, leading to the footprint being perhaps half a GB more than 5.6. See [Memory increase in 5.7](#).

Postlog

Created 2010; Refreshed Oct, 2012, Jan, 2014

The tips in this document apply to MySQL, MariaDB, and Percona.

innodb_log_spin_wait_delay	MariaDB 11.4.2
innodb_log_write_ahead_size	MariaDB 11.4.3
innodb_snapshot_isolation	MariaDB 11.4.2
max_binlog_total_size	MariaDB 11.4.0
optimizer_join_limit_pref_ratio	MariaDB 11.4.4
server_uid	MariaDB 11.4.3
slave_connections_needed_for_purge	MariaDB 11.4.0

For system variables added since the previous long-term release, [MariaDB 10.11](#), see:

- [System Variables Added in MariaDB 11.3](#)
- [System Variables Added in MariaDB 11.2](#)
- [System Variables Added in MariaDB 11.1](#) 
- [System Variables Added in MariaDB 11.0](#) 

3.3.7.1.7 Status Variables Added in MariaDB 11.4

This is a list of [status variables](#) that were added in the [MariaDB 11.4](#) series.

Variable	Added
binlog_gtid_index_hit	MariaDB 11.4.0
binlog_gtid_index_miss	MariaDB 11.4.0

For status variables added since the previous long-term release, [MariaDB 10.11](#), see:

- [Status Variables Added in MariaDB 11.0](#) 

3.3.7.1.8 System Variables Added in MariaDB 11.3

This is a list of [system variables](#) that have been added in the [MariaDB 11.3](#) series.

Variable	Added
innodb_truncate_temporary_tablespace_now	MariaDB 11.3.0 
redirect_url	MariaDB 11.3.0 

3.3.7.1.9 System Variables Added in MariaDB

11.2

This is a list of [system variables](#) that have been added in the [MariaDB 11.2](#) series.

Variable	Added
binlog_do_db	MariaDB 11.2.0
binlog_ignore_db	MariaDB 11.2.0
binlog_row_event_max_size	MariaDB 11.2.0
block_encryption_mode	MariaDB 11.2.0
character_set_collations	MariaDB 11.2.1
innodb_alter_copy_bulk	MariaDB 11.2.5
innodb_log_file_mmap	MariaDB 11.2.6
innodb_log_spin_wait_delay	MariaDB 11.2.4
innodb_log_write_ahead_size	MariaDB 11.2.5
innodb_snapshot_isolation	MariaDB 11.2.4
optimizer_join_limit_pref_ratio	MariaDB 11.2.6
server_uid	MariaDB 11.2.5

3.3.7.1.10 System Variables Added in MariaDB 10.11

This is a list of [system variables](#) that have been added in the [MariaDB 10.11](#) series.

Variable	Added
innodb_alter_copy_bulk	MariaDB 10.11.9
innodb_log_file_mmap	MariaDB 10.11.10
innodb_log_spin_wait_delay	MariaDB 10.11.8
innodb_log_write_ahead_size	MariaDB 10.11.9
innodb_snapshot_isolation	MariaDB 10.11.8
log_slow_max_warnings	MariaDB 10.11.6
log_slow_min_examined_row_limit	MariaDB 10.11.0
log_slow_query	MariaDB 10.11.0
log_slow_query_file	MariaDB 10.11.1
log_slow_query_time	MariaDB 10.11.0
optimizer_join_limit_pref_ratio	MariaDB 10.11.10
optimizer_max_sel_args	MariaDB 10.11.6
replicate_rewrite_db	MariaDB 10.11.0
server_uid	MariaDB 10.11.9
system_versioning_insert_history	MariaDB 10.11.0

For system variables added since the previous long-term release, [MariaDB 10.6](#), see:

- [System Variables Added in MariaDB 10.10](#)
- [System Variables Added in MariaDB 10.9](#)
- [System Variables Added in MariaDB 10.8](#)

For system variables that have been removed or deprecated, see [Upgrading from MariaDB 10.6 to MariaDB 10.11](#).

3.3.7.1.11 System Variables Added in MariaDB

10.6

This is a list of [system variables](#) that have been added in the [MariaDB 10.6](#) series. The list does not include variables that are not part of the default release.

Variable	Added
binlog_expire_logs_seconds	MariaDB 10.6.0
innodb_deadlock_report	MariaDB 10.6.0
innodb_read_only_compressed	MariaDB 10.6.0
innodb_snapshot_isolation	MariaDB 10.6.18
log_slow_max_warnings	MariaDB 10.6.16
note_verbosity	MariaDB 10.6.16
optimizer_adjust_secondary_key_costs	MariaDB 10.6.17
optimizer_join_limit_pref_ratio	MariaDB 10.6.20
optimizer_max_sel_args	MariaDB 10.6.16
server_uid	MariaDB 10.6.19
wsrep_mode	MariaDB 10.6.0

For system variables that have been removed or deprecated, see [Upgrading from MariaDB 10.5 to MariaDB 10.6](#).

3.3.7.1.12 Status Variables Added in MariaDB 10.6

This is a list of [status variables](#) that were added in the [MariaDB 10.6](#) series.

Variable	Added
Innodb_buffer_pool_pages_lru_freed	MariaDB 10.6.0
resultset_metadata_skipped	MariaDB 10.6.0

3.3.7.1.13 System Variables Added in MariaDB 10.5

This is a list of [system variables](#) that have been added in the [MariaDB 10.5](#) series. The list does not include variables that are not part of the default release.

Variable	Added
binlog_row_metadata	MariaDB 10.5.0
innodb_instant_alter_column_allowed	MariaDB 10.5.3
innodb_lru_flush_size	MariaDB 10.5.7
innodb_max_purge_lag_wait	MariaDB 10.5.7
optimizer_max_sel_arg_weight	MariaDB 10.5.9
performance_schema_events_transactions_history_long_size	MariaDB 10.5.2
performance_schema_events_transactions_history_size	MariaDB 10.5.2
performance_schema_max_index_stat	MariaDB 10.5.2
performance_schema_max_memory_classes	MariaDB 10.5.2
performance_schema_max_metadata_locks	MariaDB 10.5.2
performance_schema_max_prepared_statement_instances	MariaDB 10.5.2
performance_schema_max_program_instances	MariaDB 10.5.2
performance_schema_max_sql_text_length	MariaDB 10.5.2

performance_schema_max_statement_stack	MariaDB 10.5.2
performance_schema_max_table_lock_stat	MariaDB 10.5.2
require_secure_transport	MariaDB 10.5.2
s3_access_key	MariaDB 10.5
s3_block_size	MariaDB 10.5
s3_bucket	MariaDB 10.5
s3_debug	MariaDB 10.5
s3_host_name	MariaDB 10.5
s3_pagecache_age_threshold	MariaDB 10.5
s3_pagecache_buffer_size	MariaDB 10.5
s3_pagecache_division_limit	MariaDB 10.5
s3_pagecache_file_hash_size	MariaDB 10.5
s3_protocol_version	MariaDB 10.5
s3_region	MariaDB 10.5
s3_secret_key	MariaDB 10.5
server_uid	MariaDB 10.5.26
sql_if_exists	MariaDB 10.5.2
thread_pool_dedicated_listener	MariaDB 10.5.0
thread_pool_exact_stats	MariaDB 10.5.0

For system variables that have been removed or deprecated, see [Upgrading from MariaDB 10.4 to MariaDB 10.5](#).

3.3.7.1.14 Status Variables Added in MariaDB 10.5

This is a list of [status variables](#) that were added in the [MariaDB 10.5](#) series.

Variable	Added
InnoDB_adaptive_hash_hash_searches	MariaDB 10.5.0
InnoDB_adaptive_hash_non_hash_searches	MariaDB 10.5.0
InnoDB_background_log_sync	MariaDB 10.5.0
InnoDB_buffer_pool_pages_made_not_young	MariaDB 10.5.0
InnoDB_buffer_pool_pages_made_young	MariaDB 10.5.0
InnoDB_buffer_pool_pages_old	MariaDB 10.5.0
InnoDB_buffer_pool_pages_LRU_flushed	MariaDB 10.5.0
InnoDB_buffered_aio_submitted	MariaDB 10.5.0
InnoDB_checkpoint_age	MariaDB 10.5.0
InnoDB_checkpoint_max_age	MariaDB 10.5.0
InnoDB_deadlocks	MariaDB 10.5.0
InnoDB_ibuf_discarded_delete_marks	MariaDB 10.5.0
InnoDB_ibuf_discarded_deletes	MariaDB 10.5.0
InnoDB_ibuf_discarded_inserts	MariaDB 10.5.0
InnoDB_ibuf_free_list	MariaDB 10.5.0
InnoDB_ibuf_merged_delete_marks	MariaDB 10.5.0

Innodb_ibuf_merged_deletes	MariaDB 10.5.0
Innodb_ibuf_merged_inserts	MariaDB 10.5.0
Innodb_ibuf_merges	MariaDB 10.5.0
Innodb_ibuf_segment_size	MariaDB 10.5.0
Innodb_ibuf_size	MariaDB 10.5.0
Innodb_lsn_current	MariaDB 10.5.0
Innodb_lsn_flushed	MariaDB 10.5.0
Innodb_lsn_last_checkpoint	MariaDB 10.5.0
Innodb_master_thread_active_loops	MariaDB 10.5.0
Innodb_master_thread_idle_loops	MariaDB 10.5.0
Innodb_max_trx_id	MariaDB 10.5.0
Innodb_mem_adaptive_hash	MariaDB 10.5.0
Innodb_mem_dictionary	MariaDB 10.5.0
performance_schema_index_stat_lost	MariaDB 10.5.2
performance_schema_memory_classes_lost	MariaDB 10.5.2
performance_schema_metadata_lock_lost	MariaDB 10.5.2
performance_schema_nested_statement_lost	MariaDB 10.5.2
performance_schema_prepared_statements_lost	MariaDB 10.5.2
performance_schema_program_lost	MariaDB 10.5.2
performance_schema_table_lock_stat_lost	MariaDB 10.5.2

The full list of status variables are listed in the contents on this page; most are described on this page, but some are described elsewhere:

- [Aria Status Variables](#)
- [Galera Status Variables](#)
- [InnoDB Status Variables](#)
- [Mroonga Status Variables](#)
- [MyRocks Status Variables](#)
- [Performance Scheme Status Variables](#)
- [Replication and Binary Log Status Variables](#)
- [S3 Storage Engine Status Variables](#)
- [Server_Audit Status Variables](#)
- [Sphinx Status Variables](#)
- [Spider Status Variables](#)
- [TokuDB Status Variables](#) [↗](#)

See also the [Full list of MariaDB options, system and status variables](#).

Use the [SHOW STATUS](#) statement to view status variables. This information also can be obtained using the [mariadb-admin extended-status](#) command, or by querying the [Information Schema GLOBAL_STATUS](#) and [SESSION_STATUS](#) tables.

Issuing a [FLUSH STATUS](#) will reset many status variables to zero.

List of Server Status Variables

Aborted_clients

- **Description:** Number of aborted client connections. This can be due to the client not calling `mysql_close()` before exiting, the client sleeping without issuing a request to the server for more seconds than specified by [wait_timeout](#) or [interactive_timeout](#), or by the client program ending in the midst of transferring data. The global value can be flushed by [FLUSH STATUS](#) .
- **Scope:** Global
- **Data Type:** `numeric`

Aborted_connects

- **Description:** Number of failed server connection attempts. This can be due to a client using an incorrect password, a client not having privileges to connect to a database, a connection packet not containing the correct information, or if it takes more than [connect_timeout](#) seconds to get a connect packet. The global value can be flushed by [FLUSH STATUS](#) .
- **Scope:** Global
- **Data Type:** `numeric`

Aborted_connects_preauth

- **Description:** Number of connection attempts that were aborted prior to authentication (regardless of whether or not

an error occurred).

- **Scope:** Global
 - **Data Type:** numeric
-

Access_denied_errors

- **Description:** Number of access denied errors. For details on when this is incremented, see [Incrementing of the access_denied_errors status variable](#).
 - **Scope:** Global
 - **Data Type:** numeric
-

Acl_column_grants

- **Description:** Number of column permissions granted (rows in the [mysql.columns_priv table](#)).
 - **Scope:** Global
 - **Data Type:** numeric
-

Acl_database_grants

- **Description:** Number of database permissions granted (rows in the [mysql.db table](#)).
 - **Scope:** Global
 - **Data Type:** numeric
-

Acl_function_grants

- **Description:** Number of function permissions granted (rows in the [mysql.procs_priv table](#) with a routine type of `FUNCTION`).
 - **Scope:** Global
 - **Data Type:** numeric
-

Acl_package_body_grants

- **Description:**
 - **Scope:** Global
 - **Data Type:** numeric
-

Acl_package_spec_grants

- **Description:**
 - **Scope:** Global
 - **Data Type:** numeric
-

Acl_procedure_grants

- **Description:** Number of procedure permissions granted (rows in the [mysql.procs_priv table](#) with a routine type of `PROCEDURE`).
 - **Scope:** Global
 - **Data Type:** numeric
-

Acl_proxy_users

- **Description:** Number of proxy permissions granted (rows in the [mysql.proxies_priv table](#) [↗](#)).
 - **Scope:** Global
 - **Data Type:** numeric
-

Acl_role_grants

- **Description:** Number of role permissions granted (rows in the [mysql.roles_mapping](#) table).
 - **Scope:** Global
 - **Data Type:** numeric
-

Acl_roles

- **Description:** Number of roles (rows in the [mysql.user](#) table where `is_role='Y'`).
 - **Scope:** Global
 - **Data Type:** numeric
-

Acl_table_grants

- **Description:** Number of table permissions granted (rows in the [mysql.tables_priv](#) table).
 - **Scope:** Global
 - **Data Type:** numeric
-

Acl_users

- **Description:** Number of users (rows in the [mysql.user](#) table where `is_role='N'`).
 - **Scope:** Global
 - **Data Type:** numeric
-

Busy_time

- **Description:** Cumulative time in seconds of activity on connections. Part of [User Statistics](#). Requires the [userstat](#) system variable to be set in order to be recorded.
 - **Scope:** Global
 - **Data Type:** numeric
-

Bytes_received

- **Description:** Total bytes received from all clients.
 - **Scope:** Global
 - **Data Type:** numeric
-

Bytes_sent

- **Description:** Total bytes sent to all clients.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_admin_commands

- **Description:** Number of admin commands executed. These include table dumps, change users, binary log dumps, shutdowns, pings and debugs.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_alter_db

- **Description:** Number of [ALTER DATABASE](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_alter_db_upgrade

- **Description:** Number of [ALTER DATABASE ... UPGRADE](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_alter_event

- **Description:** Number of [ALTER EVENT](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_alter_function

- **Description:** Number of [ALTER FUNCTION](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_alter_procedure

- **Description:** Number of [ALTER PROCEDURE](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_alter_sequence

- **Description:** Number of [ALTER SEQUENCE](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_alter_server

- **Description:** Number of [ALTER SERVER](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_alter_table

- **Description:** Number of [ALTER TABLE](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_alter_tablespace

- **Description:** Number of [ALTER TABLESPACE](#) commands executed (unsupported by MariaDB).
 - **Scope:** Global, Session
 - **Data Type:** numeric
 - **Removed:** [MariaDB 10.7.0](#) 
-

Com_alter_user

- **Description:** Number of [ALTER USER](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_analyze

- **Description:** Number of [ANALYZE](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_assign_to_keycache

- **Description:** Number of assign to keycache commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_backup

- **Description:**
 - **Scope:** Global, Session
 - **Data Type:** numeric
 - **Removed:** [MariaDB 10.4.1](#) [↗](#)
-

Com_backup_lock

- **Description:**
 - **Scope:** Global, Session
 - **Data Type:** numeric
 - **Removed:** [MariaDB 10.4.2](#) [↗](#)
-

Com_backup_table

- **Description:** Removed in [MariaDB 5.5](#). In older versions, Com_backup_table contains the number of [BACKUP TABLE](#) [↗](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
 - **Removed:** [MariaDB 5.5](#)
-

Com_begin

- **Description:** Number of [BEGIN](#) or [START TRANSACTION](#) statements executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_binlog

- **Description:** Number of [BINLOG](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_call_procedure

- **Description:** Number of [CALL](#) procedure_name statements executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_change_db

- **Description:** Number of [USE](#) database_name commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_check

- **Description:** Number of [CHECK TABLE](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_checksum

- **Description:** Number of [CHECKSUM TABLE](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_commit

- **Description:** Number of [COMMIT](#)  commands executed. Differs from [Handler_commit](#), which counts internal commit statements.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_compound_sql

- **Description:** Number of [compound](#) sql statements.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_create_db

- **Description:** Number of [CREATE DATABASE](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_create_event

- **Description:** Number of [CREATE EVENT](#) commands executed. Differs from [Executed_events](#) in that it is incremented when the CREATE EVENT is run, and not when the event executes.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_create_function

- **Description:** Number of [CREATE FUNCTION](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_create_index

- **Description:** Number of [CREATE INDEX](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_create_package

- **Description:**
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_create_package_body

- **Description:**
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_create_procedure

- **Description:** Number of [CREATE PROCEDURE](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_create_role

- **Description:** Number of [CREATE ROLE](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_create_sequence

- **Description:** Number of [CREATE SEQUENCE](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_create_server

- **Description:** Number of [CREATE SERVER](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_create_table

- **Description:** Number of [CREATE TABLE](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_create_temporary_table

- **Description:** Number of [CREATE TEMPORARY TABLE](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_create_trigger

- **Description:** Number of [CREATE TRIGGER](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_create_udf

- **Description:** Number of [CREATE UDF](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_create_user

- **Description:** Number of [CREATE USER](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Com_create_view

- **Description:** Number of [CREATE VIEW](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Com_dealloc_sql

- **Description:** Number of [DEALLOCATE](#) [🔗](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Com_delete

- **Description:** Number of [DELETE](#) commands executed. Differs from [Handler_delete](#), which counts the number of times rows have been deleted from tables.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Com_delete_multi

- **Description:** Number of multi-table [DELETE](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Com_do

- **Description:** Number of [DO](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Com_drop_db

- **Description:** Number of [DROP DATABASE](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Com_drop_event

- **Description:** Number of [DROP EVENT](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Com_drop_function

- **Description:** Number of [DROP FUNCTION](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Com_drop_index

- **Description:** Number of [DROP INDEX](#) commands executed.

- **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_drop_package

- **Description:**
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_drop_package_body

- **Description:**
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_drop_procedure

- **Description:** Number of **DROP PROCEDURE** commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_drop_role

- **Description:** Number of **DROP ROLE** commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_drop_sequence

- **Description:** Number of **DROP SEQUENCE** commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_drop_server

- **Description:** Number of **DROP SERVER** commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_drop_table

- **Description:** Number of **DROP TABLE** commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_drop_temporary_table

- **Description:** Number of **DROP TEMPORARY TABLE** commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_drop_trigger

- **Description:** Number of **DROP TRIGGER** commands executed.
- **Scope:** Global, Session
- **Data Type:** numeric

Com_drop_user

- **Description:** Number of [DROP USER](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_drop_view

- **Description:** Number of [DROP VIEW](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_empty_query

- **Description:** Number of queries to the server that do not produce SQL queries. An SQL query simply returning no results does not increment `Com_empty_query` - see [Empty queries](#) instead. An example of an empty query sent to the server is `mariadb --comments -e '-- sql comment'`
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_execute_immediate

- **Description:** Number of [EXECUTE IMMEDIATE](#) statements executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_execute_sql

- **Description:** Number of [EXECUTE](#) statements executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_flush

- **Description:** Number of [FLUSH](#) commands executed. This differs from [Flush commands](#), which also counts internal server flush requests.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_get_diagnostics

- **Description:** Number of [GET DIAGNOSTICS](#)  commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_grant

- **Description:** Number of [GRANT](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_grant_role

- **Description:** Number of [GRANT](#) role commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_ha_close

- **Description:** Number of **HANDLER** table_name CLOSE commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_ha_open

- **Description:** Number of **HANDLER** table_name OPEN commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_ha_read

- **Description:** Number of **HANDLER** table_name READ commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_help

- **Description:** Number of **HELP** commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_insert

- **Description:** Number of **INSERT** commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_insert_select

- **Description:** Number of **INSERT ... SELECT** commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_install_plugin

- **Description:** Number of **INSTALL PLUGIN** commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_kill

- **Description:** Number of **KILL** commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_load

- **Description:** Number of LOAD commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_load_master_data

- **Description:**
 - **Scope:** Global, Session
 - **Data Type:** numeric
 - **Removed:** [MariaDB 5.5](#)
-

Com_load_master_table

- **Description:**
 - **Scope:** Global, Session
 - **Data Type:** numeric
 - **Removed:** [MariaDB 5.5](#)
-

Com_multi

- **Description:**
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_lock_tables

- **Description:** Number of [lock-tables[LOCK TABLES]] commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_optimize

- **Description:** Number of [OPTIMIZE](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_preload_keys

- **Description:**
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_prepare_sql

- **Description:** Number of [PREPARE](#) statements executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_purge

- **Description:** Number of [PURGE](#)  commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_purge_before_date

- **Description:** Number of [PURGE BEFORE](#)  commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_release_savepoint

- **Description:** Number of [RELEASE SAVEPOINT](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_rename_table

- **Description:** Number of [RENAME TABLE](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_rename_user

- **Description:** Number of [RENAME USER](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_repair

- **Description:** Number of [REPAIR TABLE](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_replace

- **Description:** Number of [REPLACE](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_replace_select

- **Description:** Number of [REPLACE ... SELECT](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_reset

- **Description:** Number of [RESET](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_resignal

- **Description:** Number of [RESIGNAL](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_restore_table

- **Description:** Removed in [MariaDB 5.5](#). In older versions, Com_restore_table contains the number of [RESTORE TABLE](#) [🔗](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
 - **Removed:** [MariaDB 5.5](#)
-

Com_revoke

- **Description:** Number of [REVOKE](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_revoke_all

- **Description:** Number of [REVOKE ALL](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_revoke_grant

- **Description:** Number of [REVOKE](#) role commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_rollback

- **Description:** Number of [ROLLBACK](#) commands executed. Differs from [Handler_rollback](#), which is the number of transaction rollback requests given to a storage engine.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_rollback_to_savepoint

- **Description:** Number of [ROLLBACK ... TO SAVEPOINT](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_savepoint

- **Description:** Number of [SAVEPOINT](#) commands executed. Differs from [Handler_savepoint](#), which is the number of transaction savepoint creation requests.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_select

- **Description:** Number of [SELECT](#) commands executed. Also includes queries that make use of the [query cache](#).
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_set_option

- **Description:** Number of [SET OPTION](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_signal

- **Description:** Number of [SIGNAL](#) statements executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_show_authors

- **Description:** Number of [SHOW AUTHORS](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_show_binlog_events

- **Description:** Number of [SHOW BINLOG EVENTS](#) statements executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_show_binlogs

- **Description:** Number of [SHOW BINARY LOGS](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_show_charsets

- **Description:** Number of [SHOW CHARACTER SET](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_show_client_statistics

- **Description:** Number of [SHOW CLIENT STATISTICS](#) commands executed. Removed in [MariaDB 10.1.1](#) when that statement was replaced by the generic [SHOW information_schema_table](#).
 - **Scope:** Global, Session
 - **Data Type:** numeric
 - **Removed:** [MariaDB 10.1.1](#)
-

Com_show_collations

- **Description:** Number of [SHOW COLLATION](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_show_column_types

- **Description:**
 - **Scope:** Global, Session
 - **Data Type:** numeric
 - **Removed:** [MariaDB 5.5](#)
-

Com_show_contributors

- **Description:** Number of [SHOW CONTRIBUTORS](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_show_create_db

- **Description:** Number of [SHOW CREATE DATABASE](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_show_create_event

- **Description:** Number of [SHOW CREATE EVENT](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_show_create_func

- **Description:** Number of [SHOW CREATE FUNCTION](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_show_create_package

- **Description:**
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_show_create_package_body

- **Description:**
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_show_create_proc

- **Description:** Number of [SHOW CREATE PROCEDURE](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_show_create_table

- **Description:** Number of [SHOW CREATE TABLE](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_show_create_trigger

- **Description:** Number of [SHOW CREATE TRIGGER](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_show_create_user

- **Description:** Number of [SHOW CREATE USER](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_show_databases

- **Description:** Number of [SHOW DATABASES](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_show_engine_logs

- **Description:** Number of [SHOW ENGINE LOGS](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_show_engine_mutex

- **Description:** Number of [SHOW ENGINE MUTEX](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_show_engine_status

- **Description:** Number of [SHOW ENGINE STATUS](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_show_events

- **Description:** Number of [SHOW EVENTS](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_show_errors

- **Description:** Number of [SHOW ERRORS](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_show_explain

- **Description:** Number of [SHOW EXPLAIN](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_show_fields

- **Description:** Number of [SHOW COLUMNS](#) or [SHOW FIELDS](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_show_function_status

- **Description:** Number of [SHOW FUNCTION STATUS](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_show_generic

- **Description:** Number of generic [SHOW](#) commands executed, such as [SHOW INDEX_STATISTICS](#) and [SHOW TABLE_STATISTICS](#)
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_show_grants

- **Description:** Number of [SHOW GRANTS](#) commands executed.

- **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_show_keys

- **Description:** Number of [SHOW INDEX](#) or SHOW KEYS commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_show_index_statistics

- **Description:** Number of [SHOW INDEX_STATISTICS](#) commands executed. Removed in [MariaDB 10.1.1](#) when that statement was replaced by the generic [SHOW information_schema_table](#).
 - **Scope:** Global, Session
 - **Data Type:** numeric
 - **Removed:** [MariaDB 10.1.1](#)
-

Com_show_open_tables

- **Description:** Number of [SHOW OPEN TABLES](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_show_package_status

- **Description:**
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_show_package_body_status

- **Description:**
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_show_plugins

- **Description:** Number of [SHOW PLUGINS](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_show_privileges

- **Description:** Number of [SHOW PRIVILEGES](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_show_procedure_status

- **Description:** Number of [SHOW PROCEDURE STATUS](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_show_processlist

- **Description:** Number of [SHOW PROCESSLIST](#) commands executed.

- **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_show_profile

- **Description:** Number of [SHOW PROFILE](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_show_profiles

- **Description:** Number of [SHOW PROFILES](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_show_relaylog_events

- **Description:** Number of [SHOW RELAYLOG EVENTS](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_show_status

- **Description:** Number of [SHOW STATUS](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric st
-

Com_show_storage_engines

- **Description:** Number of [SHOW STORAGE ENGINES](#) - or [SHOW ENGINES](#) - commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_show_table_statistics

- **Description:** Number of [SHOW TABLE STATISTICS](#) commands executed. Removed in [MariaDB 10.1.1](#) [↗](#) when that statement was replaced by the generic [SHOW information_schema_table](#) [↗](#).
 - **Scope:** Global, Session
 - **Data Type:** numeric
 - **Removed:** [MariaDB 10.1.1](#) [↗](#)
-

Com_show_table_status

- **Description:** Number of [SHOW TABLE STATUS](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_show_tables

- **Description:** Number of [SHOW TABLES](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_show_triggers

- **Description:** Number of [SHOW TRIGGERS](#) commands executed.

- **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_show_user_statistics

- **Description:** Number of [SHOW USER STATISTICS](#) commands executed. Removed in [MariaDB 10.1.1](#) when that statement was replaced by the generic [SHOW information_schema_table](#).
 - **Scope:** Global, Session
 - **Data Type:** numeric
 - **Removed:** [MariaDB 10.1.1](#)
-

Com_show_variable

- **Description:** Number of [SHOW VARIABLES](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_show_warnings

- **Description:** Number of [SHOW WARNINGS](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_shutdown

- **Description:** Number of [SHUTDOWN](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_stmt_close

- **Description:** Number of [prepared statements](#) closed ([deallocated or dropped](#)).
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_stmt_execute

- **Description:** Number of [prepared statements executed](#).
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_stmt_fetch

- **Description:** Number of [prepared statements](#) fetched.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_stmt_prepare

- **Description:** Number of [prepared statements prepared](#).
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_stmt_reprepare

- **Description:** Number of [prepared statements](#) reprepared.

- **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_stmt_reset

- **Description:** Number of [prepared statements](#) where the data of a prepared statement which was accumulated in chunks by sending long data has been reset.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_stmt_send_long_data

- **Description:** Number of [prepared statements](#) where the parameter data has been sent in chunks (long data).
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_truncate

- **Description:** Number of [TRUNCATE](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_uninstall_plugin

- **Description:** Number of [UNINSTALL PLUGIN](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_unlock_tables

- **Description:** Number of [UNLOCK TABLES](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_update

- **Description:** Number of [UPDATE](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_update_multi

- **Description:** Number of multi-table [UPDATE](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_xa_commit

- **Description:** Number of XA statements committed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_xa_end

- **Description:** Number of XA statements ended.
- **Scope:** Global, Session

- **Data Type:** numeric
-

Com_xa_prepare

- **Description:** Number of XA statements prepared.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_xa_recover

- **Description:** Number of XA RECOVER statements executed.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_xa_rollback

- **Description:** Number of XA statements rolled back.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Com_xa_start

- **Description:** Number of XA statements started.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Compression

- **Description:** Whether client-server traffic is compressed.
 - **Scope:** Session
 - **Data Type:** boolean
-

Connection_errors_accept

- **Description:** Number of errors that occurred during calls to `accept()` on the listening port. The global value can be flushed by `FLUSH STATUS`.
 - **Scope:** Global
 - **Data Type:** numeric
-

Connection_errors_internal

- **Description:** Number of refused connections due to internal server errors, for example out of memory errors, or failed thread starts. The global value can be flushed by `FLUSH STATUS`.
 - **Scope:** Global
 - **Data Type:** numeric
-

Connection_errors_max_connections

- **Description:** Number of refused connections due to the `max_connections` limit being reached. The global value can be flushed by `FLUSH STATUS`.
 - **Scope:** Global
 - **Data Type:** numeric
-

Connection_errors_peer_address

- **Description:** Number of errors while searching for the connecting client IP address. The global value can be flushed

by [FLUSH STATUS](#) .

- **Scope:** Global
 - **Data Type:** numeric
-

Connection_errors_select

- **Description:** Number of errors during calls to select() or poll() on the listening port. The client would not necessarily have been rejected in these cases. The global value can be flushed by [FLUSH STATUS](#) .
 - **Scope:** Global
 - **Data Type:** numeric
-

Connection_errors_tcpwrap

- **Description:** Number of connections the libwrap library refused. The global value can be flushed by [FLUSH STATUS](#) .
 - **Scope:** Global
 - **Data Type:** numeric
-

Connections

- **Description:** Number of connection attempts (both successful and unsuccessful)
 - **Scope:** Global
 - **Data Type:** numeric
-

Cpu_time

- **Description:** Total CPU time used. Part of [User Statistics](#). Requires the [userstat](#) system variable to be set in order to be recorded.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Created_tmp_disk_tables

- **Description:** Number of on-disk temporary tables created.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Created_tmp_files

- **Description:** Number of temporary files created. The global value can be flushed by [FLUSH STATUS](#) .
 - **Scope:** Global
 - **Data Type:** numeric
-

Created_tmp_tables

- **Description:** Number of in-memory temporary tables created.
 - **Scope:** Global
 - **Data Type:** numeric
-

Delayed_errors

- **Description:** Number of errors which occurred while doing [INSERT DELAYED](#). The global value can be flushed by [FLUSH STATUS](#) .
 - **Scope:** Global
 - **Data Type:** numeric
-

Delayed_insert_threads

- **Description:** Number of [INSERT DELAYED](#) threads.
 - **Scope:** Global
 - **Data Type:** numeric
-

Delayed_writes

- **Description:** Number of [INSERT DELAYED](#) rows written. The global value can be flushed by [FLUSH STATUS](#) .
 - **Scope:** Global
 - **Data Type:** numeric
-

Delete_scan

- **Description:** Number of [DELETEs](#) that required a full table scan.
 - **Scope:** Global
 - **Data Type:** numeric
-

Empty_queries

- **Description:** Number of queries returning no results. Note this is not the same as [Com_empty_query](#).
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Executed_events

- **Description:** Number of times events created with [CREATE EVENT](#) have executed. This differs from [Com_create_event](#) in that it is only incremented when the event has run, not when it executes.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Executed_triggers

- **Description:** Number of times triggers created with [CREATE TRIGGER](#) have executed. This differs from [Com_create_trigger](#) in that it is only incremented when the trigger has run, not when it executes.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Feature_application_time_periods

- **Description:** Number of times a table created with [periods](#) has been opened.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Feature_check_constraint

- **Description:** Number of times [constraints](#) were checked. The global value can be flushed by [FLUSH STATUS](#) .
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Feature_custom_aggregate_functions

- **Description:** Number of queries which make use of [custom aggregate functions](#).
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Feature_delay_key_write

- **Description:** Number of tables opened that are using [delay_key_write](#). The global value can be flushed by [FLUSH STATUS](#).
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Feature_dynamic_columns

- **Description:** Number of times the [COLUMN_CREATE\(\)](#) function was used.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Feature_fulltext

- **Description:** Number of times the [MATCH ... AGAINST\(\)](#) function was used.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Feature_gis

- **Description:** Number of times a table with a any of the [geometry](#) columns was opened.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Feature_insert_returning

- **Description:**
 - **Scope:** Global, Session
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 10.5.0](#)
-

Feature_invisible_columns

- **Description:** Number of invisible columns in all opened tables.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Feature_json

- **Description:** Number of times JSON functionality has been used, such as one of the [JSON functions](#). Does not include the [CONNECT engine JSON type](#), or [EXPLAIN/ANALYZE FORMAT=JSON](#).
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Feature_locale

- **Description:** Number of times the [@@lc_messages](#) variable was assigned into.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Feature_subquery

- **Description:** Number of subqueries (excluding subqueries in the FROM clause) used.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Feature_system_versioning

- **Description:** Number of times [system versioning](#) functionality has been used (opening a table WITH SYSTEM VERSIONING).
- **Scope:** Global, Session
- **Data Type:** `numeric`

Feature_timezone

- **Description:** Number of times an explicit timezone (excluding [UTC](#) and SYSTEM) was specified.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Feature_trigger

- **Description:** Number of triggers loaded.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Feature_window_functions

- **Description:** Number of times [window functions](#) were used.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Feature_xml

- **Description:** Number of times XML functions ([EXTRACTVALUE\(\)](#) and [UPDATEXML\(\)](#)) were used.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Flush_commands

- **Description:** Number of [FLUSH](#) statements executed, as well as due to internal server flush requests. This differs from [Com_flush](#), which simply counts FLUSH statements, not internal server flush operations.
- **Scope:** Global
- **Data Type:** `numeric`
- **Removed:** [MariaDB 10.5.1](#)

Handler_commit

- **Description:** Number of internal [COMMIT](#) requests. Differs from [Com_commit](#), which counts the number of [COMMIT](#) statements executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Handler_delete

- **Description:** Number of times rows have been deleted from tables. Differs from [Com_delete](#), which counts [DELETE](#) statements.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Handler_discover

- **Description:** Discovery is when the server asks the NDBCLUSTER storage engine if it knows about a table with a given name. [Handler_discover](#) indicates the number of times that tables have been discovered in this way.
- **Scope:** Global, Session

- **Data Type:** numeric
-

Handler_external_lock

- **Description:** Incremented for each call to the external_lock() function, which generally occurs at the beginning and end of access to a table instance.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Handler_icp_attempts

- **Description:** Number of times pushed index condition was checked. The smaller the ratio of Handler_icp_attempts to [Handler_icp_match](#) the better the filtering. See [Index Condition Pushdown](#).
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Handler_icp_match

- **Description:** Number of times pushed index condition was matched. The smaller the ratio of [Handler_icp_attempts](#) to Handler_icp_match the better the filtering. See [Index Condition Pushdown](#).
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Handler_mrr_init

- **Description:** Counts how many MRR (multi-range read) scans were performed. See [Multi Range Read optimization](#).
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Handler_mrr_key_refills

- **Description:** Number of times key buffer was refilled (not counting the initial fill). A non-zero value indicates there wasn't enough memory to do key sort-and-sweep passes in one go. See [Multi Range Read optimization](#).
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Handler_mrr_rowid_refills

- **Description:** Number of times rowid buffer was refilled (not counting the initial fill). A non-zero value indicates there wasn't enough memory to do rowid sort-and-sweep passes in one go. See [Multi Range Read optimization](#).
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Handler_prepare

- **Description:** Number of two-phase commit prepares.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Handler_read_first

- **Description:** Number of requests to read the first row from an index. A high value indicates many full index scans, e.g. `SELECT a FROM table_name where a is an indexed column.`
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Handler_read_key

- **Description:** Number of row read requests based on an index value. A high value indicates indexes are regularly being used, which is usually positive.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Handler_read_last

- **Description:** Number of requests to read the last row from an index. [ORDER BY DESC](#) results in a last-key request followed by several previous-key requests.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Handler_read_next

- **Description:** Number of requests to read the next row from an index (in order). Increments when doing an index scan or querying an index column with a range constraint.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Handler_read_prev

- **Description:** Number of requests to read the previous row from an index (in order). Mostly used with [ORDER BY DESC](#).
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Handler_read_retry

- **Description:** Number of read retrys triggered by `semi_consistent_read` (InnoDB feature).
 - **Scope:** Global
 - **Data Type:** numeric
-

Handler_read_rnd

- **Description:** Number of requests to read a row based on its position. If this value is high, you may not be using joins that don't use indexes properly, or be doing many full table scans.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Handler_read_rnd_deleted

- **Description:** Number of requests to delete a row based on its position.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Handler_read_rnd_next

- **Description:** Number of requests to read the next row. A large number of these may indicate many table scans and improperly used indexes.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Handler_rollback

- **Description:** Number of transaction rollback requests given to a storage engine. Differs from [Com_rollback](#), which is

the number of [ROLLBACK](#) commands executed.

- **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Handler_savepoint

- **Description:** Number of transaction savepoint creation requests. Differs from [Com_savepoint](#) which is the number of [SAVEPOINT](#) commands executed.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Handler_savepoint_rollback

- **Description:** Number of requests to rollback to a transaction [savepoint](#).
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Handler_tmp_delete

- **Description:** Number of requests to delete a row in a temporary table.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Handler_tmp_update

- **Description:** Number of requests to update a row to a temporary table.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Handler_tmp_write

- **Description:** Number of requests to write a row to a temporary table.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Handler_update

- **Description:** Number of requests to update a row in a table. Since [MariaDB 5.3](#), this no longer counts temporary tables - see [Handler_tmp_update](#).
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Handler_write

- **Description:** Number of requests to write a row to a table. Since [MariaDB 5.3](#), this no longer counts temporary tables - see [Handler_tmp_write](#).
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Key_blocks_not_flushed

- **Description:** Number of key cache blocks which have been modified but not flushed to disk.
 - **Scope:** Global
 - **Data Type:** `numeric`
-

Key_blocks_unused

- **Description:** Number of unused key cache blocks.
 - **Scope:** Global
 - **Data Type:** numeric
-

Key_blocks_used

- **Description:** Max number of key cache blocks which have been used simultaneously.
 - **Scope:** Global
 - **Data Type:** numeric
-

Key_blocks_warm

- **Description:** Number of key cache blocks in the warm list.
 - **Scope:** Global
 - **Data Type:** numeric
-

Key_read_requests

- **Description:** Number of key cache block read requests. See [Optimizing key_buffer_size](#).
 - **Scope:** Global
 - **Data Type:** numeric
-

Key_reads

- **Description:** Number of physical index block reads. See [Optimizing key_buffer_size](#).
 - **Scope:** Global
 - **Data Type:** numeric
-

Key_write_requests

- **Description:** Number of requests to write a block to the key cache.
 - **Scope:** Global
 - **Data Type:** numeric
-

Key_writes

- **Description:** Number of key cache block write requests
 - **Scope:** Global
 - **Data Type:** numeric
-

Last_query_cost

- **Description:** The most recent query optimizer query cost calculation. Can not be calculated for complex queries, such as subqueries or UNION. It will be set to 0 for complex queries.
 - **Scope:** Session
 - **Data Type:** numeric
-

Maria_*

- **Description:** When the Maria storage engine was renamed Aria, the Maria variables existing at the time were renamed at the same time. See [Aria Server Status Variables](#).
-

Max_memory_used

- **Description:** The maximum memory allocation used by the current connection.
- **Scope:** Session
- **Data Type:** `numeric`
- **Introduced:** [MariaDB 10.6.21](#)

Max_statement_time_exceeded

- **Description:** Number of queries that exceeded the execution time specified by [max_statement_time](#). See [Aborting statements that take longer than a certain time to execute](#).
- **Data Type:** `numeric`

Max_tmp_space_used

- **Description:** Maximum temporary space used. See [Limiting Size of Created Disk Temporary Files and Tables Overview](#)
- **Scope:** Global, Session
- **Data Type:** `numeric`
- **Introduced:** [MariaDB 11.5](#)

Max_used_connections

- **Description:** Max number of connections ever open at the same time. The global value can be flushed by [FLUSH STATUS](#).
- **Scope:** Global
- **Data Type:** `numeric`

Max_used_connections_time

- **Description:** The time at which the last change of [max_used_connections](#) occurred. The global value can be flushed by [FLUSH STATUS](#).
- **Scope:** Global
- **Data Type:** `datetime`
- **Introduced:** [MariaDB 11.0.2](#) [↗](#), [MariaDB 11.1.1](#) [↗](#)

Memory_used

- **Description:** Global or per-connection memory usage, in bytes. This includes all per-connection memory allocations, but excludes global allocations such as the `key_buffer`, `innodb_buffer_pool` etc.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Memory_used_initial

- **Description:** Amount of memory that was used when the server started to service the user connections.
- **Scope:** Global
- **Data Type:** `numeric`

Not_flushed_delayed_rows

- **Description:** Number of [INSERT DELAYED](#) rows waiting to be written.
- **Scope:** Global
- **Data Type:** `numeric`

Open_files

- **Description:** Number of regular files currently opened by the server. Does not include sockets or pipes, or storage engines using internal functions.
- **Scope:** Global

- **Data Type:** numeric
-

Open_streams

- **Description:** Number of currently opened streams, usually log files.
 - **Scope:** Global
 - **Data Type:** numeric
-

Open_table_definitions

- **Description:** Number of currently cached .frm files.
 - **Scope:** Global
 - **Data Type:** numeric
-

Open_tables

- **Description:** Number of currently opened tables, excluding temporary tables.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Opened_files

- **Description:** Number of files the server has opened.
 - **Scope:** Global
 - **Data Type:** numeric
-

Opened_plugin_libraries

- **Description:** Number of shared libraries that the server has opened to load [plugins](#).
 - **Scope:** Global
 - **Data Type:** numeric
-

Opened_table_definitions

- **Description:** Number of .frm files that have been cached.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Opened_tables

- **Description:** Number of tables the server has opened.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Opened_views

- **Description:** Number of views the server has opened.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Prepared_stmt_count

- **Description:** Current number of prepared statements.
 - **Scope:** Global
 - **Data Type:** numeric
-

Qcache_free_blocks

- **Description:** Number of free [query cache](#) memory blocks.
 - **Scope:** Global
 - **Data Type:** numeric
-

Qcache_free_memory

- **Description:** Amount of free [query cache](#) memory.
 - **Scope:** Global
 - **Data Type:** numeric
-

Qcache_hits

- **Description:** Number of requests served by the [query cache](#). The global value can be flushed by [FLUSH STATUS](#) .
 - **Scope:** Global
 - **Data Type:** numeric
-

Qcache_inserts

- **Description:** Number of queries ever cached in the [query cache](#). The global value can be flushed by [FLUSH STATUS](#) .
 - **Scope:** Global
 - **Data Type:** numeric
-

Qcache_lowmem_prunes

- **Description:** Number of pruning operations performed to remove old results to make space for new results in the [query cache](#). The global value can be flushed by [FLUSH STATUS](#) .
 - **Scope:** Global
 - **Data Type:** numeric
-

Qcache_not_cached

- **Description:** Number of queries that are uncacheable by the [query cache](#), or use `SQL_NO_CACHE`. The global value can be flushed by [FLUSH STATUS](#) .
 - **Scope:** Global
 - **Data Type:** numeric
-

Qcache_queries_in_cache

- **Description:** Number of queries currently cached by the [query cache](#).
 - **Scope:** Global
 - **Data Type:** numeric
-

Qcache_total_blocks

- **Description:** Number of blocks used by the [query cache](#).
 - **Scope:** Global
 - **Data Type:** numeric
-

Queries

- **Description:** Number of statements executed by the server, excluding `COM_PING` and `COM_STATISTICS`. Differs from [Questions](#) in that it also counts statements executed within [stored programs](#).
- **Scope:** Global, Session

- **Data Type:** numeric
-

Query_time

- **Description:** Cumulative time in seconds, with microsecond precision, of running queries.
- **Scope:** Global, Session
- **Data Type:** numeric
- **Introduced:** [MariaDB 11.4](#)

Questions

- **Description:** Number of statements executed by the server, excluding COM_PING, COM_STATISTICS, COM_STMT_PREPARE, COM_STMT_CLOSE, and COM_STMT_RESET statements. Differs from [Queries](#) in that it doesn't count statements executed within [stored programs](#).
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Resultset_metadata_skipped

- **Description:** Number of times sending the metadata has been skipped. Metadata is not resent if metadata does not change between prepare and execute of prepared statement, or between executes.
 - **Scope:** Global, Session
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 10.6.0](#)
-

Rows_read

- **Description:** Number of requests to read a row (excluding temporary tables).
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rows_sent

- **Description:**
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rows_tmp_read

- **Description:** Number of requests to read a row in a temporary table.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Select_full_join

- **Description:** Number of joins which did not use an index. If not zero, you may need to check table indexes.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Select_full_range_join

- **Description:** Number of joins which used a range search of the first table.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Select_range

- **Description:** Number of joins which used a range on the first table.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Select_range_check

- **Description:** Number of joins without keys that check for key usage after each row. If not zero, you may need to check table indexes.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Select_scan

- **Description:** Number of joins which used a full scan of the first table.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Slow_launch_threads

- **Description:** Number of threads which took longer than [slow_launch_time](#) to create. The global value can be flushed by `FLUSH STATUS`.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Slow_queries

- **Description:** Number of queries which took longer than [long_query_time](#) to run. The [slow query log](#) does not need to be active for this to be recorded.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Sort_merge_passes

- **Description:** Number of merge passes performed by the sort algorithm. If too high, you may need to look at improving your query indexes, or increasing the [sort_buffer_size](#).
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Sort_priority_queue_sorts

- **Description:** The number of times that sorting was done through a priority queue. (The total number of times sorting was done is a sum [Sort_range](#) and [Sort_scan](#)). See [filesort with small LIMIT optimization](#).
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Sort_range

- **Description:** Number of sorts which used a range.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Sort_rows

- **Description:** Number of rows sorted.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Sort_scan

- **Description:** Number of sorts which used a full table scan.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Subquery_cache_hit

- **Description:** Counter for all [subquery cache](#) hits. The global value can be flushed by `FLUSH STATUS`.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Subquery_cache_miss

- **Description:** Counter for all [subquery cache](#) misses. The global value can be flushed by `FLUSH STATUS`.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Syncs

- **Description:** Number of times `my_sync()` has been called, or the number of times the server has had to force data to disk. Covers the [binary log](#), `.frm` creation (if these operations are configured to sync) and some storage engines ([Archive](#), [CSV](#), [Aria](#)), but not [XtraDB/InnoDB](#)).
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Table_locks_immediate

- **Description:** Number of table locks which were completed immediately. The global value can be flushed by `FLUSH STATUS`.
 - **Scope:** Global
 - **Data Type:** numeric
-

Table_locks_waited

- **Description:** Number of table locks which had to wait. Indicates table lock contention. The global value can be flushed by `FLUSH STATUS`.
 - **Scope:** Global
 - **Data Type:** numeric
-

Table_open_cache_active_instances

- **Description:** Number of active instances for open tables cache lookups.
 - **Scope:**
 - **Data Type:** numeric
-

Table_open_cache_hits

- **Description:** Number of hits for open tables cache lookups.
 - **Scope:**
 - **Data Type:** numeric
-

Table_open_cache_misses

- **Description:** Number of misses for open tables cache lookups.
 - **Scope:**
 - **Data Type:** numeric
-

Table_open_cache_overflows

- **Description:** Number of overflows for open tables cache lookups.
 - **Scope:**
 - **Data Type:** numeric
-

Tc_log_max_pages_used

- **Description:** Max number of pages used by the memory-mapped file-based [transaction coordinator log](#). The global value can be flushed by `FLUSH STATUS`.
 - **Scope:** Global
 - **Data Type:** numeric
-

Tc_log_page_size

- **Description:** Page size of the memory-mapped file-based [transaction coordinator log](#).
 - **Scope:** Global
 - **Data Type:** numeric
-

Tc_log_page_waits

- **Description:** Number of times a two-phase commit was forced to wait for a free memory-mapped file-based [transaction coordinator log](#) page. The global value can be flushed by `FLUSH STATUS`.
 - **Scope:** Global
 - **Data Type:** numeric
-

Threads_cached

- **Description:** Number of threads cached in the thread cache. This value will be zero if the [thread pool](#) is in use.
 - **Scope:** Global
 - **Data Type:** numeric
-

Threads_connected

- **Description:** Number of clients connected to the server. See [Handling Too Many Connections](#). The `Threads_connected` name is inaccurate when the [thread pool](#) is in use, since each client connection does not correspond to a dedicated thread in that case.
 - **Scope:** Global
 - **Data Type:** numeric
-

Threads_created

- **Description:** Number of threads created to respond to client connections. If too large, look at increasing [thread_cache_size](#).
 - **Scope:** Global
 - **Data Type:** numeric
-

Threads_running

- **Description:** Number of client connections that are actively running a command, and not just sleeping while waiting to receive the next command to execute. Some internal system threads also count towards this status variable if they would show up in the output of the `SHOW PROCESSLIST` statement.
 - In [MariaDB 10.3.2](#) and before, a global counter was updated each time a client connection dispatched a command. In these versions, the global and session status variable are always the same value.
 - In [MariaDB 10.3.3](#) and later, the global counter has been removed as a performance improvement. Instead, when the global status variable is queried, it is calculated dynamically by essentially adding up all the running client connections as they would appear in `SHOW PROCESSLIST` output. A client connection is only considered

to be running if its thread `COMMAND` value is not equal to `Sleep`. When the session status variable is queried, it always returns `1`.

- **Scope:** Global
 - **Data Type:** `numeric`
-

`Tmp_space_used`

- **Description:** Temporary space used. See [Limiting Size of Created Disk Temporary Files and Tables Overview](#)
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 11.5](#)
-

`Update_scan`

- **Description:** Number of updates that required a full table scan.
 - **Scope:** Global
 - **Data Type:** `numeric`
-

`Uptime`

- **Description:** Number of seconds the server has been running.
 - **Scope:** Global
 - **Data Type:** `numeric`
-

`Uptime_since_flush_status`

- **Description:** Number of seconds since the last [FLUSH STATUS](#).
 - **Scope:** Global
 - **Data Type:** `numeric`
-

16. [Rpl_semi_sync_master_yes_tx](#)
17. [Rpl_semi_sync_slave_status](#)
18. [Rpl_semi_sync_slave_send_ack](#)

This page documents status variables related to the [Semisynchronous Replication Plugin](#) (which has been merged into the main server from [MariaDB 10.3.3](#)). See [Server Status Variables](#) for a complete list of status variables that can be viewed with `SHOW STATUS`.

See also the [Full list of MariaDB options, system and status variables](#).

`Rpl_semi_sync_master_clients`

- **Description:** Number of semisynchronous slaves.
- **Data Type:** `numeric`

`Rpl_semi_sync_master_get_ack`

- **Description:** Number of acknowledgements received by the master from slaves.
- **Data Type:** `numeric`

`Rpl_semi_sync_master_net_avg_wait_time`

- **Description:** Average time the master waited for a slave to reply, in microseconds.

- **Data Type:** numeric
-

Rpl_semi_sync_master_net_wait_time

- **Description:** Total time the master waited for slave replies, in microseconds.
 - **Data Type:** numeric
-

Rpl_semi_sync_master_net_waits

- **Description:** Total number of times the master waited for slave replies.
 - **Data Type:** numeric
-

Rpl_semi_sync_master_no_times

- **Description:** Number of times the master turned off semisynchronous replication. The global value can be flushed by `FLUSH STATUS`.
 - **Data Type:** numeric
-

Rpl_semi_sync_master_no_tx

- **Description:** Number of commits that have not been successfully acknowledged by a slave. The global value can be flushed by `FLUSH STATUS`.
 - **Data Type:** numeric
-

Rpl_semi_sync_master_request_ack

- **Description:** Number of acknowledgement requests sent to slaves.
 - **Data Type:** numeric
-

Rpl_semi_sync_master_status

- **Description:** Whether or not semisynchronous replication is currently operating on the master. The value will be `ON` if both the plugin has been enabled and a commit acknowledgment has occurred. It will be `OFF` if either the plugin has not been enabled, or the master is replicating asynchronously due to a commit acknowledgment timeout.
 - **Data Type:** boolean
-

Rpl_semi_sync_master_timefunc_failures

- **Description:** Number of times the master failed when calling a time function, such as `gettimeofday()`. The global value can be flushed by `FLUSH STATUS`.
 - **Data Type:** numeric
-

Rpl_semi_sync_master_tx_avg_wait_time

- **Description:** Average time the master waited for each transaction, in microseconds.
 - **Data Type:** numeric
-

Rpl_semi_sync_master_tx_wait_time

- **Description:** Total time the master waited for transactions, in microseconds.
 - **Data Type:** numeric
-

Rpl_semi_sync_master_tx_waits

- **Description:** Total number of times the master waited for transactions.
- **Data Type:** `numeric`

`Rpl_semi_sync_master_wait_pos_backtraverse`

- **Description:** Total number of times the master waited for an event that had binary coordinates lower than previous events waited for. Occurs if the order in which transactions start waiting for a reply is different from the order in which their binary log events were written. The global value can be flushed by `FLUSH STATUS`.
- **Data Type:** `numeric`

`Rpl_semi_sync_master_wait_sessions`

- **Description:** Number of sessions that are currently waiting for slave replies.
- **Data Type:** `numeric`

`Rpl_semi_sync_master_yes_tx`

- **Description:** Number of commits that have been successfully acknowledged by a slave. The global value can be flushed by `FLUSH STATUS`.
- **Data Type:** `numeric`

`Rpl_semi_sync_slave_status`

- **Description:** Whether or not semisynchronous replication is currently operating on the slave. `ON` if both semi-sync has been enabled for the replica (i.e. by setting the variable `rpl_semi_sync_slave_enabled` to `TRUE`) and the slave I/O thread is running.
- **Data Type:** `boolean`

`Rpl_semi_sync_slave_send_ack`

- **Description:** Number of acknowledgements the slave sent to the master.
- **Data Type:** `numeric`

 5. [sql_error_log_size_limit](#)
 6. [sql_error_log_warnings](#)
 7. [sql_error_log_with_db_and_thread_info](#)

This page documents system variables and options related to the [SQL_Error_Log Plugin](#). See [Server System Variables](#) for a complete list of system variables and instructions on setting them.

See also the [Full list of MariaDB options, system and status variables](#).

Options

sql_error_log

- **Description:** Controls how the server should treat the plugin when the server starts up.
 - Valid values are:
 - `OFF` - Disables the plugin without removing it from the `mysql.plugins` table.
 - `ON` - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
 - `FORCE` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
 - `FORCE_PLUS_PERMANENT` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with `UNINSTALL SONAME` or `UNINSTALL PLUGIN` while the server is running.
 - See [Plugin Overview: Configuring Plugin Activation at Server Startup](#) for more information.
 - **Commandline:** `--sql-error-log=value`
 - **Data Type:** `enumerated`
 - **Default Value:** `ON`
 - **Valid Values:** `OFF`, `ON`, `FORCE`, `FORCE_PLUS_PERMANENT`
-

System Variables

sql_error_log_filename

- **Description:** The name (and optionally path) of the logfile containing the errors. Rotation will use a naming convention such as `sql_error_log_filename.001`. If no path is specified, the log file will be written to the [data directory](#).
 - **Commandline:** `--sql-error-log-filename=value`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `string`
 - **Default Value:** `sql_errors.log`
-

sql_error_log_rate

- **Description:** The logging sampling rate. Setting to `10`, for example, means that one in ten errors will be logged. If set to zero, logging is disabled. The default, `1`, logs every error.
 - **Commandline:** `--sql-error-log-rate=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `1`
-

sql_error_log_rotate

- **Description:** Setting to `#1` forces log rotation.
 - **Commandline:** `--sql-error-log-rotate[={0|1}]`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
-

sql_error_log_rotations

- **Description:** Number of rotations before the log is removed. When rotated, the current log file is stored and a new, empty, log is created. Any rotations older than this setting are removed.
 - **Commandline:** `--sql-error-log-rotations=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `9`
 - **Range:** `1` to `999`
-

sql_error_log_size_limit

- **Description:** The log file size limit in bytes. After reaching this size, the log file is rotated.
 - **Commandline:** `--sql-error-log-size-limit=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:** `1000000`
 - **Range:** `100` to `9223372036854775807`
-

sql_error_log_warnings

- **Description:** If set, log warnings in addition to errors.
 - **Commandline:** `--sql-error-log-warnings={0,1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
 - **Introduced:** [MariaDB 10.11.5](#)
-

sql_error_log_with_db_and_thread_info

- **Description:** If enabled, it prints the database name and the thread ID in the log in addition to already existing columns.
 - **Commandline:** `--sql-error-log-with-db-and-thread-info=value`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
 - **Introduced:** [MariaDB 10.6.17](#), [MariaDB 10.11.7](#), [MariaDB 11.0.5](#) [↗](#), [MariaDB 11.1.4](#) [↗](#), [MariaDB 11.2.3](#) [↗](#)

 1. [extra_max_connections](#)
 2. [extra_port](#)
 3. [thread_handling](#)
 4. [thread_pool_dedicated_listener](#)
 5. [thread_pool_exact_stats](#)
 6. [thread_pool_idle_timeout](#)
 7. [thread_pool_max_threads](#)
 8. [thread_pool_min_threads](#)
 9. [thread_pool_oversubscribe](#)
 10. [thread_pool_prio_kickup_timer](#)
 11. [thread_pool_priority](#)
 12. [thread_pool_size](#)
 13. [thread_pool_stall_limit](#)
2. [Status variables](#)
 1. [Threadpool_idle_threads](#)
 2. [Threadpool_threads](#)

System variables

`extra_max_connections`

- **Description:** The number of connections on the `extra_port`.
 - See [Thread Pool in MariaDB: Configuring the Extra Port](#) for more information.
 - **Commandline:** `--extra-max-connections=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `1`
 - **Range:** `1` to `100000`
-

`extra_port`

- **Description:** Extra port number to use for TCP connections in a `one-thread-per-connection` manner. If set to `0`, then no extra port is used.
 - See [Thread Pool in MariaDB: Configuring the Extra Port](#) for more information.
 - **Commandline:** `--extra-port=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:** `0`
-

`thread_handling`

- **Description:** Determines how the server handles threads for client connections. In addition to threads for client connections, this also applies to certain internal server threads, such as [Galera slave threads](#). On Windows, if you would like to use the thread pool, then you do not need to do anything, because the default for the `thread_handling` system variable is already preset to `pool-of-threads`.
 - When the default `one-thread-per-connection` mode is enabled, the server uses one thread to handle each client connection.
 - When the `pool-of-threads` mode is enabled, the server uses the [thread pool](#) for client connections.
 - When the `no-threads` mode is enabled, the server uses a single thread for all client connections, which is really only usable for debugging.
 - **Commandline:** `--thread-handling=name`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `enumeration`
 - **Default Value:** `one-thread-per-connection` (non-Windows), `pool-of-threads` (Windows)
 - **Valid Values:** `no-threads`, `one-thread-per-connection`, `pool-of-threads`.
 - **Documentation:** [Using the thread pool](#).
 - **Notes:** In MySQL, the thread pool is only available in MySQL Enterprise. In MariaDB it's available in all versions.
-

`thread_pool_dedicated_listener`

- **Description:** If set to `1`, then each group will have its own dedicated listener, and the listener thread will not pick up work items. As a result, the queueing time in the [Information Schema Threadpool_Queues](#) and the actual queue size in the [Information Schema Threadpool_Groups](#) table will be more exact, since IO requests are immediately dequeued from poll, without delay.
 - This system variable is only meaningful on **Unix**.
 - **Commandline:** `thread-pool-dedicated-listener={0|1}`
 - **Scope:**
 - **Dynamic:**
 - **Data Type:** `boolean`
 - **Default Value:** `0`
 - **Introduced:** [MariaDB 10.5.0](#)
-

thread_pool_exact_stats

- **Description:** If set to 1, provides better queuing time statistics by using a high precision timestamp, at a small performance cost, for the time when the connection was added to the queue. This timestamp helps calculate the queuing time shown in the [Information Schema Threadpool_Queues](#) table.
 - This system variable is only meaningful on **Unix**.
 - **Commandline:** `thread-pool-exact-stats={0|1}`
 - **Scope:**
 - **Dynamic:**
 - **Data Type:** `boolean`
 - **Default Value:** `0`
 - **Introduced:** [MariaDB 10.5.0](#)
-

thread_pool_idle_timeout

- **Description:** The number of seconds before an idle worker thread exits. The default value is `60`. If there is currently no work to do, how long should an idle thread wait before exiting?
 - This system variable is only meaningful on **Unix**.
 - The `thread_pool_min_threads` system variable is comparable for Windows.
 - **Commandline:** `thread-pool-idle-timeout=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `60`
 - **Documentation:** [Using the thread pool.](#)
-

thread_pool_max_threads

- **Description:** The maximum number of threads in the [thread pool](#). Once this limit is reached, no new threads will be created in most cases.
 - On Unix, in rare cases, the actual number of threads can slightly exceed this, because each [thread group](#) needs at least two threads (i.e. at least one worker thread and at least one listener thread) to prevent deadlocks.
 - **Scope:**
 - **Commandline:** `thread-pool-max-threads=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:**
 - `65536` ([>= MariaDB 10.2.4](#))
 - `1000` ([<= MariaDB 10.2.3](#), [>= MariaDB 10.1](#))
 - `500` ([<= MariaDB 10.0](#))
 - **Range:** `1` to `65536`
 - **Documentation:** [Using the thread pool.](#)
-

thread_pool_min_threads

- **Description:** Minimum number of threads in the [thread pool](#). In bursty environments, after a period of inactivity, threads would normally be retired. When the next burst arrives, it would take time to reach the optimal level. Setting this value higher than the default would prevent thread retirement even if inactive.
 - This system variable is only meaningful on **Windows**.
 - The `thread_pool_idle_timeout` system variable is comparable for Unix.
 - **Commandline:** `thread-pool-min-threads=#`
 - **Data Type:** `numeric`
 - **Default Value:** `1`
 - **Documentation:** [Using the thread pool.](#)
-

thread_pool_oversubscribe

- **Description:** Determines how many worker threads in a thread group can remain active at the same time once a thread group is oversubscribed due to stalls. The default value is `3`. Usually, a thread group only has one active

worker thread at a time. However, the timer thread can add more active worker threads to a thread group if it detects a stall. There are trade-offs to consider when deciding whether to allow **only one** thread per CPU to run at a time, or whether to allow **more than one** thread per CPU to run at a time. Allowing only one thread per CPU means that the thread can have unrestricted access to the CPU while its running, but it also means that there is additional overhead from putting threads to sleep or waking them up more frequently. Allowing more than one thread per CPU means that the threads have to share the CPU, but it also means that there is less overhead from putting threads to sleep or waking them up.

- See [Thread Groups in the Unix Implementation of the Thread Pool: Thread Group Oversubscription](#) for more information.
 - This is primarily for **internal** use, and it is **not** meant to be changed for most users.
 - This system variable is only meaningful on **Unix**.
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** numeric
 - **Default Value:** 3
 - **Range:** 1 to 65536
 - **Documentation:** [Using the thread pool.](#)
-

thread_pool_prio_kickup_timer

- **Description:** Time in milliseconds before a dequeued low-priority statement is moved to the high-priority queue.
 - This system variable is only meaningful on **Unix**.
 - **Commandline:** thread-pool-kickup-timer=#
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** numeric
 - **Default Value:** 1000
 - **Range:** 0 to 4294967295
 - **Introduced:** [MariaDB 10.2.2](#) [↗](#)
 - **Documentation:** [Using the thread pool.](#)
-

thread_pool_priority

- **Description:** [Thread pool](#) priority. High-priority connections usually start executing earlier than low-priority. If set to 'auto' (the default), the actual priority (low or high) is determined by whether or not the connection is inside a transaction.
 - **Commandline:** --thread-pool-priority=#
 - **Scope:** Global,Connection
 - **Data Type:** enum
 - **Default Value:** auto
 - **Valid Values:** high, low, auto.
 - **Introduced:** [MariaDB 10.2.2](#) [↗](#)
 - **Documentation:** [Using the thread pool.](#)
-

thread_pool_size

- **Description:** The number of [thread groups](#) in the [thread pool](#), which determines how many statements can execute simultaneously. The default value is the number of CPUs on the system. When setting this system variable's value at system startup, the max value is 100000. However, it is not a good idea to set it that high. When setting this system variable's value dynamically, the max value is either 128 or the value that was set at system startup--whichever value is higher.
 - See [Thread Groups in the Unix Implementation of the Thread Pool](#) for more information.
 - This system variable is only meaningful on **Unix**.
 - **Commandline:** --thread-pool-size=#
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** numeric
 - **Default Value:** Based on the number of processors (but see [MDEV-7806](#) [↗](#)).
 - **Range:** 1 to 128 (< [MariaDB 5.5.37](#) [↗](#), [MariaDB 10.0.11](#) [↗](#)), 1 to 100000 (>= [MariaDB 5.5.37](#) [↗](#), [MariaDB 10.0.11](#) [↗](#))
 - **Documentation:** [Using the thread pool.](#)
-

`thread_pool_stall_limit`

- **Description:** The number of milliseconds between each stall check performed by the timer thread. The default value is `500`. Stall detection is used to prevent a single client connection from monopolizing a thread group. When the timer thread detects that a thread group is stalled, it wakes up a sleeping worker thread in the thread group, if one is available. If there isn't one, then it creates a new worker thread in the thread group. This temporarily allows several client connections in the thread group to run in parallel. However, note that the timer thread will not create a new worker thread if the number of threads in the thread pool is already greater than or equal to the maximum defined by the `thread_pool_max_threads` variable, unless the thread group does not already have a listener thread.
 - See [Thread Groups in the Unix Implementation of the Thread Pool: Thread Group Stalls](#) for more information.
 - This system variable is only meaningful on **Unix**.
 - Note that if you are migrating from the MySQL Enterprise thread pool plugin, then the unit used in their implementation is 10ms, not 1ms.
- **Commandline:** `--thread-pool-stall-limit=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `500`
- **Range:** `10` to `4294967295` (< [MariaDB 10.5](#)), `1` to `4294967295` (>= [MariaDB 10.5](#))
- **Documentation:** [Using the thread pool](#).

Status variables

`Threadpool_idle_threads`

- **Description:** Number of inactive threads in the [thread pool](#). Threads become inactive for various reasons, such as by waiting for new work. However, an inactive thread is not necessarily one that has not been assigned work. Threads are also considered inactive if they are being blocked while waiting on disk I/O, or while waiting on a lock, etc.
 - This status variable is only meaningful on **Unix**.
- **Scope:** Global, Session
- **Data Type:** `numeric`

`Threadpool_threads`

- **Description:** Number of threads in the [thread pool](#). In rare cases, this can be slightly higher than `thread_pool_max_threads`, because each thread group needs at least two threads (i.e. at least one worker thread and at least one listener thread) to prevent deadlocks.
- **Scope:** Global, Session
- **Data Type:** `numeric`

3.3.7.32 MariaDB Optimization for MySQL Users

MariaDB contains many new options and optimizations which, for compatibility or other reasons, are not enabled in the default install. Enabling them helps you gain extra performance from the same hardware when upgrading from MySQL to MariaDB. This article contains information on options and settings which you should enable, or at least look in to, when making the switch.

```
aria-pagecache-buffer-size=##
```

If you are using a log of on-disk temporary tables, increase the above to as much as you can afford. See [Aria Storage Engine](#) for more details.

```
key-cache-segments=8
```

If you use/have a lot of MyISAM files, increase the above to 4 or 8. See [Segmented Key Cache](#) and [Segmented Key Cache Performance](#) for more information.

```
thread-handling=pool-of-threads
```

Threadpool is a great way to increase performance in situations where queries are relatively short and the load is CPU bound (e.g. OLTP workloads). To enable it, add the above to your my.cnf file. See [Threadpool in 5.5](#) for more information.

5.3.2.7 InnoDB Buffer Pool

5.3.2.8 InnoDB Change Buffering

3.3.7.35 Optimizing table_open_cache

`table_open_cache` can be a useful variable to adjust to improve performance.

Each concurrent session accessing the same table does so independently. This improves performance, although it comes at a cost of extra memory usage.

`table_open_cache` indicates the maximum number of tables the server can keep open in any one table cache instance. Ideally, you'd like this set so as to re-open a table as infrequently as possible.

However, note that this is not a hard limit. When the server needs to open a table, it evicts the least recently used closed table from the cache, and adds the new table. If all tables are used, the server adds the new table and does not evict any table. As soon as a table is not used anymore, it will be evicted from the list even if no table needs to be open, until the number of open tables will be equal to `table_open_cache`

`table_open_cache` has defaulted to 2000 since [MariaDB 10.1.7](#). Before that, the default was 400.

You can view the current setting in the my.cnf file, or by running:

```
select @@table_open_cache;
+-----+
| @@table_open_cache |
+-----+
|                400 |
+-----+
```

To evaluate whether you could do with a higher `table_open_cache`, look at the number of opened tables, in conjunction with the server uptime ([Opened_tables](#) and [Uptime](#) status variables):

```
show global status like 'opened_tables';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Opened_tables | 354858 |
+-----+-----+
```

If the number of opened tables is increasing rapidly, you should look at increasing the `table_open_cache` value. Try to find a value that sees a slow, or possibly even no, increase in the number of opened tables.

Make sure that your operating system can cope with the number of open file descriptors required by the `table_open_cache` setting. If `table_open_cache` is set too high, MariaDB may start to refuse connections as the operating system runs out of file descriptors. Also note that the MyISAM (and Aria?) storage engines need two file descriptors per open table.

It's possible that the `open_table_cache` can even be reduced.

If your number of `open_tables` has not yet reached the `table_open_cache_size`, and the server has been up a while, you can look at decreasing the value.

```
show global status like 'open_tables';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Open_tables   | 354   |
+-----+-----+
```

The open table cache can be emptied with [FLUSH TABLES](#) or with the `flush-tables` or `refresh` [mariadb-admin](#) commands.

Automatic Creation of New Table Open Cache Instances

MariaDB Server can create multiple instances of the table open cache. It initially creates just a single instance. However, whenever it detects contention on the existing instances, it will automatically create a new instance. When the number of instances has been increased due to contention, it does not decrease again.

When MariaDB Server creates a new instance, it prints a message like the following to the [error log](#):

```
[Note] Detected table cache mutex contention at instance 1: 25% waits. Additional
table cache instance activated. Number of instances after activation: 2.
```

The maximum number of instances is defined by the [table_open_cache_instances](#) system variable. The default value of the [table_open_cache_instances](#) system variable is `8`, which is expected to handle up to 100 CPU cores. If your system is larger than this, then you may benefit from increasing the value of this system variable.

Depending on the ratio of actual available file handles, and [table_open_cache](#) size, the max. instance count may be auto adjusted to a lower value on server startup.

The implementation and behavior of this feature is different than the same feature in MySQL 5.6.

3.3.7.36 Optimizing key_buffer_size

[key_buffer_size](#) is a [MyISAM](#) variable which determines the size of the index buffers held in memory, which affects the speed of index reads. Note that Aria tables by default make use of an alternative setting, [aria-pagecache-buffer-size](#).

A good rule of thumb for servers consisting particularly of MyISAM tables is for about 25% or more of the available server memory to be dedicated to the key buffer.

A good way to determine whether to adjust the value is to compare the [key_read_requests](#) value, which is the total value of requests to read an index, and the [key_reads](#) values, the total number of requests that had to be read from disk.

The ratio of [key_reads](#) to [key_read_requests](#) should be as low as possible, 1:100 is the highest acceptable, 1:1000 is better, and 1:10 is terrible.

The effective maximum size might be lower than what is set, depending on the server's available physical RAM and the per-process limit determined by the operating system.

If you don't make use of MyISAM tables at all, you can set this to a very low value, such as 64K.

5.3.13.8 Segmented Key Cache

3.3.7.38 Big Query Settings

MariaDB 5.3 and beyond have a number of features that are targeted at big queries and so are disabled by default.

This page describes recommended settings for IO-bound queries that shovel through lots of records.

First, turn on [Batched Key Access](#):

```
# Turn on disk-ordered reads
optimizer_switch='mrr=on'
optimizer_switch='mrr_cost_based=off'

# Turn on Batched Key Access (BKA)
join_cache_level = 6
```

Give BKA buffer space to operate on. Ideally, it should have enough space to fit all the data examined by the query.

```
# Size limit for the whole join
join_buffer_space_limit = 300M

# Limit for each individual table
join_buffer_size = 100M
```

Turn on [index_merge/sort-intersection](#):

```
optimizer_switch='index_merge_sort_intersection=on'
```

If your queries examine big fraction of the tables (somewhere more than ~ 30%), turn on [hash join](#):

```
# Turn on both Hash Join and Batched Key Access
join_cache_level = 8
```

3.3.7.39 Sample my.cnf Files

Place holder for sample my.cnf files, customized for different memory size and storage engines. In addition, we'd like to hear from you what works for you, so the knowledge can be crowd-sourced and shared.

3.3.7.40 Handling Too Many Connections

Systems that get too busy can return the `too_many_connections` error.

When the number of `threads_connected` exceeds the `max_connections` server variable, it's time to make a change. Viewing the `threads_connected` status variable shows only the current number of connections, but it's more useful to see what the value has peaked at, and this is shown by the `max_used_connections` status variable.

This error may be a symptom of slow queries and other bottlenecks, but if the system is running smoothly this can be addressed by increasing the value of `max_connections`.

2.1.14.1.11 System Variable Differences between MariaDB and MySQL

3.3.6 MariaDB Memory Allocation

3.3.7.43 Setting Innodb Buffer Pool Size Dynamically

Resizing the buffer pool is performed in chunks determined by the size of the `innodb_buffer_pool_chunk_size` variable.

The resize operation waits until all active transactions and operations are completed, and new transactions and operations that need to access the buffer pool must wait until the resize is complete (although when decreasing the size, access is permitted when defragmenting and withdrawing pages).

Nested transactions may fail if started after the buffer pool resize has begun.

The new buffer pool size must be a multiple of `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances` (note that `innodb_buffer_pool_instances` is ignored from [MariaDB 10.5](#), and removed in [MariaDB 10.6](#), as the buffer pool is no longer split into multiple instances). If you attempt to set a different figure, the value is automatically adjusted to a multiple of at least the attempted size. Note that adjusting the `innodb_buffer_pool_chunk_size` setting can result in a change in the buffer pool size.

The number of chunks as calculated by `innodb_buffer_pool_size / innodb_buffer_pool_chunk_size` should not exceed 1000 in order to avoid performance issues.

A background thread performs the resizing operation. The `innodb_buffer_pool_resize_status` status variable shows the progress of the resizing operation, for example:

```
SHOW STATUS LIKE 'Innodb_buffer_pool_resize_status';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Innodb_buffer_pool_resize_status | Resizing also other hash tables. |
+-----+-----+
```

or

```
SHOW STATUS LIKE 'Innodb_buffer_pool_resize_status';
```

Variable_name	Value
Innodb_buffer_pool_resize_status	Completed resizing buffer pool at 161103 16:26:54.

Progress is also logged in the [error log](#).

Problem That Thread Pools Solve

The task of scalable server software (and a DBMS like MariaDB is an example of such software) is to maintain top performance with an increasing number of clients. MySQL traditionally assigned a thread for every client connection, and as the number of concurrent users grows this model shows performance drops. Many active threads are a performance killer, because increasing the number of threads leads to extensive context switching, bad locality for CPU caches, and increased contention for hot locks. An ideal solution that would help to reduce context switching is to maintain a lower number of threads than the number of clients. But this number should not be too low either, since we also want to utilize CPUs to their fullest, so ideally, there should be a single active thread for each CPU on the machine.

MariaDB Thread Pool Features

The current MariaDB thread pool was implemented in [MariaDB 5.5](#). It replaced the legacy thread pool that was introduced in [MariaDB 5.1](#). The main drawback of the previous solution was that this pool was static—it had a fixed number of threads. Static thread pools can have their merits, for some limited use cases, such as cases where callbacks executed by the threads never block and do not depend on each other. For example, imagine something like an echo server.

However, DBMS clients are more complicated. For example, a thread may depend on another thread's completion, and they may block each other via locks and/or I/O. Thus it is very hard, and sometimes impossible, to predict how many threads would be ideal or even sufficient to prevent deadlocks in every situation. [MariaDB 5.5](#) implements a dynamic/adaptive pool that itself takes care of creating new threads in times of high demand and retiring threads if they have nothing to do. This is a complete reimplement of the legacy `pool-of-threads` scheduler, with the following goals:

- Make the pool dynamic, so that it will grow and shrink whenever required.
- Minimize the amount of overhead that is required to maintain the thread pool itself.
- Make the best use of underlying OS capabilities. For example, if a native thread pool implementation is available, then it should be used, and if not, then the best I/O multiplexing method should be used.
- Limit the resources used by threads.

There are currently two different low-level implementations – depending on OS. One implementation is designed specifically for Windows which utilizes a native `CreateThreadpool` API. The second implementation is primarily intended to be used in Unix-like systems. Because the implementations are different, some system variables differ between Windows and Unix.

When to Use the Thread Pool

Thread pools are most efficient in situations where queries are relatively short and the load is CPU-bound, such as in OLTP workloads. If the workload is not CPU-bound, then you might still benefit from limiting the number of threads to save memory for the database memory buffers.

When the Thread Pool is Less Efficient

There are special, rare cases where the thread pool is likely to be less efficient.

- If you have a **very bursty workload**, then the thread pool may not work well for you. These tend to be workloads in which there are long periods of inactivity followed by short periods of very high activity by many users. These also tend to be workloads in which delays cannot be tolerated, so the throttling of thread creation that the thread pool uses is not ideal. Even in this situation, performance can be improved by tweaking how often threads are retired. For example, with `thread_pool_idle_timeout` on Unix, or with `thread_pool_min_threads` on Windows.
- If you have **many concurrent, long, non-yielding** queries, then the thread pool may not work well for you. In this context, a "non-yielding" query is one that never waits or which does not indicate waits to the thread pool. These kinds of workloads are mostly used in data warehouse scenarios. Long-running, non-yielding queries will delay execution of other queries. However, the thread pool has stall detection to prevent them from totally monopolizing the thread pool. See [Thread Groups in the Unix Implementation of the Thread Pool: Thread Group Stalls](#) for more information. Even when the whole thread pool is blocked by non-yielding queries, you can still connect to the server through the `extra-port` TCP/IP port.
- If you rely on the fact that **simple queries always finish quickly**, no matter how loaded your database server is, then the thread pool may not work well for you. When the thread pool is enabled on a busy server, even simple queries might be queued to be executed later. This means that even if the statement itself doesn't take much time to execute, even a simple `SELECT 1`, might take a bit longer when the thread pool is enabled than with `one-thread-per-connection` if it gets queued.

Configuring the Thread Pool

The `thread_handling` system variable is the primary system variable that is used to configure the thread pool.

There are several other system variables as well, which are described in the sections below. Many of the system variables documented below are dynamic, meaning that they can be changed with `SET GLOBAL` on a running server.

Generally, there is no need to tweak many of these system variables. The goal of the thread pool was to provide good performance out-of-the box. However, the system variable values can be changed, and we intended to expose as many knobs from the underlying implementation as we could. Feel free to tweak them as you see fit.

If you find any issues with any of the default behavior, then we encourage you to [submit a bug report](#).

See [Thread Pool System and Status Variables](#) for the full list of the thread pool's system variables.

Configuring the Thread Pool on Unix

On Unix, if you would like to use the thread pool, then you can use the thread pool by setting the `thread_handling` system variable to `pool-of-threads` in a server [option group](#) in an [option file](#) prior to starting up the server. For example:

```
[mariadb]
...
thread_handling=pool-of-threads
```

The following system variables can also be configured on Unix:

- `thread_pool_size` – The number of [thread groups](#) in the thread pool, which determines how many statements can execute simultaneously. The default value is the number of CPUs on the system. When setting this system variable's value at system startup, the max value is 100000. However, it is not a good idea to set it that high. When setting this system variable's value dynamically, the max value is either 128 or the value that was set at system startup-- whichever value is higher. See [Thread Groups in the Unix Implementation of the Thread Pool](#) for more information.
- `thread_pool_max_threads` – The maximum number of threads in the thread pool. Once this limit is reached, no new threads will be created in most cases. In rare cases, the actual number of threads can slightly exceed this, because each [thread group](#) needs at least two threads (i.e. at least one worker thread and at least one listener thread) to prevent deadlocks. The default value in [MariaDB 5.5](#) and [MariaDB 10.0](#) is 500. The default value in [MariaDB 10.1](#) is 1000 in [MariaDB 10.1](#). The default value in [MariaDB 10.2](#) and later is 65536.

- `thread_pool_stall_limit` – The number of milliseconds between each stall check performed by the timer thread. The default value is `500`. Stall detection is used to prevent a single client connection from monopolizing a thread group. When the timer thread detects that a thread group is stalled, it wakes up a sleeping worker thread in the thread group, if one is available. If there isn't one, then it creates a new worker thread in the thread group. This temporarily allows several client connections in the thread group to run in parallel. However, note that the timer thread will not create a new worker thread if the number of threads in the thread pool is already greater than or equal to the maximum defined by the `thread_pool_max_threads` variable, unless the thread group does not already have a listener thread. See [Thread Groups in the Unix Implementation of the Thread Pool: Thread Group Stalls](#) for more information.
- `thread_pool_oversubscribe` – Determines how many worker threads in a thread group can remain active at the same time once a thread group is oversubscribed due to stalls. The default value is `3`. Usually, a thread group only has one active worker thread at a time. However, the timer thread can add more active worker threads to a thread group if it detects a stall. There are trade-offs to consider when deciding whether to allow **only one** thread per CPU to run at a time, or whether to allow **more than one** thread per CPU to run at a time. Allowing only one thread per CPU means that the thread can have unrestricted access to the CPU while its running, but it also means that there is additional overhead from putting threads to sleep or waking them up more frequently. Allowing more than one thread per CPU means that the threads have to share the CPU, but it also means that there is less overhead from putting threads to sleep or waking them up. This is primarily for **internal** use, and it is **not** meant to be changed for most users. See [Thread Groups in the Unix Implementation of the Thread Pool: Thread Group Oversubscription](#) for more information.
- `thread_pool_idle_timeout` – The number of seconds before an idle worker thread exits. The default value is `60`. If there is currently no work to do, how long should an idle thread wait before exiting?

Configuring the Thread Pool on Windows

The Windows implementation of the thread pool uses a native thread pool created with the [CreateThreadpool](#)  API.

On Windows, if you would like to use the thread pool, then you do not need to do anything, because the default for the `thread_handling` system variable is already preset to `pool-of-threads`.

However, if you would like to use the old one thread per-connection behavior on Windows, then you can use that by setting the `thread_handling` system variable to `one-thread-per-connection` in a server [option group](#) in an [option file](#) prior to starting up the server. For example:

```
[mariadb]
...
thread_handling=one-thread-per-connection
```

On older versions of Windows, such as XP and 2003, `pool-of-threads` is not implemented, and the server will silently switch to using the legacy `one-thread-per-connection` method.

The native [CreateThreadpool](#)  API allows applications to set the minimum and maximum number of threads in the pool. The following system variables can be used to configure those values on Windows:

- `thread_pool_min_threads` – The minimum number of threads in the pool. Default is 1. This applicable in a special case of very “bursty” workloads. Imagine having longer periods of inactivity after periods of high activity. While the thread pool is idle, Windows would decide to retire pool threads (based on experimentation, this seems to happen after thread had been idle for 1 minute). Next time high load comes, it could take some milliseconds or seconds until the thread pool size stabilizes again to optimal value. To avoid thread retirement, one could set the parameter to a higher value.
- `thread_pool_max_threads` – The maximum number of threads in the pool. Threads are not created when this value is reached. The default from [MariaDB 5.5](#) to [MariaDB 10.0](#) is 500 (this has been increased to 1000 in [MariaDB 10.1](#)). This parameter can be used to prevent the creation of new threads if the pool can have short periods where many or all clients are blocked (for example, with “FLUSH TABLES WITH READ LOCK”, high contention on row locks, or similar). New threads are created if a blocking situation occurs (such as after a throttling interval), but sometimes you want to cap the number of threads, if you’re familiar with the application and need to, for example, save memory. If your application constantly pegs at 500 threads, it might be a strong indicator for high contention in the application, and the thread pool does not help much.

Configuring Priority Scheduling

Starting with [MariaDB 10.2.2](#) , it is possible to configure connection prioritization. The priority behavior is configured by the `thread_pool_priority` system variable.

By default, if `thread_pool_priority` is set to `auto`, then queries would be given a higher priority, in case the current connection is inside a transaction. This allows the running transaction to finish faster, and has the effect of lowering the number of transactions running in parallel. The default setting will generally improve throughput for transactional workloads. But it is also possible to explicitly set the priority for the current connection to either 'high' or 'low'.

There is also a mechanism in place to ensure that higher priority connections are not monopolizing the worker threads in the pool (which would cause indefinite delays for low priority connections). On Unix, low priority connections are put into the high priority queue after the timeout specified by the `thread_pool_prio_kickup_timer` system variable.

Configuring the Extra Port

MariaDB allows you to configure an extra port for administrative connections. This is primarily intended to be used in situations where all threads in the thread pool are blocked, and you still need a way to access the server. However, it can also be used to ensure that monitoring systems (including MaxScale's monitors) always have access to the system, even when all connections on the main port are used. This extra port uses the old `one-thread-per-connection` thread handling.

You can enable this and configure a specific port by setting the `extra_port` system variable.

You can configure a specific number of connections for this port by setting the `extra_max_connections` system variable.

These system variables can be set in a server [option group](#) in an [option file](#) prior to starting up the server. For example:

```
[mariadb]
...
extra_port = 8385
extra_max_connections = 10
```

Once you have the extra port configured, you can use the `mariadb` client with the `-P` option to connect to the port.

```
$ mariadb -u root -P 8385 -p
```

Monitoring Thread Pool Activity

Currently there are two status variables exposed to monitor pool activity.

Variable	Description
<code>Threadpool_threads</code>	Number of threads in the thread pool. In rare cases, this can be slightly higher than <code>thread_pool_max_threads</code> , because each thread group needs at least two threads (i.e. at least one worker thread and at least one listener thread) to prevent deadlocks.
<code>Threadpool_idle_threads</code>	Number of inactive threads in the thread pool. Threads become inactive for various reasons, such as by waiting for new work. However, an inactive thread is not necessarily one that has not been assigned work. Threads are also considered inactive if they are being blocked while waiting on disk I/O, or while waiting on a lock, etc. This status variable is only meaningful on Unix .

Thread Groups in the Unix Implementation of the Thread Pool

On Unix, the thread pool implementation uses objects called thread groups to divide up client connections into many independent sets of threads. See [Thread Groups in the Unix Implementation of the Thread Pool](#) for more information.

Fixing a Blocked Thread Pool

When using global locks, even with a high value on the `thread_pool_max_threads` system variable, it is still possible to block the entire pool.

Imagine the case where a client performs `FLUSH TABLES WITH READ LOCK` then pauses. If then the number of other clients connecting to the server to start write operations exceeds the maximum number of threads allowed in the pool, it can block the Server. This makes it impossible to issue the `UNLOCK TABLES` statement. It can also block MaxScale from monitoring the Server.

To mitigate the issue, MariaDB allows you to configure an extra port for administrative connections. See [Configuring the Extra Port](#) for information on how to configure this.

Once you have the extra port configured, you can use the [mariadb](#) client with the `-P` option to connect to the port.

```
$ mariadb -u root -P 8385 -p
```

This ensures that your administrators can access the server in cases where the number of threads is already equal to the configured value of the `thread_pool_max_threads` system variable, and all threads are blocked. It also ensures that MaxScale can still access the server in such situations for monitoring information.

Once you are connected to the extra port, you can solve the issue by increasing the value on the `thread_pool_max_threads` system variable, or by killing the offending connection, (that is, the connection that holds the global lock, which would be in the `sleep` state).

Information Schema

The following Information Schema tables relate to the thread pool:

- [Information Schema THREAD_POOL_GROUPS Table](#)
- [Information Schema THREAD_POOL_QUEUES Table](#)
- [Information Schema THREAD_POOL_STATS Table](#)
- [Information Schema THREAD_POOL_WAITS Table](#)

MariaDB Thread Pool vs Oracle MySQL Enterprise Thread Pool

Commercial editions of MySQL since 5.5 include an Oracle MySQL Enterprise thread pool implemented as a plugin, which delivers similar functionality. A detailed discussion about the design of the feature is at [Mikael Ronstrom's blog](#). Here is the summary of similarities and differences, based on the above materials.

Similarities

- On Unix, both MariaDB and Oracle MySQL Enterprise Threadpool will partition client connections into groups. The `thread_pool_size` parameter thus has the same meaning for both MySQL and MariaDB.
- Both implementations use similar schema checking for thread stalls, and both have the same parameter name for `thread_pool_stall_limit` (though in MariaDB it is measured using millisecond units, not 10ms units like in Oracle MySQL).

Differences

- The Windows implementation is completely different – MariaDB's uses native Windows threadpooling, while Oracle's implementation includes a convenience function `WSAPoll()` (provided for convenience to port Unix applications). As a consequence of relying on `WSAPoll()`, Oracle's implementation will not work with named pipes and shared memory connections.
- MariaDB uses the most efficient I/O multiplexing facilities for each operating system: Windows (the I/O completion port is used internally by the native threadpool), Linux (epoll), Solaris (event ports), FreeBSD and OSX (kevent). Oracle uses optimized I/O multiplexing only on Linux, with epoll, and uses `poll()` otherwise.
- Unlike Oracle MySQL Enterprise Threadpool, MariaDB's one is builtin, not a plugin.

MariaDB Thread Pool vs Percona Thread Pool

[Percona's implementation](#) is a port of the MariaDB's threadpool with some added features. In particular, Percona added priority scheduling to its 5.5-5.7 releases. [MariaDB 10.2](#) and Percona priority scheduling work in a similar fashion, but there are some differences in details.

- MariaDB's 10.2 `thread_pool_priority=auto,high, low` correspond to Percona's `thread_pool_high_prio_mode=transactions,statements,none`
- Percona has a `thread_pool_high_prio_tickets` connection variable to allow every nth low priority query to be put into the high priority queue. MariaDB does not have corresponding settings.
- MariaDB has a `thread_pool_prio_kickup_timer` setting, which Percona does not have.

Thread Pool Internals

Low-level implementation details are documented in the [WL#246](#)

Running Benchmarks

When running sysbench and maybe other benchmarks, that create many threads on the same machine as the server, it is advisable to run benchmark driver and server on different CPUs to get the realistic results. Running lots of driver threads and only several server threads on the same CPUs will have the effect that OS scheduler will schedule benchmark driver threads to run with much higher probability than the server threads, that is driver will pre-empt the server. Use "taskset -c" on Linuxes, and "set /affinity" on Windows to separate benchmark driver and server CPUs, as the preferred method to fix this situation.

A possible alternative on Unix (if taskset or a separate machine running the benchmark is not desired for some reason) would be to increase `thread_pool_size` to make the server threads more "competitive" against the client threads.

When running sysbench, a good rule of thumb could be to give 1/4 of all CPUs to the sysbench, and 3/4 of CPUs to mariadb. It is also good idea to run sysbench and mariadb on different NUMA nodes, if possible.

Notes

The `thread_cache_size` system variable is not used when the thread pool is used and the `Threads_cached` status variable will have a value of 0.

3.3.8.3 Thread Groups in the Unix Implementation of the Thread Pool

This article does not apply to the thread pool implementation on Windows. On Windows, MariaDB uses a native thread pool created with the `CreateThreadpool` API, which has its own methods to distribute threads between CPUs.

Contents

1. [Distributing Client Connections Between Thread Groups](#)

 5. [Thread Creation Throttling](#)
4. [Thread Group Stalls](#)
 1. [Thread Group Oversubscription](#)

On Unix, the thread pool implementation uses objects called thread groups to divide up client connections into many independent sets of threads. The `thread_pool_size` system variable defines the number of thread groups on a system. Generally speaking, the goal of the thread group implementation is to have one running thread on each CPU on the system at a time. Therefore, the default value of the `thread_pool_size` system variable is auto-sized to the number of CPUs on the system.

When setting the `thread_pool_size` system variable's value at system startup, the max value is `100000`. However, it is not a good idea to set it that high. When setting its value dynamically, the max value is either `128` or the value that was set at system startup--whichever value is higher. It can be changed dynamically with `SET GLOBAL`. For example:

```
SET GLOBAL thread_pool_size=32;
```

It can also be set in a server [option group](#) in an [option file](#) prior to starting up the server. For example:

```
[mariadb]
..
thread_handling=pool-of-threads
thread_pool_size=32
```

If you do not want MariaDB to use all CPUs on the system for some reason, then you can set it to a lower value than the number of CPUs. For example, this would make sense if the MariaDB Server process is limited to certain CPUs with the `taskset` utility on Linux.

If you set the value to the number of CPUs and if you find that the CPUs are still underutilized, then try increasing the value.

The `thread_pool_size` system variable tends to have the most visible performance effect. It is roughly equivalent to the number of threads that can run at the same time. In this case, run means use CPU, rather than sleep or wait. If a client connection needs to sleep or wait for some reason, then it wakes up another client connection in the thread group before it does so.

One reason that CPU underutilization may occur in rare cases is that the thread pool is not always informed when a thread is going to wait. For example, some waits, such as a page fault or a miss in the OS buffer cache, cannot be detected by MariaDB. Prior to [MariaDB 10.0](#), network I/O related waits could also be missed.

Distributing Client Connections Between Thread Groups

When a new client connection is created, its thread group is determined using the following calculation:

```
thread_group_id = connection_id % thread_pool_size
```

The `connection_id` value in the above calculation is the same monotonically increasing number that you can use to identify connections in `SHOW PROCESSLIST` output or the `information_schema.PROCESSLIST` table.

This calculation should assign client connections to each thread group in a round-robin manner. In general, this should result in an even distribution of client connections among thread groups.

Types of Threads

Thread Group Threads

Thread groups have two different kinds of threads: a **listener thread** and **worker threads**.

- A thread group's **worker threads** actually perform work on behalf of client connections. A thread group can have many **worker threads**, but usually, only one will be actively running at a time. This is not always the case. For example, the thread group can become *oversubscribed* if the thread pool's **timer thread** detects that the thread group is *stalled*. This is explained more in the sections below.
- A thread group's **listener thread** listens for I/O events and distributes work to the **worker threads**. If it detects that there is a request that needs to be worked on, then it can wake up a sleeping **worker thread** in the thread group, if any exist. If the **listener thread** is the only thread in the thread group, then it can also create a new **worker thread**. If there is only one request to handle, and if the `thread_pool_dedicated_listener` system variable is not enabled, then the **listener thread** can also become a **worker thread** and handle the request itself. This helps decrease the overhead that may be introduced by excessively waking up sleeping **worker threads** and excessively creating new **worker threads**.

Global Threads

The thread pool has one global thread: a **timer thread**. The **timer thread** performs tasks, such as:

- Checks each thread group for stalls.
- Ensures that each thread group has a **listener thread**.

Thread Creation

A new thread is created in a thread group in the scenarios listed below.

In all of the scenarios below, the thread pool implementation prefers to wake up a sleeping **worker thread** that already exists in the thread group, rather than to create a new thread.

Worker Thread Creation by Listener Thread

A thread group's **listener thread** can create a new **worker thread** when it has more client connection requests to distribute, but no pre-existing **worker threads** are available to work on the requests. This can help to ensure that the thread group always has enough threads to keep one **worker thread** active at a time.

A thread group's **listener thread** creates a new **worker thread** if all of the following conditions are met:

- The **listener thread** receives a client connection request that needs to be worked on.

- There are more client connection requests in the thread group's work queue that the **listener thread** still needs to distribute to **worker threads**, so the **listener thread** should not become a **worker thread**.
- There are no active **worker threads** in the thread group.
- There are no sleeping **worker threads** in the thread group that the **listener thread** can wake up.
- And one of the following conditions is also met:
 - The entire thread pool has fewer than `thread_pool_max_threads`.
 - There are fewer than two threads in the thread group. This is to guarantee that each thread group can have at least two threads, even if `thread_pool_max_threads` has already been reached or exceeded.

Thread Creation by Worker Threads during Waits

A thread group's **worker thread** can create a new **worker thread** when the thread has to wait on something, and the thread group has more client connection requests queued, but no pre-existing **worker threads** are available to work on them. This can help to ensure that the thread group always has enough threads to keep one **worker thread** active at a time. For most workloads, this tends to be the primary mechanism that creates new **worker threads**.

A thread group's **worker thread** creates a new thread if all of the following conditions are met:

- The **worker thread** has to wait on some request. For example, it might be waiting on disk I/O, or it might be waiting on a lock, or it might just be waiting for a query that called the `SLEEP()` function to finish.
- There are no active **worker threads** in the thread group.
- There are no sleeping **worker threads** in the thread group that the **worker thread** can wake up.
- And one of the following conditions is also met:
 - The entire thread pool has fewer than `thread_pool_max_threads`.
 - There are fewer than two threads in the thread group. This is to guarantee that each thread group can have at least two threads, even if `thread_pool_max_threads` has already been reached or exceeded.
- And one of the following conditions is also met:
 - There are more client connection requests in the thread group's work queue that the **listener thread** still needs to distribute to **worker threads**. In this case, the new thread is intended to be a **worker thread**.
 - There is currently no **listener thread** in the thread group. For example, if the `thread_pool_dedicated_listener` system variable is not enabled, then the thread group's **listener thread** can become a **worker thread**, so that it could handle some client connection request. In this case, the new thread can become the thread group's **listener thread**.

Listener Thread Creation by Timer Thread

The thread pool's **timer thread** can create a new **listener thread** for a thread group when the thread group has more client connection requests that need to be distributed, but the thread group does not currently have a **listener thread** to distribute them. This can help to ensure that the thread group does not miss client connection requests because it has no **listener thread**.

The thread pool's **timer thread** creates a new **listener thread** for a thread group if all of the following conditions are met:

- The thread group has not handled any I/O events since the last check by the timer thread.
- There is currently no **listener thread** in the thread group. For example, if the `thread_pool_dedicated_listener` system variable is not enabled, then the thread group's **listener thread** can become a **worker thread**, so that it could handle some client connection request. In this case, the new thread can become the thread group's **listener thread**.
- There are no sleeping **worker threads** in the thread group that the **timer thread** can wake up.
- And one of the following conditions is also met:
 - The entire thread pool has fewer than `thread_pool_max_threads`.
 - There are fewer than two threads in the thread group. This is to guarantee that each thread group can have at least two threads, even if `thread_pool_max_threads` has already been reached or exceeded.
- If the thread group already has active **worker threads**, then the following condition also needs to be met:
 - A **worker thread** has not been created for the thread group within the *throttling interval*.

Worker Thread Creation by Timer Thread during Stalls

The thread pool's **timer thread** can create a new **worker thread** for a thread group when the thread group is stalled. This can help to ensure that a long query can't monopolize its thread group.

The thread pool's **timer thread** creates a new **worker thread** for a thread group if all of the following conditions are met:

- The **timer thread** thinks that the thread group is stalled. This means that the following conditions have been met:
 - There are more client connection requests in the thread group's work queue that the **listener thread** still needs to distribute to **worker threads**.
 - No client connection requests have been allowed to be dequeued to run since the last stall check by the **timer thread**.
- There are no sleeping **worker threads** in the thread group that the **timer thread** can wake up.

- And one of the following conditions is also met:
 - The entire thread pool has fewer than `thread_pool_max_threads`.
 - There are fewer than two threads in the thread group. This is to guarantee that each thread group can have at least two threads, even if `thread_pool_max_threads` has already been reached or exceeded.
- A **worker thread** has not been created for the thread group within the *throttling interval*.

Thread Creation Throttling

In some of the scenarios listed above, a thread is only created within a thread group if no new threads have been created for the thread group within the *throttling interval*. The throttling interval depends on the number of threads that are already in the thread group.

MariaDB starting with 10.5

In [MariaDB 10.5](#) and later, thread creation is not throttled until a thread group has more than $1 + \text{thread_pool_oversubscribe}$ threads:

Number of Threads in Thread Group	Throttling Interval (milliseconds)
$0 - (1 + \text{thread_pool_oversubscribe})$	0
4-7	$50 * \text{THROTTLING_FACTOR}$
8-15	$100 * \text{THROTTLING_FACTOR}$
16-65536	$20 * \text{THROTTLING_FACTOR}$

$\text{THROTTLING_FACTOR} = (\text{thread_pool_stall_limit} / \text{MAX}(500, \text{thread_pool_stall_limit}))$

MariaDB until 10.4

In [MariaDB 10.4](#) and before, thread creation is throttled when a thread group has more than 3 threads:

Number of Threads in Thread Group	Throttling Interval (milliseconds)
0-3	0
4-7	50
8-15	100
16-65536	200

Thread Group Stalls

The thread pool has a feature that allows it to detect if a client connection is executing a long-running query that may be monopolizing its thread group. If a client connection were to monopolize its thread group, then that could prevent other client connections in the thread group from running their queries. In other words, the thread group would appear to be *stalled*.

This stall detection feature is implemented by creating a **timer thread** that periodically checks if any of the thread groups are stalled. There is only a single **timer thread** for the entire thread pool. The `thread_pool_stall_limit` system variable defines the number of milliseconds between each stall check performed by the timer thread. The default value is 500. It can be changed dynamically with `SET GLOBAL`. For example:

```
SET GLOBAL thread_pool_stall_limit=300;
```

It can also be set in a server [option group](#) in an [option file](#) prior to starting up the server. For example:

```
[mariadb]
..
thread_handling=pool-of-threads
thread_pool_size=32
thread_pool_stall_limit=300
```

The **timer thread** considers a thread group to be stalled if the following is true:

- There are more client connection requests in the thread group's work queue that the **listener thread** still needs to distribute to **worker threads**.
- No client connection requests have been allowed to be dequeued to run since the last stall check by the **timer thread**.

This indicates that the one or more client connections currently using the active **worker threads** may be monopolizing the thread group, and preventing the queued client connections from performing work. When the **timer thread** detects that a thread group is stalled, it wakes up a sleeping **worker thread** in the thread group, if one is available. If there isn't one, then it creates a new **worker thread** in the thread group. This temporarily allows several client connections in the thread group to run in parallel.

The `thread_pool_stall_limit` system variable essentially defines the limit for what a "fast query" is. If a query takes longer than `thread_pool_stall_limit`, then the thread pool is likely to think that it is too slow, and it will either wake up a sleeping worker thread or create a new worker thread to let another client connection in the thread group run a query in parallel.

In general, changing the value of the `thread_pool_stall_limit` system variable has the following effect:

- Setting it to **higher** values can help avoid starting too many parallel threads if you expect a lot of client connections to execute long-running queries.
- Setting it to **lower** values can help prevent deadlocks.

Thread Group Oversubscription

If the **timer thread** were to detect a stall in a thread group, then it would either wake up a sleeping **worker thread** or create a new **worker thread** in that thread group. At that point, the thread group would have multiple active **worker threads**. In other words, the thread group would be *oversubscribed*.

You might expect that the thread pool would shutdown one of the **worker threads** when the stalled client connection finished what it was doing, so that the thread group would only have one active **worker thread** again. However, this does not always happen. Once a thread group is oversubscribed, the `thread_pool_oversubscribe` system variable defines the upper limit for when **worker threads** start shutting down after they finish work for client connections. The default value is `3`. It can be changed dynamically with `SET GLOBAL`. For example:

```
SET GLOBAL thread_pool_oversubscribe=10;
```

It can also be set in a server [option group](#) in an [option file](#) prior to starting up the server. For example:

```
[mariadb]
..
thread_handling=pool-of-threads
thread_pool_size=32
thread_pool_stall_limit=300
thread_pool_oversubscribe=10
```

To clarify, the `thread_pool_oversubscribe` system variable does not play any part in the creation of new **worker threads**. The `thread_pool_oversubscribe` system variable is only used to determine how many **worker threads** should remain active in a thread group, once a thread group is already oversubscribed due to stalls.

In general, the default value of `3` should be adequate for most users. Most users should not need to change the value of the `thread_pool_oversubscribe` system variable.

3.3.7.31 Thread Pool System and Status Variables

3.3.8.5 Thread Pool in MariaDB 5.1 - 5.3

Contents

1. [About pool of threads](#)
2. [Instructions](#)

This article describes the old thread pool in [MariaDB 5.1 - 5.3](#).

[MariaDB 5.5](#) and later use an improved thread pool - see [Thread pool in MariaDB](#).

About pool of threads

This is an extended version of the pool-of-threads code from MySQL 6.0. This allows you to use a limited set of threads to handle all queries, instead of the old 'one-thread-per-connection' style. In recent times, its also been referred to as "thread pool" or "thread pooling" as this feature (in a different implementation) is available in Enterprise editions of MySQL (not in the Community edition).

This can be a very big win if most of your queries are short running queries and there are few table/row locks in your system.

Instructions

To enable pool-of-threads you must first run configure with the `--with-libevent` option. (This is automatically done if you use any 'max' scripts in the BUILD directory):

```
./configure --with-libevent
```

When starting mysqld with the pool of threads code you should use

```
mysqld --thread-handling=pool-of-threads --thread-pool-size=20
```

Default values are:

```
thread-handling= one-thread-per-connection
thread-pool-size= 20
```

One issue with pool-of-threads is that if all worker threads are doing work (like running long queries) or are locked by a row/table lock no new connections can be established and you can't login and find out what's wrong or login and kill queries.

To help this, we have introduced two new options for mysqld; [extra_port](#) and [extra_max_connections](#):

```
--extra-port=#           (Default 0)
--extra-max-connections=# (Default 1)
```

If [extra-port](#) is $\neq 0$ then you can connect `max_connections` number of normal threads + 1 extra SUPER user through the 'extra-port' TCP/IP port. These connections use the old one-thread-per-connection method.

To connect with through the extra port, use:

```
mysql --port='number-of-extra-port' --protocol=tcp
```

This allows you to freely use, on connection bases, the optimal connection/thread model.

3.3.9 Thread States

Thread states can be viewed with the `STATE` values listed by the [SHOW PROCESSLIST](#) statement or in the [Information Schema PROCESSLIST Table](#) as well as the `PROCESSLIST_STATE` value listed in the [Performance Schema threads Table](#). `Slave_IO_State` shown by [SHOW SLAVE STATUS](#) also shows slave-related thread states.

Delayed Insert Connection Thread States

Thread states related to the connection thread that processes INSERT DELAYED statements

Delayed Insert Handler Thread States

Thread states related to the handler thread that inserts the results of INSERT DELAYED statements

Event Scheduler Thread States

Thread states related to the Event Scheduler

General Thread States

Thread states

Master Thread States

Thread states related to replication master threads

Query Cache Thread States

Thread states related to the query cache

Replica I/O Thread States

[Thread states related to replica I/O threads](#)

Slave Connection Thread States

[Thread states related to slave connection threads](#)

Slave SQL Thread States

[Thread states related to replication slave SQL threads.](#)

3.3.9.1 Delayed Insert Connection Thread States

This article documents thread states that are related to the connection thread that processes `INSERT DELAYED` statements.

These correspond to the `STATE` values listed by the `SHOW PROCESSLIST` statement or in the [Information Schema PROCESSLIST Table](#) as well as the `PROCESSLIST_STATE` value listed in the [Performance Schema threads Table](#).

Value	Description
allocating local table	Preparing to allocate rows to the delayed-insert handler thread. Follows from the <code>got handler lock</code> state.
Creating delayed handler	Creating a handler for the delayed-inserts.
got handler lock	Lock to access the delayed-insert handler thread has been received. Follows from the <code>waiting for handler lock</code> state and before the <code>allocating local table</code> state.
got old table	The initialization phase is over. Follows from the <code>waiting for handler open</code> state.
storing row into queue	Adding new row to the list of rows to be inserted by the delayed-insert handler thread.
waiting for delay_list	Initializing (trying to find the delayed-insert handler thread).
waiting for handler insert	Waiting for new inserts, as all inserts have been processed.
waiting for handler lock	Waiting for delayed insert-handler lock to access the delayed-insert handler thread.
waiting for handler open	Waiting for the delayed-insert handler thread to initialize. Follows from the <code>Creating delayed handler</code> state and before the <code>got old table</code> state.

3.3.9.2 Delayed Insert Handler Thread States

This article documents thread states that are related to the handler thread that inserts the results of `INSERT DELAYED` statements.

These correspond to the `STATE` values listed by the `SHOW PROCESSLIST` statement or in the [Information Schema PROCESSLIST Table](#) as well as the `PROCESSLIST_STATE` value listed in the [Performance Schema threads Table](#).

Value	Description
insert	About to insert rows into the table.
reschedule	Sleeping in order to let other threads function, after inserting a number of rows into the table.
upgrading lock	Attempting to get lock on the table in order to insert rows.
Waiting for INSERT	Waiting for the delayed-insert connection thread to add rows to the queue.

3.3.9.3 Event Scheduler Thread States

This article documents thread states that are related to `event` scheduling and execution. These include the Event Scheduler

thread, threads that terminate the Event Scheduler, and threads for executing events.

These correspond to the `STATE` values listed by the [SHOW PROCESSLIST](#) statement or in the [Information Schema PROCESSLIST Table](#) as well as the `PROCESSLIST_STATE` value listed in the [Performance Schema threads Table](#)

Value	Description
Clearing	Thread is terminating.
Initialized	Thread has be initialized.
Waiting for next activation	The event queue contains items, but the next activation is at some time in the future.
Waiting for scheduler to stop	Waiting for the event scheduler to stop after issuing <code>SET GLOBAL event_scheduler=OFF</code> .
Waiting on empty queue	Sleeping, as the event scheduler's queue is empty.

3.3.9.4 General Thread States

This article documents the major general thread states. More specific lists related to [delayed inserts](#), [replication](#), the [query cache](#) and the [event scheduler](#) are listed in:

- [Event Scheduler Thread States](#)
- [Query Cache Thread States](#)
- [Master Thread States](#)
- [Slave Connection Thread States](#)
- [Slave I/O Thread States](#)
- [Slave SQL Thread States](#)

These correspond to the `STATE` values listed by the [SHOW PROCESSLIST](#) statement or in the [Information Schema PROCESSLIST Table](#) as well as the `PROCESSLIST_STATE` value listed in the [Performance Schema threads Table](#)

Value	Description
After create	The function that created (or tried to create) a table (temporary or non-temporary) has just ended.
Analyzing	Calculating table key distributions, such as when running an ANALYZE TABLE statement.
checking permissions	Checking to see whether the permissions are adequate to perform the statement.
Checking table	Checking the table.
cleaning up	Preparing to reset state variables and free memory after executing a command.
closing tables	Flushing the changes to disk and closing the table. This state will only persist if the disk is full or under extremely high load.
converting HEAP to Aria	Converting an internal MEMORY temporary table into an on-disk Aria temporary table.
converting HEAP to MyISAM	Converting an internal MEMORY temporary table into an on-disk MyISAM temporary table.
copy to tmp table	A new table has been created as part of an ALTER TABLE statement, and rows are about to be copied into it.
Copying to group table	Sorting the rows by group and copying to a temporary table, which occurs when a statement has different GROUP BY and ORDER BY criteria.
Copying to tmp table	Copying to a temporary table in memory.
Copying to tmp table on disk	Copying to a temporary table on disk, as the resultset is too large to fit into memory.
Creating index	Processing an ALTER TABLE ... ENABLE KEYS for an Aria or MyISAM table.
Creating sort index	Processing a SELECT statement resolved using an internal temporary table.
creating table	Creating a table (temporary or non-temporary).
Creating tmp table	Creating a temporary table (in memory or on-disk).
deleting from main table	Deleting from the first table in a multi-table delete , saving columns and offsets for use in deleting from the other tables.
deleting from reference tables	Deleting matched rows from secondary reference tables as part of a multi-table delete .

discard_or_import_tablespace	Processing an ALTER TABLE ... IMPORT TABLESPACE or ALTER TABLE ... DISCARD TABLESPACE statement.
end	State before the final cleanup of an ALTER TABLE , CREATE VIEW , DELETE , INSERT , SELECT , or UPDATE statement.
executing	Executing a statement.
Execution of init_command	Executing statements specified by the <code>--init_command</code> mariadb client option.
filling schema table	A table in the information_schema database is being built.
freeing items	Freeing items from the query cache after executing a command. Usually followed by the <code>cleaning up</code> state.
Flushing tables	Executing a FLUSH TABLES statement and waiting for other threads to close their tables.
FULLTEXT initialization	Preparing to run a full-text search. This includes running the fulltext search (<code>MATCH ... AGAINST</code>) and creating a list of the result in memory
init	About to initialize an ALTER TABLE , DELETE , INSERT , SELECT , or UPDATE statement. Could be performing query cache cleanup, or flushing the binary log or InnoDB log.
Killed	Thread will abort next time it checks the kill flag. Requires waiting for any locks to be released.
Locked	Query has been locked by another query.
logging slow query	Writing statement to the slow query log .
NULL	State used for SHOW PROCESSLIST .
login	Connection thread has not yet been authenticated.
manage keys	Enabling or disabling a table index.
Opening table[s]	Trying to open a table. Usually very quick unless the limit set by table_open_cache has been reached, or an ALTER TABLE or LOCK TABLE is in progress.
optimizing	Server is performing initial optimizations in for a query.
preparing	State occurring during query optimization.
Purging old relay logs	Relay logs that are no longer needed are being removed.
query end	Query has finished being processed, but items have not yet been freed (the <code>freeing items</code> state).
Reading file	Server is reading the file (for example during LOAD DATA INFILE).
Reading from net	Server is reading a network packet.
Removing duplicates	Duplicated rows being removed before sending to the client. This happens when <code>SELECT DISTINCT</code> is used in a way that the distinct operation could not be optimized at an earlier point.
removing tmp table	Removing an internal temporary table after processing a SELECT statement.
rename	Renaming a table.
rename result table	Renaming a table that results from an ALTER TABLE statement having created a new table.
Reopen tables	Table is being re-opened after thread obtained a lock but the underlying table structure had changed, so the lock was released.
Repair by sorting	Indexes are being created with the use of a sort. Much faster than the related <code>Repair with keycache</code> .
Repair done	Multi-threaded repair has been completed.
Repair with keycache	Indexes are being created through the key cache, one-by-one. Much slower than the related <code>Repair by sorting</code> .
Rolling back	A transaction is being rolled back.
Saving state	New table state is being saved. For example, after, analyzing a MyISAM table, the key distributions, rowcount etc. are saved to the <code>.MYI</code> file.

Searching rows for update	Finding matching rows before performing an UPDATE , which is needed when the UPDATE would change the index used for the UPDATE
Sending data	Sending data to the client as part of processing a SELECT statement or other statements that returns data like INSERT ... RETURNING . Often the longest-occurring state as it also include all reading from tables and disk read activities. Where an aggregation or un-indexed filtering occurs there is significantly more rows read than what is sent to the client.
setup	Setting up an ALTER TABLE operation.
Sorting for group	Sorting as part of a GROUP BY
Sorting for order	Sorting as part of an ORDER BY
Sorting index	Sorting index pages as part of a table optimization operation.
Sorting result	Processing a SELECT statement using a non-temporary table.
statistics	Calculating statistics as part of deciding on a query execution plan. Usually a brief state unless the server is disk-bound.
System lock	Requesting or waiting for an <i>external</i> lock for a specific table. The storage engine determines what kind of <i>external</i> lock to use. For example, the MyISAM storage engine uses file-based locks. However, MyISAM's <i>external</i> locks are disabled by default, due to the default value of the skip_external_locking system variable. Transactional storage engines such as InnoDB also register the transaction or statement with MariaDB's transaction coordinator while in this thread state. See MDEV-19391 for more information about that.
Table lock	About to request a table's <i>internal</i> lock after acquiring the table's <i>external</i> lock. This thread state occurs after the <i>System lock</i> thread state.
update	About to start updating table.
Updating	Searching for and updating rows in a table.
updating main table	Updating the first table in a multi-table update, and saving columns and offsets for use in the other tables.
updating reference tables	Updating the secondary (reference) tables in a multi-table update
updating status	This state occurs after a query's execution is complete. If the query's execution time exceeds long_query_time , then Slow_queries is incremented, and if the slow query log is enabled, then the query is logged. If the SERVER_AUDIT plugin is enabled, then the query is also logged into the audit log at this stage. If the userstats plugin is enabled, then CPU statistics are also updated at this stage.
User lock	About to request or waiting for an advisory lock from a GET LOCK() call. For SHOW PROFILE , means requesting a lock only.
User sleep	A SLEEP() call has been invoked.
Waiting for commit lock	FLUSH TABLES WITH READ LOCK is waiting for a commit lock, or a statement resulting in an explicit or implicit commit is waiting for a read lock to be released. This state was called <code>Waiting for all running commits to finish</code> in earlier versions.
Waiting for global read lock	Waiting for a global read lock.
Waiting for table level lock	External lock acquired, and internal lock about to be requested. Occurs after the <code>System lock</code> state. In earlier versions, this was called <code>Table lock</code> .
Waiting for xx lock	Waiting to obtain a lock of type <code>xx</code> .
Waiting on cond	Waiting for an unspecified condition to occur.
Writing to net	Writing a packet to the network.

3.3.9.5 Master Thread States

This article documents thread states that are related to [replication](#) master threads. These correspond to the `STATE` values listed by the [SHOW PROCESSLIST](#) statement or in the [Information Schema PROCESSLIST Table](#) as well as the `PROCESSLIST_STATE` value listed in the [Performance Schema threads Table](#).

Value	Description
-------	-------------

Finished reading one binlog; switching to next binlog	After completing one binary log , the next is being opened for sending to the slave.
Master has sent all binlog to slave; waiting for binlog to be updated	All events have been read from the binary logs and sent to the slave. Now waiting for the binary log to be updated with new events.
Sending binlog event to slave	An event has been read from the binary log , and is now being sent to the slave.
Waiting to finalize termination	State that only occurs very briefly while the thread is terminating.

3.3.9.6 Query Cache Thread States

This article documents thread states that are related to the [Query Cache](#). These correspond to the `STATE` values listed by the [SHOW PROCESSLIST](#) statement or in the [Information Schema PROCESSLIST Table](#) as well as the `PROCESSLIST_STATE` value listed in the [Performance Schema threads Table](#).

Value	Description
checking privileges on cached query	Checking whether the user has permission to access a result in the query cache.
checking query cache for query	Checking whether the current query exists in the query cache.
invalidating query cache entries	Marking query cache entries as invalid as the underlying tables have changed.
sending cached result to client	A result found in the query cache is being sent to the client.
storing result in query cache	Saving the the result of a query into the query cache.
Waiting for query cache lock	Waiting to take a query cache lock.

3.3.9.7 Slave Connection Thread States

This article documents thread states that are related to connection threads that occur on a [replication](#) slave. These correspond to the `STATE` values listed by the [SHOW PROCESSLIST](#) statement or in the [Information Schema PROCESSLIST Table](#) as well as the `PROCESSLIST_STATE` value listed in the [Performance Schema threads Table](#).

Value	Description
Changing master	Processing a CHANGE MASTER TO statement.
Killing slave	Processing a STOP SLAVE statement.
Opening master dump table	A table has been created from a master dump and is now being opened.
Reading master dump table data	After the table created by a master dump (the <code>Opening master dump table state</code>) the table is now being read.
Rebuilding the index on master dump table	After the table created by a master dump has been opened and read (the <code>Reading master dump table data state</code>), the index is built.

3.3.9.8 Replica I/O Thread States

This article documents thread states that are related to [replica](#) I/O threads. These correspond to the `Slave_IO_State` shown by [SHOW REPLICA STATUS](#) and the `STATE` values listed by the [SHOW PROCESSLIST](#) statement or in the [Information Schema PROCESSLIST Table](#) as well as the `PROCESSLIST_STATE` value listed in the [Performance Schema threads Table](#).

Value	Description
Checking master version	Checking the primary's version, which only occurs very briefly after establishing a connection with the primary.
Connecting to master	Attempting to connect to primary.

Queueing master event to the relay log	Event is being copied to the relay log after being read, where it can be processed by the SQL thread.
Reconnecting after a failed binlog dump request	Attempting to reconnect to the primary after a previously failed binary log dump request.
Reconnecting after a failed master event read	Attempting to reconnect to the primary after a previously failed request. After successfully connecting, the state will change to <code>Waiting for master to send event</code> .
Registering slave on master	Registering the replica on the primary, which only occurs very briefly after establishing a connection with the primary.
Requesting binlog dump	Requesting the contents of the binary logs from the given log file name and position. Only occurs very briefly after establishing a connection with the primary.
Waiting for master to send event	Waiting for binary log events to arrive after successfully connecting. If there are no new events on the primary, this state can persist for as many seconds as specified by the <code>slave_net_timeout</code> system variable, after which the thread will reconnect. Prior to MariaDB 10.6.18 , MariaDB 10.11.8 , MariaDB 11.0.6 , MariaDB 11.1.5 , MariaDB 11.2.4 and MariaDB 11.4.2 , the time was from SLAVE START. From these versions, the time is since reading the last event.
Waiting for slave mutex on exit	Waiting for replica mutex while the thread is stopping. Only occurs very briefly.
Waiting for the slave SQL thread to free enough relay log space.	Relay log has reached its maximum size, determined by <code>relay_log_space_limit</code> (no limit by default), so waiting for the SQL thread to free up space by processing enough relay log events.
Waiting for master update	State before connecting to primary.
Waiting to reconnect after a failed binlog dump request	Waiting to reconnect after a binary log dump request has failed due to disconnection. The length of time in this state is determined by the <code>MASTER_CONNECT_RETRY</code> clause of the CHANGE MASTER TO statement.
Waiting to reconnect after a failed master event read	Sleeping while waiting to reconnect after a disconnection error. The time in seconds is determined by the <code>MASTER_CONNECT_RETRY</code> clause of the CHANGE MASTER TO statement.

3.3.9.9 Slave SQL Thread States

This article documents thread states that are related to [replication](#) slave SQL threads. These correspond to the `Slave_SQL_State` shown by [SHOW SLAVE STATUS](#) as well as the `STATE` values listed by the [SHOW PROCESSLIST](#) statement and the [Information Schema PROCESSLIST](#) as well as the `PROCESSLIST_STATE` value listed in the [Performance Schema threads Table](#).

Value	Description
Apply log event	Log event is being applied.
Making temp file	Creating a temporary file containing the row data as part of a LOAD DATA INFILE statement.
Reading event from the relay log	Reading an event from the relay log in order to process the event.

Slave has read all relay log; waiting for the slave I/O thread to update it	All relay log events have been processed, now waiting for the I/O thread to write new events to the relay log.
Waiting for work from SQL thread	In parallel replication the worker thread is waiting for more things from the SQL thread.
Waiting for prior transaction to start commit before starting next transaction	In parallel replication the worker thread is waiting for conflicting things to end before starting executing.
Waiting for worker threads to be idle	Happens in parallel replication when moving to a new binary log after a master restart. All slave temporary files are deleted and worker threads are restarted.
Waiting due to global read lock	In parallel replication when worker threads are waiting for a global read lock to be released.
Waiting for worker threads to pause for global read lock	FLUSH TABLES WITH READ LOCK is waiting for worker threads to finish what they are doing.
Waiting while replication worker thread pool is busy	Happens in parallel replication during a FLUSH TABLES WITH READ LOCK or when changing number of parallel workers.
Waiting for other master connection to process GTID received on multiple master connections	A worker thread noticed that there is already another thread executing the same GTID from another connection and it's waiting for the other to complete.
Waiting for slave mutex on exit	Thread is stopping. Only occurs very briefly.
Waiting for the next event in relay log	State before reading next event from the relay log .

5.3.2.7 InnoDB Buffer Pool

5.3.2.8 InnoDB Change Buffering

3.3.9.12 Query Cache

Contents

1. [Setting Up the Query Cache](#)
2. [How the Query Cache Works](#)
3. [Queries Stored in the Query Cache](#)

10. [Transactions and the Query Cache](#)
11. [Query Cache Internal Structure](#)
12. [Timeout and Mutex Contention](#)
13. [SQL_NO_CACHE and SQL_CACHE](#)

The query cache stores results of SELECT queries so that if the identical query is received in future, the results can be quickly returned.

This is extremely useful in high-read, low-write environments (such as most websites). It does not scale well in environments with high throughput on multi-core machines, so it is disabled by default.

Note that the query cache cannot be enabled in certain environments. See [Limitations](#).

Setting Up the Query Cache

Unless MariaDB has been specifically built without the query cache, the query cache will always be available, although inactive. The [have_query_cache](#) server variable will show whether the query cache is available.

```
SHOW VARIABLES LIKE 'have_query_cache';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| have_query_cache | YES |
+-----+-----+
```

If this is set to `NO`, you cannot enable the query cache unless you rebuild or reinstall a version of MariaDB with the cache available.

To see if the cache is enabled, view the `query_cache_type` server variable. It is enabled by default in MariaDB versions up to 10.1.6, but disabled starting with [MariaDB 10.1.7](#) - if needed enable it by setting `query_cache_type` to `1`.

Although enabled in versions prior to [MariaDB 10.1.7](#), the `query_cache_size` is by default 0KB there, which effectively disables the query cache. From 10.1.7 on the cache size defaults to 1MB. If needed set the cache to a size large enough amount, for example:

```
SET GLOBAL query_cache_size = 1000000;
```

Starting from [MariaDB 10.1.7](#), `query_cache_type` is automatically set to `ON` if the server is started with the `query_cache_size` set to a non-zero (and non-default) value.

See [Limiting the size of the Query Cache](#) below for details.

How the Query Cache Works

When the query cache is enabled and a new `SELECT` query is processed, the query cache is examined to see if the query appears in the cache.

Queries are considered identical if they use the same database, same protocol version and same default character set. Prepared statements are always considered as different to non-prepared statements, see [Query cache internal structure](#) for more info.

If the identical query is not found in the cache, the query will be processed normally and then stored, along with its result set, in the query cache. If the query is found in the cache, the results will be pulled from the cache, which is much quicker than processing it normally.

Queries are examined in a case-sensitive manner, so :

```
SELECT * FROM t
```

Is different from :

```
select * from t
```

Comments are also considered and can make the queries differ, so :

```
/* retry */SELECT * FROM t
```

Is different from :

```
/* retry2 */SELECT * FROM t
```

See the `query_cache_strip_comments` server variable for an option to strip comments before searching.

Each time changes are made to the data in a table, all affected results in the query cache are cleared. It is not possible to retrieve stale data from the query cache.

When the space allocated to query cache is exhausted, the oldest results will be dropped from the cache.

When using `query_cache_type=ON`, and the query specifies `SQL_NO_CACHE` (case-insensitive), the server will not cache the query and will not fetch results from the query cache.

When using `query_cache_type=DEMAND` (after [MDEV-6631](#) feature request) and the query specifies `SQL_CACHE`, the server will cache the query.

One important point of [MDEV-6631](#) is : switching between `query_cache_type=ON` and `query_cache_type=DEMAND` can "turn off" query cache of old queries without the `SQL_CACHE` string, that's not yet defined if we should include another

Queries Stored in the Query Cache

If the `query_cache_type` system variable is set to `1`, or `ON`, all queries fitting the size constraints will be stored in the cache unless they contain a `SQL_NO_CACHE` clause, or are of a nature that caching makes no sense, for example making use of a function that returns the current time. Queries with `SQL_NO_CACHE` will not attempt to acquire query cache lock.

If any of the following functions are present in a query, it will not be cached. Queries with these functions are sometimes called 'non-deterministic' - don't get confused with the use of this term in other contexts.

<code>BENCHMARK()</code>	<code>CONNECTION_ID()</code>
<code>CONVERT_TZ()</code>	<code>CURDATE()</code>
<code>CURRENT_DATE()</code>	<code>CURRENT_TIME()</code>
<code>CURRENT_TIMESTAMP()</code>	<code>CURTIME()</code>
<code>DATABASE()</code>	<code>ENCRYPT()</code> (one parameter)
<code>FOUND_ROWS()</code>	<code>GET_LOCK()</code>
<code>LAST_INSERT_ID()</code>	<code>LOAD_FILE()</code>
<code>MASTER_POS_WAIT()</code>	<code>NOW()</code>
<code>RAND()</code>	<code>RELEASE_LOCK()</code>
<code>SLEEP()</code>	<code>SYSDATE()</code>
<code>UNIX_TIMESTAMP()</code> (no parameters)	<code>USER()</code>
<code>UUID()</code>	<code>UUID_SHORT()</code>

A query will also not be added to the cache if:

- It is of the form:
 - `SELECT SQL_NO_CACHE ...`
 - `SELECT ... INTO OUTFILE ...`
 - `SELECT ... INTO DUMPFILE ...`
 - `SELECT ... FOR UPDATE`
 - `SELECT * FROM ... WHERE autoincrement_column IS NULL`
 - `SELECT ... LOCK IN SHARE MODE`
- It uses `TEMPORARY` table
- It uses no tables at all
- It generates a warning
- The user has a column-level privilege on any table in the query
- It accesses a table from `INFORMATION_SCHEMA`, `mysql` or the `performance_schema` database
- It makes use of user or local variables
- It makes use of stored functions
- It makes use of user-defined functions
- It is inside a transaction with the `SERIALIZABLE` isolation level
- It is querying a table inside a transaction after the same table executed a query cache invalidation using `INSERT`, `UPDATE` or `DELETE`

The query itself can also specify that it is not to be stored in the cache by using the `SQL_NO_CACHE` attribute. Query-level control is an effective way to use the cache more optimally.

It is also possible to specify that *no* queries must be stored in the cache unless the query requires it. To do this, the `query_cache_type` server variable must be set to `2`, or `DEMAND`. Then, only queries with the `SQL_CACHE` attribute are cached.

Limiting the Size of the Query Cache

There are two main ways to limit the size of the query cache. First, the overall size in bytes is determined by the `query_cache_size` server variable. About 40KB is needed for various query cache structures.

The query cache size is allocated in 1024 byte-blocks, thus it should be set to a multiple of 1024.

The query result is stored using a minimum block size of `query_cache_min_res_unit`. Check two conditions to use a good value of this variable: Query cache insert result blocks with locks, each new block insert lock query cache, a small value will increase locks and fragmentation and waste less memory for small results, a big value will increase memory use wasting more memory for small results but it reduce locks. Test with your workload for fine tune this variable.

If the [strict mode](#) is enabled, setting the query cache size to an invalid value will cause an error. Otherwise, it will be set to the nearest permitted value, and a warning will be triggered.

```
SHOW VARIABLES LIKE 'query_cache_size';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| query_cache_size | 67108864 |
+-----+-----+

SET GLOBAL query_cache_size = 8000000;
Query OK, 0 rows affected, 1 warning (0.03 sec)

SHOW VARIABLES LIKE 'query_cache_size';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| query_cache_size | 7999488 |
+-----+-----+
```

The ideal size of the query cache is very dependent on the specific needs of each system. Setting a value too small will result in query results being dropped from the cache when they could potentially be re-used later. Setting a value too high could result in reduced performance due to lock contention, as the query cache is locked during updates.

The second way to limit the cache is to have a maximum size for each set of query results. This prevents a single query with a huge result set taking up most of the available memory and knocking a large number of smaller queries out of the cache. This is determined by the [query_cache_limit](#) server variable.

If you attempt to set a query cache that is too small (the amount depends on the architecture), the resizing will fail and the query cache will be set to zero, for example :

```
SET GLOBAL query_cache_size=40000;
Query OK, 0 rows affected, 2 warnings (0.03 sec)

SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1292 | Truncated incorrect query_cache_size value: '40000' |
| Warning | 1282 | Query cache failed to set size 39936; new query cache size is 0 |
+-----+-----+-----+
```

Examining the Query Cache

A number of status variables provide information about the query cache.

```
SHOW STATUS LIKE 'Qcache%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Qcache_free_blocks | 1158 |
| Qcache_free_memory | 3760784 |
| Qcache_hits | 31943398 |
| Qcache_inserts | 42998029 |
| Qcache_lowmem_prunes | 34695322 |
| Qcache_not_cached | 652482 |
| Qcache_queries_in_cache | 4628 |
| Qcache_total_blocks | 11123 |
+-----+-----+
```

`Qcache_inserts` contains the number of queries added to the query cache, `Qcache_hits` contains the number of queries that have made use of the query cache, while `Qcache_lowmem_prunes` contains the number of queries that were dropped from the cache due to lack of memory.

The above example could indicate a poorly performing cache. More queries have been added, and more queries have been dropped, than have actually been used.

Note that before [MariaDB 5.5](#), queries returned from the query cache did not increment the `Com_select` status variable, so to find the total number of valid queries run on the server, add `Com_select` to `Qcache_hits`. Starting from [MariaDB 5.5](#), results returned by the query cache count towards `Com_select` (see [MDEV-4981](#) [↗](#)).

The [QUERY_CACHE_INFO](#) plugin creates the [QUERY_CACHE_INFO](#) table in the [INFORMATION_SCHEMA](#), allowing you to examine the contents of the query cache.

Query Cache Fragmentation

The Query Cache uses blocks of variable length, and over time may become fragmented. A high `Qcache_free_blocks` relative to `Qcache_total_blocks` may indicate fragmentation. [FLUSH QUERY CACHE](#) will defragment the query cache without dropping any queries :

```
FLUSH QUERY CACHE;
```

After this, there will only be one free block :

```
SHOW STATUS LIKE 'Qcache%';
```

Variable_name	Value
Qcache_free_blocks	1
Qcache_free_memory	6101576
Qcache_hits	31981126
Qcache_inserts	43002404
Qcache_lowmem_prunes	34696486
Qcache_not_cached	655607
Qcache_queries_in_cache	4197
Qcache_total_blocks	8833

Emptying and disabling the Query Cache

To empty or clear all results from the query cache, use [RESET QUERY CACHE](#). [FLUSH TABLES](#) will have the same effect.

Setting either `query_cache_type` or `query_cache_size` to 0 will disable the query cache, but to free up the most resources, set both to 0 when you wish to disable caching.

Limitations

- The query cache needs to be disabled in order to use [OQGRAPH](#).
- The query cache is not used by the [Spider](#) storage engine (amongst others).
- The query cache also needs to be disabled for MariaDB [Galera](#) cluster versions prior to "5.5.40-galera", "10.0.14-galera" and "10.1.2".

LOCK TABLES and the Query Cache

The query cache can be used when tables have a write lock (which may seem confusing since write locks should avoid table reads). This behaviour can be changed by setting the `query_cache_wlock_invalidate` system variable to `ON`, in which case each write lock will invalidate the table query cache. Setting to `OFF`, the default, means that cached queries can be returned even when a table lock is being held. For example:

```

1> SELECT * FROM T1
+----+
| a |
+----+
| 1 |
+----+
-- Here the query is cached

-- From another connection execute:
2> LOCK TABLES T1 WRITE;

-- Expected result with: query_cache_wlock_invalidate = OFF
1> SELECT * FROM T1
+----+
| a |
+----+
| 1 |
+----+
-- read from query cache

-- Expected result with: query_cache_wlock_invalidate = ON
1> SELECT * FROM T1
-- Waiting Table Write Lock

```

Transactions and the Query Cache

The query cache handles transactions. Internally a flag (FLAGS_IN_TRANS) is set to 0 when a query was executed outside a transaction, and to 1 when the query was inside a transaction (**BEGIN** / **COMMIT** / **ROLLBACK**). This flag is part of the "query cache hash", in others words one query inside a transaction is different from a query outside a transaction.

Queries that change rows (**INSERT** / **UPDATE** / **DELETE** / **TRUNCATE**) inside a transaction will invalidate all queries from the table, and turn off the query cache to the changed table. Transactions that don't end with **COMMIT** / **ROLLBACK** check that even without **COMMIT** / **ROLLBACK**, the query cache is turned off to allow row level locking and consistency level.

Examples:

```

SELECT * FROM T1 <first insert to query cache, using FLAGS_IN_TRANS=0>
+----+
| a |
+----+
| 1 |
+----+

```

```

BEGIN;
SELECT * FROM T1 <first insert to query cache, using FLAGS_IN_TRANS=1>
+----+
| a |
+----+
| 1 |
+----+

```

```

SELECT * FROM T1 <result from query cache, using FLAGS_IN_TRANS=1>
+----+
| a |
+----+
| 1 |
+----+

```

```

INSERT INTO T1 VALUES(2); <invalidate queries from table T1 and disable query cache to table T1>

```

```
SELECT * FROM T1 <don't use query cache, a normal query from innodb table>
+----+
| a |
+----+
| 1 |
| 2 |
+----+
```

```
SELECT * FROM T1 <don't use query cache, a normal query from innodb table>
+----+
| a |
+----+
| 1 |
| 2 |
+----+
```

```
COMMIT; <query cache is now turned on to T1 table>
```

```
SELECT * FROM T1 <first insert to query cache, using FLAGS_IN_TRANS=0>
+----+
| a |
+----+
| 1 |
+----+
```

```
SELECT * FROM T1 <result from query cache, using FLAGS_IN_TRANS=0>
+----+
| a |
+----+
| 1 |
+----+
```

Query Cache Internal Structure

Internally, each flag that can change a result using the same query is a different query. For example, using the latin1 charset and using the utf8 charset with the same query are treated as different queries by the query cache.

Some fields that differentiate queries are (from "Query_cache_query_flags" internal structure) :

- query (string)
- current database schema name (string)
- client long flag (0/1)
- client protocol 4.1 (0/1)
- protocol type (internal value)
- more results exists (protocol flag)
- in trans (inside transaction or not)
- autocommit ([autocommit](#) session variable)
- pkt_nr (protocol flag)
- character set client ([character_set_client](#) session variable)
- character set results ([character_set_results](#) session variable)
- collation connection ([collation_connection](#) session variable)
- limit ([sql_select_limit](#) session variable)
- time zone ([time_zone](#) session variable)
- sql_mode ([sql_mode](#) session variable)
- max_sort_length ([max_sort_length](#) session variable)
- group_concat_max_len ([group_concat_max_len](#) session variable)
- default_week_format ([default_week_format](#) session variable)
- div_precision_increment ([div_precision_increment](#) session variable)
- lc_time_names ([lc_time_names](#) session variable)

More information can be found by viewing the source code ([MariaDB 10.1](#)) :

- https://github.com/MariaDB/server/blob/10.1/sql/sql_cache.cc
- https://github.com/MariaDB/server/blob/10.1/sql/sql_cache.h

Timeout and Mutex Contention

When searching for a query inside the query cache, a `try_lock` function waits with a timeout of 50ms. If the lock fails, the query isn't executed via the query cache. This timeout is hard coded ([MDEV-6766](#) include two variables to tune this timeout).

From the `sql_cache.cc`, function "try_lock" using `TIMEOUT` :

```
struct timespec waittime;
set_timespec_nsec(waittime, (ulong) (50000000L)); /* Wait for 50 msec */
int res= mysql_cond_timedwait(&COND_cache_status_changed,
                             &structure_guard_mutex, &waittime);

if (res == ETIMEDOUT)
    break;
```

When inserting a query inside the query cache or aborting a query cache insert (using the `KILL` command for example), a `try_lock` function waits until the query cache returns; no timeout is used in this case.

When two processes execute the same query, only the last process stores the query result. All other processes increase the `Qcache_not_cached` status variable.

SQL_NO_CACHE and SQL_CACHE

There are two aspects to the query cache: placing a query in the cache, and retrieving it from the cache.

1. Adding a query to the query cache. This is done automatically for cacheable queries (see ([Queries Stored in the Query Cache](#)) when the `query_cache_type` system variable is set to `1`, or `ON` and the query contains no `SQL_NO_CACHE` clause, or when the `query_cache_type` system variable is set to `2`, or `DEMAND`, and the query contains the `SQL_CACHE` clause.
2. Retrieving a query from the cache. This is done after the server receives the query and before the query parser. In this case one point should be considered:

When using `SQL_NO_CACHE`, it should be after the first `SELECT` hint, for example :

```
SELECT SQL_NO_CACHE .... FROM (SELECT SQL_CACHE ...) AS temp_table
```

instead of

```
SELECT SQL_CACHE .... FROM (SELECT SQL_NO_CACHE ...) AS temp_table
```

The second query will be checked. The query cache only checks if `SQL_NO_CACHE/SQL_CACHE` exists after the first `SELECT`. (More info at [MDEV-6631](#))

5.3.13.8 Segmented Key Cache

3.3.4.2.5 Subquery Cache

3.3.9.15 Thread Command Values

A thread can have any of the following `COMMAND` values (displayed by the `COMMAND` field listed by the `SHOW PROCESSLIST` statement or in the [Information Schema PROCESSLIST Table](#), as well as the `PROCESSLIST_COMMAND` value listed in the [Performance Schema threads Table](#)). These indicate the nature of the thread's activity.

Value	Description
Binlog Dump	Master thread for sending binary log contents to a slave.
Change user	Executing a change user operation.
Close stmt	Closing a prepared statement .
Connect	Replication slave is connected to its master.
Connect Out	Replication slave is in the process of connecting to its master.
Create DB	Executing an operation to create a database.

Daemon	Internal server thread rather than for servicing a client connection.
Debug	Generating debug information.
Delayed insert	A delayed-insert handler.
Drop DB	Executing an operation to drop a database.
Error	Error.
Execute	Executing a prepared statement .
Fetch	Fetching the results of an executed prepared statement .
Field List	Retrieving table column information.
Init DB	Selecting default database.
Kill	Killing another thread.
Long Data	Retrieving long data from the result of executing a prepared statement .
Ping	Handling a server ping request.
Prepare	Preparing a prepared statement .
Processlist	Preparing processlist information about server threads.
Query	Executing a statement.
Quit	In the process of terminating the thread.
Refresh	Flushing a table, logs or caches, or refreshing replication server or status variable information.
Register Slave	Registering a slave server.
Reset stmt	Resetting a prepared statement .
Set option	Setting or resetting a client statement execution option.
Sleep	Waiting for the client to send a new statement.
Shutdown	Shutting down the server.
Statistics	Preparing status information about the server.
Table Dump	Sending the contents of a table to a slave.
Time	Not used.

3.3.10 Optimizing Data Structure

Good database design is an important part of a well-run system. This section looks at some of the elements to consider.

Numeric vs String Fields

[Choosing numeric over string fields](#)

Optimizing MEMORY Tables

[MEMORY tables are a good choice for data that needs to be accessed often, a...](#)

Optimizing String and Character Fields

[Optimizations when comparing string columns and VARCHAR vs BLOB](#)

3.3.10.1 Numeric vs String Fields

A large numeric value is stored in far fewer bytes than the equivalent string value. It is therefore faster to move and compare numeric data, so it's best to choose numeric columns for unique id's and other similar fields.

3.3.10.2 Optimizing MEMORY Tables

MEMORY tables are a good choice for data that needs to be accessed often, and is rarely updated. Being in memory, it's not suitable for critical data or for storage, but if data can be moved to memory for reading without needing to be regenerated often, if at all, it can provide a significant performance boost.

The **MEMORY Storage Engine** has a key feature in that it permits its indexes to be either B-tree or Hash. Choosing the best index type can lead to better performance. See **Storage Engine index types** for more on the characteristics of each index type.

3.3.10.3 Optimizing String and Character Fields

Comparing String Columns

When values from different columns are compared, the comparison runs more quickly when the columns are of the same character set and collation. If they are different, the strings need to be converted while the query runs. So, where possible, declare string columns using the same character set and collation when you may need to compare them.

VARCHAR vs BLOB

ORDER BY and GROUP BY clauses can generate temporary tables in memory (see **MEMORY Storage Engine**) if the original table doesn't contain any BLOB fields. If a column is less than 8KB, you can make use of a Binary VARCHAR rather than a BLOB.

5.3.2.20 Binary Log Group Commit and InnoDB Flushing Performance

3.3.11.2 Fair Choice Between Range and Index_merge Optimizations

`index_merge` is a method used by the optimizer to retrieve rows from a single table using several index scans. The results

of the scans are then merged.

When using `EXPLAIN`, if `index_merge` is the plan chosen by the optimizer, it will show up in the "type" column. For example:

```

MariaDB [ontime]> SELECT COUNT(*) FROM ontime;
+-----+
| count(*) |
+-----+
| 1578171 |
+-----+

MySQL [ontime]> EXPLAIN SELECT * FROM ontime WHERE (Origin='SEA' OR Dest='SEA');
+-----+-----+-----+-----+-----+-----+-----+-----+-----+
|id|select_type|table |type           |possible_keys|key           |key_len|ref |rows |Extra
|
+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| 1|SIMPLE     |ontime|index_merge   |Origin, Dest |Origin, Dest |6,6    |NULL|92800|Using union
(Origin, Dest); Using where|
+-----+-----+-----+-----+-----+-----+-----+-----+-----+

```

The "rows" column gives us a way to compare efficiency between `index_merge` and other plans.

It is sometimes necessary to discard `index_merge` in favor of a different plan to avoid a combinatorial explosion of possible range and/or `index_merge` strategies. But, the old logic in MySQL for when `index_merge` was rejected caused some good `index_merge` plans to not even be considered. Specifically, additional `AND` predicates in `WHERE` clauses could cause an `index_merge` plan to be rejected in favor of a less efficient plan. The slowdown could be anywhere from 10x to over 100x. Here are two examples (based on the previous query) using MySQL:

```

MySQL [ontime]> EXPLAIN SELECT * FROM ontime WHERE (Origin='SEA' OR Dest='SEA') AND
securitydelay=0;
+-----+-----+-----+-----+-----+-----+-----+-----+-----+
|id|select_type|table |type           |possible_keys|key           |key_len|ref |rows |Extra
|
+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| 1|SIMPLE     |ontime|ref           |Origin, Dest, SecurityDelay|SecurityDelay|5      |const|791546|Using
where|
+-----+-----+-----+-----+-----+-----+-----+-----+-----+

MySQL [ontime]> EXPLAIN SELECT * FROM ontime WHERE (Origin='SEA' OR Dest='SEA') AND depdelay <
12*60;
+-----+-----+-----+-----+-----+-----+-----+-----+-----+
|id|select_type|table |type           |possible_keys|key           |key_len|ref |rows |Extra
|
+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| 1|SIMPLE     |ontime|ALL          |Origin, DepDelay, Dest|NULL|NULL  |NULL|1583093|Using where|
+-----+-----+-----+-----+-----+-----+-----+-----+-----+

```

In the above output, the "rows" column shows that the first is almost 10x less efficient and the second is over 15x less efficient than `index_merge`.

Starting in [MariaDB 5.3](#), the optimizer will delay discarding potential `index_merge` plans until the point where it is really necessary. See [MWL#24](#) for more information.

By not discarding potential `index_merge` plans until absolutely necessary, the two queries stay just as efficient as the original:

```

MariaDB [ontime]> EXPLAIN SELECT * FROM ontime WHERE (Origin='SEA' or Dest='SEA');
+-----+-----+-----+-----+-----+-----+-----+-----+-----+
|id|select_type|table |type          |possible_keys|key          |key_len|ref  |rows |Extra
|-----+-----+-----+-----+-----+-----+-----+-----+-----+
| 1|SIMPLE      |ontime|index_merge   |Origin, Dest |Origin, Dest|6,6    |NULL|92800|Using
union(Origin, Dest); Using where|
+-----+-----+-----+-----+-----+-----+-----+-----+-----+

MariaDB [ontime]> EXPLAIN SELECT * FROM ontime WHERE (Origin='SEA' or Dest='SEA') AND
securitydelay=0;
+-----+-----+-----+-----+-----+-----+-----+-----+-----+
|id|select_type|table |type          |possible_keys|key          |key_len|ref  |rows |Extra
|-----+-----+-----+-----+-----+-----+-----+-----+-----+
| 1|SIMPLE      |ontime|index_merge   |Origin, Dest, SecurityDelay|Origin, Dest|6,6    |NULL|92800|Using
union(Origin, Dest); Using where|
+-----+-----+-----+-----+-----+-----+-----+-----+-----+

MariaDB [ontime]> EXPLAIN SELECT * FROM ontime WHERE (Origin='SEA' or Dest='SEA') AND depdelay
< 12*60;
+-----+-----+-----+-----+-----+-----+-----+-----+-----+
|id|select_type|table |type          |possible_keys|key          |key_len|ref  |rows |Extra
|-----+-----+-----+-----+-----+-----+-----+-----+-----+
| 1|SIMPLE      |ontime|index_merge   |Origin, DepDelay, Dest|Origin, Dest|6,6    |NULL|92800|Using
union(Origin, Dest); Using where|
+-----+-----+-----+-----+-----+-----+-----+-----+-----+

```

This new behavior is always on and there is no need to enable it. There are no known issues or gotchas with this new optimization.

5. [Differences from MySQL](#)

Multi Range Read is an optimization aimed at improving performance for IO-bound queries that need to scan lots of rows.

Multi Range Read can be used with

- `range access`
- `ref` and `eq_ref` access, when they are using [Batched Key Access](#)

as shown in this diagram:

Possible ways to use MRR

The Idea

Case 1: Rowid Sorting for Range Access

Consider a range query:

```
explain select * from tbl where tbl.key1 between 1000 and 2000;
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| id | select_type | table | type | possible_keys | key | key_len | ref | rows | Extra |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| 1 | SIMPLE | tbl | range | key1 | key1 | 5 | NULL | 960 | Using index condition |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
-----+
```

When this query is executed, disk IO access pattern will follow the red line in this figure:

Execution will hit the table rows in random places, as marked with the blue line/numbers in the figure.

When the table is sufficiently big, each table record read will need to actually go to disk (and be served from buffer pool or OS cache), and query execution will be too slow to be practical. For example, a 10,000 RPM disk drive is able to make 167 seeks per second, so in the worst case, query execution will be capped at reading about 167 records per second.

SSD drives do not need to do disk seeks, so they will not be hurt as badly, however the performance will still be poor in many cases.

Multi-Range-Read optimization aims to make disk access faster by sorting record read requests and then doing one ordered disk sweep. If one enables Multi Range Read, `EXPLAIN` will show that a "Rowid-ordered scan" is used:

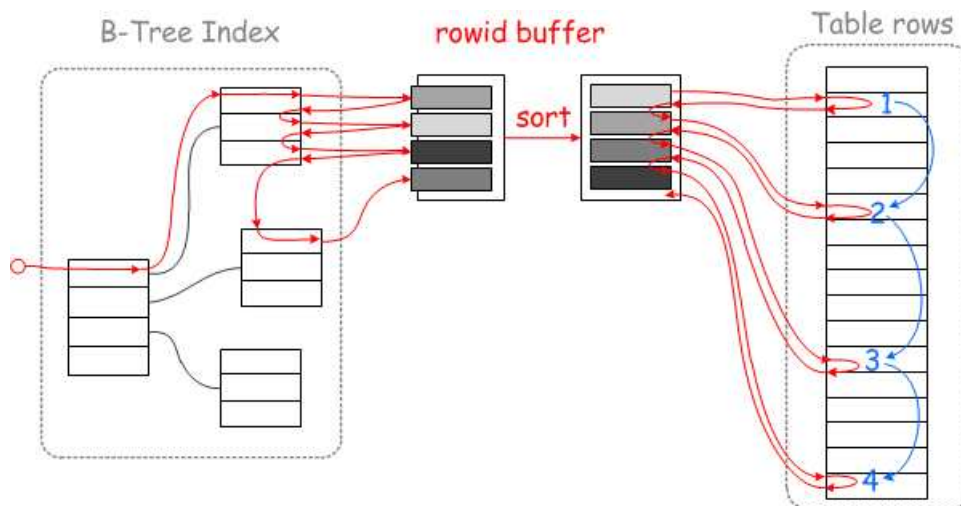

```

set optimizer_switch='mrr=on';
Query OK, 0 rows affected (0.06 sec)

explain select * from tbl where tbl.key1 between 1000 and 2000;
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| id | select_type | table | type | possible_keys | key | key_len | ref | rows | Extra |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| 1 | SIMPLE | tbl | range | key1 | key1 | 5 | NULL | 960 | Using index condition; Rowid-ordered scan |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
1 row in set (0.03 sec)

```

and the execution will proceed as follows:

Reading disk data sequentially is generally faster, because

- Rotating drives do not have to move the head back and forth
- One can take advantage of IO-prefetching done at various levels
- Each disk page will be read exactly once, which means we won't rely on disk cache (or buffer pool) to save us from reading the same page multiple times.

The above can make a huge difference on performance. There is also a catch, though:

- If you're scanning small data ranges in a table that is sufficiently small so that it completely fits into the OS disk cache, then you may observe that the only effect of MRR is that extra buffering/sorting adds some CPU overhead.
- `LIMIT n` and `ORDER BY ... LIMIT n` queries with small values of `n` may become slower. The reason is that MRR reads data *in disk order*, while `ORDER BY ... LIMIT n` wants first `n` records *in index order*.

Case 2: Rowid Sorting for Batched Key Access

Batched Key Access can benefit from rowid sorting in the same way as range access does. If one has a join that uses index lookups:

```

explain select * from t1,t2 where t2.key1=t1.col1;
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| id | select_type | table | type | possible_keys | key | key_len | ref | rows | Extra |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| 1 | SIMPLE | t1 | ALL | NULL | NULL | NULL | NULL | 1000 | Using where |
| 1 | SIMPLE | t2 | ref | key1 | key1 | 5 | test.t1.col1 | 1 | |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
2 rows in set (0.00 sec)

```

Execution of this query will cause table `t2` to be hit in random locations by lookups made through `t2.key1=t1.col1`. If

you enable Multi Range and and Batched Key Access, you will get table `t2` to be accessed using a Rowid-ordered scan :

```

set optimizer_switch='mrr=on';
Query OK, 0 rows affected (0.06 sec)

set join_cache_level=6;
Query OK, 0 rows affected (0.00 sec)

explain select * from t1,t2 where t2.key1=t1.col1;
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| id | select_type | table | type | possible_keys | key | key_len | ref | rows |
Extra |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| 1 | SIMPLE | t1 | ALL | NULL | NULL | NULL | NULL | 1000 |
Using where |
| 1 | SIMPLE | t2 | ref | key1 | key1 | 5 | test.t1.col1 | 1 |
Using join buffer (flat, BKA join); Rowid-ordered scan |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
2 rows in set (0.00 sec)

```

The benefits will be similar to those listed for `range` access.

An additional source of speedup is this property: if there are multiple records in `t1` that have the same value of `t1.col1`, then regular Nested-Loops join will make multiple index lookups for the same value of `t2.key1=t1.col1`. The lookups may or may not hit the cache, depending on how big the join is. With Batched Key Access and Multi-Range Read, no duplicate index lookups will be made.

Case 3: Key Sorting for Batched Key Access

Let us consider again the nested loop join example, with `ref` access on the second table:

```

explain select * from t1,t2 where t2.key1=t1.col1;
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| id | select_type | table | type | possible_keys | key | key_len | ref | rows |
Extra |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| 1 | SIMPLE | t1 | ALL | NULL | NULL | NULL | NULL | 1000 |
Using where |
| 1 | SIMPLE | t2 | ref | key1 | key1 | 5 | test.t1.col1 | 1 |
|
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+

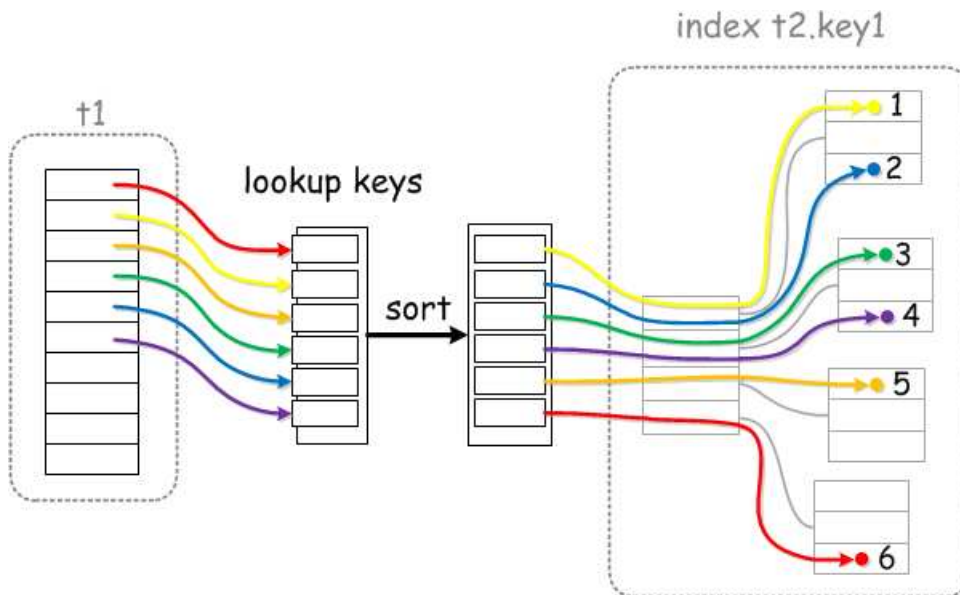

```

Execution of this query plan will cause random hits to be made into the index `t2.key1`, as shown in this picture:

Regular Nested Loops Join will hit the index at random

In particular, on step #5 we'll read the same index page that we've read on step #2, and the page we've read on step #4 will be re-read on step#6. If all pages you're accessing are in the cache (in the buffer pool, if you're using InnoDB, and in the key cache, if you're using MyISAM), this is not a problem. However, if your hit ratio is poor and you're going to hit the disk, it makes sense to sort the lookup keys, like shown in this figure:

With *Batched Nested Loops Join* and *Key-Ordered retrieval*, index lookups are done in one "sweep"

This is roughly what `Key-ordered scan` optimization does. In EXPLAIN, it looks as follows:

```

set optimizer_switch='mrr=on,mrr_sort_keys=on';
Query OK, 0 rows affected (0.00 sec)

set join_cache_level=6;
Query OK, 0 rows affected (0.02 sec)
explain select * from t1,t2 where t2.key1=t1.col1\G
***** 1. row *****
      id: 1
    select_type: SIMPLE
      table: t1
      type: ALL
possible_keys: a
      key: NULL
     key_len: NULL
      ref: NULL
      rows: 1000
    Extra: Using where
***** 2. row *****
      id: 1
    select_type: SIMPLE
      table: t2
      type: ref
possible_keys: key1
      key: key1
     key_len: 5
      ref: test.t1.col1
      rows: 1
    Extra: Using join buffer (flat, BKA join); Key-ordered Rowid-ordered scan
2 rows in set (0.00 sec)

```

((TODO: a note about why sweep-read over InnoDB's clustered primary index scan (which is, actually the whole InnoDB table itself) will use `Key-ordered scan` algorithm, but not `Rowid-ordered scan` algorithm, even though conceptually they are the same thing in this case))

Buffer Space Management

As was shown above, Multi Range Read requires sort buffers to operate. The size of the buffers is limited by system variables. If MRR has to process more data than it can fit into its buffer, it will break the scan into multiple passes. The more passes are made, the less is the speedup though, so one needs to balance between having too big buffers (which consume lots of memory) and too small buffers (which limit the possible speedup).

Range Access

When MRR is used for `range` access, the size of its buffer is controlled by the `mrr_buffer_size` system variable. Its value specifies how much space can be used for each table. For example, if there is a query which is a 10-way join and MRR is used for each table, `10*@mrr_buffer_size` bytes may be used.

Batched Key Access

When Multi Range Read is used by Batched Key Access, then buffer space is managed by BKA code, which will automatically provide a part of its buffer space to MRR. You can control the amount of space used by BKA by setting

- `join_buffer_size` to limit how much memory BKA uses for each table, and
- `join_buffer_space_limit` to limit the total amount of memory used by BKA in the join.

Status Variables

There are three status variables related to Multi Range Read:

Variable name	Meaning
<code>Handler_mrr_init</code>	Counts how many Multi Range Read scans were performed
<code>Handler_mrr_key_refills</code>	Number of times key buffer was refilled (not counting the initial fill)
<code>Handler_mrr_rowid_refills</code>	Number of times rowid buffer was refilled (not counting the initial fill)

Non-zero values of `Handler_mrr_key_refills` and/or `Handler_mrr_rowid_refills` mean that Multi Range Read

scan did not have enough memory and had to do multiple key/rowid sort-and-sweep passes. The greatest speedup is achieved when Multi Range Read runs everything in one pass, if you see lots of refills it may be beneficial to increase sizes of relevant buffers `mrr_buffer_size` `join_buffer_size` and `join_buffer_space_limit`

Effect on Other Status Variables

When a Multi Range Read scan makes an index lookup (or some other "basic" operation), the counter of the "basic" operation, e.g. `Handler_read_key`, will also be incremented. This way, you can still see total number of index accesses, including those made by MRR. `Per-user/table/index statistics` counters also include the row reads made by Multi Range Read scans.

Why Using Multi Range Read Can Cause Higher Values in Status Variables

Multi Range Read is used for scans that do full record reads (i.e., they are not "Index only" scans). A regular non-index-only scan will read

1. an index record, to get a rowid of the table record
2. a table record Both actions will be done by making one call to the storage engine, so the effect of the call will be that the relevant `Handler_read_XXX` counter will be incremented BY ONE, and `Innodb_rows_read` will be incremented BY ONE.

Multi Range Read will make separate calls for steps #1 and #2, causing TWO increments to `Handler_read_XXX` counters and TWO increments to `Innodb_rows_read` counter. To the uninformed, this looks as if Multi Range Read was making things worse. Actually, it doesn't - the query will still read the same index/table records, and actually Multi Range Read may give speedups because it reads data in disk order.

Multi Range Read Factsheet

- Multi Range Read is used by
 - `range` access method for range scans.
 - [Batched Key Access](#) for joins
- Multi Range Read can cause slowdowns for small queries over small tables, so it is disabled by default.
- There are two strategies:
 - Rowid-ordered scan
 - Key-ordered scan
- : and you can tell if either of them is used by checking the `Extra` column in `EXPLAIN` output.
- There are three `optimizer_switch` flags you can switch ON:
 - `mrr=on` - enable MRR and rowid ordered scans
 - `mrr_sort_keys=on` - enable Key-ordered scans (you must also set `mrr=on` for this to have any effect)
 - `mrr_cost_based=on` - enable cost-based choice whether to use MRR. Currently not recommended, because cost model is not sufficiently tuned yet.

Differences from MySQL

- MySQL supports only `Rowid ordered scan` strategy, which it shows in `EXPLAIN` as `Using MRR`.
- `EXPLAIN` in MySQL shows `Using MRR`, while in MariaDB it may show
 - `Rowid-ordered scan`
 - `Key-ordered scan`
 - `Key-ordered Rowid-ordered scan`
- MariaDB uses `mrr_buffer_size` as a limit of MRR buffer size for `range` access, while MySQL uses `read_rnd_buffer_size`.
- MariaDB has three MRR counters: `Handler_mrr_init`, `Handler_mrr_extra_rowid_sorts`, `Handler_mrr_extra_key_sorts`, while MySQL has only `Handler_mrr_init`, and it will only count MRR scans that were used by BKA. MRR scans used by range access are not counted.

3.3.12 Compression

Need help tuning your MariaDB database? Ask the experts!

There are a number of different kinds of compression in MariaDB

Encryption, Hashing and Compression Functions

Functions used for encryption, hashing and compression.

Storage-Engine Independent Column Compression

Storage-engine independent support for column compression.

InnoDB Page Compression

InnoDB page compression, which is more sophisticated than the COMPRESSED row format.

Compression Plugins

Five MariaDB compression libraries are available as plugins.

Compressing Events to Reduce Size of the Binary Log

Binlog events can be compressed to save space on disk and in network transfers.

InnoDB COMPRESSED Row Format

Similar to the COMPACT row format, but can store even more data on overflow pages.

ColumnStore Compression Mode

ColumnStore has the ability to compress data

1.2.8.2 Encryption, Hashing and Compression Functions

3.3.12.2 Storage-Engine Independent Column Compression

Contents

1. [Field Length Compatibility](#)
2. [New System Variables](#)
 1. [column_compression_threshold](#)
 2. [column_compression_zlib_level](#)
 3. [column_compression_zlib_strategy](#)
 4. [column_compression_zlib_wrap](#)
3. [New Status Variables](#)
 1. [Column_compressions](#)
 2. [Column_decompressions](#)
4. [Limitations](#)
5. [Comparison with InnoDB Page Compression](#)
6. [Examples](#)

Storage-engine independent column compression enables [TINYBLOB](#), [BLOB](#), [MEDIUMBLOB](#), [LONGBLOB](#), [TINYTEXT](#), [TEXT](#), [MEDIUMTEXT](#), [LONGTEXT](#), [VARCHAR](#) and [VARBINARY](#) columns to be compressed.

This is performed by means of a new COMPRESSED [column attribute](#): `COMPRESSED[=<compression_method>]`

Currently the only supported compression method is `zlib`.

Field Length Compatibility

When using the `COMPRESSED` attribute, note that FIELD LENGTH is reduced by 1; for example, a BLOB has a length of 65535, while BLOB COMPRESSED has 65535-1. See [MDEV-15592](#).

New System Variables

`column_compression_threshold`

- **Description:** Minimum column data length eligible for compression.
 - **Commandline:** `--column-compression-threshold=#`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `100`
 - **Range:** `0` to `4294967295`
-

`column_compression_zlib_level`

- **Description:** zlib compression level (1 gives best speed, 9 gives best compression).
 - **Commandline:** `--column-compression-zlib-level=#`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `6`
 - **Range:** `1` to `9`
-

`column_compression_zlib_strategy`

- **Description:** The strategy parameter is used to tune the compression algorithm. Use the value `DEFAULT_STRATEGY` for normal data, `FILTERED` for data produced by a filter (or predictor), `HUFFMAN_ONLY` to force Huffman encoding only (no string match), or `RLE` to limit match distances to one (run-length encoding). Filtered data consists mostly of small values with a somewhat random distribution. In this case, the compression algorithm is tuned to compress them better. The effect of `FILTERED` is to force more Huffman coding and less string matching; it is somewhat intermediate between `DEFAULT_STRATEGY` and `HUFFMAN_ONLY`. `RLE` is designed to be almost as fast as `HUFFMAN_ONLY`, but give better compression for PNG image data. The strategy parameter only affects the compression ratio but not the correctness of the compressed output even if it is not set appropriately. `FIXED` prevents the use of dynamic Huffman codes, allowing for a simpler decoder for special applications.
 - **Commandline:** `--column-compression-zlib-strategy=#`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `enum`
 - **Default Value:** `DEFAULT_STRATEGY`
 - **Valid Values:** `DEFAULT_STRATEGY`, `FILTERED`, `HUFFMAN_ONLY`, `RLE`, `FIXED`
-

`column_compression_zlib_wrap`

- **Description:** If set to `1` (`0` is default), generate zlib header and trailer and compute Adler32 check value. It can be used with storage engines that don't provide data integrity verification to detect data corruption.
 - **Commandline:** `--column-compression-zlib-wrap={0|1}`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
-

New Status Variables

`Column_compressions`

- **Description:** Incremented each time field data is compressed.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

`Column_decompressions`

- **Description:** Incremented each time field data is decompressed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Limitations

- The only supported method currently is zlib.
- The [CSV](#) storage engine stores data uncompressed on-disk even if the COMPRESSED attribute is present.
- It is not possible to create indexes over compressed columns.

Comparison with InnoDB Page Compression

Storage-independent column compression is different to [InnoDB Page Compression](#) in a number of ways.

- It is storage engine independent, while InnoDB page compression applies to InnoDB only.
- By being specific to a column, one can access non-compressed fields without the decompression overhead.
- Only zlib is available, while InnoDB page compression can offer alternative compression algorithms.
- It is not recommended to use multiple forms of compression over the same data.
- It is intended for compressing large blobs, while InnoDB page compression is suitable for a more general case.
- Columns cannot be indexed, while with InnoDB page compression indexes are possible as usual.

Examples

```
CREATE TABLE cmp (i TEXT COMPRESSED);  
  
CREATE TABLE cmp2 (i TEXT COMPRESSED=zlib);
```

5.3.2.21 InnoDB Page Compression

5.4.11.11 Compression Plugins

3.1.14.15 Compressing Events to Reduce Size of the Binary Log

5.3.2.12.5 InnoDB COMPRESSED Row Format

3.3.12.7 ColumnStore Compression Mode

MariaDB ColumnStore has the ability to compress data and this is controlled through a compression mode. This compression mode may be set as a default for the instance or set at the session level.

To set the compression mode at the session level, the following command is used. Once the session has ended, any subsequent session will return to the default for the instance.

```
set infinidb_compression_type = n
```

where n is:

- 0) compression is turned off. Any subsequent table create statements run will have compression turned off for that table unless any statement overrides have been performed. Any alter statements run to add a column will have compression turned off for that column unless any statement override has been performed.
- 2) compression is turned on. Any subsequent table create statements run will have compression turned on for that table unless any statement overrides have been performed. Any alter statements run to add a column will have compression turned on for that column unless any statement override has been performed. ColumnStore uses snappy compression in this mode.

3.4 Connection Redirection Mechanism in the MariaDB Client/Server Protocol

Want to improve your MariaDB database performance? Let us help!

MariaDB starting with 11.3

A connection redirection mechanism was added in [MariaDB 11.3.0](#) (MDEV-15935)

Redirection mechanisms are widely used in proxy-based scenarios.

Previously, when multiple servers shared one proxy, the proxy forwarded all packets between servers and clients. Thus, the proxy added latency, consuming computing resources and impacting overall performance. For scenarios with many short connections, such as WordPress, latency can be a critical issue.

With a redirection mechanism, much like HTTP redirects or Oracle redirected connections, clients get the servers' address from proxies and connect to servers transparently, without latency and without wasting resources.

Usage

Redirection is handled through a new system variable, `redirect_url`. The value defaults to an empty string, but can also contain a connection string in the conventional format (in the style of a Connector/C etc. connection url), that is:

```
{mysql,mariadb}://host[:port]
```

where `host` is an arbitrary string not containing colons, and `port` is a number between 0 and 65535 inclusive.

This variable is appended to the default value of the `session_track_system_variables` system variable. If not empty, clients will be redirected to the specified server.

Possible Use Cases

- Always redirect all clients to a new location:
 - set `@@global.redirect_url`, start the server with `--redirect-url=`, or put it in `my.cnf`
- redirect to a group of servers randomly
 - create a table with connection urls, one per row.
 - use an sql script that selects a random row from it and sets `@@redirect_url` to this value
 - specify this script in the `--init-connect` server parameter
- dynamically redirect from the primary to one of the replicas
 - same as above, but use `INFORMATION_SCHEMA.PROCESSLIST` to get the list of active replicas.

Example

```
set global redirect_url="mysql://mariadb.org:12345";
```

Invalid formats are not permitted:

```
set global redirect_url="mysql://mariadb.org:";
ERROR 1231 (42000): Variable 'redirect_url' can't be set to the value of 'mysql://mariadb.org:'
```

4 Programming & Customizing MariaDB

Ways to add simple code to SQL statements, or create your own functions or stored procedures.

Programmatic & Compound Statements

Compound SQL statements for stored routines and in general.

Stored Routines

Stored procedures and functions.

Triggers & Events

Creating triggers and scheduled events within MariaDB.

 **Views**
Stored queries for generating a virtual table.

 **User-Defined Functions**
Extending MariaDB with custom functions.

There are [1 related questions](#).

1.1.1.6 Programmatic & Compound Statements

4.2 Stored Routines

Stored procedures and stored functions.

 **Stored Procedures**
Routine invoked with a CALL statement.

 **Stored Functions**
Defined functions for use with SQL statements.

 **Stored Routine Statements**
SQL statements related to creating and using stored routines.

 **Binary Logging of Stored Routines**
Stored routines require extra consideration when binary logging.

 **Stored Routine Limitations**
SQL statements not permitted in stored programs.

 **Stored Routine Privileges**
Privileges associated with stored functions and stored procedures.

4.2.1 Stored Procedures

A stored procedure is a routine invoked with a CALL statement. It may have input parameters, output parameters and parameters that are both input parameters and output parameters.

 **Stored Procedure Overview**
A Stored Procedure is a routine invoked with a CALL statement.

 **Stored Routine Privileges**
Privileges associated with stored functions and stored procedures.

 **CREATE PROCEDURE**
Creates a stored procedure.

 **ALTER PROCEDURE**
Change stored procedure characteristics.

 **DROP PROCEDURE**
Drop stored procedure.

 **SHOW CREATE PROCEDURE**
Shows the CREATE statement that creates the specific stored procedure.

 **SHOW PROCEDURE CODE**
Display internal implementation of a stored procedure.

 **SHOW PROCEDURE STATUS**
Stored procedure characteristics.

Binary Logging of Stored Routines

Stored routines require extra consideration when binary logging.

Information Schema ROUTINES Table

Stored procedures and stored functions information

SQL_MODE=ORACLE

4.2.1.1 Stored Procedure Overview

Contents

1. [Creating a Stored Procedure](#)
2. [Why use Stored Procedures?](#)
3. [Stored Procedure listings and definitions](#)
4. [Dropping and Updating a Stored Procedure](#)
5. [Permissions in Stored Procedures](#)

A Stored Procedure is a routine invoked with a [CALL](#) statement. It may have input parameters, output parameters and parameters that are both input parameters and output parameters.

Creating a Stored Procedure

Here's a skeleton example to see a stored procedure in action:

```
DELIMITER //

CREATE PROCEDURE Reset_animal_count()
MODIFIES SQL DATA
UPDATE animal_count SET animals = 0;
//

DELIMITER ;
```

First, the delimiter is changed, since the function definition will contain the regular semicolon delimiter. The procedure is named `Reset_animal_count`. `MODIFIES SQL DATA` indicates that the procedure will perform a write action of sorts, and modify data. It's for advisory purposes only. Finally, there's the actual SQL statement - an UPDATE.

```
SELECT * FROM animal_count;
+-----+
| animals |
+-----+
|    101 |
+-----+

CALL Reset_animal_count();

SELECT * FROM animal_count;
+-----+
| animals |
+-----+
|        0 |
+-----+
```

A more complex example, with input parameters, from an actual procedure used by banks:

```

CREATE PROCEDURE
Withdraw                                     /* Routine name */
(parameter_amount DECIMAL(6,2),             /* Parameter list */
parameter_teller_id INTEGER,
parameter_customer_id INTEGER)
MODIFIES SQL DATA                          /* Data access clause */
BEGIN                                       /* Routine body */
    UPDATE Customers
        SET balance = balance - parameter_amount
        WHERE customer_id = parameter_customer_id;
    UPDATE Tellers
        SET cash_on_hand = cash_on_hand + parameter_amount
        WHERE teller_id = parameter_teller_id;
    INSERT INTO Transactions VALUES (
        parameter_customer_id,
        parameter_teller_id,
        parameter_amount);
END;

```

See [CREATE PROCEDURE](#) for full syntax details.

Why use Stored Procedures?

Security is a key reason. Banks commonly use stored procedures so that applications and users don't have direct access to the tables. Stored procedures are also useful in an environment where multiple languages and clients are all used to perform the same operations.

Stored Procedure listings and definitions

To find which stored functions are running on the server, use [SHOW PROCEDURE STATUS](#).

```

SHOW PROCEDURE STATUS\G
***** 1. row *****
      Db: test
      Name: Reset_animal_count
      Type: PROCEDURE
      Definer: root@localhost
      Modified: 2013-06-03 08:55:03
      Created: 2013-06-03 08:55:03
      Security_type: DEFINER
      Comment:
character_set_client: utf8
collation_connection: utf8_general_ci
Database Collation: latin1_swedish_ci

```

or query the [routines table](#) in the INFORMATION_SCHEMA database directly:

```

SELECT ROUTINE_NAME FROM INFORMATION_SCHEMA.ROUTINES
WHERE ROUTINE_TYPE='PROCEDURE';
+-----+
| ROUTINE_NAME |
+-----+
| Reset_animal_count |
+-----+

```

To find out what the stored procedure does, use [SHOW CREATE PROCEDURE](#).

```

SHOW CREATE PROCEDURE Reset_animal_count\G
***** 1. row *****
      Procedure: Reset_animal_count
      sql_mode:
      Create Procedure: CREATE DEFINER=`root`@`localhost` PROCEDURE `Reset_animal_count`()
      MODIFIES SQL DATA
      UPDATE animal_count SET animals = 0
character_set_client: utf8
collation_connection: utf8_general_ci
Database Collation: latin1_swedish_ci

```

Dropping and Updating a Stored Procedure

To drop a stored procedure, use the [DROP PROCEDURE](#) statement.

```
DROP PROCEDURE Reset_animal_count();
```

To change the characteristics of a stored procedure, use [ALTER PROCEDURE](#). However, you cannot change the parameters or body of a stored procedure using this statement; to make such changes, you must drop and re-create the procedure using [CREATE OR REPLACE PROCEDURE](#) (which retains existing privileges), or [DROP PROCEDURE](#) followed [CREATE PROCEDURE](#).

Permissions in Stored Procedures

See the article [Stored Routine Privileges](#).

4.2.1.2 Stored Routine Privileges

Contents

1. [Creating Stored Routines](#)
2. [Altering Stored Routines](#)
3. [Running Stored Routines](#)
 1. [DEFINER Clause](#)
 2. [SQL SECURITY Clause](#)
4. [Dropping Stored Routines](#)

It's important to give careful thought to the privileges associated with [stored functions](#) and [stored procedures](#). The following is an explanation of how they work.

Creating Stored Routines

- To create a stored routine, the [CREATE ROUTINE](#) privilege is needed. The [SUPER](#) privilege is required if a [DEFINER](#) is declared that's not the creator's account (see [DEFINER clause](#) below). The [SUPER](#) privilege is also required if statement-based binary logging is used. See [Binary Logging of Stored Routines](#) for more details.

Altering Stored Routines

- To make changes to, or drop, a stored routine, the [ALTER ROUTINE](#) privilege is needed. The creator of a routine is temporarily granted this privilege if they attempt to change or drop a routine they created, unless the [automatic_sp_privileges](#) variable is set to 0 (it defaults to 1).
- The [SUPER](#) privilege is also required if statement-based binary logging is used. See [Binary Logging of Stored Routines](#) for more details.

Running Stored Routines

- To run a stored routine, the [EXECUTE](#) privilege is needed. This is also temporarily granted to the creator if they attempt to run their routine unless the [automatic_sp_privileges](#) variable is set to 0.
- The [SQL SECURITY clause](#) (by default [DEFINER](#)) specifies what privileges are used when a routine is called. If [SQL SECURITY is INVOKER](#), the function body will be evaluated using the privileges of the user calling the function. If [SQL SECURITY is DEFINER](#), the function body is always evaluated using the privileges of the definer account. [DEFINER](#) is the default. Thus, by default, users who can access the database associated with the stored routine can also run the routine, and potentially perform operations they wouldn't normally have permissions for.
- The creator of a routine is the account that ran the [CREATE FUNCTION](#) or [CREATE PROCEDURE](#) statement, regardless of whether a [DEFINER](#) is provided. The definer is by default the creator unless otherwise specified.
- The server automatically changes the privileges in the [mysql.proc](#) table as required, but will not look out for manual changes.

DEFINER Clause

If left out, the [DEFINER](#) is treated as the account that created the stored routine or view. If the account creating the routine has the [SUPER](#) privilege, another account can be specified as the [DEFINER](#).

SQL SECURITY Clause

This clause specifies the context the stored routine or view will run as. It can take two values - `DEFINER` or `INVOKER`. `DEFINER` is the account specified as the `DEFINER` when the stored routine or view was created (see the section above). `INVOKER` is the account invoking the routine or view.

As an example, let's assume a routine, created by a superuser who's specified as the `DEFINER`, deletes all records from a table. If `SQL SECURITY=DEFINER`, anyone running the routine, regardless of whether they have delete privileges, will be able to delete the records. If `SQL SECURITY = INVOKER`, the routine will only delete the records if the account invoking the routine has permission to do so.

`INVOKER` is usually less risky, as a user cannot perform any operations they're normally unable to. However, it's not uncommon for accounts to have relatively limited permissions, but be specifically granted access to routines, which are then invoked in the `DEFINER` context.

Dropping Stored Routines

All privileges that are specific to a stored routine will be dropped when a `DROP FUNCTION` or `DROP ROUTINE` is run. However, if a `CREATE OR REPLACE FUNCTION` or `CREATE OR REPLACE PROCEDURE` is used to drop and replace and the routine, any privileges specific to that routine will not be dropped.

Implementation Specification for Stored Procedures

How Parsing and Execution of Queries Work

In order to execute a query, the function `sql_parse.cc:mysql_parse()` is called, which in turn calls the parser (`yyparse()`) with an updated Lex structure as the result. `mysql_parse()` then calls `mysql_execute_command()` which dispatches on the command code (in Lex) to the corresponding code for executing that particular query.

There are three structures involved in the execution of a query which are of interest to the [stored procedure](#) implementation:

- Lex (mentioned above) is the "compiled" query, that is the output from the parser and what is then interpreted to do the actual work. It contains an enum value (`sql_command`) which is the query type, and all the data collected by the parser needed for the execution (table names, fields, values, etc).
- THD is the "run-time" state of a connection, containing all that is needed for a particular client connection, and, among other things, the Lex structure currently being executed.
- `Item_*`: During parsing, all data is translated into "items", objects of the subclasses of "Item", such as `Item_int`, `Item_real`, `Item_string`, etc., for basic datatypes, and also various more specialized Item types for expressions

to be evaluated (`Item_func` objects).

How to Fit Stored Procedures into this Scheme

Overview of the Classes and Files for Stored Procedures

(More detailed APIs at the end of this page)

```
class sp_head (sp_head.{cc,h})
```

This contains, among other things, an array of "instructions" and the method for executing the procedure.

```
class sp_pcontext (sp_pcontext.{cc,h})
```

This is the parse context for the procedure. It's primarily used during parsing to keep track of local parameters, variables and labels, but it's also used at [CALL](#) time to find the parameters mode (IN, OUT or INOUT) and type when setting up the runtime context.

```
class sp_instr (sp_head.{cc,h})
```

This is the base class for "instructions", that is, what is generated by the parser. It turns out that we only need a minimum of 5 different sub classes:

- `sp_instr_stmt` Execute a statement. This is the "call-out" any normal SQL statement, like a [SELECT](#), [INSERT](#) etc. It contains the Lex structure for the statement in question.
- `sp_instr_set` Set the value of a local variable (or parameter)
- `sp_instr_jump` An unconditional jump.
- `sp_instr_jump_if_not` Jump if condition is not true. It turns out that the negative test is most convenient when generating the code for the flow control constructs.
- `sp_instr_freturn` Return a value from a FUNCTION and exit. For condition HANDLERS some special instructions are also needed, see that section below.

```
class sp_rcontext (sp_rcontext.h)
```

This is the runtime context in the THD structure. It contains an array of items, the parameters and local variables for the currently executing stored procedure. This means that variable value lookup in runtime is constant time, a simple index operation.

```
class Item_splocal (Item.{cc,h})
```

This is a subclass of `Item`. Its sole purpose is to hide the fact that the real `Item` is actually in the current frame (runtime context). It contains the frame offset and defers all methods to the real `Item` in the frame. This is what the parser generates for local variables.

```
Utility Functions (sp.{cc,h})
```

This contains functions for creating, dropping and finding a stored procedure in the [mysql.proc table](#) (or the internal cache).

Parsing CREATE PROCEDURE

When parsing a [CREATE PROCEDURE](#) the parser first initializes the `sphead` and `spcont` (runtime context) fields in the Lex. The `sql_command` code for the result of parsing a is `SQLCOM_CREATE_PROCEDURE`.

The parsing of the parameter list and body is relatively straightforward:

- Parameters: name, type and mode (IN/OUT/INOUT) is pushed to `spcont`
- Declared local variables: Same as parameters (mode is then IN)
- Local Variable references: If an identifier is found in in `spcont`, an `Item_splocal` is created with the variable's frame index, otherwise an `Item_field` or `Item_ref` is created (as before).
- Statements: The Lex in THD is replaced by a new Lex structure and the statement, is parsed as usual. A `sp_instr_stmt` is created, containing the new Lex, and added to the instructions in `sphead`. Afterwards, the procedure's Lex is restored in THD.
- SET var: Setting a local variable generates a `sp_instr_set` instruction, containing the variable's frame offset, the expression (an `Item`), and the type.
- Flow control: Flow control constructs such as [IF](#), [WHILE](#), etc, generate a conditional and unconditional jumps in the "obvious" way, but a few notes may be required:
- Forward jumps: When jumping forward, the exact destination is not known at the time of the creation of the jump instruction. The

The simplest way would be to just leave it at that, and re-read the procedure from the database each time it is called. (And in fact, that's the way the earliest implementation will work.) However, this is not very efficient, and we can do better. The full implementation should work like this:

1. Upon creation time, parse and store the procedure. Note that we still need to parse it to catch syntax errors, but we can't check if called procedures exists for instance.
2. Upon first CALL, read from the database, parse it, and cache the resulting Lex in memory. This time we can do more error checking.
3. Upon subsequent CALLs, use the cached Lex.

Note that this implies that the Lex structure with its spread must be reentrant, that is, reusable and shareable between different threads and calls. The runtime state for a procedure is kept in the `sp_rcontext` in THD.

The mechanisms of storing, finding, and dropping procedures are encapsulated in the files `sp.{cc,h}`.

CALLING a Procedure

A `CALL` is parsed just like any statement. The resulting Lex has the `sql_command` `SQLCOM_CALL`, the procedure's name and the parameters are pushed to the Lex' `value_list`.

`sql_parse.cc:mysql_execute_command()` then uses `sp.cc:sp_find()` to get the `sp_head` for the procedure (which may have been read from the database or fetched from the in-memory cache) and calls the `sp_head`'s method `execute()`. Note: It's important that substatements called by the procedure do not do `send_ok()`. Fortunately, there is a flag in THD->net to disable this during CALLs. If a substatement fails, it will however send an error back to the client, so the CALL mechanism must return immediately and without sending an error.

The `sp_head::execute()` method works as follows:

1. Keep a pointer to the old runtime context in THD (if any)
2. Create a new runtime context. The information about the required size is in `sp_head`'s parse time context.
3. Push each parameter (from the CALL's Lex->value_list) to the new context. If it's an OUT or INOUT parameter, the parameter's offset in the caller's frame is set in the new context as well.
4. For each instruction, call its `execute()` method. The result is a pointer to the next instruction to execute (or NULL) if an error occurred.
5. On success, set the new values of the OUT and INOUT parameters in the caller's frame.

USE database

Before executing the instruction we also keeps the current default database (if any). If this was changed during execution (i.e. a `USE` statement has been executed), we restore the current database to the original.

This is the most useful way to handle `USE` in procedures. If we didn't, the caller would find himself in a different database after calling a function, which can be confusing. Restoring the database also gives full freedom to the procedure writer: - It's possible to write "general" procedures that are independent of the actual database name. - It's possible to write procedures that work on a particular database by calling `USE`, without having to use fully qualified table names everywhere (which doesn't help if you want to call other, "general", procedures anyway).

Evaluating Items

There are three occasions where we need to evaluate an expression:

- When SETing a variable
- When CALLing a procedure
- When testing an expression for a branch (in IF, WHILE, etc)

The semantics in stored procedures is "call-by-value", so we have to evaluate any "func" Items at the point of the CALL or SET, otherwise we would get a kind of "lazy" evaluation with unexpected results with respect to OUT parameters for instance. For this the support function, `sp_head.cc:eval_func_item()` is needed.

Calling a FUNCTION

Functions don't have an explicit call keyword like procedures. Instead, they appear in expressions with the conventional syntax `fun(arg, ...)`. The problem is that we already have [User Defined Functions](#) (UDFs) which are called the same way. A UDF is detected by the lexical analyzer (not the parser!), in the `find_keyword()` function, and returns a `UDF_*_FUNC` or `UDA_*_SUM` token with the `udf_func` object as the `yyval`.

So, stored functions must be handled in a similar way, and as a consequence, UDFs and functions must not have the same name.

Detecting and Parsing a FUNCTION Invocation

The existence of UDFs are checked during the lexical analysis (in `sql_lex.cc:find_keyword()`). This has the drawback that they must exist before they are referred to, which was ok before SPs existed, but then it becomes a problem. The first implementation of SP FUNCTIONS will work the same way, but this should be fixed a.s.a.p. (This will require some reworking of the way UDFs are handled, which is why it's not done from the start.) For the time being, a FUNCTION is detected the same way, and returns the token `SP_FUNC`. During the parsing we only check for the *existence* of the function, we don't parse it, since we can't call the parser recursively.

When encountering a `SP_FUNC` with parameters in the expression parser, an instance of the new `Item_func_sp` class is created. Unlike UDFs, we don't have different classes for different return types, since we at this point don't know the type.

Collecting FUNCTIONS to invoke

A FUNCTION differs from a PROCEDURE in one important aspect: Whereas a PROCEDURE is CALLED as statement by itself, a FUNCTION is invoked "on-the-fly" during the execution of *another* statement. This makes things a lot more complicated compared to CALL: - We can't read and parse the FUNCTION from the [mysql.proc table](#) at the point of invocation; the server requires that all tables used are opened and locked at the beginning of the query execution. One "obvious" solution would be to simply push "mysql.proc" to the list of tables used by the query, but this implies a "join" with this table if the query is a select, so it doesn't work (and we can't exclude this table easily; since a privileged user might in fact want to search the proc table). Another solution would of course be to allow the opening and closing of the [mysql.proc table](#) during a query execution, but this is not possible at the present.

So, the solution is to collect the names of the referred FUNCTIONS during parsing in the lex. Then, before doing anything else in `mysql_execute_command()`, read all functions from the database and keep them in the THD, where the function `sp_find_function()` can find them during the execution. Note: Even with an in-memory cache, we must still make sure that the functions are indeed read and cached at this point. The code that read and cache functions from the database must also be invoked recursively for each read FUNCTION to make sure we have *all* the functions we need.

Parsing DROP PROCEDURE/FUNCTION

The procedure name is pushed to `Lex->value_list`. The `sql_command` code for the result of parsing a is `SQLCOM_DROP_PROCEDURE / SQLCOM_DROP_FUNCTION`.

Dropping is done by simply getting the procedure with the `sp_find()` function and calling `sp_drop()` (both in `sp.{cc,h}`).

[DROP PROCEDURE/DROP FUNCTION](#) also supports the non-standard "IF EXISTS", analogous to other [DROP](#) statements in MariaDB.

Condition and Handlers

Condition names are lexical entities and are kept in the parser context just like variables. But, conditions are just "aliases" for SQLSTATE strings, or MySQL error codes (which is a non-standard extension in MySQL), and are only used during parsing.

Handlers come in three types, CONTINUE, EXIT and UNDO. The latter is like an EXIT handler with an implicit rollback, and is currently not implemented. The EXIT handler jumps to the end of its BEGIN-END block when finished. The CONTINUE handler returns to the statement following that which invoked the handler.

The handlers in effect at any point is part of each thread's runtime state, so we need to push and pop handlers in the `sp_rcontext` during execution. We use special instructions for this: - `sp_instr_hpush_jump` Push a handler. The instruction contains the necessary information, like which conditions we handle and the location of the handler. The jump takes us to the location after the handler code. - `sp_instr_hpop` Pop the handlers of the current frame (which we are just leaving).

It might seem strange to jump past the handlers like that, but there's no extra cost in doing this, and for technical reasons it's easiest for the parser to generate the handler instructions when they occur in the source.

When an error occurs, one of the error routines is called and an error message is normally sent back to the client immediately. Catching a condition must be done in these error routines (there are quite a few) to prevent them from doing this. We do this by calling a method in the THD's `sp_rcontext` (if there is one). If a handler is found, this is recorded in the context and the routine returns without sending the error message. The execution loop (`sp_head::execute()`) checks for this after each statement and invokes the handler that has been found. If several errors or warnings occur during one statement, only the first is caught, the rest are ignored.

Invoking and returning from a handler is trivial in the EXIT case. We simply jump to it, and it will have an `sp_instr_jump` as its last instruction.

Calling and returning from a CONTINUE handler poses some special problems. Since we need to return to the point after its invocation, we push the return location on a stack in the `sp_rcontext` (this is done by the execution loop). The handler then ends with a special instruction, `sp_instr_hreturn`, which returns to this location.

CONTINUE handlers have one additional problem: They are parsed at the lexical level where they occur, so variable offsets will assume that it's actually called at that level. However, a handler might be invoked from a sub-block where additional local variables have been declared, which will then share the location of any local variables in the handler itself. So, when calling a CONTINUE handler, we need to save any local variables above the handler's frame offset, and restore them upon

return. (This is not a problem for EXIT handlers, since they will leave the block anyway.) This is taken care of by the execution loop and the `sp_instr_hreturn` instruction.

Examples

EXIT handler:

```
begin
  declare x int default 0;

  begin
    declare exit handler for 'XXXXX' set x = 1;

    (statement1);
    (statement2);
  end;
  (statement3);
end
```

```
Pos.  Instruction
0    sp_instr_set(0, '0')
1    sp_instr_hpush_jump(4, 1)      # location and frame size
2    sp_instr_set(0, '1')
3    sp_instr_jump(6)
4    sp_instr_stmt('statement1')
5    sp_instr_stmt('statement2')
6    sp_instr_hpop(1)
7    sp_instr_stmt('statement3')
```

CONTINUE handler:

```
create procedure hndlr1(val int)
begin
  declare x int default 0;
  declare foo condition for 1146;
  declare continue handler for foo set x = 1;

  insert into t3 values ("hndlr1", val);      # Non-existing table?
  if x>0 then
    insert into t1 values ("hndlr1", val);    # This instead then
  end if;
end
```

```
Pos.  Instruction
0    sp_instr_set(1, '0')
1    sp_instr_hpush_jump(4, 2)
2    sp_instr_set(1, '1')
3    sp_instr_hreturn(2)              # frame size
4    sp_instr_stmt('insert ... t3 ...')
5    sp_instr_jump_if_not(7, 'x>0')
6    sp_instr_stmt('insert ... t1 ...')
7    sp_instr_hpop(2)
```

Cursors

For stored procedures to be really useful, you want to have cursors. MySQL doesn't yet have "real" cursor support (with API and ODBC support, allowing updating, arbitrary scrolling, etc), but a simple asensitive, non-scrolling, read-only cursor can be implemented in SPs using the class `Protocol_cursor`. This class intercepts the creation and sending of results sets and instead stores it in-memory, as `MYSQL_FIELDS` and `MYSQL_ROWS` (as in the client API).

To support this, we need the usual name binding support in `sp_pcontext` (similar to variables and conditions) to keep track on declared cursor names, and a corresponding run-time mechanism in `sp_rcontext`. Cursors are lexically scoped like everything with a body or BEGIN/END block, so they are pushed and popped as usual (see conditions and variables above). The basic operations on a cursor are OPEN, FETCH and CLOSE, which will each have a corresponding instruction. In addition, we need instructions to push a new cursor (this will encapsulate the LEX of the SELECT statement of the cursor), and a pop instruction: - `sp_instr_cpsh` Push a cursor to the `sp_rcontext`. This instruction contains the LEX for the select statement - `sp_instr_cpop` Pop a number of cursors from the `sp_rcontext`. - `sp_instr_copen` Open a cursor: This will execute the select and get the result set in a separate memroot. - `sp_instr_cfetch` Fetch the next row from the in-memory result set. The instruction contains a list of the variables (frame offsets) to set. - `sp_instr_cclose` Free the result set.

A cursor is a separate class, `sp_cursor` (defined in `sp_rcontext.h`) which encapsulates the basic operations used by the above instructions. This class contains the `LEX`, `Protocol_cursor` object, and its `memroot`, as well as the cursor's current state. Compiling and executing is fairly straight-forward. `sp_instr_copen` is a subclass of `sp_instr_stmt` and uses its mechanism to execute a substatement.

Example

```
begin
  declare x int;
  declare c cursor for select a from t1;

  open c;
  fetch c into x;
  close c;
end
```

```
Pos.  Instruction
0    sp_instr_cpush('select a from ...')
1    sp_instr_copen(0)                # The 0'th cursor
2    sp_instr_cfetch(0)              # Contains the variable list
3    sp_instr_cclose(0)
4    sp_instr_cpop(1)
```

The SP cache

There are two ways to cache SPs:

1. one global cache, share by all threads/connections,
2. one cache per thread.

There are pros and cons with both methods:

1.
 - Pros: Save memory, each SP only read from table once,
 - Cons: Needs locking (= serialization at access), requires thread-safe data structures,
2.
 - Pros: Fast, no locking required (almost), limited thread-safe requirement,
 - Cons: Uses more memory, each SP read from table once per thread.

Unfortunately, we cannot use alternative 1 for the time being, as most of the data structures to be cached (`lex` and `items`) are not reentrant and thread-safe. (Things are modified at execution, we have `THD` pointers stored everywhere, etc.) This leaves us with alternative 2, one cache per thread; or actually two, since we keep `FUNCTIONs` and `PROCEDUREs` in separate caches. This is not that terrible; the only case when it will perform significantly worse than a global cache is when we have an application where new threads are connecting, calling a procedure, and disconnecting, over and over again.

The cache implementation itself is simple and straightforward, a hashtable wrapped in a class and a C API (see APIs below).

There is however one issue with multiple caches: dropping and altering procedures. Normally, this should be a very rare event in a running system; it's typically something you do during development and testing, so it's not unthinkable that we would simply ignore the issue and let any threads running with a cached version of an SP keep doing so until its disconnected. But assuming we want to keep the caches consistent with respect to drop and alter, it can be done:

1. A global counter is needed, initialized to 0 at start.
2. At each `DROP` or `ALTER`, increase the counter by one.
3. Each cache has its own copy of the counter, copied at the last read.
4. When looking up a name in the cache, first check if the global counter is larger than the local copy. If so, clear the cache and return "not found", and update the local counter; otherwise, lookup as usual.

This minimizes the cost to a single brief lock for the access of an integer when operating normally. Only in the event of an actual drop or alter, is the cache cleared. This may seem to be drastic, but since we assume that this is a rare event, it's not a problem. It would of course be possible to have a much more fine-grained solution, keeping track of each SP, but the overhead of doing so is not worth the effort.

Class and Function APIs

This is an outline of the key types. Some types and other details in the actual files have been omitted for readability.

The parser context: `sp_pcontext.h`

```
typedef enum
{
  sp_param_in,
```

```

    sp_param_out,
    sp_param_inout
} sp_param_mode_t;

typedef struct
{
    LEX_STRING name;
    enum enum_field_types type;
    sp_param_mode_t mode;
    uint offset;                // Offset in current frame
    my_bool isset;
} sp_pvar_t;

typedef struct sp_cond_type
{
    enum { number, state, warning, notfound, exception } type;
    char sqlstate[6];
    uint mysqlerr;
} sp_cond_type_t;

class sp_pcontext
{
    sp_pcontext();

    // Return the maximum frame size
    uint max_framesize();

    // Return the current frame size
    uint current_framesize();

    // Return the number of parameters
    uint params();

    // Set the number of parameters to the current frame size
    void set_params();

    // Set type of the variable at offset 'i' in the frame
    void set_type(uint i, enum enum_field_types type);

    // Mark the i:th variable to "set" (i.e. having a value) with
    // 'val' true.
    void set_isset(uint i, my_bool val);

    // Push the variable 'name' to the frame.
    void push_var(LEX_STRING *name,
                 enum enum_field_types type, sp_param_mode_t mode);

    // Pop 'num' variables from the frame.
    void pop_var(uint num = 1);

    // Find variable by name
    sp_pvar_t *find_pvar(LEX_STRING *name);

    // Find variable by index
    sp_pvar_t *find_pvar(uint i);

    // Push label 'name' of instruction index 'ip' to the label context
    sp_label_t *push_label(char *name, uint ip);

    // Find label 'name' in the context
    sp_label_t *find_label(char *name);

    // Return the last pushed label
    sp_label_t *last_label();

    // Return and remove the last pushed label.
    sp_label_t *pop_label();

    // Push a condition to the context
    void push_cond(LEX_STRING *name, sp_cond_type_t *val);

    // Pop a 'num' condition from the context
    void pop_cond(uint num);

    // Find a condition in the context

```

```

// Find a condition in the context
sp_cond_type_t *find_cond(LEX_STRING *name);

// Increase the handler count
void add_handler();

// Returns the handler count
uint handlers();

// Push a cursor
void push_cursor(LEX_STRING *name);

// Find a cursor
my_bool find_cursor(LEX_STRING *name, uint *poff);

// Pop 'num' cursors
void pop_cursor(uint num);

// Return the number of cursors
uint cursors();
}

```

Run-time context (call frame): sp_rcontext.h:

```

#define SP_HANDLER_NONE      0
#define SP_HANDLER_EXIT     1
#define SP_HANDLER_CONTINUE 2
#define SP_HANDLER_UNDO    3

typedef struct
{
    struct sp_cond_type *cond;
    uint handler;          // Location of handler
    int type;
    uint foffset;         // Frame offset for the handlers declare level
} sp_handler_t;

class sp_rcontext
{
public:
    // 'fsize' is the max size of the context, 'hmax' the number of handlers,
    // 'cmax' the number of cursors
    sp_rcontext(uint fsize, uint hmax, , uint cmax);

    // Push value (parameter) 'i' to the frame
    void push_item(Item *i);

    // Set slot 'idx' to value 'i'
    void set_item(uint idx, Item *i);

    // Return the item in slot 'idx'
    Item *get_item(uint idx);

    // Set the "out" index 'oidx' for slot 'idx'. If it's an IN slot,
    // use 'oidx' -1.
    void set_oindex(uint idx, int oidx);

    // Return the "out" index for slot 'idx'
    int get_oindex(uint idx);

    // Set the FUNCTION result
    void set_result(Item *i);

    // Get the FUNCTION result
    Item *get_result();

    // Push handler at location 'h' for condition 'cond'. 'f' is the
    // current variable frame size.
    void push_handler(sp_cond_type_t *cond, uint h, int type, uint f);

    // Pop 'count' handlers
    void pop_handlers(uint count);

    // Find a handler for this error. This sets the state for a found
    // handler in the context. If called repeatedly without clearing,

```

```

// only the first call's state is kept.
int find_handler(uint sql_errno);

// Returns 1 if a handler has been found, with '*ip' and '*fp' set
// to the handler location and frame size respectively.
int found_handler(uint *ip, uint *fp);

// Clear the found handler state.
void clear_handler();

// Push a return address for a CONTINUE handler
void push_hstack(uint ip);

// Pop the CONTINUE handler return stack
uint pop_hstack();

// Save variables from frame index 'fp' and up.
void save_variables(uint fp);

// Restore saved variables from to frame index 'fp' and up.
void restore_variables(uint fp);

// Push a cursor for the statement (lex)
void push_cursor(LEX *lex);

// Pop 'count' cursors
void pop_cursors(uint count);

// Pop all cursors
void pop_all_cursors();

// Get the 'i'th cursor
sp_cursor *get_cursor(uint i);

}

```

The procedure: sp_head.h:

```

#define TYPE_ENUM_FUNCTION 1
#define TYPE_ENUM_PROCEDURE 2

class sp_head
{
    int m_type;                // TYPE_ENUM_FUNCTION or TYPE_ENUM_PROCEDURE

    sp_head();

    void init(LEX_STRING *name, LEX *lex, LEX_STRING *comment, char suid);

    // Store this procedure in the database. This is a wrapper around
    // the function sp_create_procedure().
    int create(THD *);

    // Invoke a FUNCTION
    int
    execute_function(THD *thd, Item **args, uint argcount, Item **resp);

    // CALL a PROCEDURE
    int
    execute_procedure(THD *thd, List<Item> *args);

    // Add the instruction to this procedure.
    void add_instr(sp_instr *);

    // Returns the number of instructions.
    uint instructions();

    // Returns the last instruction
    sp_instr *last_instruction();

    // Resets lex in 'thd' and keeps a copy of the old one.
    void reset_lex(THD *);

    // Restores lex in 'thd' from our copy, but keeps some status from the
    // one in 'thd', like ptr, tables, fields, etc.
    void restore_lex(THD *);

    // Put the instruction on the backpatch list, associated with
    // the label.
    void push_backpatch(sp_instr *, struct sp_label *);

    // Update all instruction with this label in the backpatch list to
    // the current position.
    void backpatch(struct sp_label *);

    // Returns the SP name (with optional length in '*lenp').
    char *name(uint *lenp = 0);

    // Returns the result type for a function
    Item_result result();

    // Sets various attributes
    void sp_set_info(char *creator, uint creatorlen,
                    longlong created, longlong modified,
                    bool suid, char *comment, uint commentlen);
}

```

Instructions

The base class

```

class sp_instr
{
    // 'ip' is the index of this instruction
    sp_instr(uint ip);

    // Execute this instruction.
    // '*nextp' will be set to the index of the next instruction
    // to execute. (For most instruction this will be the
    // instruction following this one.)
    // Returns 0 on success, non-zero if some error occurred.
    virtual int execute(THD *, uint *nextp)
}
<<code>>

```

```

==== Statement instruction
<<code>>
class sp_instr_stmt : public sp_instr
{
    sp_instr_stmt(uint ip);

    int execute(THD *, uint *nextp);

    // Set the statement's Lex
    void set_lex(LEX *);

    // Return the statement's Lex
    LEX *get_lex();
}

```

SET instruction

```

class sp_instr_set : public sp_instr
{
    // 'offset' is the variable's frame offset, 'val' the value,
    // and 'type' the variable type.
    sp_instr_set(uint ip,
                 uint offset, Item *val, enum enum_field_types type);

    int execute(THD *, uint *nextp);
}

```

Unconditional jump

```

class sp_instr_jump : public sp_instr
{
    // No destination, must be set.
    sp_instr_jump(uint ip);

    // 'dest' is the destination instruction index.
    sp_instr_jump(uint ip, uint dest);

    int execute(THD *, uint *nextp);

    // Set the destination instruction 'dest'.
    void set_destination(uint dest);
}

```

Conditional jump

```

class sp_instr_jump_if_not : public sp_instr_jump
{
    // Jump if 'i' evaluates to false. Destination not set yet.
    sp_instr_jump_if_not(uint ip, Item *i);

    // Jump to 'dest' if 'i' evaluates to false.
    sp_instr_jump_if_not(uint ip, Item *i, uint dest)

    int execute(THD *, uint *nextp);
}

```

Return a function value

```

class sp_instr_freturn : public sp_instr
{
    // Return the value 'val'
    sp_instr_freturn(uint ip, Item *val, enum enum_field_types type);

    int execute(THD *thd, uint *nextp);
}

```

Push a handler and jump

```

class sp_instr_hpush_jump : public sp_instr_jump
{
    // Push handler of type 'htype', with current frame size 'fp'
    sp_instr_hpush_jump(uint ip, int htype, uint fp);

    int execute(THD *thd, uint *nextp);

    // Add condition for this handler
    void add_condition(struct sp_cond_type *cond);
}

```

Pops handlers

```

class sp_instr_hpop : public sp_instr
{
    // Pop 'count' handlers
    sp_instr_hpop(uint ip, uint count);

    int execute(THD *thd, uint *nextp);
}

```

Return from a CONTINUE handler

```

class sp_instr_hreturn : public sp_instr
{
    // Return from handler, and restore variables to 'fp'.
    sp_instr_hreturn(uint ip, uint fp);

    int execute(THD *thd, uint *nextp);
}

```

Push a CURSOR

```

class sp_instr_cpush : public sp_instr_stmt
{
    // Push a cursor for statement 'lex'
    sp_instr_cpush(uint ip, LEX *lex)

    int execute(THD *thd, uint *nextp);
}

```

Pop CURSORS

```

class sp_instr_cpop : public sp_instr_stmt
{
    // Pop 'count' cursors
    sp_instr_cpop(uint ip, uint count)

    int execute(THD *thd, uint *nextp);
}

```

Open a CURSOR

```

class sp_instr_copen : public sp_instr_stmt
{
    // Open the 'c'th cursor
    sp_instr_copen(uint ip, uint c);

    int execute(THD *thd, uint *nextp);
}

```

Close a CURSOR

```

class sp_instr_cclose : public sp_instr
{
    // Close the 'c'th cursor
    sp_instr_cclose(uint ip, uint c);

    int execute(THD *thd, uint *nextp);
}

```

Fetch a row with CURSOR

```

class sp_instr_cfetch : public sp_instr
{
    // Fetch next with the 'c'th cursor
    sp_instr_cfetch(uint ip, uint c);

    int execute(THD *thd, uint *nextp);

    // Add a target variable for the fetch
    void add_to_varlist(struct sp_pvar *var);
}

```

Utility functions: sp.h

```

#define SP_OK                0
#define SP_KEY_NOT_FOUND    -1
#define SP_OPEN_TABLE_FAILED -2
#define SP_WRITE_ROW_FAILED -3
#define SP_DELETE_ROW_FAILED -4
#define SP_GET_FIELD_FAILED -5
#define SP_PARSE_ERROR      -6

// Finds a stored procedure given its name. Returns NULL if not found.
sp_head *sp_find_procedure(THD *, LEX_STRING *name);

// Store the procedure 'name' in the database. 'def' is the complete
// definition string ("create procedure ...").
int sp_create_procedure(THD *,
                       char *name, uint namelen,
                       char *def, uint deflen,
                       char *comment, uint commentlen, bool suid);

// Drop the procedure 'name' from the database.
int sp_drop_procedure(THD *, char *name, uint namelen);

// Finds a stored function given its name. Returns NULL if not found.
sp_head *sp_find_function(THD *, LEX_STRING *name);

// Store the function 'name' in the database. 'def' is the complete
// definition string ("create function ...").
int sp_create_function(THD *,
                      char *name, uint namelen,
                      char *def, uint deflen,
                      char *comment, uint commentlen, bool suid);

// Drop the function 'name' from the database.
int sp_drop_function(THD *, char *name, uint namelen);

```

The cache: sp_cache.h

```

/* Initialize the SP caching once at startup */
void sp_cache_init();

/* Clear the cache *cp and set *cp to NULL */
void sp_cache_clear(sp_cache **cp);

/* Insert an SP to cache. If **cp points to NULL, it's set to a
new cache */
void sp_cache_insert(sp_cache **cp, sp_head *sp);

/* Lookup an SP in cache */
sp_head *sp_cache_lookup(sp_cache **cp, char *name, uint namelen);

/* Remove an SP from cache */
void sp_cache_remove(sp_cache **cp, sp_head *sp);

```

The mysql.proc schema

This is the [mysql.proc table](#) used in [MariaDB 10.4](#):

```

CREATE TABLE `proc` (
  `db` char(64) CHARACTER SET utf8 COLLATE utf8_bin NOT NULL DEFAULT '',

4.2.2 Stored Functions

A stored function is a defined function that is called from within an SQL statement like a regular function, and returns a single value.

Stored Function Overview

Function called from within an SQL statement, returning a single value

Stored Routine Privileges

Privileges associated with stored functions and stored procedures.

CREATE FUNCTION

Creates a stored function.

ALTER FUNCTION

Change the characteristics of a stored function.

DROP FUNCTION

Drop a stored function.

SHOW CREATE FUNCTION

Shows the CREATE statement that creates the function.

SHOW FUNCTION STATUS

Stored function characteristics

SHOW FUNCTION CODE

Representation of the internal implementation of the stored function

Stored Aggregate Functions

Custom aggregate functions.

Binary Logging of Stored Routines

Stored routines require extra consideration when binary logging.

Stored Function Limitations

Restrictions applying to stored functions

Information Schema ROUTINES Table

Stored procedures and stored functions information

4.2.2.1 Stored Function Overview

Contents

1. [Creating Stored Functions](#)
2. [Stored Function listings and definitions](#)
3. [Dropping and Updating Stored Functions](#)
4. [Permissions in Stored Functions](#)

A Stored Function is a defined function that is called from within an SQL statement like a regular function, and returns a single value.

Creating Stored Functions

Here's a skeleton example to see a stored function in action:

```
DELIMITER //

CREATE FUNCTION FortyTwo() RETURNS TINYINT DETERMINISTIC
BEGIN
  DECLARE x TINYINT;
  SET x = 42;
  RETURN x;
END

//

DELIMITER ;
```

First, the delimiter is changed, since the function definition will contain the regular semicolon delimiter. See [Delimiters in the mariadb client](#) for more. Then the function is named `FortyTwo` and defined to return a `tinyint`. The `DETERMINISTIC` keyword is not necessary in all cases (although if binary logging is on, leaving it out will throw an error), and is to help the query optimizer choose a query plan. A deterministic function is one that, given the same arguments, will always return the same result.

Next, the function body is placed between `BEGIN` and `END` statements. It declares a `tinyint`, `x`, which is simply set to 42, and this is the result returned.

```
SELECT FortyTwo();
+-----+
| FortyTwo() |
+-----+
|          42 |
+-----+
```

Of course, a function that doesn't take any arguments is of little use. Here's a more complex example:

```
DELIMITER //
CREATE FUNCTION VatCents(price DECIMAL(10,2)) RETURNS INT DETERMINISTIC
BEGIN
  DECLARE x INT;
  SET x = price * 114;
  RETURN x;
END //
Query OK, 0 rows affected (0.04 sec)
DELIMITER ;
```

This function takes an argument, `price` which is defined as a DECIMAL, and returns an INT.

Take a look at the [CREATE FUNCTION](#) page for more details.

From [MariaDB 10.3.3](#), it is also possible to create [stored aggregate functions](#).

Stored Function listings and definitions

To find which stored functions are running on the server, use [SHOW FUNCTION STATUS](#).

```
SHOW FUNCTION STATUS\G
***** 1. row *****
      Db: test
      Name: VatCents
      Type: FUNCTION
      Definer: root@localhost
      Modified: 2013-06-01 12:40:31
      Created: 2013-06-01 12:40:31
      Security_type: DEFINER
      Comment:
character_set_client: utf8
collation_connection: utf8_general_ci
      Database Collation: latin1_swedish_ci
1 row in set (0.00 sec)
```

or query the [routines table](#) in the INFORMATION_SCHEMA database directly:

```
SELECT ROUTINE_NAME FROM INFORMATION_SCHEMA.ROUTINES WHERE
      ROUTINE_TYPE='FUNCTION';
+-----+
| ROUTINE_NAME |
+-----+
| VatCents     |
+-----+
```

To find out what the stored function does, use [SHOW CREATE FUNCTION](#).

```
SHOW CREATE FUNCTION VatCents\G
***** 1. row *****
      Function: VatCents
      sql_mode:
      Create Function: CREATE DEFINER=`root`@`localhost` FUNCTION `VatCents` (price
DECIMAL(10,2)) RETURNS int(11)
      DETERMINISTIC
BEGIN
      DECLARE x INT;
      SET x = price * 114;
      RETURN x;
END
character_set_client: utf8
collation_connection: utf8_general_ci
      Database Collation: latin1_swedish_ci
```

Dropping and Updating Stored Functions

To drop a stored function, use the [DROP FUNCTION](#) statement.

```
DROP FUNCTION FortyTwo;
```

To change the characteristics of a stored function, use [ALTER FUNCTION](#). Note that you cannot change the parameters or body of a stored function using this statement; to make such changes, you must drop and re-create the function using `DROP FUNCTION` and `CREATE FUNCTION`.

Permissions in Stored Functions

See the article [Stored Routine Privileges](#).

4.2.1.2 Stored Routine Privileges

1.1.1.3.1.3 CREATE FUNCTION

1.1.1.2.1.1.4 ALTER FUNCTION

1.1.1.3.3.3 DROP FUNCTION

1.1.1.2.8.14 SHOW CREATE FUNCTION

1.1.1.2.8.31 SHOW FUNCTION STATUS

4.2.2.8 SHOW FUNCTION CODE

Syntax

```
SHOW FUNCTION CODE func_name
```

Description

`SHOW FUNCTION CODE` shows a representation of the internal implementation of the stored function.

It is similar to `SHOW PROCEDURE CODE` but for [stored functions](#).

1.2.4.1 Stored Aggregate Functions

3.1.14.5 Binary Logging of Stored Routines

4.2.2.11 Stored Function Limitations

The following restrictions apply to [stored functions](#).

- All of the restrictions listed in [Stored Routine Limitations](#).
- Any statements that return a result set are not permitted. For example, a regular `SELECTs` is not permitted, but a `SELECT INTO` is. A cursor and `FETCH` statement is permitted.
- `FLUSH` statements are not permitted.
- Statements that perform explicit or implicit commits or rollbacks are not permitted
- Cannot be used recursively.
- Cannot make changes to a table that is already in use (reading or writing) by the statement invoking the stored function.
- Cannot refer to a temporary table multiple times under different aliases, even in different statements.
- `ROLLBACK TO SAVEPOINT` and `RELEASE SAVEPOINT` statement which are in a stored function cannot refer to a savepoint which has been defined out of the current function.
- Prepared statements (`PREPARE`, `EXECUTE`, `DEALLOCATE PREPARE` [☞](#)) cannot be used, and therefore nor can statements be constructed as strings and then executed.

1.1.1.2.9.1.1.40 Information Schema ROUTINES Table

1.1.1.7 Stored Routine Statements

3.1.14.5 Binary Logging of Stored Routines

4.2.5 Stored Routine Limitations

The following SQL statements are not permitted inside any [stored routines](#) ([stored functions](#), [stored procedures](#), [events](#) or [triggers](#)).

- [ALTER VIEW](#); you can use [CREATE OR REPLACE VIEW](#) instead.
- [LOAD DATA](#) and [LOAD TABLE](#) .
- [CHANGE MASTER TO](#)
- [INSERT DELAYED](#) is permitted, but the statement is handled as a regular [INSERT](#).
- [LOCK TABLES](#) and [UNLOCK TABLES](#).
- References to [local variables](#) within prepared statements inside a stored routine (use [user-defined variables](#) instead).
- [BEGIN \(WORK\)](#) is treated as the beginning of a [BEGIN END](#) block, not a transaction, so [START TRANSACTION](#) needs to be used instead.
- The number of permitted recursive calls is limited to [max_sp_recursion_depth](#). If this variable is 0 (default), recursivity is disabled. The limit does not apply to stored functions.
- Most statements that are not permitted in prepared statements are not permitted in stored programs. See [Prepare Statement: Permitted statements](#) for a list of statements that can be used. [SIGNAL](#), [RESIGNAL](#) and [GET DIAGNOSTICS](#)  are exceptions, and may be used in stored routines.

There are also further limitations specific to the kind of stored routine.

Note that, if a stored program calls another stored program, the latter will inherit the caller's limitations. So, for example, if a stored procedure is called by a stored function, that stored procedure will not be able to produce a result set, because stored functions can't do this.

4.2.1.2 Stored Routine Privileges

4.3 Triggers & Events

Triggers

Set of statements that run when an event occurs on a table.

Event Scheduler

Named database objects containing SQL statements to be executed at a later stage.

4.3.1 Triggers

A trigger is a set of statements that run when an event occurs on a table.

Trigger Overview

Statements run when an event occurs on a table.

Binary Logging of Stored Routines

Stored routines require extra consideration when binary logging.

CREATE TRIGGER

Create a new trigger.

DROP TRIGGER

Drops a trigger.

There are [4 related questions](#)

4.3.1.1 Trigger Overview

Contents

- [1. Events](#)
- [2. Triggers and Errors](#)
- [3. Creating a Trigger](#)
- [4. Dropping Triggers](#)
- [5. Triggers Metadata](#)
- [6. More Complex Triggers](#)
- [7. Trigger Errors](#)

A trigger, as its name suggests, is a set of statements that run, or are triggered, when an event occurs on a table.

Events

The event can be an INSERT, an UPDATE or a DELETE. The trigger can be executed BEFORE or AFTER the event. Until [MariaDB 10.2.3](#) , a table could have only one trigger defined for each event/timing combination: for example, a table could only have one BEFORE INSERT trigger.

The [LOAD DATA INFILE](#) and [LOAD XML](#) statements invoke INSERT triggers for each row that is being inserted.

The [REPLACE](#) statement is executed with the following workflow:

- BEFORE INSERT;
- BEFORE DELETE (only if a row is being deleted);
- AFTER DELETE (only if a row is being deleted);
- AFTER INSERT.

The [INSERT ... ON DUPLICATE KEY UPDATE](#) statement, when a row already exists, follows the following workflow:

- BEFORE INSERT;
- BEFORE UPDATE;
- AFTER UPDATE.

Otherwise, it works like a normal INSERT statement.

Note that [TRUNCATE TABLE](#) does not activate any triggers.

Triggers and Errors

With non-transactional storage engines, if a BEFORE statement produces an error, the statement will not be executed. Statements that affect multiple rows will fail before inserting the current row.

With transactional engines, triggers are executed in the same transaction as the statement that invoked them.

If a warning is issued with the SIGNAL or RESIGNAL statement (that is, an error with an SQLSTATE starting with '01'), it will be treated like an error.

Creating a Trigger

Here's a simple example to demonstrate a trigger in action. Using these two tables as an example:

```
CREATE TABLE animals (id mediumint(9)
NOT NULL AUTO_INCREMENT,
name char(30) NOT NULL,
PRIMARY KEY (`id`));

CREATE TABLE animal_count (animals int);

INSERT INTO animal_count (animals) VALUES (0);
```

We want to increment a counter each time a new animal is added. Here's what the trigger will look like:

```
CREATE TRIGGER increment_animal
AFTER INSERT ON animals
FOR EACH ROW
UPDATE animal_count SET animal_count.animals = animal_count.animals+1;
```

The trigger has:

- a *name* (in this case `increment_animal`)
- a trigger time (in this case *after* the specified trigger event)
- a trigger event (an `INSERT`)
- a table with which it is associated (`animals`)
- a set of statements to run (here, just the one `UPDATE` statement)

`AFTER INSERT` specifies that the trigger will run *after* an `INSERT`. The trigger could also be set to run *before*, and the statement causing the trigger could be a `DELETE` or an `UPDATE` as well. You can also have multiple triggers for an action. In this case you can use `FOLLOWS | PRECEDES other_trigger_name` to specify the order of the triggers.

The set of statements to run are the statements on the table of the trigger, therefore columns/values that change are always just a column name or an expression like `NEW.column_name`. Table references of other tables must come from explicit table references.

Now, if we insert a record into the `animals` table, the trigger will run, incrementing the `animal_count` table;

```
SELECT * FROM animal_count;
+-----+
| animals |
+-----+
|      0 |
+-----+

INSERT INTO animals (name) VALUES('aardvark');
INSERT INTO animals (name) VALUES('baboon');

SELECT * FROM animal_count;
+-----+
| animals |
+-----+
|      2 |
+-----+
```

For more details on the syntax, see [CREATE TRIGGER](#).

Dropping Triggers

To drop a trigger, use the [DROP TRIGGER](#) statement. Triggers are also dropped if the table with which they are associated is also dropped.

```
DROP TRIGGER increment_animal;
```

Triggers Metadata

The [Information Schema TRIGGERS Table](#) stores information about triggers.

The [SHOW TRIGGERS](#) statement returns similar information.

The [SHOW CREATE TRIGGER](#) statement returns a `CREATE TRIGGER` statement that creates the given trigger.

More Complex Triggers

Triggers can consist of multiple statements enclosed by a [BEGIN and END](#). If you're entering multiple statements on the command line, you'll want to temporarily set a new delimiter so that you can use a semicolon to delimit the statements inside your trigger. See [Delimiters in the mariadb client](#) for more.

```

DROP TABLE animals;

UPDATE animal_count SET animals=0;

CREATE TABLE animals (id mediumint(9) NOT NULL AUTO_INCREMENT,
name char(30) NOT NULL,
PRIMARY KEY (`id`))
ENGINE=InnoDB;

DELIMITER //
CREATE TRIGGER the_moose_are_loose
AFTER INSERT ON animals
FOR EACH ROW
BEGIN
  IF NEW.name = 'Moose' THEN
    UPDATE animal_count SET animal_count.animals = animal_count.animals+100;
  ELSE
    UPDATE animal_count SET animal_count.animals = animal_count.animals+1;
  END IF;
END; //

DELIMITER ;

INSERT INTO animals (name) VALUES('Aardvark');

SELECT * FROM animal_count;
+-----+
| animals |
+-----+
|      1 |
+-----+

INSERT INTO animals (name) VALUES('Moose');

SELECT * FROM animal_count;
+-----+
| animals |
+-----+
|     101 |
+-----+

```

Trigger Errors

If a trigger contains an error and the engine is transactional, or it is a BEFORE trigger, the trigger will not run, and will prevent the original statement from running as well. If the engine is non-transactional, and it is an AFTER trigger, the trigger will not run, but the original statement will.

Here, we'll drop the above examples, and then recreate the trigger with an error, a field that doesn't exist, first using the default [InnoDB](#), a transactional engine, and then again using [MyISAM](#), a non-transactional engine.

```

DROP TABLE animals;

CREATE TABLE animals (id mediumint(9) NOT NULL AUTO_INCREMENT,
name char(30) NOT NULL,
PRIMARY KEY (`id`))
ENGINE=InnoDB;

CREATE TRIGGER increment_animal
AFTER INSERT ON animals
FOR EACH ROW
UPDATE animal_count SET animal_count.id = animal_count.id+1;

INSERT INTO animals (name) VALUES('aardvark');
ERROR 1054 (42S22): Unknown column 'animal_count.id' in 'field list'

SELECT * FROM animals;
Empty set (0.00 sec)

```

And now the identical procedure, but with a MyISAM table.

```

DROP TABLE animals;

CREATE TABLE animals (id mediumint(9) NOT NULL AUTO_INCREMENT,
name char(30) NOT NULL,
PRIMARY KEY (`id`))
ENGINE=MyISAM;

CREATE TRIGGER increment_animal
AFTER INSERT ON animals
FOR EACH ROW
UPDATE animal_count SET animal_count.id = animal_count.id+1;

INSERT INTO animals (name) VALUES('aardvark');
ERROR 1054 (42S22): Unknown column 'animal_count.id' in 'field list'

SELECT * FROM animals;
+----+-----+
| id | name      |
+----+-----+
|  1 | aardvark |
+----+-----+

```

The following example shows how to use a trigger to validate data. The `SIGNAL` statement is used to intentionally produce an error if the email field is not a valid email. As the example shows, in that case the new row is not inserted (because it is a `BEFORE` trigger).

```

CREATE TABLE user (
  id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  first_name CHAR(20),
  last_name CHAR(20),
  email CHAR(100)
)
ENGINE = MyISAM;

DELIMITER //
CREATE TRIGGER bi_user
  BEFORE INSERT ON user
  FOR EACH ROW
BEGIN
  IF NEW.email NOT LIKE '_%@%._%' THEN
    SIGNAL SQLSTATE '45000' SET MESSAGE_TEXT = 'Email field is not valid';
  END IF;
END; //
DELIMITER ;

INSERT INTO user (first_name, last_name, email) VALUES ('John', 'Doe', 'john_doe.example.net');
ERROR 1644 (45000): Email field is not valid

SELECT * FROM user;
Empty set (0.00 sec)

```

4.3.1.9 Trigger Limitations

Contents

The following restrictions apply to [triggers](#).

- All of the restrictions listed in [Stored Routine Limitations](#).
- All of the restrictions listed in [Stored Function Limitations](#).
- Until [MariaDB 10.2.3](#), each table can have only one trigger for each timing/event combination (ie: you can't define two BEFORE INSERT triggers for the same table).
- Triggers are always executed for each row. The standard `FOR EACH STATEMENT` option is not supported in MariaDB.
- Triggers cannot operate on any tables in the `mysql`, `information_schema` or `performance_schema` database.
- Cannot return a resultset.
- The `RETURN` statement is not permitted, since triggers don't return any values. Use `LEAVE` to immediately exit a trigger.
- Triggers are not activated by [foreign key](#) actions.
- If a trigger is loaded into cache, it is not automatically reloaded when the table metadata changes. In this case a trigger can operate using the outdated metadata.
- By default, with row-based replication, triggers run on the master, and the effects of their executions are replicated to the slaves. However, starting from [MariaDB 10.1.1](#), it is possible to run triggers on the slaves. See [Running triggers on the slave for Row-based events](#).

4.3.1.10 Triggers and Implicit Locks

A [trigger](#) may reference multiple tables, and if a `LOCK TABLES` statement is used on one of the tables, other tables may at the same time also implicitly be locked due to the trigger.

If the trigger only reads from the other table, that table will be read locked. If the trigger writes to the other table, it will be write locked. If a table is read-locked for reading via `LOCK TABLES`, but needs to be write-locked because it could be modified by a trigger, a write lock is taken.

All locks are acquired together when the `LOCK TABLES` statement is issued and they are released together on `UNLOCK TABLES`.

Example

```
LOCK TABLE table1 WRITE
```

Assume `table1` contains the following trigger:

```
CREATE TRIGGER trigger1 AFTER INSERT ON table1 FOR EACH ROW
BEGIN
  INSERT INTO table2 VALUES (1);
  UPDATE table3 SET writes = writes+1
    WHERE id = NEW.id AND EXISTS (SELECT id FROM table4);
END;
```

Not only is `table1` write locked, `table2` and `table3` are also write locked, due to the possible `INSERT` and `UPDATE`, while `table4` is read locked due to the `SELECT`.

4.3.2 Event Scheduler

Events are named database objects containing SQL statements that are to be executed at a later stage, either once off, or at regular intervals.

Events Overview

[Scheduled events.](#)

Event Limitations

There are [2 related questions](#).

4.3.2.1 Events Overview

Contents

- [Creating Events](#)
 - [Example](#)
- [Executing Events](#)
- [Viewing Current Events](#)
 - [Example](#)
- [Altering Events](#)
 - [Example](#)
- [Dropping Events](#)
 - [Example](#)

Events are named database objects containing SQL statements that are to be executed at a later stage, either once off, or at regular intervals.

They function very similarly to the Windows Task Scheduler or Unix cron jobs.

Creating, modifying or deleting events requires the [EVENT privilege](#).

Creating Events

Events are created with the [CREATE EVENT](#) statement.

Example

```
CREATE EVENT test_event
ON SCHEDULE EVERY 1 MINUTE DO
UPDATE test.t1 SET a = a + 1;
```

Executing Events

Events are only executed if the event scheduler is running. This is determined by the value of the [event_scheduler](#) system variable, which needs to be set to `on` for the event scheduler to be running.

You can check if the Event scheduler is running with:

```

SHOW PROCESSLIST;
+----+-----+-----+-----+-----+-----+-----+-----+
| Id | User          | Host          | db   | Command | Time | State |
+----+-----+-----+-----+-----+-----+-----+
| 40 | root          | localhost    | test | Sleep   | 4687 |      |
NULL |              | 0.000 |
| 41 | root          | localhost    | test | Query   | 0    | init |
SHOW PROCESSLIST | 0.000 |
| 42 | event_scheduler | localhost    | NULL | Daemon  | 30   | Waiting for next activation | NULL
| 0.000 |
+----+-----+-----+-----+-----+-----+-----+

```

If the event scheduler is not running and `event_scheduler` has been set to `OFF`, use:

```
SET GLOBAL event_scheduler = ON;
```

to activate it. If `event_scheduler` has been set to `Disabled`, you cannot change the value at runtime. Changing the value of the `event_scheduler` variable requires the `SUPER` privilege.

Since [MariaDB 10.0.22](#), setting the `event_scheduler` system variable will also try to reload the `mysql.event` table if it was not properly loaded at startup.

Viewing Current Events

A list of current events can be obtained with the `SHOW EVENTS` statement. This only shows the event name and interval - the full event details, including the SQL, can be seen by querying the `Information Schema EVENTS` table, or with `SHOW CREATE EVENT`.

If an event is currently being executed, it can be seen by querying the `Information Schema PROCESSLIST` table, or with the `SHOW PROCESSLIST` statement.

Example

```

SHOW EVENTS\G;
***** 1. row *****
      Db: test
      Name: test_event
      Definer: root@localhost
      Time zone: SYSTEM
      Type: RECURRING
      Execute at: NULL
      Interval value: 1
      Interval field: MINUTE
      Starts: 2013-05-20 13:46:56
      Ends: NULL
      Status: ENABLED
      Originator: 1
character_set_client: utf8
collation_connection: utf8_general_ci
  Database Collation: latin1_swedish_ci

```

```

SHOW CREATE EVENT test_event\G
***** 1. row *****
      Event: test_event
      sql_mode:
      time_zone: SYSTEM
      Create Event: CREATE DEFINER=`root`@`localhost` EVENT `test_event` ON SCHEDULE EVERY 1
MINUTE STARTS '2013-05-20 13:46:56' ON COMPLETION NOT PRESERVE ENABLE DO UPDATE test.t1 SET a =
a + 1
character_set_client: utf8
collation_connection: utf8_general_ci
  Database Collation: latin1_swedish_ci

```

Altering Events

An event can be changed with the [ALTER EVENT](#) statement.

Example

```
ALTER EVENT test_event ON SCHEDULE EVERY '2:3' DAY_HOUR;
```

Dropping Events

Events are dropped with the [DROP EVENT](#) statement. Events are also automatically dropped once they have run for the final time according to their schedule, unless the `ON COMPLETION PRESERVE` clause has been specified.

Example

```
DROP EVENT test_event;  
Query OK, 0 rows affected (0.00 sec)
```

4.3.2.2 Event Limitations

The following restrictions apply to [Events](#).

- All of the restrictions listed in [Stored Routine Limitations](#).
- Events cannot return a resultset.
- Event names are case insensitive, so it's not possible to define two events in the same database if their case insensitive names will match. This restriction has applied since MariaDB/MySQL 5.1.8. If you are upgrading from an older version of MySQL, and have events that could clash, these events need to be renamed before the upgrade.
- Events do not support dates beyond the maximum that can be represented in the Unix epoch (2038-01-19).
- Events cannot be created, dropped or altered by another stored program, trigger or event.
- Events cannot create, drop or alter stored programs or triggers
- Event timings cannot be strictly predicted. The intervals MONTH, YEAR_MONTH, QUARTER and YEAR are all resolved in months. All others are resolved in seconds. A delay of up to two seconds is possible in extreme cases, and events scheduled to run at the same second cannot be executed in a given order. The `LAST_EXECUTED` column in the `INFORMATION_SCHEMA.EVENTS` table will however always be accurate to within a second.
- A new connection is used for each execution of statements within the body of an event, so the session counts for [server status variables](#) such as `Com_delete` and `Com_select` will not reflect these.
- Because the Event Scheduler depends on grant tables for its functionality, it is automatically disabled when the server is running with `--skip-grant-tables`.

4.4 Views

Views are stored queries that act as a virtual table.

Creating & Using Views

A tutorial on creating and using views.

CREATE VIEW

Create or replace a view.

ALTER VIEW

Change a view definition.

DROP VIEW

Removes one or more views.

SHOW CREATE VIEW

Shows the CREATE VIEW statement that creates a view.

Inserting and Updating with Views

Views can be used for inserting or updating with certain limitations.

RENAME TABLE

Change a table's name.

View Algorithms

Optional ALGORITHM clause when creating views

Information Schema VIEWS Table

Information about views.

SHOW TABLES

List of non-temporary tables, views or sequences.

6.2.3 Creating & Using Views

4.4.6 Inserting and Updating with Views

Contents

1. [Updating with views](#)
2. [Inserting with views](#)
3. [Checking whether a view is updatable](#)
4. [WITH CHECK OPTION](#)
5. [Examples](#)

A [view](#) can be used for inserting or updating. However, there are certain limitations.

Updating with views

A view cannot be used for updating if it uses any of the following:

- `ALGORITHM=TEMPTABLE` (see [View Algorithms](#))

- [HAVING](#)
- [GROUP BY](#)
- [DISTINCT](#)
- [UNION](#)
- [UNION ALL](#)
- An aggregate function, such as [MAX\(\)](#), [MIN\(\)](#), [SUM\(\)](#) or [COUNT\(\)](#)
- subquery in the SELECT list
- subquery in the WHERE clause referring to a table in the FROM clause
- if it has no underlying table because it refers only to literal values
- the FROM clause contains a non-updatable view.
- multiple references to any base table column
- an outer join
- an inner join where more than one table in the view definition is being updated
- if there's a LIMIT clause, the view does not contain all primary or not null unique key columns from the underlying table and the [updatable_views_with_limit](#) system variable is set to 0 .

Inserting with views

A view cannot be used for inserting if it fails any of the criteria for [updating](#), and must also meet the following conditions:

- the view contains all base table columns that don't have default values
- no base table columns are present in view select list more than once
- the view columns are all simple columns, and not derived in any way. The following are examples of derived columns
 - `column_name + 25`
 - `LOWER(column_name)`
 - `(subquery)`
 - `9.5`
 - `column1 / column2`

Checking whether a view is updatable

MariaDB stores an IS_UPDATABLE flag with each view, so it is always possible to see if MariaDB considers a view updatable (although not necessarily insertable) by querying the IS_UPDATABLE column in the INFORMATION_SCHEMA.VIEWS table.

WITH CHECK OPTION

The WITH CHECK OPTION clause is used to prevent updates or inserts to views unless the WHERE clause in the SELECT statement is true.

There are two keywords that can be applied. WITH LOCAL CHECK OPTION restricts the CHECK OPTION to only the view being defined, while WITH CASCADED CHECK OPTION checks all underlying views as well. CASCADED is treated as default if neither keyword is given.

If a row is rejected because of the CHECK OPTION, an error similar to the following is produced:

```
ERROR 1369 (HY000): CHECK OPTION failed 'db_name.view_name'
```

A view with a WHERE which is always false (like `WHERE 0`) and WITH CHECK OPTION is similar to a [BLACKHOLE](#) table: no row is ever inserted and no row is ever returned. An insertable view with a WHERE which is always false but no CHECK OPTION is a view that accepts data but does not show them.

Examples

```
CREATE TABLE table1 (x INT);

CREATE VIEW view1 AS SELECT x, 99 AS y FROM table1;
```

Checking whether the view is updateable:

```
SELECT TABLE_NAME, IS_UPDATABLE FROM INFORMATION_SCHEMA.VIEWS;
+-----+-----+
| TABLE_NAME | IS_UPDATABLE |
+-----+-----+
| view1      | YES          |
+-----+-----+
```

This query works, as the view is updateable:

```
UPDATE view1 SET x = 5;
```

This query fails, since column `y` is a literal.

```
UPDATE view1 SET y = 5;
ERROR 1348 (HY000): Column 'y' is not updateable
```

Here are three views to demonstrate the WITH CHECK OPTION clause.

```
CREATE VIEW view_check1 AS SELECT * FROM table1 WHERE x < 100 WITH CHECK OPTION;
CREATE VIEW view_check2 AS SELECT * FROM view_check1 WHERE x > 10 WITH LOCAL CHECK OPTION;
CREATE VIEW view_check3 AS SELECT * FROM view_check1 WHERE x > 10 WITH CASCADED CHECK OPTION;
```

This insert succeeds, as `view_check2` only checks the insert against `view_check2`, and the WHERE clause evaluates to true (150 is >10).

```
INSERT INTO view_check2 VALUES (150);
```

This insert fails, as `view_check3` checks the insert against both `view_check3` and the underlying views. The WHERE clause for `view_check1` evaluates as false (150 is >10, but 150 is not <100), so the insert fails.

```
INSERT INTO view_check3 VALUES (150);
ERROR 1369 (HY000): CHECK OPTION failed 'test.view_check3'
```

1.1.1.2.1.12 RENAME TABLE

4.4.8 View Algorithms

Contents

1. [Description](#)
2. [MERGE Limitations](#)
3. [MERGE Examples](#)
 1. [Example 1](#)
 2. [Example 2](#)

Description

The `CREATE VIEW` statement accepts an optional `ALGORITHM` clause, an extension to standard SQL for [Views](#).

It can contain one of three values: `MERGE`, `TEMPTABLE` or `UNDEFINED`, and affects how MariaDB will process the view.

With `MERGE`, the view definition and the related portion of the statement referring to the view are merged. If `TEMPTABLE` is selected, the view results are stored in a temporary table.

`MERGE` is usually more efficient, and a view can only be updated with this algorithm. `TEMPTABLE` can be useful in certain situations, as locks on the underlying tables can be released before the statement is finished processing.

If it's `UNDEFINED` (or the `ALGORITHM` clause is not used), MariaDB will choose what it thinks is the best algorithm. An algorithm can also be `UNDEFINED` if its defined as `MERGE`, but the view requires a temporary table.

Views with definition `ALGORITHM=MERGE` or `ALGORITHM=TEMPTABLE` got accidentally swapped between MariaDB and MySQL. When upgrading, you have to re-create views created with either of these definitions (see

MERGE Limitations

A view cannot be of type ALGORITHM=MERGE if it uses any of the following:

- [HAVING](#)
- [LIMIT](#)
- [GROUP BY](#)
- [DISTINCT](#)
- [UNION](#)
- [UNION ALL](#)
- An aggregate function, such as [MAX\(\)](#), [MIN\(\)](#), [SUM\(\)](#) or [COUNT\(\)](#)
- subquery in the SELECT list
- if it has no underlying table because it refers only to literal values

MERGE Examples

Example 1

Here's an example of how MariaDB handles a view with a MERGE algorithm. Take a view defined as follows:

```
CREATE ALGORITHM = MERGE VIEW view_name (view_field1, view_field2) AS
SELECT field1, field2 FROM table_name WHERE field3 > '2013-06-01';
```

Now, if we run a query on this view, as follows:

```
SELECT * FROM view_name;
```

to execute the view `view_name` becomes the underlying table, `table_name`, the `*` becomes the fields `view_field1` and `view_field2`, corresponding to `field1` and `field2` and the `WHERE` clause, `WHERE field3 > 100` is added, so the actual query executed is:

```
SELECT field1, field2 FROM table_name WHERE field3 > '2013-06-01'
```

Example 2

Given the same view as above, if we run the query:

```
SELECT * FROM view_name WHERE view_field < 8000;
```

everything occurs as it does in the previous example, but `view_field < 8000` takes the corresponding field name and becomes `field1 < 8000`, connected with `AND` to the `field3 > '2013-06-01'` part of the query.

So the resulting query is:

```
SELECT field1, field2 FROM table_name WHERE (field3 > '2013-06-01') AND (field1 < 8000);
```

When connecting with `AND`, parentheses are added to make sure the correct precedence is used.

1.1.1.2.8.54 SHOW TABLES

4.5 User-Defined Functions

A user-defined function (UDF) is a historical way to extend MariaDB with a new function that works similar to a native (built-in) MariaDB function such as [ABS\(\)](#) or [CONCAT\(\)](#). It was introduced in 1998 and is generally limited to supporting features that existed at that time.

Statements making use of user-defined functions are not [safe for replication](#).

For an example, see `sql/udf_example.cc` in the source tree. For a collection of existing UDFs go to the [UDF Repository on GitHub](#).

There are alternative ways to add a new function: a native function, which requires modifying and compiling the server source code; a [function plugin](#); or a [stored function](#).

Creating User-Defined Functions

How to create user-defined functions in C/C++.

User-Defined Functions Calling Sequences

Declaring the functions required in a user-defined function.

User-Defined Functions Security

MariaDB imposes a number of limitations on user-defined functions for security purposes.

CREATE FUNCTION UDF

Create a user-defined function.

DROP FUNCTION UDF

Drop a user-defined function.

There are [2 related questions](#).

4.5.1 Creating User-Defined Functions

Contents

1. [Simple Functions](#)
 1. [x\(\)](#)
 2. [x_init\(\)](#)
 3. [x_deinit\(\)](#)
 4. [Description](#)
2. [Aggregate Functions](#)
 1. [x_clear\(\)](#)
 2. [x_add\(\)](#)
 3. [x_remove\(\)](#)
 4. [Description](#)
3. [Examples](#)

[User-defined functions](#) allow MariaDB to be extended with a new function that works like a native (built-in) MariaDB function such as [ABS\(\)](#) or [CONCAT\(\)](#). It was introduced in 1998 and is generally limited to supporting features that existed at that time. There are alternative ways to add a new function: a native function, which requires modifying and compiling the server source code; a [function plugin](#); or a [stored function](#).

Statements making use of user-defined functions are not [safe for replication](#).

Functions are written in C or C++, and to make use of them, the operating system must support dynamic loading.

Each new SQL function requires corresponding functions written in C/C++. In the list below, at least the main function - `x()` - and one other, are required. `x` should be replaced by the name of the function you are creating.

All functions need to be thread-safe, so not global or static variables that change can be allocated. Memory is allocated in `x_init()/` and freed in `x_deinit()`.

Simple Functions

`x()`

Required for all UDFs; this is where the results are calculated.

C/C++ type **SQL type**

char * [STRING](#)
long long [INTEGER](#)
double [REAL](#)

DECIMAL functions return string values, and so should be written accordingly. It is not possible to create ROW functions.

x_init()

Initialization function for `x()`. Can be used for the following:

- Check the number of arguments to `X()` (the SQL equivalent).
- Verify the argument types, or to force arguments to be of a particular type after the function is called.
- Specify whether the result can be NULL.
- Specify the maximum result length.
- For REAL functions, specify the maximum number of decimals for the result.
- Allocate any required memory.

x_deinit()

De-initialization function for `x()`. Used to de-allocate memory that was allocated in `x_init()`.

Description

Each time the SQL function `X()` is called:

- MariaDB will first call the C/C++ initialization function, `x_init()`, assuming it exists. All setup will be performed, and if it returns an error, the SQL statement is aborted and no further functions are called.
- If there is no `x_init()` function, or it has been called and did not return an error, `x()` is then called once per row.
- After all rows have finished processing, `x_deinit()` is called, if present, to clean up by de-allocating any memory that was allocated in `x_init()`.
- See [User-defined Functions Calling Sequences](#) for more details on the functions.

Aggregate Functions

The following functions are required for aggregate functions, such as [AVG\(\)](#) and [SUM\(\)](#). When using [CREATE FUNCTION](#), the [AGGREGATE](#) keyword is required.

x_clear()

Used to reset the current aggregate, but without inserting the argument as the initial aggregate value for the new group.

x_add()

Used to add the argument to the current aggregate.

x_remove()

Starting from [MariaDB 10.4](#), improves the support of [window functions](#) (so it is not obligatory to add it) and should remove the argument from the current aggregate.

Description

Each time the aggregate SQL function `X()` is called:

- MariaDB will first call the C/C++ initialization function, `x_init()`, assuming it exists. All setup will be performed, and if it returns an error, the SQL statement is aborted and no further functions are called.
- If there is no `x_init()` function, or it has been called and did not return an error, `x()` is then called once per row.
- After all rows have finished processing, `x_deinit()` is called, if present, to clean up by de-allocating any memory that was allocated in `x_init()`.
- MariaDB will first call the C/C++ initialization function, `x_init()`, assuming it exists. All setup will be performed, and if it returns an error, the SQL statement is aborted and no further functions are called.
- The table is sorted according to the [GROUP BY](#) expression.
- `x_clear()` is called for the first row of each new group.

- `x_add()` is called once per row for each row in the same group.
- `x()` is called when the group changes, or after the last row, to get the aggregate result.
- The latter three steps are repeated until all rows have been processed.
- After all rows have finished processing, `x_deinit()` is called, if present, to clean up by de-allocating any memory that was allocated in `x_init()`.

Examples

For an example, see `sql/udf_example.cc` in the source tree. For a collection of existing UDFs see <https://github.com/mysqludf>.

4.5.2 User-Defined Functions Calling Sequences

Contents

1. [Simple Functions](#)
 1. [x\(\)](#)
 2. [x_init\(\)](#)
 3. [x_deinit\(\)](#)
 4. [Description](#)
2. [Aggregate Functions](#)
 1. [x_clear\(\)](#)
 2. [x_reset\(\)](#)
 3. [x_add\(\)](#)
 4. [x_remove\(\)](#)

The functions described in [Creating User-defined Functions](#) are expanded on this page. They are declared as follows:

Simple Functions

x()

If `x()` returns an integer, it is declared as follows:

```
long long x(UDF_INIT *initid, UDF_ARGS *args,
            char *is_null, char *error);
```

If `x()` returns a string (DECIMAL functions also return string values), it is declared as follows:

```
char *x(UDF_INIT *initid, UDF_ARGS *args,
        char *result, unsigned long *length,
        char *is_null, char *error);
```

If `x()` returns a real, it is declared as follows:

```
double x(UDF_INIT *initid, UDF_ARGS *args,
         char *is_null, char *error);
```

x_init()

```
my_bool x_init(UDF_INIT *initid, UDF_ARGS *args, char *message);
```

x_deinit()

```
void x_deinit(UDF_INIT *initid);
```

Description

`initid` is a parameter passed to all three functions that points to a `UDF_INIT` structure, used for communicating information

between the functions. Its structure members are:

- my_bool maybe_null
 - *maybe_null* should be set to 1 if *x_init* can return a NULL value, Defaults to 1 if any arguments are declared *maybe_null*.
- unsigned int decimals
 - Number of decimals after the decimal point. The default, if an explicit number of decimals is passed in the arguments to the main function, is the maximum number of decimals, so if 9.5, 9.55 and 9.555 are passed to the function, the default would be three (based on 9.555, the maximum). If there are no explicit number of decimals, the default is set to 31, or one more than the maximum for the DOUBLE, FLOAT and DECIMAL types. This default can be changed in the function to suit the actual calculation.
- unsigned int max_length
 - Maximum length of the result. For integers, the default is 21. For strings, the length of the longest argument. For reals, the default is 13 plus the number of decimals indicated by *initid->decimals*. The length includes any signs or decimal points. Can also be set to 65KB or 16MB in order to return a BLOB. The memory remains unallocated, but this is used to decide on the data type to use if the data needs to be temporarily stored.
- char *ptr
 - A pointer for use as required by the function. Commonly, *initid->ptr* is used to communicate allocated memory, with *x_init()* allocating the memory and assigning it to this pointer, *x()* using it, and *x_deinit()* de-allocating it.
- my_bool const_item
 - Should be set to 1 in *x_init()* if *x()* always returns the same value, otherwise 0.

Aggregate Functions

x_clear()

x_clear() is a required function for aggregate functions, and is declared as follows:

```
void x_clear(UDF_INIT *initid, char *is_null, char *error);
```

It is called when the summary results need to be reset, that is at the beginning of each new group. but also to reset the values when there were no matching rows.

is_null is set to point to CHAR(0) before calling *x_clear()*.

In the case of an error, you can store the value to which the error argument points (a single-byte variable, not a string string buffer) in the variable.

x_reset()

x_reset() is declared as follows:

```
void x_reset(UDF_INIT *initid, UDF_ARGS *args,
             char *is_null, char *error);
```

It is called on finding the first row in a new group. Should reset the summary variables, and then use *UDF_ARGS* as the first value in the group's internal summary value. The function is not required if the UDF interface uses *x_clear()*.

x_add()

x_add() is declared as follows:

```
void x_add(UDF_INIT *initid, UDF_ARGS *args,
           char *is_null, char *error);
```

It is called for all rows belonging to the same group, and should be used to add the value in *UDF_ARGS* to the internal summary variable.

x_remove()

x_remove() was added in [MariaDB 10.4](#) and is declared as follows (same as *x_add()*):

```
void x_remove(UDF_INIT* initid, UDF_ARGS* args,
              char* is_null, char *error );
```

It adds more efficient support of aggregate UDFs as [window functions](#). `x_remove()` should "subtract" the row (reverse `x_add()`). In [MariaDB 10.4](#) aggregate UDFs will work as WINDOW functions without `x_remove()` but it will not be so efficient.

If `x_remove()` supported (defined) detected automatically.

4.5.3 User-Defined Functions Security

The MariaDB server imposes a number of limitations on [user-defined functions](#) for security purposes.

- The INSERT privilege for the mysql database is required to run [CREATE FUNCTION](#), as a record will be added to the [mysql.func-table](#).
- The DELETE privilege for the mysql database is required to run [DROP FUNCTION](#) as the corresponding record will be removed from the [mysql.func-table](#).
- UDF object files can only be placed in the plugin directory, as specified by the value of the [plugin_dir](#) system variable.
- At least one symbol, beyond the required `x()` - corresponding to an SQL function `X()` - is required. These can be `x_init()`, `x_deinit()`, `xxx_reset()`, `x_clear()` and `x_add()` functions (see [Creating User-defined Functions](#)). The [allow-suspicious-udfs](#) mariadb option (by default unset) provides a workaround, permitting only one symbol to be used. This is not recommended, as it opens the possibility of loading shared objects that are not legitimate user-defined functions.

1.1.1.3.1.4 CREATE FUNCTION UDF

1.1.1.3.3.4 DROP FUNCTION UDF

Data Types in MariaDB

Numeric Data Types

Numeric Data Type Overview

[Overview and usage of the numeric data types.](#)

TINYINT

[Tiny integer, -128 to 127 signed.](#)

BOOLEAN

[Synonym for TINYINT\(1\).](#)

SMALLINT

[Small integer from -32768 to 32767 signed.](#)

MEDIUMINT

[Medium integer from -8388608 to 8388607 signed.](#)

INT

Integer from -2147483648 to 2147483647 signed.

INTEGER

Synonym for INT

BIGINT

Large integer.

DECIMAL

A packed "exact" fixed-point number.

DEC, NUMERIC, FIXED

Synonyms for DECIMAL

NUMBER

Synonym for DECIMAL in Oracle mode.

FLOAT

Single-precision floating-point number

DOUBLE

Normal-size (double-precision) floating-point number

DOUBLE PRECISION

REAL and DOUBLE PRECISION are synonyms for DOUBLE.

BIT

Bit field type.

VECTOR

Vector data type.

Floating-point Accuracy

Not all floating-point numbers can be stored with exact precision

INT1

A synonym for TINYINT.

INT2

Synonym for SMALLINT.

INT3

Synonym for MEDIUMINT.

INT4

Synonym for INT.

INT8

Synonym for BIGINT.

String Data Types

String Literals

Strings are sequences of characters and are enclosed with quotes.

BINARY

Fixed-length binary byte string.

BLOB

Binary large object up to 65,535 bytes.

BLOB and TEXT Data Types

Binary large object data types and the corresponding TEXT types.

CHAR

Fixed-length string.

CHAR BYTE

Alias for BINARY.

ENUM

Enumeration, or string object that can have one value chosen from a list of values.

INET4

For storage of IPv4 addresses.

INET6

For storage of IPv6 addresses.

JSON Data Type

Compatibility data type that is an alias for LONGTEXT.

MEDIUMBLOB

Medium binary large object up to 16,777,215 bytes.

MEDIUMTEXT

A TEXT column with a maximum length of 16,777,215 characters.

LOBLOB

Long BLOB holding up to 4GB.

LONG and LONG VARCHAR

LONG and LONG VARCHAR are synonyms for MEDIUMTEXT.

LONGTEXT

A TEXT column with a maximum length of 4,294,967,295 characters.

ROW

Data type for stored procedure variables.

TEXT

A TEXT column with a maximum length of 65,535 characters.

TINYBLOB

Tiny binary large object up to 255 bytes.

TINYTEXT

A TEXT column with a maximum length of 255 characters.

VARBINARY

Variable-length binary byte string.

VARCHAR

Variable-length string.

SET Data Type

Set, or string object that can have 0 or more values chosen from a list of values.

UUID Data Type

Data type intended for the storage of UUID data.

Data Type Storage Requirements

Storage requirements for the various data types.

Supported Character Sets and Collations

MariaDB supports the following character sets and collations.

Character Sets and Collations

Setting character set and collation for a language.

Date and Time Data Types

DATE

The date type YYYY-MM-DD.

TIME

Time format HH:MM:SS.ssssss

DATETIME

Date and time combination displayed as YYYY-MM-DD HH:MM:SS.

TIMESTAMP

YYYY-MM-DD HH:MM:SS

YEAR Data Type

A four-digit year.

A synonym for TINYINT.

**INT2**

Synonym for SMALLINT.

**INT3**

Synonym for MEDIUMINT.

**INT4**

Synonym for INT.

**INT8**

Synonym for BIGINT.

5.1.1.1 Numeric Data Type Overview

Contents

1. [SIGNED, UNSIGNED and ZEROFILL](#)

3. [Auto_increment](#)

There are a number of numeric data types:

- [TINYINT](#)
- [BOOLEAN](#) - Synonym for [TINYINT\(1\)](#)
- [INT1](#) - Synonym for [TINYINT](#)
- [SMALLINT](#)
- [INT2](#) - Synonym for [SMALLINT](#)
- [MEDIUMINT](#)
- [INT3](#) - Synonym for [MEDIUMINT](#)
- [INT](#), [INTEGER](#)
- [INT4](#) - Synonym for [INT](#)
- [BIGINT](#)
- [INT8](#) - Synonym for [BIGINT](#)
- [DECIMAL](#), [DEC](#), [NUMERIC](#), [FIXED](#)
- [FLOAT](#)
- [DOUBLE](#), [DOUBLE PRECISION](#), [REAL](#)
- [BIT](#)
- [VECTOR](#)

See the specific articles for detailed information on each.

SIGNED, UNSIGNED and ZEROFILL

Most numeric types can be defined as `SIGNED`, `UNSIGNED` or `ZEROFILL`, for example:

```
TINYINT[(M)] [SIGNED | UNSIGNED | ZEROFILL]
```

If `SIGNED`, or no attribute, is specified, a portion of the numeric type will be reserved for the sign (plus or minus). For example, a `TINYINT SIGNED` can range from -128 to 127.

If `UNSIGNED` is specified, no portion of the numeric type is reserved for the sign, so for integer types range can be larger. For example, a `TINYINT UNSIGNED` can range from 0 to 255. Floating point and fixed-point types also can be `UNSIGNED`, but this only prevents negative values from being stored and doesn't alter the range.

If `ZEROFILL` is specified, the column will be set to `UNSIGNED` and the spaces used by default to pad the field are replaced with zeros. `ZEROFILL` is ignored in expressions or as part of a [UNION](#). `ZEROFILL` is a non-standard MySQL and MariaDB enhancement.

Note that although the preferred syntax indicates that the attributes are exclusive, more than one attribute can be specified.

Until [MariaDB 10.2.7](#) [\(MDEV-8659\)](#), any combination of the attributes could be used in any order, with duplicates. In this case:

- the presence of `ZEROFILL` makes the column `UNSIGNED ZEROFILL`.
- the presence of `UNSIGNED` makes the column `UNSIGNED`.

From [MariaDB 10.2.8](#), only the following combinations are supported:

- `SIGNED`
- `UNSIGNED`
- `ZEROFILL`
- `UNSIGNED ZEROFILL`
- `ZEROFILL UNSIGNED`

The latter two should be replaced with simply `ZEROFILL`, but are still accepted by the parser.

Examples

```

CREATE TABLE zf (
  i1 TINYINT SIGNED,
  i2 TINYINT UNSIGNED,
  i3 TINYINT ZEROFILL
);

INSERT INTO zf VALUES (2,2,2);

SELECT * FROM zf;
+-----+-----+-----+
| i1  | i2  | i3  |
+-----+-----+-----+
|  2  |  2  | 002 |
+-----+-----+-----+

```

Range

When attempting to add a value that is out of the valid range for the numeric type, MariaDB will react depending on the [strict SQL_MODE](#) setting.

If [strict_mode](#) has been set (the default from [MariaDB 10.2.4](#)), MariaDB will return an error.

If [strict_mode](#) has not been set (the default until [MariaDB 10.2.3](#)), MariaDB will adjust the number to fit in the field, returning a warning.

Examples

With [strict_mode](#) set:

```

SHOW VARIABLES LIKE 'sql_mode';
+-----+-----+-----+
| Variable_name | Value
+-----+-----+-----+
| sql_mode      | STRICT_TRANS_TABLES,ERROR_FOR_DIVISION_BY_ZERO,NO_AUTO_CREATE_USER,NO_ENGINE_SUBSTITUTION
+-----+-----+-----+

CREATE TABLE ranges (i1 TINYINT, i2 SMALLINT, i3 TINYINT UNSIGNED);

INSERT INTO ranges VALUES (257,257,257);
ERROR 1264 (22003): Out of range value for column 'i1' at row 1

SELECT * FROM ranges;
Empty set (0.10 sec)

```

With [strict_mode](#) unset:

```

SHOW VARIABLES LIKE 'sql_mode%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| sql_mode      |      |
+-----+-----+

CREATE TABLE ranges (i1 TINYINT, i2 SMALLINT, i3 TINYINT UNSIGNED);

INSERT INTO ranges VALUES (257,257,257);
Query OK, 1 row affected, 2 warnings (0.00 sec)

SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1264 | Out of range value for column 'i1' at row 1 |
| Warning | 1264 | Out of range value for column 'i3' at row 1 |
+-----+-----+-----+
2 rows in set (0.00 sec)

SELECT * FROM ranges;
+-----+-----+-----+
| i1 | i2 | i3 |
+-----+-----+-----+
| 127 | 257 | 255 |
+-----+-----+-----+

```

Auto_increment

The `AUTO_INCREMENT` attribute can be used to generate a unique identity for new rows. For more details, see [auto_increment](#).

5.1.1.2 TINYINT

Syntax

```
TINYINT[(M)] [SIGNED | UNSIGNED | ZEROFILL]
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

Description

A very small [integer](#). The signed range is -128 to 127. The unsigned range is 0 to 255. For details on the attributes, see [Numeric Data Type Overview](#).

`INT1` is a synonym for `TINYINT`. `BOOL` and `BOOLEAN` are synonyms for `TINYINT(1)`.

Examples

```
CREATE TABLE tinyints (a TINYINT,b TINYINT UNSIGNED,c TINYINT ZEROFILL);
```

With `strict_mode` set, the default from [MariaDB 10.2.4](#) 

```

INSERT INTO tinyints VALUES (-10,-10,-10);
ERROR 1264 (22003): Out of range value for column 'b' at row 1

INSERT INTO tinyints VALUES (-10,10,-10);
ERROR 1264 (22003): Out of range value for column 'c' at row 1

INSERT INTO tinyints VALUES (-10,10,10);

SELECT * FROM tinyints;
+-----+-----+-----+
| a     | b     | c     |
+-----+-----+-----+
| -10   | 10    | 010   |
+-----+-----+-----+

INSERT INTO tinyints VALUES (128,128,128);
ERROR 1264 (22003): Out of range value for column 'a' at row 1

INSERT INTO tinyints VALUES (127,128,128);

SELECT * FROM tinyints;
+-----+-----+-----+
| a     | b     | c     |
+-----+-----+-----+
| -10   | 10    | 010   |
| 127   | 128   | 128   |
+-----+-----+-----+

```

With `strict_mode` unset, the default until [MariaDB 10.2.3](#):

```

INSERT INTO tinyints VALUES (-10,-10,-10);
Query OK, 1 row affected, 2 warnings (0.08 sec)
Warning (Code 1264): Out of range value for column 'b' at row 1
Warning (Code 1264): Out of range value for column 'c' at row 1

INSERT INTO tinyints VALUES (-10,10,-10);
Query OK, 1 row affected, 1 warning (0.11 sec)
Warning (Code 1264): Out of range value for column 'c' at row 1

INSERT INTO tinyints VALUES (-10,10,10);

SELECT * FROM tinyints;
+-----+-----+-----+
| a     | b     | c     |
+-----+-----+-----+
| -10   | 0     | 000   |
| -10   | 10    | 000   |
| -10   | 10    | 010   |
+-----+-----+-----+

INSERT INTO tinyints VALUES (128,128,128);
Query OK, 1 row affected, 1 warning (0.19 sec)
Warning (Code 1264): Out of range value for column 'a' at row 1

INSERT INTO tinyints VALUES (127,128,128);

SELECT * FROM tinyints;
+-----+-----+-----+
| a     | b     | c     |
+-----+-----+-----+
| -10   | 0     | 000   |
| -10   | 10    | 000   |
| -10   | 10    | 010   |
| 127   | 128   | 128   |
| 127   | 128   | 128   |
+-----+-----+-----+

```

5.1.1.3 BOOLEAN

Description

These types are synonyms for [TINYINT\(1\)](#). A value of zero is considered false. Non-zero values are considered true.

However, the values TRUE and FALSE are merely aliases for 1 and 0. See [Boolean Literals](#), as well as the [IS operator](#) for testing values against a boolean.

Examples

```
CREATE TABLE boo (i BOOLEAN);

DESC boo;
+-----+-----+-----+-----+
| Field | Type      | Null | Key | Default | Extra |
+-----+-----+-----+-----+
| i     | tinyint(1) | YES  |     | NULL    |      |
+-----+-----+-----+-----+
```

```
SELECT IF(0, 'true', 'false');
+-----+
| IF(0, 'true', 'false') |
+-----+
| false                   |
+-----+
```

```
SELECT IF(1, 'true', 'false');
+-----+
| IF(1, 'true', 'false') |
+-----+
| true                    |
+-----+
```

```
SELECT IF(2, 'true', 'false');
+-----+
| IF(2, 'true', 'false') |
+-----+
| true                    |
+-----+
```

TRUE and FALSE as aliases for 1 and 0:

```

SELECT IF(0 = FALSE, 'true', 'false');
+-----+
| IF(0 = FALSE, 'true', 'false') |
+-----+
| true                             |
+-----+

SELECT IF(1 = TRUE, 'true', 'false');
+-----+
| IF(1 = TRUE, 'true', 'false') |
+-----+
| true                             |
+-----+

SELECT IF(2 = TRUE, 'true', 'false');
+-----+
| IF(2 = TRUE, 'true', 'false') |
+-----+
| false                            |
+-----+

SELECT IF(2 = FALSE, 'true', 'false');
+-----+
| IF(2 = FALSE, 'true', 'false') |
+-----+
| false                            |
+-----+

```

The last two statements display the results shown because 2 is equal to neither 1 nor 0.

5.1.1.4 SMALLINT

Syntax

```
SMALLINT[M] [SIGNED | UNSIGNED | ZEROFILL]
```

Description

A small [integer](#). The signed range is -32768 to 32767. The unsigned range is 0 to 65535.

If a column has been set to ZEROFILL, all values will be prepended by zeros so that the SMALLINT value contains a number of M digits.

Note: If the ZEROFILL attribute has been specified, the column will automatically become UNSIGNED.

INT2 is a synonym for SMALLINT.

For more details on the attributes, see [Numeric Data Type Overview](#).

Examples

```
CREATE TABLE smallints (a SMALLINT, b SMALLINT UNSIGNED, c SMALLINT ZEROFILL);
```

With [strict_mode](#) set, the default from [MariaDB 10.2.4](#) [↗](#):

```

INSERT INTO smallints VALUES (-10,-10,-10);
ERROR 1264 (22003): Out of range value for column 'b' at row 1

INSERT INTO smallints VALUES (-10,10,-10);
ERROR 1264 (22003): Out of range value for column 'c' at row 1

INSERT INTO smallints VALUES (-10,10,10);

INSERT INTO smallints VALUES (32768,32768,32768);
ERROR 1264 (22003): Out of range value for column 'a' at row 1

INSERT INTO smallints VALUES (32767,32768,32768);

SELECT * FROM smallints;
+-----+-----+-----+
| a      | b      | c      |
+-----+-----+-----+
| -10   | 10    | 00010  |
| 32767 | 32768 | 32768  |
+-----+-----+-----+

```

With `strict_mode` unset, the default until [MariaDB 10.2.3](#):

```

INSERT INTO smallints VALUES (-10,-10,-10);
Query OK, 1 row affected, 2 warnings (0.09 sec)
Warning (Code 1264): Out of range value for column 'b' at row 1
Warning (Code 1264): Out of range value for column 'c' at row 1

INSERT INTO smallints VALUES (-10,10,-10);
Query OK, 1 row affected, 1 warning (0.08 sec)
Warning (Code 1264): Out of range value for column 'c' at row 1

INSERT INTO smallints VALUES (-10,10,10);

INSERT INTO smallints VALUES (32768,32768,32768);
Query OK, 1 row affected, 1 warning (0.04 sec)
Warning (Code 1264): Out of range value for column 'a' at row 1

INSERT INTO smallints VALUES (32767,32768,32768);

SELECT * FROM smallints;
+-----+-----+-----+
| a      | b      | c      |
+-----+-----+-----+
| -10   | 0     | 00000  |
| -10   | 10    | 00000  |
| -10   | 10    | 00010  |
| 32767 | 32768 | 32768  |
| 32767 | 32768 | 32768  |
+-----+-----+-----+

```

5.1.1.5 MEDIUMINT

Syntax

```
MEDIUMINT[(M)] [SIGNED | UNSIGNED | ZEROFILL]
```

Description

A medium-sized integer. The signed range is -8388608 to 8388607. The unsigned range is 0 to 16777215.

`ZEROFILL` pads the integer with zeroes and assumes `UNSIGNED` (even if `UNSIGNED` is not specified).

`INT3` is a synonym for `MEDIUMINT`.

For details on the attributes, see [Numeric Data Type Overview](#).

Examples

```
CREATE TABLE mediumints (a MEDIUMINT,b MEDIUMINT UNSIGNED,c MEDIUMINT ZEROFILL);
```

```
DESCRIBE mediumints;
```

Field	Type	Null	Key	Default	Extra
a	mediumint(9)	YES		NULL	
b	mediumint(8) unsigned	YES		NULL	
c	mediumint(8) unsigned zerofill	YES		NULL	

With `strict_mode` set, the default from [MariaDB 10.2.4](#):

```
INSERT INTO mediumints VALUES (-10,-10,-10);
ERROR 1264 (22003): Out of range value for column 'b' at row 1
```

```
INSERT INTO mediumints VALUES (-10,10,-10);
ERROR 1264 (22003): Out of range value for column 'c' at row 1
```

```
INSERT INTO mediumints VALUES (-10,10,10);
```

```
INSERT INTO mediumints VALUES (8388608,8388608,8388608);
ERROR 1264 (22003): Out of range value for column 'a' at row 1
```

```
INSERT INTO mediumints VALUES (8388607,8388608,8388608);
```

```
SELECT * FROM mediumints;
```

a	b	c
-10	10	00000010
8388607	8388608	08388608

With `strict_mode` unset, the default until [MariaDB 10.2.3](#):

```
INSERT INTO mediumints VALUES (-10,-10,-10);
Query OK, 1 row affected, 2 warnings (0.05 sec)
Warning (Code 1264): Out of range value for column 'b' at row 1
Warning (Code 1264): Out of range value for column 'c' at row 1
```

```
INSERT INTO mediumints VALUES (-10,10,-10);
Query OK, 1 row affected, 1 warning (0.08 sec)
Warning (Code 1264): Out of range value for column 'c' at row 1
```

```
INSERT INTO mediumints VALUES (-10,10,10);
```

```
INSERT INTO mediumints VALUES (8388608,8388608,8388608);
Query OK, 1 row affected, 1 warning (0.05 sec)
Warning (Code 1264): Out of range value for column 'a' at row 1
```

```
INSERT INTO mediumints VALUES (8388607,8388608,8388608);
```

```
SELECT * FROM mediumints;
```

a	b	c
-10	0	00000000
-10	0	00000000
-10	10	00000000
-10	10	00000010
8388607	8388608	08388608
8388607	8388608	08388608

5.1.1.6 INT

Syntax

```
INT[(M)] [SIGNED | UNSIGNED | ZEROFILL]
INTEGER[(M)] [SIGNED | UNSIGNED | ZEROFILL]
```

Description

A normal-size integer. When marked UNSIGNED, it ranges from 0 to 4294967295, otherwise its range is -2147483648 to 2147483647 (SIGNED is the default). If a column has been set to ZEROFILL, all values will be prepended by zeros so that the INT value contains a number of M digits. INTEGER is a synonym for INT.

Note: If the ZEROFILL attribute has been specified, the column will automatically become UNSIGNED.

INT4 is a synonym for INT.

For details on the attributes, see [Numeric Data Type Overview](#).

Examples

```
CREATE TABLE ints (a INT,b INT UNSIGNED,c INT ZEROFILL);
```

With `strict_mode` set, the default from [MariaDB 10.2.4](#):

```
INSERT INTO ints VALUES (-10,-10,-10);
ERROR 1264 (22003): Out of range value for column 'b' at row 1

INSERT INTO ints VALUES (-10,10,-10);
ERROR 1264 (22003): Out of range value for column 'c' at row 1

INSERT INTO ints VALUES (-10,10,10);

INSERT INTO ints VALUES (2147483648,2147483648,2147483648);
ERROR 1264 (22003): Out of range value for column 'a' at row 1

INSERT INTO ints VALUES (2147483647,2147483648,2147483648);

SELECT * FROM ints;
+-----+-----+-----+
| a          | b          | c          |
+-----+-----+-----+
|      -10  |         10 | 0000000010 |
| 2147483647 | 2147483648 | 2147483648 |
+-----+-----+-----+
```

With `strict_mode` unset, the default until [MariaDB 10.2.3](#):

```

INSERT INTO ints VALUES (-10,-10,-10);
Query OK, 1 row affected, 2 warnings (0.10 sec)
Warning (Code 1264): Out of range value for column 'b' at row 1
Warning (Code 1264): Out of range value for column 'c' at row 1

INSERT INTO ints VALUES (-10,10,-10);
Query OK, 1 row affected, 1 warning (0.08 sec)
Warning (Code 1264): Out of range value for column 'c' at row 1

INSERT INTO ints VALUES (-10,10,10);

INSERT INTO ints VALUES (2147483648,2147483648,2147483648);
Query OK, 1 row affected, 1 warning (0.07 sec)
Warning (Code 1264): Out of range value for column 'a' at row 1

INSERT INTO ints VALUES (2147483647,2147483648,2147483648);

SELECT * FROM ints;
+-----+-----+-----+
| a      | b      | c      |
+-----+-----+-----+
|      -10 |         0 | 0000000000 |
|      -10 |         10 | 0000000000 |
|      -10 |         10 | 0000000010 |
| 2147483647 | 2147483648 | 2147483648 |
| 2147483647 | 2147483648 | 2147483648 |
+-----+-----+-----+

```

5.1.1.7 INTEGER

Syntax

```
INTEGER[(M)] [SIGNED | UNSIGNED | ZEROFILL]
```

Description

This type is a synonym for [INT](#).

5.1.1.8 BIGINT

Syntax

```
BIGINT[(M)] [SIGNED | UNSIGNED | ZEROFILL]
```

Description

A large integer. The signed range is `-9223372036854775808` to `9223372036854775807`. The unsigned range is `0` to `18446744073709551615`.

If a column has been set to `ZEROFILL`, all values will be prepended by zeros so that the `BIGINT` value contains a number of `M` digits.

Note: If the `ZEROFILL` attribute has been specified, the column will automatically become `UNSIGNED`.

For more details on the attributes, see [Numeric Data Type Overview](#).

`SERIAL` is an alias for:

```
BIGINT UNSIGNED NOT NULL AUTO_INCREMENT UNIQUE
```

`INT8` is a synonym for `BIGINT`.

Examples

```
CREATE TABLE bigints (a BIGINT,b BIGINT UNSIGNED,c BIGINT ZEROFILL);
```

With `strict_mode` set, the default from [MariaDB 10.2.4](#):

```
INSERT INTO bigints VALUES (-10,-10,-10);
ERROR 1264 (22003): Out of range value for column 'b' at row 1

INSERT INTO bigints VALUES (-10,10,-10);
ERROR 1264 (22003): Out of range value for column 'c' at row 1

INSERT INTO bigints VALUES (-10,10,10);

INSERT INTO bigints VALUES (9223372036854775808,9223372036854775808,9223372036854775808);
ERROR 1264 (22003): Out of range value for column 'a' at row 1

INSERT INTO bigints VALUES (9223372036854775807,9223372036854775808,9223372036854775808);

SELECT * FROM bigints;
+-----+-----+-----+
| a          | b          | c          |
+-----+-----+-----+
|          -10 |          10 | 00000000000000000010 |
| 9223372036854775807 | 9223372036854775808 | 09223372036854775808 |
+-----+-----+-----+
```

With `strict_mode` unset, the default until [MariaDB 10.2.3](#):

```
INSERT INTO bigints VALUES (-10,-10,-10);
Query OK, 1 row affected, 2 warnings (0.08 sec)
Warning (Code 1264): Out of range value for column 'b' at row 1
Warning (Code 1264): Out of range value for column 'c' at row 1

INSERT INTO bigints VALUES (-10,10,-10);
Query OK, 1 row affected, 1 warning (0.08 sec)
Warning (Code 1264): Out of range value for column 'c' at row 1

INSERT INTO bigints VALUES (-10,10,10);

INSERT INTO bigints VALUES (9223372036854775808,9223372036854775808,9223372036854775808);
Query OK, 1 row affected, 1 warning (0.07 sec)
Warning (Code 1264): Out of range value for column 'a' at row 1

INSERT INTO bigints VALUES (9223372036854775807,9223372036854775808,9223372036854775808);

SELECT * FROM bigints;
+-----+-----+-----+
| a          | b          | c          |
+-----+-----+-----+
|          -10 |           0 | 00000000000000000000 |
|          -10 |          10 | 00000000000000000000 |
|          -10 |          10 | 00000000000000000010 |

+-----+-----+-----+
```

5.1.1.9 DECIMAL

Syntax

```
DECIMAL[(M[,D])] [SIGNED | UNSIGNED | ZEROFILL]
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

Description

A packed "exact" fixed-point number. `M` is the total number of digits (the precision) and `D` is the number of digits after the decimal point (the scale).

- The decimal point and (for negative numbers) the "-" sign are not counted in `M`.
- If `D` is `0`, values have no decimal point or fractional part and on [INSERT](#) the value will be rounded to the nearest `DECIMAL`.
- The maximum number of digits (`M`) for `DECIMAL` is 65.
- The maximum number of supported decimals (`D`) is 30 before [MariaDB 10.2.1](#) and 38 afterwards.
- If `D` is omitted, the default is 0. If `M` is omitted, the default is 10.

`UNSIGNED`, if specified, disallows negative values.

`ZEROFILL`, if specified, pads the number with zeros, up to the total number of digits specified by `M`.

All basic calculations (+, -, *, /) with `DECIMAL` columns are done with a precision of 65 digits.

For more details on the attributes, see [Numeric Data Type Overview](#).

`DEC`, `NUMERIC` and `FIXED` are synonyms, as well as `NUMBER` in [Oracle mode from MariaDB 10.3](#).

Examples

```
CREATE TABLE t1 (d DECIMAL UNSIGNED ZEROFILL);

INSERT INTO t1 VALUES (1), (2), (3), (4.0), (5.2), (5.7);
Query OK, 6 rows affected, 2 warnings (0.16 sec)
Records: 6 Duplicates: 0 Warnings: 2

Note (Code 1265): Data truncated for column 'd' at row 5
Note (Code 1265): Data truncated for column 'd' at row 6

SELECT * FROM t1;
+-----+
| d      |
+-----+
| 0000000001 |
| 0000000002 |
| 0000000003 |
| 0000000004 |
| 0000000005 |
| 0000000006 |
+-----+
```

With `strict_mode` set, the default from [MariaDB 10.2.4](#):

```
INSERT INTO t1 VALUES (-7);
ERROR 1264 (22003): Out of range value for column 'd' at row 1
```

With `strict_mode` unset, the default until [MariaDB 10.2.3](#):

```

INSERT INTO t1 VALUES (-7);
Query OK, 1 row affected, 1 warning (0.02 sec)
Warning (Code 1264): Out of range value for column 'd' at row 1

SELECT * FROM t1;
+-----+
| d      |
+-----+
| 000000001 |
| 000000002 |
| 000000003 |
| 000000004 |
| 000000005 |
| 000000006 |
| 000000000 |
+-----+

```

5.1.1.10 DEC, NUMERIC, FIXED

Syntax

```

DEC[(M[,D])] [SIGNED | UNSIGNED | ZEROFILL]

NUMERIC[(M[,D])] [SIGNED | UNSIGNED | ZEROFILL]

FIXED[(M[,D])] [SIGNED | UNSIGNED | ZEROFILL]

```

Description

These types are synonyms for [DECIMAL](#). The `FIXED` synonym is available for compatibility with other database systems.

5.1.1.11 NUMBER

```

NUMBER[(M[,D])] [SIGNED | UNSIGNED | ZEROFILL]

```

In [Oracle mode](#), `NUMBER` is a synonym for [DECIMAL](#).

5.1.1.12 FLOAT

Syntax

```

FLOAT[(M,D)] [SIGNED | UNSIGNED | ZEROFILL]

```

Contents

1. [Syntax](#)
2. [Description](#)

Description

A small (single-precision) floating-point number (see [DOUBLE](#) for a regular-size floating point number). Allowable values are:

- -3.402823466E+38 to -1.175494351E-38
- 0
- 1.175494351E-38 to 3.402823466E+38.

These are the theoretical limits, based on the IEEE standard. The actual range might be slightly smaller depending on your hardware or operating system.

M is the total number of digits and D is the number of digits following the decimal point. If M and D are omitted, values are stored to the limits allowed by the hardware. A single-precision floating-point number is accurate to approximately 7 decimal places.

UNSIGNED, if specified, disallows negative values.

Using FLOAT might give you some unexpected problems because all calculations in MariaDB are done with double precision. See [Floating Point Accuracy](#).

For more details on the attributes, see [Numeric Data Type Overview](#).

5.1.1.13 DOUBLE

Syntax

```
DOUBLE[(M,D)] [SIGNED | UNSIGNED | ZEROFILL]
DOUBLE PRECISION[(M,D)] [SIGNED | UNSIGNED | ZEROFILL]
REAL[(M,D)] [SIGNED | UNSIGNED | ZEROFILL]
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

Description

A normal-size (double-precision) floating-point number (see [FLOAT](#) for a single-precision floating-point number).

Allowable values are:

- -1.7976931348623157E+308 *to* -2.2250738585072014E-308
- 0
- 2.2250738585072014E-308 *to* 1.7976931348623157E+308

These are the theoretical limits, based on the IEEE standard. The actual range might be slightly smaller depending on your hardware or operating system.

M is the total number of digits and D is the number of digits following the decimal point. If M and D are omitted, values are stored to the limits allowed by the hardware. A double-precision floating-point number is accurate to approximately 15 decimal places.

UNSIGNED, if specified, disallows negative values.

ZEROFILL, if specified, pads the number with zeros, up to the total number of digits specified by M.

REAL and DOUBLE PRECISION are synonyms, unless the REAL_AS_FLOAT [SQL mode](#) is enabled, in which case REAL is a synonym for [FLOAT](#) rather than DOUBLE.

See [Floating Point Accuracy](#) for issues when using floating-point numbers.

For more details on the attributes, see [Numeric Data Type Overview](#).

Examples

```
CREATE TABLE t1 (d DOUBLE(5,0) zerofill);
INSERT INTO t1 VALUES (1), (2), (3), (4);
SELECT * FROM t1;
+-----+
| d     |
+-----+
| 00001 |
| 00002 |
| 00003 |
| 00004 |
+-----+
```

5.1.1.14 DOUBLE PRECISION

Syntax

```
DOUBLE PRECISION[(M,D)] [SIGNED | UNSIGNED | ZEROFILL]  
REAL[(M,D)] [SIGNED | UNSIGNED | ZEROFILL]
```

Description

REAL and DOUBLE PRECISION are synonyms for [DOUBLE](#).

Exception: If the REAL_AS_FLOAT [SQL mode](#) is enabled, REAL is a synonym for [FLOAT](#) rather than [DOUBLE](#).

5.1.1.15 BIT

Syntax

```
BIT[(M)]
```

Description

A bit-field type. *M* indicates the number of bits per value, from 1 to 64. The default is 1 if *M* is omitted.

Bit values can be inserted with `b'value'` notation, where *value* is the bit value in 0's and 1's.

Bit fields are automatically zero-padded from the left to the full length of the bit, so for example in a BIT(4) field, '10' is equivalent to '0010'.

Bits are returned as binary, so to display them, either add 0, or use a function such as [HEX](#), [OCT](#) or [BIN](#) to convert them.

Examples

```
CREATE TABLE b ( b1 BIT(8) );
```

With [strict_mode](#) set, the default from [MariaDB 10.2.4](#):

```
INSERT INTO b VALUES (b'11111111');  
INSERT INTO b VALUES (b'01010101');  
INSERT INTO b VALUES (b'1111111111111111');  
ERROR 1406 (22001): Data too long for column 'b1' at row 1  
  
SELECT b1+0, HEX(b1), OCT(b1), BIN(b1) FROM b;  
+-----+-----+-----+-----+  
| b1+0 | HEX(b1) | OCT(b1) | BIN(b1) |  
+-----+-----+-----+-----+  
| 255 | FF      | 377     | 11111111 |  
| 85 | 55      | 125     | 1010101  |  
+-----+-----+-----+-----+
```

With [strict_mode](#) unset, the default until [MariaDB 10.2.3](#):

```
INSERT INTO b VALUES (b'11111111'), (b'01010101'), (b'111111111111');
Query OK, 3 rows affected, 1 warning (0.10 sec)
Records: 3 Duplicates: 0 Warnings: 1
```

```
SHOW WARNINGS;
```

```
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1264 | Out of range value for column 'b1' at row 3 |
+-----+-----+-----+
```

```
SELECT b1+0, HEX(b1), OCT(b1), BIN(b1) FROM b;
```

```
+-----+-----+-----+
| b1+0 | HEX(b1) | OCT(b1) | BIN(b1) |
+-----+-----+-----+
| 255 | FF | 377 | 11111111 |
| 85 | 55 | 125 | 1010101 |
| 255 | FF | 377 | 11111111 |
+-----+-----+-----+
```

5.1.1.16 VECTOR

The Next Generation of MariaDB: Powered by Vector Search

Watch the Webinar [↗](#)

MariaDB starting with [11.7.1](#) [↗](#)

The VECTOR data type was added in [MariaDB 11.7.1](#)

Syntax

```
VECTOR ([M])
```

Contents

- [Syntax](#)
- [Description](#)
- [Example](#)

Description

The VECTOR data type was added as part of the [vectors](#) feature, which permits MariaDB Server to perform as a relational vector database.

Example

```
CREATE TABLE t1 (id INT AUTO_INCREMENT PRIMARY KEY, v VECTOR(5) NOT NULL, VECTOR INDEX (v));
```

5.1.1.17 Floating-point Accuracy

Due to their nature, not all floating-point numbers can be stored with exact precision. Hardware architecture, the CPU or even the compiler version and optimization level may affect the precision.

If you are comparing [DOUBLES](#) or [FLOATS](#) with numeric decimals, it is not safe to use the [equality](#) operator.

Sometimes, changing a floating-point number from single-precision (FLOAT) to double-precision (DOUBLE) will fix the problem.

Example

f1, f2 and f3 have seemingly identical values across each row, but due to floating point accuracy, the results may be unexpected.

```
CREATE TABLE fpn (id INT, f1 FLOAT, f2 DOUBLE, f3 DECIMAL (10,3));
INSERT INTO fpn VALUES (1,2,2,2), (2,0.1,0.1,0.1);

SELECT * FROM fpn WHERE f1*f1 = f2*f2;
+-----+-----+-----+-----+
| id   | f1   | f2   | f3   |
+-----+-----+-----+-----+
| 1   | 2    | 2    | 2.000 |
+-----+-----+-----+-----+
```

The reason why only one instead of two rows was returned becomes clear when we see how the floating point squares were evaluated.

```
SELECT f1*f1, f2*f2, f3*f3 FROM fpn;
+-----+-----+-----+
| f1*f1          | f2*f2          | f3*f3          |
+-----+-----+-----+
| 4              | 4              | 4.000000      |
| 0.010000000298023226 | 0.010000000000000002 | 0.010000      |
+-----+-----+-----+
```

5.1.1.18 INT1

INT1 is a synonym for [TINYINT](#).

```
CREATE TABLE t1 (x INT1);

DESC t1;
+-----+-----+-----+-----+
| Field | Type          | Null | Key | Default | Extra |
+-----+-----+-----+-----+
| x     | tinyint(4)   | YES  |    | NULL    |      |
+-----+-----+-----+-----+
```

5.1.1.19 INT2

INT2 is a synonym for [SMALLINT](#).

```
CREATE TABLE t1 (x INT2);

DESC t1;
+-----+-----+-----+-----+
| Field | Type          | Null | Key | Default | Extra |
+-----+-----+-----+-----+
| x     | smallint(6)  | YES  |    | NULL    |      |
+-----+-----+-----+-----+
```

5.1.1.20 INT3

INT3 is a synonym for [MEDIUMINT](#).

```
CREATE TABLE t1 (x INT3);
```

```
DESC t1;
```

Field	Type	Null	Key	Default	Extra
x	mediumint(9)	YES		NULL	

5.1.1.21 INT4

INT4 is a synonym for INT.

```
CREATE TABLE t1 (x INT4);
```

```
DESC t1;
```

Field	Type	Null	Key	Default	Extra
x	int(11)	YES		NULL	

5.1.1.22 INT8

INT8 is a synonym for BIGINT.

```
CREATE TABLE t1 (x INT8);
```

```
DESC t1;
```

Field	Type	Null	Key	Default	Extra
x	bigint(20)	YES		NULL	

5.1.2 String Data Types

String Literals

Strings are sequences of characters and are enclosed with quotes.

BINARY

Fixed-length binary byte string.

BLOB

Binary large object up to 65,535 bytes.

BLOB and TEXT Data Types

Binary large object data types and the corresponding TEXT types.

CHAR

Fixed-length string.

CHAR BYTE

Alias for BINARY.

ENUM

Enumeration, or string object that can have one value chosen from a list of values.

INET4

For storage of IPv4 addresses.

INET6

For storage of IPv6 addresses.

JSON Data Type

Compatibility data type that is an alias for LONGTEXT.

MEDIUMBLOB

Medium binary large object up to 16,777,215 bytes.

MEDIUMTEXT

A TEXT column with a maximum length of 16,777,215 characters.

LOBLOB

Long BLOB holding up to 4GB.

LONG and LONG VARCHAR

LONG and LONG VARCHAR are synonyms for MEDIUMTEXT.

LONGTEXT

A TEXT column with a maximum length of 4,294,967,295 characters.

ROW

Data type for stored procedure variables.

TEXT

A TEXT column with a maximum length of 65,535 characters.

TINYBLOB

Tiny binary large object up to 255 bytes.

TINYTEXT

A TEXT column with a maximum length of 255 characters.

VARBINARY

Variable-length binary byte string.

VARCHAR

Variable-length string.

SET Data Type

Set, or string object that can have 0 or more values chosen from a list of values.

UUID Data Type

Data type intended for the storage of UUID data.

Data Type Storage Requirements

Storage requirements for the various data types.

Supported Character Sets and Collations

MariaDB supports the following character sets and collations.

Character Sets and Collations

Setting character set and collation for a language.

1.1.2.13 String Literals

5.1.2.2 BINARY

This page describes the BINARY data type. For details about the operator, see [Binary Operator](#).

Syntax

BINARY (M)

Contents

1. [Description](#)
2. [Examples](#)

Description

The `BINARY` type is similar to the `CHAR` type, but stores binary byte strings rather than non-binary character strings. `M` represents the column length in bytes.

It contains no character set, and comparison and sorting are based on the numeric value of the bytes.

If the maximum length is exceeded, and `SQL strict mode` is not enabled, the extra characters will be dropped with a warning. If strict mode is enabled, an error will occur.

`BINARY` values are right-padded with `0x00` (the zero byte) to the specified length when inserted. The padding is *not* removed on select, so this needs to be taken into account when sorting and comparing, where all bytes are significant. The zero byte, `0x00` is less than a space for comparison purposes.

Examples

Inserting too many characters, first with strict mode off, then with it on:

```
CREATE TABLE bins (a BINARY(10));

INSERT INTO bins VALUES ('12345678901');
Query OK, 1 row affected, 1 warning (0.04 sec)

SELECT * FROM bins;
+-----+
| a      |
+-----+
| 1234567890 |
+-----+

SET sql_mode='STRICT_ALL_TABLES';

INSERT INTO bins VALUES ('12345678901');
ERROR 1406 (22001): Data too long for column 'a' at row 1
```

Sorting is performed with the byte value:

```
TRUNCATE bins;

INSERT INTO bins VALUES ('A'), ('B'), ('a'), ('b');

SELECT * FROM bins ORDER BY a;
+-----+
| a      |
+-----+
| A      |
| B      |
| a      |
| b      |
+-----+
```

Using `CAST` to sort as a `CHAR` instead:

```
SELECT * FROM bins ORDER BY CAST(a AS CHAR);
+-----+
| a     |
+-----+
| a     |
| A     |
| b     |
| B     |
+-----+
```

The field is a BINARY(10), so padding of two '0's are inserted, causing comparisons that don't take this into account to fail:

```
TRUNCATE bins;

INSERT INTO bins VALUES ('12345678');

SELECT a = '12345678', a = '12345678\0\0' from bins;
+-----+-----+
| a = '12345678' | a = '12345678\0\0' |
+-----+-----+
|                0 |                1 |
+-----+-----+
```

5.1.2.3 BLOB

Syntax

```
BLOB[ (M) ]
```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [Indexing](#)
 2. [Oracle Mode](#)

Description

A BLOB column with a maximum length of 65,535 ($2^{16} - 1$) bytes. Each BLOB value is stored using a two-byte length prefix that indicates the number of bytes in the value.

An optional length *M* can be given for this type. If this is done, MariaDB creates the column as the smallest BLOB type large enough to hold values *M* bytes long.

BLOBS can also be used to store [dynamic columns](#).

BLOB and TEXT columns can both be assigned a [DEFAULT](#) value.

Indexing

MariaDB starting with [10.4](#)
 From [MariaDB 10.4](#), it is possible to set a [unique index](#) on a column that uses the BLOB data type. In previous releases this was not possible, as the index would only guarantee the uniqueness of a fixed number of characters.

Oracle Mode

In [Oracle mode from MariaDB 10.3](#), BLOB is a synonym for LONGBLOB.

5.1.2.4 BLOB and TEXT Data Types

Description

A `BLOB` is a binary large object that can hold a variable amount of data. The four `BLOB` types are

- `TINYBLOB`,
- `BLOB`,
- `MEDIUMBLOB`, and
- `LONGBLOB`.

These differ only in the maximum length of the values they can hold.

The `TEXT` types are

- `TINYTEXT`,
- `TEXT`,
- `MEDIUMTEXT`, and
- `LONGTEXT`.
- `JSON` (alias for `LONGTEXT`)

These correspond to the four `BLOB` types and have the same maximum lengths and [storage requirements](#).

`BLOB` and `TEXT` columns can have a `DEFAULT` value.

MariaDB starting with [10.4.3](#)

From [MariaDB 10.4](#), it is possible to set a [unique index](#) on columns that use the `BLOB` or `TEXT` data types.

5.1.2.5 CHAR

This article covers the `CHAR` data type. See [CHAR Function](#) for the function.

Syntax

```
[NATIONAL] CHAR[(M)] [CHARACTER SET charset_name] [COLLATE collation_name]
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [NO PAD Collations](#)

Description

A fixed-length string that is always right-padded with spaces to the specified length when stored. `M` represents the column length in characters. The range of `M` is 0 to 255. If `M` is omitted, the length is 1.

`CHAR(0)` columns can contain 2 values: an empty string or `NULL`. Such columns cannot be part of an index. The [CONNECT](#) storage engine does not support `CHAR(0)`.

Note: Trailing spaces are removed when `CHAR` values are retrieved unless the `PAD_CHAR_TO_FULL_LENGTH` [SQL mode](#) is enabled.

Before [MariaDB 10.2](#), all collations were of type `PADSPACE`, meaning that `CHAR` (as well as `VARCHAR` and `TEXT`) values are compared without regard for trailing spaces. This does not apply to the [LIKE](#) pattern-matching operator, which takes into account trailing spaces.

If a unique index consists of a column where trailing pad characters are stripped or ignored, inserts into that column where values differ only by the number of trailing pad characters will result in a duplicate-key error.

Examples

Trailing spaces:

```

CREATE TABLE strttest (c CHAR(10));
INSERT INTO strttest VALUES('Maria ');

SELECT c='Maria',c='Maria ' FROM strttest;
+-----+-----+
| c='Maria' | c='Maria ' |
+-----+-----+
|          1 |          1 |
+-----+-----+

SELECT c LIKE 'Maria',c LIKE 'Maria ' FROM strttest;
+-----+-----+
| c LIKE 'Maria' | c LIKE 'Maria ' |
+-----+-----+
|          1 |          0 |
+-----+-----+

```

NO PAD Collations

NO PAD collations regard trailing spaces as normal characters. You can get a list of all NO PAD collations by querying the [Information Schema Collations](#) table, for example:

```

SELECT collation_name FROM information_schema.collations
WHERE collation_name LIKE "%nopad%";
+-----+-----+
| collation_name |
+-----+-----+
| big5_chinese_nopad_ci |
| big5_nopad_bin |
| ...

```

5.1.2.6 CHAR BYTE

Description

The `CHAR BYTE` data type is an alias for the `BINARY` data type. This is a compatibility feature.

5.1.2.7 ENUM

Syntax

```
ENUM('value1','value2',...) [CHARACTER SET charset_name] [COLLATE collation_name]
```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [NULL and empty values](#)
 2. [Numeric index](#)
3. [Examples](#)

Description

An enumeration. A string object that can have only one value, chosen from the list of values 'value1', 'value2', ..., NULL or the special " error value. In theory, an `ENUM` column can have a maximum of 65,535 distinct values; in practice, the real maximum depends on many factors. `ENUM` values are represented internally as integers.

Trailing spaces are automatically stripped from `ENUM` values on table creation.

`ENUMs` require relatively little storage space compared to strings, either one or two bytes depending on the number of enumeration values.

NULL and empty values

An ENUM can also contain NULL and empty values. If the ENUM column is declared to permit NULL values, NULL becomes a valid value, as well as the default value (see below). If [strict SQL Mode](#) is not enabled, and an invalid value is inserted into an ENUM, a special empty string, with an index value of zero (see [Numeric index](#), below), is inserted, with a warning. This may be confusing, because the empty string is also a possible value, and the only difference if that is this case its index is not 0. Inserting will fail with an error if strict mode is active.

If a `DEFAULT` clause is missing, the default value will be:

- NULL if the column is nullable;
- otherwise, the first value in the enumeration.

Numeric index

ENUM values are indexed numerically in the order they are defined, and sorting will be performed in this numeric order. We suggest not using ENUM to store numerals, as there is little to no storage space benefit, and it is easy to confuse the enum integer with the enum numeral value by leaving out the quotes.

An ENUM defined as `ENUM('apple','orange','pear')` would have the following index values:

Index	Value
NULL	NULL
0	"
1	'apple'
2	'orange'
3	'pear'

Examples

```
CREATE TABLE fruits (  
  id INT NOT NULL auto_increment PRIMARY KEY,  
  fruit ENUM('apple','orange','pear'),  
  bushels INT);  
  
DESCRIBE fruits;  
+-----+-----+-----+-----+-----+  
| Field | Type                | Null | Key | Default | Extra          |  
+-----+-----+-----+-----+-----+  
| id    | int(11)              | NO   | PRI | NULL    | auto_increment |  
| fruit | enum('apple','orange','pear') | YES  |     | NULL    |                |  
| bushels | int(11)              | YES  |     | NULL    |                |  
+-----+-----+-----+-----+-----+  
  
INSERT INTO fruits  
  (fruit,bushels) VALUES  
  ('pear',20),  
  ('apple',100),  
  ('orange',25);  
  
INSERT INTO fruits  
  (fruit,bushels) VALUES  
  ('avocado',10);  
ERROR 1265 (01000): Data truncated for column 'fruit' at row 1  
  
SELECT * FROM fruits;  
+-----+-----+-----+  
| id | fruit | bushels |  
+-----+-----+-----+  
| 1 | pear  | 20      |  
| 2 | apple | 100     |  
| 3 | orange | 25     |  
+-----+-----+-----+
```

Selecting by numeric index:

```

SELECT * FROM fruits WHERE fruit=2;
+-----+
| id | fruit | bushels |
+-----+
| 3 | orange | 25 |
+-----+

```

Sorting is according to the index value:

```

CREATE TABLE enums (a ENUM('2','1'));

INSERT INTO enums VALUES ('1'),('2');

SELECT * FROM enums ORDER BY a ASC;
+-----+
| a |
+-----+
| 2 |
| 1 |
+-----+

```

It's easy to get confused between returning the enum integer with the stored value, so we don't suggest using ENUM to store numerals. The first example returns the 1st indexed field ('2' has an index value of 1, as it's defined first), while the second example returns the string value '1'.

```

SELECT * FROM enums WHERE a=1;
+-----+
| a |
+-----+
| 2 |
+-----+

SELECT * FROM enums WHERE a='1';
+-----+
| a |
+-----+
| 1 |
+-----+

```

5.1.2.8 INET4

MariaDB starting with [10.10.0](#)
The INET4 data type was added in [MariaDB 10.10.0](#)

Syntax

```
INET4
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

Description

INET4 is a data type to store IPv4 addresses, as 4-byte binary strings.

From [MariaDB 11.3.0](#), casting from INET4 data types to INET6 is permitted, allowing for example comparisons between the two data types, and for INET 4 values to be inserted into INET6 columns.

Examples

```

CREATE OR REPLACE TABLE t1 (a INET4);

INSERT INTO t1 VALUES ('0.0.0.0'), ('255.10.0.0'), ('255.255.255.255');

INSERT INTO t1 VALUES (0xa0000001);
INSERT INTO t1 VALUES (0xf0000000);
INSERT INTO t1 VALUES (0xff000001);

SELECT HEX(a), a FROM t1 ORDER BY a;
+-----+-----+
| HEX(a) | a           |
+-----+-----+
| 00000000 | 0.0.0.0    |
| A0000001 | 160.0.0.1  |
| F0000000 | 240.0.0.0  |
| FF000001 | 255.0.0.1  |
| FFOA0000 | 255.10.0.0 |
| FFFFFFFF | 255.255.255.255 |
+-----+-----+

```

Casting from INET4 to [INET6](#) is permitted, allowing direct inserts.

Before [MariaDB 11.3](#):

```

CREATE TABLE t1 (a INET6);

INSERT INTO t1 VALUES ('0.0.0.0'), ('255.10.0.0'), ('255.255.255.255');
ERROR 1292 (22007): Incorrect inet6 value: '0.0.0.0' for column `test`.`t1`.`a` at row 1

```

From [MariaDB 11.3](#):

```

CREATE TABLE t1 (a INET6);

INSERT INTO t1 VALUES ('0.0.0.0'), ('255.10.0.0'), ('255.255.255.255');
Query OK, 3 rows affected (0.027 sec)

```

Comparisons are also permitted from [MariaDB 11.3](#):

```

CREATE OR REPLACE TABLE t1 (i4 INET4, i6 INET6);
INSERT INTO t1 VALUES ('10.10.10.10', '::ffff:192.168.0.1');

SELECT LEAST(i4,i6) FROM t1;
+-----+
| LEAST(i4,i6) |
+-----+
| ::ffff:10.10.10.10 |
+-----+

```

5.1.2.9 INET6

MariaDB starting with [10.5.0](#)
The INET6 data type was added in [MariaDB 10.5.0](#)

Syntax

```
INET6
```

 6. [Casting from INET4 to INET6](#)

Description

The `INET6` data type is intended for storage of IPv6 addresses, as well as IPv4 addresses assuming conventional mapping of IPv4 addresses into IPv6 addresses.

Both short and long IPv6 notation are permitted, according to RFC-5952.

- Values are stored as a 16-byte fixed length binary string, with most significant byte first.
- Storage engines see `INET6` as `BINARY(16)`.
- Clients see `INET6` as `CHAR(39)` and get text representation on retrieval.

The IPv4-compatible notation is considered as deprecated. It is supported for compatibility with the `INET6_ATON` function, which also understands this format. It's recommended to use the mapped format to store IPv4 addresses in `INET6`.

When an IPv4 mapped (or compatible) value is stored in `INET6`, it still occupies 16 bytes:

Retrieval

On retrieval, in the client-server text protocol, `INET6` values are converted to the short text representation, according to RFC-5952, that is with all leading zeroes in each group removed and with consequent zero groups compressed.

Besides creating one's own [stored function](#), there is no a way to retrieve an `INET6` value using long text representation.

Casting

- `CAST` from a character string to `INET6` understands addresses in short or long text notation (including IPv4 mapped and compatible addresses). `NULL` is returned if the format is not understood.
- `CAST` from a binary string to `INET6` requires a 16-byte string as an argument. `NULL` is returned if the argument length is not equal to 16.
- `CAST` from other data types to `INET6` first converts data to a character string, then `CAST` from character string to `INET6` is applied.
- `CAST` from `INET6` to `CHAR` returns short text address notation.
- `CAST` from `INET6` to `BINARY` returns its 16-byte binary string representation.
- `CAST` from `INET6` to data types other than `CHAR` (e.g. `SIGNED`, `UNSIGNED`, `TIME`, etc) returns an error.

Comparisons

An `INET6` expression can be compared to:

- another `INET6` expression
- a character string expression with a text (short or long) address representation:
- a 16-byte binary string expression:

Attempting to compare `INET6` to an expression of any other data type returns an error.

Mixing INET6 Values for Result

An `INET6` expression can be mixed for result (i.e. `UNION`, `CASE..THEN`, `COALESCE` etc) with:

- another `INET6` expression. The resulting data type is `INET6`.
- a character string in text (short or long) address representation. The result data type is `INET6`. The character string

counterpart is automatically converted to INET6. If the string format is not understood, it's converted with a warning to either NULL or to '::', depending on the NULL-ability of the result.

- a 16-byte binary string. The resulting data type is INET6. The binary string counterpart is automatically converted to INET6. If the length of the binary string is not equal to 16, it's converted with a warning to NULL or to '::' depending on the NULL-ability of the result.

Attempts to mix INET6 for result with other data types will return an error.

Mixing INET6 with other data types for [LEAST](#) and [GREATEST](#), when mixing for comparison and mixing for result are involved at the same time, uses the same rules with mixing for result, described in the previous paragraphs.

Functions and Operators

- [HEX\(\)](#) with an INET6 argument returns a hexadecimal representation of the underlying 16-byte binary string
- Arithmetic operators (+,-,*,/,MOD,DIV) are not supported for INET6. This may change in the future.
- The [INET6_ATON](#) function now understands INET6 values as an argument
- The prototypes of the [IS_IPV4_COMPAT](#) and [IS_IPV4_MAPPED](#) functions have changed from a `BINARY(16)` to a `INET6`,
- When the argument for these two functions is not INET6, automatic implicit CAST to INET6 is applied. As a consequence, both functions now understand arguments in both text representation and binary(16) representation. Before [MariaDB 10.5.0](#), these functions understood only binary(16) representation.

Prepared Statement Parameters

INET6 understands both [text](#) and [binary\(16\)](#) address representation in [prepared statement](#) parameters ([PREPARE..EXECUTE](#) and [EXECUTE IMMEDIATE](#) statements).

Migration between BINARY(16) and INET6

Before [MariaDB 10.5.0](#), you may have used [BINARY\(16\)](#) as a storage for IPv6 internet addresses, in combination with [INET6_ATON](#) and [INET6_NTOA](#) to respectively insert and retrieve data.

From 10.5, you can [ALTER BINARY\(16\)](#) columns storing IPv6 addresses to INET6. After such an alter, there is no a need to use [INET6_ATON\(\)](#) and [INET6_NTOA\(\)](#). Addresses can be inserted and retrieved directly.

It is also possible to convert INET6 columns to BINARY(16) and continue using the data in combination with [INET6_NTOA\(\)](#) and [INET6_ATON\(\)](#).

Examples

```
CREATE TABLE t1 (a INET6);
```

Inserting using short text address notation:

```
INSERT INTO t1 VALUES ('2001:db8::ff00:42:8329');
```

Long text address notation:

```
INSERT INTO t1 VALUES ('2001:0db8:0000:0000:0000:ff00:0042:8329');
```

16-byte binary string notation:

```
INSERT INTO t1 VALUES (0x20010DB8000000000000FF0000428329);
INSERT INTO t1 VALUES (UNHEX('20010DB8000000000000FF0000428329'));
```

IPv4 addresses, using IPv4-mapped and IPv4-compatible notations:

```
INSERT INTO t1 VALUES ('::ffff:192.0.2.128'); -- mapped
INSERT INTO t1 VALUES ('::192.0.2.128'); -- compatible
```

```

SELECT * FROM t1;
+-----+
| a |
+-----+
| 2001:db8::ff00:42:8329 |
| 2001:db8::ff00:42:8329 |
| 2001:db8::ff00:42:8329 |
| 2001:db8::ff00:42:8329 |
| ::ffff:192.0.2.128 |
| ::192.0.2.128 |
+-----+

```

IPv4 mapped (or compatible) values still occupy 16 bytes:

```

CREATE OR REPLACE TABLE t1 (a INET6);

INSERT INTO t1 VALUES ('::ffff:192.0.2.128');

SELECT * FROM t1;
+-----+
| a |
+-----+
| ::ffff:192.0.2.128 |
+-----+

SELECT HEX(a) FROM t1;
+-----+
| HEX(a) |
+-----+
| 00000000000000000000000000000000FFFFC0000280 |
+-----+

```

Casting from INET6 to anything other than `CHAR` returns an error:

```

SELECT CAST(a AS DECIMAL) FROM t1;

ERROR 4079 (HY000): Illegal parameter data type inet6 for operation 'decimal_typecast'

```

Comparison Examples

Comparison with another INET6 expression:

```

CREATE OR REPLACE TABLE t1 (a INET6);
CREATE OR REPLACE TABLE t2 (a INET6);

INSERT INTO t1 VALUES ('2001:db8::ff00:42:8328'), ('2001:db8::ff00:42:8329');
INSERT INTO t2 VALUES ('2001:db8::ff00:42:832a'), ('2001:db8::ff00:42:8329');

SELECT t1.* FROM t1,t2 WHERE t1.a=t2.a;
+-----+
| a |
+-----+
| 2001:db8::ff00:42:8329 |
+-----+

```

With a character string expression with a text (short or long) address representation:

```

CREATE OR REPLACE TABLE t1 (a INET6);

INSERT INTO t1 VALUES ('2001:db8::ff00:42:8329');

SELECT * FROM t1 WHERE a='2001:db8::ff00:42:8329';
+-----+
| a |
+-----+
| 2001:db8::ff00:42:8329 |
+-----+

```

With a 16-byte binary string expression:

```

CREATE OR REPLACE TABLE t1 (a INET6);

INSERT INTO t1 VALUES ('2001:db8::ff00:42:8329');

SELECT * FROM t1 WHERE a=X'20010DB8000000000000FF0000428329';
+-----+
| a                |
+-----+
| 2001:db8::ff00:42:8329 |
+-----+

```

With an expression of another data type:

```

SELECT * FROM t1 WHERE a=1;
ERROR 4078 (HY000): Illegal parameter data types inet6 and int for operation '='

```

Mixing for Result Examples

Mixed with another INET6 expression, returning an INET6 data type:

```

CREATE OR REPLACE TABLE t1 (a INET6, b INET6);

INSERT INTO t1 VALUES (NULL, '2001:db8::ff00:42:8329');

SELECT a FROM t1 UNION SELECT b FROM t1;
+-----+
| a                |
+-----+
| NULL             |
| 2001:db8::ff00:42:8329 |
+-----+

SELECT COALESCE(a, b) FROM t1;
+-----+
| COALESCE(a, b)   |
+-----+
| 2001:db8::ff00:42:8329 |
+-----+

```

Mixed with a character string in text (short or long) address representation:

```

CREATE OR REPLACE TABLE t1 (a INET6, b VARCHAR(64));

INSERT INTO t1 VALUES (NULL, '2001:db8::ff00:42:8328');

INSERT INTO t1 VALUES (NULL, '2001:db8::ff00:42:832a garbage');

SELECT COALESCE(a,b) FROM t1;
+-----+
| COALESCE(a,b)    |
+-----+
| 2001:db8::ff00:42:8328 |
| NULL             |
+-----+
2 rows in set, 1 warning (0.001 sec)

SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1292 | Incorrect inet6 value: '2001:db8::ff00:42:832a garbage' |
+-----+-----+-----+

```

Mixed with a 16-byte binary string:

```

CREATE OR REPLACE TABLE t1 (a INET6, b VARBINARY(16));

INSERT INTO t1 VALUES (NULL, CONCAT(0xFFFF, REPEAT(0x0000, 6), 0xFFFF));

INSERT INTO t1 VALUES (NULL, 0x00/*garbage*/);

SELECT COALESCE(a,b) FROM t1;
+-----+
| COALESCE(a,b) |
+-----+
| ffff::ffff    |
| NULL          |
+-----+
2 rows in set, 1 warning (0.001 sec)

SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1292 | Incorrect inet6 value: '\x00' |
+-----+-----+-----+

```

Mixing with other data types:

```

SELECT CAST('ffff::ffff' AS INET6) UNION SELECT 1;
ERROR 4078 (HY000): Illegal parameter data types inet6 and int for operation 'UNION'

```

Functions and Operators Examples

[HEX](#) with an INET6 argument returning a hexadecimal representation:

```

SELECT HEX(CAST('2001:db8::ff00:42:8329' AS INET6));
+-----+
| HEX(CAST('2001:db8::ff00:42:8329' AS INET6)) |
+-----+
| 20010DB8000000000000FF0000428329 |
+-----+

```

[INET6_ATON](#) now understands INET6 values as an argument:

```

CREATE OR REPLACE TABLE t1 (a INET6);

INSERT INTO t1 VALUES ('2001:db8::ff00:42:8329');

SELECT a, HEX(INET6_ATON(a)) FROM t1;
+-----+-----+
| a | HEX(INET6_ATON(a)) |
+-----+-----+
| 2001:db8::ff00:42:8329 | 20010DB8000000000000FF0000428329 |
+-----+-----+

```

[IS_IPV4_COMPAT](#) and [IS_IPV4_MAPPED](#) prototype now a BINARY(16) :

```

CREATE OR REPLACE TABLE t1 (a INET6);

INSERT INTO t1 VALUES ('2001:db8::ff00:42:8329');
INSERT INTO t1 VALUES ('::ffff:192.168.0.1');
INSERT INTO t1 VALUES ('::192.168.0.1');

SELECT a, IS_IPV4_MAPPED(a), IS_IPV4_COMPAT(a) FROM t1;
+-----+-----+-----+
| a | IS_IPV4_MAPPED(a) | IS_IPV4_COMPAT(a) |
+-----+-----+-----+
| 2001:db8::ff00:42:8329 | 0 | 0 |
| ::ffff:192.168.0.1 | 1 | 0 |
| ::192.168.0.1 | 0 | 1 |
+-----+-----+-----+

```

```

CREATE OR REPLACE TABLE t1 (
  a INET6,
  b VARCHAR(39) DEFAULT a
);

INSERT INTO t1 (a) VALUES ('ffff::ffff'),('::ffff:192.168.0.1');

SELECT a, IS_IPV4_MAPPED(a), b, IS_IPV4_MAPPED(b) FROM t1;
+-----+-----+-----+-----+
| a          | IS_IPV4_MAPPED(a) | b          | IS_IPV4_MAPPED(b) |
+-----+-----+-----+-----+
| ffff::ffff | 0 | ffff::ffff | 0 |
| ::ffff:192.168.0.1 | 1 | ::ffff:192.168.0.1 | 1 |
+-----+-----+-----+-----+

CREATE OR REPLACE TABLE t1 (
  a INET6,
  b BINARY(16) DEFAULT UNHEX(HEX(a))
);

INSERT INTO t1 (a) VALUES ('ffff::ffff'),('::ffff:192.168.0.1');

SELECT a, IS_IPV4_MAPPED(a), HEX(b), IS_IPV4_MAPPED(b) FROM t1;
+-----+-----+-----+-----+
| a          | IS_IPV4_MAPPED(a) | HEX(b)          | IS_IPV4_MAPPED(b) |
+-----+-----+-----+-----+
| ffff::ffff | 0 | FFFF0000000000000000000000000000FFFF |
| ::ffff:192.168.0.1 | 1 | 000000000000000000000000FFFFC0A80001 |
+-----+-----+-----+-----+

```

Prepared Statement Parameters Examples

```

CREATE OR REPLACE TABLE t1 (a INET6);

EXECUTE IMMEDIATE 'INSERT INTO t1 VALUES (?)' USING 'ffff::fffe';
EXECUTE IMMEDIATE 'INSERT INTO t1 VALUES (?)' USING X'FFFF0000000000000000000000000000FFFF';

SELECT * FROM t1;
+-----+
| a          |
+-----+
| ffff::fffe |
| ffff::ffff |
+-----+

EXECUTE IMMEDIATE 'SELECT * FROM t1 WHERE a=?' USING 'ffff::fffe';
+-----+
| a          |
+-----+
| ffff::fffe |
+-----+

EXECUTE IMMEDIATE 'SELECT * FROM t1 WHERE a=?' USING X'FFFF0000000000000000000000000000FFFF';
+-----+
| a          |
+-----+
| ffff::ffff |
+-----+

```

Migration between BINARY(16) and INET6 Examples

Before [MariaDB 10.5](#):

```

CREATE OR REPLACE TABLE t1 (a BINARY(16));

INSERT INTO t1 VALUES (INET6_ATON('ffff::ffff'));

SELECT INET6_NTOA(a) FROM t1;
+-----+
| INET6_NTOA(a) |
+-----+
| ffff::ffff    |
+-----+

```

Migrating to INET6, from [MariaDB 10.5](#):

```

ALTER TABLE t1 MODIFY a INET6;

INSERT INTO t1 VALUES ('ffff::fffe');

SELECT * FROM t1;
+-----+
| a          |
+-----+
| ffff::ffff |
| ffff::fffe |
+-----+

```

Migration from INET6 to BINARY(16):

```

CREATE OR REPLACE TABLE t1 (a INET6);

INSERT INTO t1 VALUES ('2001:db8::ff00:42:8329');
INSERT INTO t1 VALUES ('::ffff:192.168.0.1');
INSERT INTO t1 VALUES ('::192.168.0.1');

ALTER TABLE t1 MODIFY a BINARY(16);

SELECT INET6_NTOA(a) FROM t1;
+-----+
| INET6_NTOA(a) |
+-----+
| 2001:db8::ff00:42:8329 |
| ::ffff:192.168.0.1    |
| ::192.168.0.1        |
+-----+

```

Casting from INET4 to INET6

From [MariaDB 11.3.0](#), casting from [INET4](#) data types to INET6 is permitted, allowing INET4 values to be inserted into INET6 columns.

Before [MariaDB 11.3](#):

```

CREATE TABLE t1 (a INET6);

INSERT INTO t1 VALUES('0.0.0.0'), ('255.10.0.0'), ('255.255.255.255');
ERROR 1292 (22007): Incorrect inet6 value: '0.0.0.0' for column `test`.`t1`.`a` at row 1

```

From [MariaDB 11.3](#):

```

CREATE TABLE t1 (a INET6);

INSERT INTO t1 VALUES('0.0.0.0'), ('255.10.0.0'), ('255.255.255.255');
Query OK, 3 rows affected (0.027 sec)

```

5.1.2.10 JSON Data Type

The JSON alias was added to make it possible to use JSON columns in [statement based replication](#) from MySQL to MariaDB and to make it possible for MariaDB to read [mysqldumps](#) from MySQL.

Contents

1. [Examples](#)
2. [Replicating JSON Data Between MySQL and MariaDB](#)
3. [Converting a MySQL TABLE with JSON Fields to MariaDB](#)
4. [Differences Between MySQL JSON Strings and MariaDB JSON Strings](#)

JSON is an alias for `LONGTEXT COLLATE utf8mb4_bin` introduced for compatibility reasons with MySQL's JSON data type. MariaDB implements this as a `LONGTEXT` rather, as the JSON data type contradicts the SQL:2016 standard, and MariaDB's benchmarks indicate that performance is at least equivalent.

In order to ensure that a a valid json document is inserted, the `JSON_VALID` function can be used as a `CHECK constraint`. This constraint is automatically included for types using the JSON alias from [MariaDB 10.4.3](#).

Examples

```
CREATE TABLE t (j JSON);

DESC t;
+-----+-----+-----+-----+-----+-----+
| Field | Type      | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| j     | longtext | YES  |     | NULL    |      |
+-----+-----+-----+-----+-----+-----+
```

With validation:

```
CREATE TABLE t2 (
  j JSON
  CHECK (JSON_VALID(j))
);

INSERT INTO t2 VALUES ('invalid');
ERROR 4025 (23000): CONSTRAINT `j` failed for `test`.`t2`

INSERT INTO t2 VALUES ('{"id": 1, "name": "Monty"}');
Query OK, 1 row affected (0.13 sec)
```

Replicating JSON Data Between MySQL and MariaDB

The JSON type in MySQL stores the JSON object in a compact form, not as `LONGTEXT` as in MariaDB. This means that row based replication will not work for JSON types from MySQL to MariaDB.

There are a few different ways to solve this:

- Use statement based replication.
- Change the JSON column to type TEXT in MySQL
- If you must use row-based replication and cannot change the MySQL master from JSON to TEXT, you can try to introduce an intermediate MySQL slave and change the column type from JSON to TEXT on it. Then you replicate from this intermediate slave to MariaDB.

Converting a MySQL TABLE with JSON Fields to MariaDB

MariaDB can't directly access MySQL's JSON format.

There are a few different ways to move the table to MariaDB:

- From [MariaDB 10.5.7](#), see the you can use the `mysql_json` plugin. See [Making MariaDB understand MySQL JSON](#).
- Change the JSON column to type TEXT in MySQL. After this, MariaDB can directly use the table without any need for a dump and restore.
- [Use mysqldump to copy the table.](#)

Differences Between MySQL JSON Strings and MariaDB JSON Strings

- In MySQL, JSON is an object and is [compared according to json values](#). In MariaDB JSON strings are normal strings and compared as strings. One exception is when using `JSON_EXTRACT()` in which case strings are unescaped before comparison.

5.1.2.11 MEDIUMBLOB

Syntax

```
MEDIUMBLOB
```

Description

A **BLOB** column with a maximum length of 16,777,215 ($2^{24} - 1$) bytes. Each MEDIUMBLOB value is stored using a three-byte length prefix that indicates the number of bytes in the value.

5.1.2.12 MEDIUMTEXT

Syntax

```
MEDIUMTEXT [CHARACTER SET charset_name] [COLLATE collation_name]
```

Description

A **TEXT** column with a maximum length of 16,777,215 ($2^{24} - 1$) characters. The effective maximum length is less if the value contains multi-byte characters. Each MEDIUMTEXT value is stored using a three-byte length prefix that indicates the number of bytes in the value.

5.1.2.13 LONGBLOB

Syntax

```
LONGBLOB
```

Description

A **BLOB** column with a maximum length of 4,294,967,295 bytes or 4GB ($2^{32} - 1$). The effective maximum length of LONGBLOB columns depends on the configured maximum packet size in the client/server protocol and available memory. Each LONGBLOB value is stored using a four-byte length prefix that indicates the number of bytes in the value.

Oracle Mode

In [Oracle mode from MariaDB 10.3](#), `BLOB` is a synonym for `LONGBLOB`.

5.1.2.14 LONG and LONG VARCHAR

`LONG` and `LONG VARCHAR` are synonyms for [MEDIUMTEXT](#).

```
CREATE TABLE t1 (a LONG, b LONG VARCHAR);
```

```
DESC t1;
```

Field	Type	Null	Key	Default	Extra
a	mediumtext	YES		NULL	
b	mediumtext	YES		NULL	

5.1.2.15 LONGTEXT

Syntax

```
LONGTEXT [CHARACTER SET charset_name] [COLLATE collation_name]
```

Contents

- [Syntax](#)
- [Description](#)
- [Oracle Mode](#)

Description

A [TEXT](#) column with a maximum length of 4,294,967,295 or 4GB ($2^{32} - 1$) characters. The effective maximum length is less if the value contains multi-byte characters. The effective maximum length of LONGTEXT columns also depends on the configured maximum packet size in the client/server protocol and available memory. Each LONGTEXT value is stored using a four-byte length prefix that indicates the number of bytes in the value.

From [MariaDB 10.2.7](#), [JSON](#) is an alias for LONGTEXT. See [JSON Data Type](#) for details.

Oracle Mode

In [Oracle mode from MariaDB 10.3](#), [CLOB](#) is a synonym for LONGTEXT.

5.1.2.16 ROW

Syntax

```
ROW (<field name> <data type> [{, <field name> <data type>}... ])
```

Contents

- [Syntax](#)
- [Description](#)
- [Features](#)
 - [ROW fields as normal variables](#)
 - [ROW type variables as FETCH targets](#)
 - [ROW type variables as SELECT...INTO targets](#)
- [Features not implemented](#)
- [Examples](#)
 - [Declaring a ROW in a stored procedure](#)
 - [FETCH Examples](#)
 - [SELECT...INTO Examples](#)

Description

ROW is a data type for [stored procedure](#) variables.

Features

ROW fields as normal variables

ROW fields (members) act as normal variables, and are able to appear in all query parts where a stored procedure variable is allowed:

- Assignment is using the `:=` operator and the [SET](#) command:

```
a.x:= 10;
a.x:= b.x;
SET a.x= 10, a.y=20, a.z= b.z;
```

- Passing to functions and operators:

```
SELECT fl(rec.a), rec.a<10;
```

- Clauses (select list, WHERE, HAVING, LIMIT, etc...):

```
SELECT var.a, t1.b FROM t1 WHERE t1.b=var.b LIMIT var.c;
```

- INSERT values:

```
INSERT INTO t1 VALUES (rec.a, rec.b, rec.c);
```

- SELECT .. INTO targets

```
SELECT a,b INTO rec.a, rec.b FROM t1 WHERE t1.id=10;
```

- Dynamic SQL out parameters ([EXECUTE](#) and [EXECUTE IMMEDIATE](#))

```
EXECUTE IMMEDIATE 'CALL proc_with_out_param(?)' USING rec.a;
```

ROW type variables as FETCH targets

ROW type variables are allowed as [FETCH](#) targets:

```
FETCH cur INTO rec;
```

where `cur` is a `CURSOR` and `rec` is a `ROW` type stored procedure variable.

Note, currently an attempt to use `FETCH` for a `ROW` type variable returns this error:

```
ERROR 1328 (HY000): Incorrect number of FETCH variables
```

`FETCH` from a cursor `cur` into a `ROW` variable `rec` works as follows:

- The number of fields in `cur` must match the number of fields in `rec`. Otherwise, an error is reported.
- Assignment is done from left to right. The first cursor field is assigned to the first variable field, the second cursor field is assigned to the second variable field, etc.
- Field names in `rec` are not important and can differ from field names in `cur`.

See [FETCH Examples](#) (below) for examples of using this with `sql_mode=ORACLE` and `sql_mode=DEFAULT`.

ROW type variables as SELECT...INTO targets

ROW type variables are allowed as `SELECT...INTO` targets with some differences depending on which `sql_mode` is in use.

- When using `sql_mode=ORACLE`, `table%ROWTYPE` and `cursor%ROWTYPE` variables can be used as `SELECT...INTO` targets.

- Using multiple `ROW` variables in the `SELECT...INTO` list will report an error.
- Using `ROW` variables with a different column count than in the `SELECT...INTO` list will report an error.

See [SELECT...INTO Examples](#) (below) for examples of using this with `sql_mode=ORACLE` and `sql_mode=DEFAULT`.

Features not implemented

The following features are planned, but not implemented yet:

- Returning a `ROW` type expression from a stored function (see [MDEV-12252](#)). This will need some grammar change to support field names after parentheses:

```
SELECT f1().x FROM DUAL;
```

- Returning a `ROW` type expression from a built-in hybrid type function, such as `CASE`, `IF`, etc.
- `ROW` of `ROWS`

Examples

Declaring a `ROW` in a stored procedure

```
DELIMITER $$
CREATE PROCEDURE p1()
BEGIN
  DECLARE r ROW (c1 INT, c2 VARCHAR(10));
  SET r.c1= 10;
  SET r.c2= 'test';
  INSERT INTO t1 VALUES (r.c1, r.c2);
END;
$$
DELIMITER ;
CALL p1();
```

FETCH Examples

A complete `FETCH` example for `sql_mode=ORACLE`:

```
DROP TABLE IF EXISTS t1;
CREATE TABLE t1 (a INT, b VARCHAR(32));
INSERT INTO t1 VALUES (10,'b10');
INSERT INTO t1 VALUES (20,'b20');
INSERT INTO t1 VALUES (30,'b30');

SET sql_mode=oracle;
DROP PROCEDURE IF EXISTS p1;
DELIMITER $$
CREATE PROCEDURE p1 AS
  rec ROW(a INT, b VARCHAR(32));
  CURSOR c IS SELECT a,b FROM t1;
BEGIN
  OPEN c;
  LOOP
    FETCH c INTO rec;
    EXIT WHEN c%NOTFOUND;
    SELECT ('rec=(' || rec.a || ',' || rec.b || ')');
  END LOOP;
  CLOSE c;
END;
$$
DELIMITER ;
CALL p1();
```

A complete `FETCH` example for `sql_mode=DEFAULT`:

```

DROP TABLE IF EXISTS t1;
CREATE TABLE t1 (a INT, b VARCHAR(32));
INSERT INTO t1 VALUES (10,'b10');
INSERT INTO t1 VALUES (20,'b20');
INSERT INTO t1 VALUES (30,'b30');

SET sql_mode=DEFAULT;
DROP PROCEDURE IF EXISTS p1;
DELIMITER $$
CREATE PROCEDURE p1()
BEGIN
    DECLARE done INT DEFAULT FALSE;
    DECLARE rec ROW(a INT, b VARCHAR(32));
    DECLARE c CURSOR FOR SELECT a,b FROM t1;
    DECLARE CONTINUE HANDLER FOR NOT FOUND SET done = TRUE;
    OPEN c;
read_loop:
    LOOP
        FETCH c INTO rec;
        IF done THEN
            LEAVE read_loop;
        END IF;
        SELECT CONCAT('rec=(',rec.a,',',rec.b,')');
    END LOOP;
    CLOSE c;
END;
$$
DELIMITER ;
CALL p1();

```

SELECT...INTO Examples

A SELECT...INTO example for sql_mode=DEFAULT:

```

SET sql_mode=DEFAULT;
DROP TABLE IF EXISTS t1;
DROP PROCEDURE IF EXISTS p1;
CREATE TABLE t1 (a INT, b VARCHAR(32));
INSERT INTO t1 VALUES (10,'b10');
DELIMITER $$
CREATE PROCEDURE p1()
BEGIN
    DECLARE rec1 ROW(a INT, b VARCHAR(32));
    SELECT * FROM t1 INTO rec1;
    SELECT rec1.a, rec1.b;
END;
$$
DELIMITER ;
CALL p1();

```

The above example returns:

```

+-----+-----+
| rec1.a | rec1.b |
+-----+-----+
|    10 | b10    |
+-----+-----+

```

A SELECT...INTO example for sql_mode=ORACLE:

```

SET sql_mode=ORACLE;
DROP TABLE IF EXISTS t1;
DROP PROCEDURE IF EXISTS p1;
CREATE TABLE t1 (a INT, b VARCHAR(32));
INSERT INTO t1 VALUES (10,'b10');
DELIMITER $$
CREATE PROCEDURE p1 AS
    rec1 ROW(a INT, b VARCHAR(32));
BEGIN
    SELECT * FROM t1 INTO rec1;
    SELECT rec1.a, rec1.b;
END;
$$
DELIMITER ;
CALL p1();

```

The above example returns:

```

+-----+-----+
| rec1.a | rec1.b |
+-----+-----+
|      10 | b10    |
+-----+-----+

```

An example for `sql_mode=ORACLE` using `table%ROWTYPE` variables as `SELECT..INTO` targets:

```

SET sql_mode=ORACLE;
DROP TABLE IF EXISTS t1;
DROP PROCEDURE IF EXISTS p1;
CREATE TABLE t1 (a INT, b VARCHAR(32));
INSERT INTO t1 VALUES (10,'b10');
DELIMITER $$
CREATE PROCEDURE p1 AS
    rec1 t1%ROWTYPE;
BEGIN
    SELECT * FROM t1 INTO rec1;
    SELECT rec1.a, rec1.b;
END;
$$
DELIMITER ;
CALL p1();

```

The above example returns:

```

+-----+-----+
| rec1.a | rec1.b |
+-----+-----+
|      10 | b10    |
+-----+-----+

```

An example for `sql_mode=ORACLE` using `cursor%ROWTYPE` variables as `SELECT..INTO` targets:

```

SET sql_mode=ORACLE;
DROP TABLE IF EXISTS t1;
DROP PROCEDURE IF EXISTS p1;
CREATE TABLE t1 (a INT, b VARCHAR(32));
INSERT INTO t1 VALUES (10,'b10');
DELIMITER $$
CREATE PROCEDURE p1 AS
    CURSOR cur1 IS SELECT * FROM t1;
    rec1 cur1%ROWTYPE;
BEGIN
    SELECT * FROM t1 INTO rec1;
    SELECT rec1.a, rec1.b;
END;
$$
DELIMITER ;
CALL p1();

```

The above example returns:

```
+-----+-----+
| rec1.a | rec1.b |
+-----+-----+
|      10 | b10   |
+-----+-----+
```

5.1.2.17 TEXT

Syntax

```
TEXT[(M)] [CHARACTER SET charset_name] [COLLATE collation_name]
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [Indexing](#)
5. [Difference between VARCHAR and TEXT](#)
 1. [For Storage Engine Developers](#)

Description

A `TEXT` column with a maximum length of 65,535 ($2^{16} - 1$) characters. The effective maximum length is less if the value contains multi-byte characters. Each `TEXT` value is stored using a two-byte length prefix that indicates the number of bytes in the value. If you need a bigger storage, consider using `MEDIUMTEXT` instead.

An optional length `M` can be given for this type. If this is done, MariaDB creates the column as the smallest `TEXT` type large enough to hold values `M` characters long.

Before [MariaDB 10.2](#), all MariaDB [collations](#) were of type `PADSPACE`, meaning that `TEXT` (as well as `VARCHAR` and `CHAR` values) are compared without regard for trailing spaces. This does not apply to the `LIKE` pattern-matching operator, which takes into account trailing spaces.

`BLOB` and `TEXT` columns can be assigned a `DEFAULT` value. This was not possible prior to [MariaDB 10.2](#).

Examples

Trailing spaces:

```
CREATE TABLE strttest (d TEXT(10));
INSERT INTO strttest VALUES('Maria ');

SELECT d='Maria',d='Maria  ' FROM strttest;
+-----+-----+
| d='Maria' | d='Maria  ' |
+-----+-----+
|          1 |             1 |
+-----+-----+

SELECT d LIKE 'Maria',d LIKE 'Maria  ' FROM strttest;
+-----+-----+
| d LIKE 'Maria' | d LIKE 'Maria  ' |
+-----+-----+
|                0 |                   1 |
+-----+-----+
```

Indexing

A [unique index](#) can be created on a `TEXT` column. This was not possible prior to [MariaDB 10.4](#)

Internally, this uses hash indexing to quickly check the values and if a hash collision is found, the actual stored values are compared in order to retain the uniqueness.

Difference between **VARCHAR** and **TEXT**

- **VARCHAR** columns can be fully indexed. **TEXT** columns can only be indexed over a specified length.
- Using **TEXT** or **BLOB** in a **SELECT** query that uses temporary tables for storing intermediate results will force the temporary table to be disk based (using the **Aria storage engine** instead of the **memory storage engine**, which is a bit slower. This is not that bad as the **Aria storage engine** caches the rows in memory. To get the benefit of this, one should ensure that the **aria_pagecache_buffer_size** variable is big enough to hold most of the row and index data for temporary tables.

For Storage Engine Developers

- Internally the full length of the **VARCHAR** column is allocated inside each **TABLE** objects record[] structure. As there are three such buffers, each open table will allocate 3 times max-length-to-store-varchar bytes of memory.
- **TEXT** and **BLOB** columns are stored with a pointer (4 or 8 bytes) + a 1-4 bytes length. The **TEXT** data is only stored once. This means that internally **TEXT** uses less memory for each open table but instead has the additional overhead that each **TEXT** object needs to be allocated and freed for each row access (with some caching in between).

5.1.2.18 TINYBLOB

Syntax

```
TINYBLOB
```

Description

A **BLOB** column with a maximum length of 255 ($2^8 - 1$) bytes. Each **TINYBLOB** value is stored using a one-byte length prefix that indicates the number of bytes in the value.

5.1.2.19 TINYTEXT

Syntax

```
TINYTEXT [CHARACTER SET charset_name] [COLLATE collation_name]
```

Description

A **TEXT** column with a maximum length of 255 ($2^8 - 1$) characters. The effective maximum length is less if the value contains multi-byte characters. Each **TINYTEXT** value is stored using a one-byte length prefix that indicates the number of bytes in the value.

5.1.2.20 VARBINARY

Syntax

```
VARBINARY (M)
```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [Oracle Mode](#)
3. [Examples](#)

Description

The VARBINARY type is similar to the [VARCHAR](#) type, but stores binary byte strings rather than non-binary character strings. `M` represents the maximum column length in bytes.

It contains no [character set](#), and comparison and sorting are based on the numeric value of the bytes.

If the maximum length is exceeded, and [SQL strict mode](#) is not enabled, the extra characters will be dropped with a warning. If strict mode is enabled, an error will occur.

Unlike [BINARY](#) values, VARBINARYs are not right-padded when inserting.

Oracle Mode

In [Oracle mode from MariaDB 10.3](#), `RAW` is a synonym for `VARBINARY`.

Examples

Inserting too many characters, first with strict mode off, then with it on:

```
CREATE TABLE varbins (a VARBINARY(10));

INSERT INTO varbins VALUES('12345678901');
Query OK, 1 row affected, 1 warning (0.04 sec)

SELECT * FROM varbins;
+-----+
| a      |
+-----+
| 1234567890 |
+-----+

SET sql_mode='STRICT_ALL_TABLES';

INSERT INTO varbins VALUES('12345678901');
ERROR 1406 (22001): Data too long for column 'a' at row 1
```

Sorting is performed with the byte value:

```
TRUNCATE varbins;

INSERT INTO varbins VALUES('A'),('B'),('a'),('b');

SELECT * FROM varbins ORDER BY a;
+-----+
| a      |
+-----+
| A      |
| B      |
| a      |
| b      |
+-----+
```

Using [CAST](#) to sort as a [CHAR](#) instead:

```
SELECT * FROM varbins ORDER BY CAST(a AS CHAR);
+-----+
| a      |
+-----+
| a      |
| A      |
| b      |
| B      |
+-----+
```

5.1.2.21 VARCHAR

Syntax

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [Truncation](#)
5. [Difference Between VARCHAR and TEXT](#)
6. [Oracle Mode](#)
 1. [For Storage Engine Developers](#)

Description

A variable-length string. M represents the maximum column length in characters. The range of M is 0 to 65,532. The effective maximum length of a VARCHAR is subject to the maximum row size and the character set used. For example, utf8 characters can require up to three bytes per character, so a VARCHAR column that uses the utf8 character set can be declared to be a maximum of 21,844 characters.

Note: For the [ColumnStore](#) engine, M represents the maximum column length in bytes.

MariaDB stores VARCHAR values as a one-byte or two-byte length prefix plus data. The length prefix indicates the number of bytes in the value. A VARCHAR column uses one length byte if values require no more than 255 bytes, two length bytes if values may require more than 255 bytes.

MariaDB follows the standard SQL specification, and does not remove trailing spaces from VARCHAR values.

VARCHAR(0) columns can contain 2 values: an empty string or NULL. Such columns cannot be part of an index. The [CONNECT](#) storage engine does not support VARCHAR(0).

VARCHAR is shorthand for CHARACTER VARYING. NATIONAL VARCHAR is the standard SQL way to define that a VARCHAR column should use some predefined character set. MariaDB uses utf8 as this predefined character set, as does MySQL 4.1 and up. NVARCHAR is shorthand for NATIONAL VARCHAR.

Before [MariaDB 10.2](#), all MariaDB [collations](#) were of type `PADSPACE`, meaning that VARCHAR (as well as [CHAR](#) and [TEXT](#) values) are compared without regard for trailing spaces. This does not apply to the [LIKE](#) pattern-matching operator, which takes into account trailing spaces. From [MariaDB 10.2](#), a number of [NO PAD collations](#) are available.

If a unique index consists of a column where trailing pad characters are stripped or ignored, inserts into that column where values differ only by the number of trailing pad characters will result in a duplicate-key error.

Examples

The following are equivalent:

```
VARCHAR(30) CHARACTER SET utf8
NATIONAL VARCHAR(30)
NVARCHAR(30)
NCHAR VARCHAR(30)
NATIONAL CHARACTER VARYING(30)
NATIONAL CHAR VARYING(30)
```

Trailing spaces:

```
CREATE TABLE strttest (v VARCHAR(10));
INSERT INTO strttest VALUES('Maria ');

SELECT v='Maria',v='Maria ' FROM strttest;
+-----+-----+
| v='Maria' | v='Maria ' |
+-----+-----+
|          1 |          1 |
+-----+-----+

SELECT v LIKE 'Maria',v LIKE 'Maria ' FROM strttest;
+-----+-----+
| v LIKE 'Maria' | v LIKE 'Maria ' |
+-----+-----+
|          0 |          1 |
+-----+-----+
```

Truncation

- Depending on whether or not [strict sql mode](#) is set, you will either get a warning or an error if you try to insert a string that is too long into a VARCHAR column. If the extra characters are spaces, the spaces that can't fit will be removed and you will always get a warning, regardless of the [sql mode](#) setting.

Difference Between VARCHAR and TEXT

- VARCHAR columns can be fully indexed. TEXT columns can only be indexed over a specified length.
- Using TEXT or BLOB in a SELECT query that uses temporary tables for storing intermediate results will force the temporary table to be disk based (using the [Aria storage engine](#) instead of the [memory storage engine](#), which is a bit slower. This is not that bad as the [Aria storage engine](#) caches the rows in memory. To get the benefit of this, one should ensure that the [aria_pagecache_buffer_size](#) variable is big enough to hold most of the row and index data for temporary tables.

Oracle Mode

In [Oracle mode from MariaDB 10.3](#), VARCHAR2 is a synonym.

For Storage Engine Developers

- Internally the full length of the VARCHAR column is allocated inside each TABLE objects record[] structure. As there are three such buffers, each open table will allocate 3 times max-length-to-store-varchar bytes of memory.
- TEXT and BLOB columns are stored with a pointer (4 or 8 bytes) + a 1-4 bytes length. The TEXT data is only stored once. This means that internally TEXT uses less memory for each open table but instead has the additional overhead that each TEXT object needs to be allocated and freed for each row access (with some caching in between).

5.1.2.22 SET Data Type

Syntax

```
SET('value1','value2',...) [CHARACTER SET charset_name] [COLLATE collation_name]
```

Description

A set. A string object that can have zero or more values, each of which must be chosen from the list of values 'value1', 'value2', ... A SET column can have a maximum of 64 members. SET values are represented internally as integers.

SET values cannot contain commas.

If a SET contains duplicate values, an error will be returned if [strict mode](#) is enabled, or a warning if strict mode is not enabled.

5.1.2.23 UUID Data Type

MariaDB starting with [10.7](#)
The UUID data type was added in [MariaDB 10.7](#).

Syntax

```
UUID
```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [Retrieval](#)
 2. [Casting](#)
 3. [Storage](#)
3. [Examples](#)

Description

The `UUID` data type is intended for the storage of 128-bit UUID (Universally Unique Identifier) data. See the [UUID function](#) page for more details on UUIDs themselves.

Retrieval

Data retrieved by this data type is in the string representation defined in [RFC4122](#).

Casting

[String literals](#) of hexadecimal characters and [CHAR/VARCHAR/TEXT](#) can be cast to the UUID data type. Likewise [hexadecimal literals](#), [binary-literals](#), and [BINARY/VARBINARY/BLOB](#) types can also be cast to UUID.

The data type will not accept a short UUID generated with the `UUID_SHORT` function, but will accept a value without the `-` character generated by the `SYS_GUID` function (or inserted directly). Hyphens can be partially omitted as well, or included after any group of two digits.

The type does not accept UUIDs in braces, permitted by some implementations.

Storage

UUID are stored in an index friendly manner, the order of a UUID of `llllllll-mmmm-Vhhh-vsss-nnnnnnnnnnnn` is stored as:

```
nnnnnnnnnnnn-vsss-Vhhh-mmmm-llllllllll
```

This provides a sorting order, assuming a UUIDv1 (node and timestamp) is used, of the node, followed by the timestamp. The key aspect is the timestamps are sequential.

MariaDB starting with 10.10

Starting from [MariaDB 10.10.6](#) and [MariaDB 10.11.5](#), taking into account that UUIDv7 and other versions are designed around time ordering, UUIDs version ≥ 6 are now stored without byte-swapping, and UUIDs with version ≥ 8 and variant=0 are now considered invalid (as the standard expects)

Examples

```
CREATE TABLE t1 (id UUID);
```

Directly Inserting via [string literals](#):

```
INSERT INTO t1 VALUES ('123e4567-e89b-12d3-a456-426655440000');
```

Directly Inserting via [hexadecimal literals](#):

```
INSERT INTO t1 VALUES (x'ffffffffffffffffffffffffffffffffe');
```

Generating and inserting via the [UUID function](#).

```
INSERT INTO t1 VALUES (UUID());
```

Retrieval:

```

SELECT * FROM t1;
+-----+
| id |
+-----+
| 123e4567-e89b-12d3-a456-426655440000 |
| ffffffff-ffff-ffff-ffff-ffffffffffffe |
| 93aac041-1a14-11ec-ab4e-f859713e4be4 |
+-----+

```

The `UUID_SHORT` function does not generate valid full-length UUID:

```

INSERT INTO t1 VALUES (UUID_SHORT());
ERROR 1292 (22007): Incorrect uuid value: '99440417627439104'
for column `test`.`t1`.`id` at row 1

```

Accepting a value without the `-` character, either directly or generated by the `SYS_GUID` function:

```

INSERT INTO t1 VALUES (SYS_GUID());

SELECT * FROM t1;
+-----+
| id |
+-----+
| 123e4567-e89b-12d3-a456-426655440000 |
| ffffffff-ffff-ffff-ffff-ffffffffffffe |
| 93aac041-1a14-11ec-ab4e-f859713e4be4 |
| ea0368d3-1a14-11ec-ab4e-f859713e4be4 |
+-----+

SELECT SYS_GUID();
+-----+
| SYS_GUID() |
+-----+
| ff5b6bcc1a1411ecab4ef859713e4be4 |
+-----+

INSERT INTO t1 VALUES ('ff5b6bcc1a1411ecab4ef859713e4be4');

SELECT * FROM t1;
+-----+
| id |
+-----+
| 123e4567-e89b-12d3-a456-426655440000 |
| ffffffff-ffff-ffff-ffff-ffffffffffffe |
| 93aac041-1a14-11ec-ab4e-f859713e4be4 |
| ea0368d3-1a14-11ec-ab4e-f859713e4be4 |
| ff5b6bcc-1a14-11ec-ab4e-f859713e4be4 |
+-----+

```

Valid and invalid hyphen and brace usage:

```

TRUNCATE t1;

INSERT INTO t1 VALUES ('f8aa-ed66-1a1b-11ec-ab4e-f859-713e-4be4');

INSERT INTO t1 VALUES ('1b80667f1a1c-11ecab4ef859713e4be4');

INSERT INTO t1 VALUES ('2fd6c945-1a-1c-11ec-ab4e-f859713e4be4');

INSERT INTO t1 VALUES ('49-c9-f9-59-1a-1c-11ec-ab4e-f859713e4be4');

INSERT INTO t1 VALUES ('57-96-da-c1-1a-1c-11-ec-ab-4e-f8-59-71-3e-4b-e4');

INSERT INTO t1 VALUES ('6-eb74f8f-1a1c-11ec-ab4e-f859713e4be4');

INSERT INTO t1 VALUES ('{29bad136-1a1d-11ec-ab4e-f859713e4be4}');
ERROR 1292 (22007): Incorrect uuid value: '{29bad136-1a1d-11ec-ab4e-f859713e4be4}'
  for column `test`.`t1`.`id` at row 1

SELECT * FROM t1;
+-----+
| id |
+-----+
| f8aaed66-1a1b-11ec-ab4e-f859713e4be4 |
| 1b80667f-1a1c-11ec-ab4e-f859713e4be4 |
| 2fd6c945-1a1c-11ec-ab4e-f859713e4be4 |
| 49c9f959-1a1c-11ec-ab4e-f859713e4be4 |

5.1.2.24 Data Type Storage Requirements

Contents

1. [Numeric Data Types](#)
 1. [Decimal](#)
2. [String Data Types](#)
 1. [Examples](#)
3. [Date and Time Data Types](#)
 1. [Microseconds](#)
 1. [MySQL 5.6+ and MariaDB 10.1+](#)
 2. [MariaDB 5.3 - MariaDB 10.0](#)
4. [NULLs](#)

The following tables indicate the approximate data storage requirements for each data type.

Numeric Data Types

Data Type	Storage Requirement
TINYINT	1 byte
SMALLINT	2 bytes
MEDIUMINT	3 bytes
INT	4 bytes
BIGINT	8 bytes
FLOAT(p)	4 bytes if p <= 24, otherwise 8 bytes
DOUBLE	8 bytes
DECIMAL	See table below
BIT(M)	(M+7)/8 bytes

Note that MEDIUMINT columns will require 4 bytes in memory (for example, in InnoDB buffer pool).

Decimal

Decimals are stored using a binary format, with the integer and the fraction stored separately. Each nine-digit multiple requires 4 bytes, followed by a number of bytes for whatever remains, as follows:

Remaining digits	Storage Requirement
0	0 bytes
1	1 byte
2	1 byte
3	2 bytes
4	2 bytes
5	3 bytes
6	3 bytes
7	4 bytes
8	4 bytes

String Data Types

In the descriptions below, `M` is the declared column length (in characters or in bytes), while `len` is the actual length in bytes of the value.

Data Type	Storage Requirement
ENUM	1 byte for up to 255 enum values, 2 bytes for 256 to 65,535 enum values
CHAR(M)	$M \times w$ bytes, where w is the number of bytes required for the maximum-length character in the character set
BINARY(M)	M bytes
VARCHAR(M), VARBINARY(M)	$len + 1$ bytes if column is 0 – 255 bytes, $len + 2$ bytes if column may require more than 255 bytes
TINYBLOB, TINYTEXT	$len + 1$ bytes
BLOB, TEXT	$len + 2$ bytes
MEDIUMBLOB, MEDIUMTEXT	$len + 3$ bytes
LOBLOB, LONGTEXT	$len + 4$ bytes
SET	Given M members of the set, $(M+7)/8$ bytes, rounded up to 1, 2, 3, 4, or 8 bytes
INET6	16 bytes
UUID	16 bytes

In some character sets, not all characters use the same number of bytes. utf8 encodes characters with one to three bytes per character, while utf8mb4 requires one to four bytes per character.

When using field the COMPRESSED attribute, 1 byte is reserved for metadata. For example, VARCHAR(255) will use +2 bytes instead of +1.

Examples

Assuming a single-byte character-set:

Value	CHAR(2)	Storage Required	VARCHAR(2)	Storage Required
"	' '	2 bytes	"	1 byte
'1'	'1 '	2 bytes	'1'	2 bytes
'12'	'12'	2 bytes	'12'	3 bytes

Date and Time Data Types

Data Type	Storage Requirement
DATE	3 bytes
TIME	3 bytes
DATETIME	8 bytes
TIMESTAMP	4 bytes
YEAR	1 byte

Microseconds

MariaDB 5.3 and MySQL 5.6 introduced [microseconds](#). The underlying storage implementations were different, but from [MariaDB 10.1](#), MariaDB defaults to the MySQL format (by means of the [mysql56_temporal_format](#) variable). Microseconds have the following additional storage requirements:

MySQL 5.6+ and [MariaDB 10.1+](#)

Precision	Storage Requirement
0	0 bytes
1,2	1 byte
3,4	2 bytes
5,6	3 bytes

[MariaDB 5.3 - MariaDB 10.0](#)

Precision	Storage Requirement
0	0 bytes
1,2	1 byte
3,4,5	2 bytes
6	3 bytes

NULLs

For the InnoDB [COMPACT](#), [DYNAMIC](#) and [COMPRESSED](#) row formats, a number of bytes will be allocated in the record header for the nullable fields. If there are between 1 and 8 nullable fields, 1 such byte will be allocated. In the record payload area, no space will be reserved for values that are NULL.

For the [InnoDB REDUNDANT row format](#), the overhead is 1 bit in the record header (as a part of the 1-byte or 2-byte "end of field" pointer). In that format, a NULL fixed-length field will consume the same amount of space as any NOT NULL value in the record payload area. The motivation is that it is possible to update in place between NOT NULL and NULL values.

In other formats, NULL values usually require 1 bit in the data file, 1 byte in the index file.

5.1.2.25 Supported Character Sets and Collations

Contents

1. [Character Sets](#)
2. [Collations](#)
3. [Case Sensitivity](#)
4. [NO PAD Collations](#)
5. [Accent Insensitivity](#)
6. [Changes](#)

Character Sets

You can see which character sets are available in a particular version by running the [SHOW CHARACTER SET](#) statement or by querying the [Information Schema CHARACTER_SETS Table](#).

From [MariaDB 11.2](#), it is possible to change the default collation associated with a character set. See [Changing Default Collation](#)

MariaDB supports the following character sets:

Charset	Description	Default collation	Maxlen
armscii8	ARMScii-8 Armenian	armscii8_general_ci	1
ascii	US ASCII	ascii_general_ci	1
big5	Big5 Traditional Chinese	big5_chinese_ci	2
binary	Binary pseudo charset	binary	1
cp1250	Windows Central European	cp1250_general_ci	1
cp1251	Windows Cyrillic	cp1251_general_ci	1
cp1256	Windows Arabic	cp1256_general_ci	1
cp1257	Windows Baltic	cp1257_general_ci	1
cp850	DOS West European	cp850_general_ci	1
cp852	DOS Central European	cp852_general_ci	1
cp866	DOS Russian	cp866_general_ci	1
cp932	SJIS for Windows Japanese	cp932_japanese_ci	2

koi8u	KOI8-U Ukrainian	koi8u_general_ci	1
latin1	cp1252 West European	latin1_swedish_ci	1
latin2	ISO 8859-2 Central European	latin2_general_ci	1
latin5	ISO 8859-9 Turkish	latin5_turkish_ci	1
latin7	ISO 8859-13 Baltic	latin7_general_ci	1
macce	Mac Central European	macce_general_ci	1
macroman	Mac West European	macroman_general_ci	1
sjis	Shift-JIS Japanese	sjis_japanese_ci	2
swe7	7bit Swedish	swe7_swedish_ci	1

tis620	TIS620 Thai	tis620_thai_ci	1
ucs2	UCS-2 Unicode	ucs2_general_ci (<= MariaDB 11.4) ucs2_uca1400_ai_ci (>=MariaDB 11.5)	2
ujis	EUC-JP Japanese	ujis_japanese_ci	3
utf8	UTF-8 Unicode	utf8_general_ci	3/4 (see OLD_MODE)
utf16	UTF-16 Unicode	utf16_general_ci (<= MariaDB 11.4) utf16_uca1400_ai_ci (>=MariaDB 11.5)	4
utf16le	UTF-16LE Unicode	utf16le_general_ci	4
utf32	UTF-32 Unicode	utf32_general_ci (<= MariaDB 11.4) utf32_uca1400_ai_ci (>=MariaDB 11.5)	4
utf8mb3	UTF-8 Unicode	utf8mb3_general_ci (<= MariaDB 11.4) utf8mb3_uca1400_ai_ci (>=MariaDB 11.5)	3
utf8mb4	UTF-8 Unicode	utf8mb4_general_ci (<= MariaDB 11.4) utf8mb4_uca1400_ai_ci (>=MariaDB 11.5)	4

Note that the [Mroonga Storage Engine](#) only supports a limited number of character sets. See [Mroonga available character sets](#).

Collations

MariaDB supports the following collations (from [MariaDB 11.4.5](#)):

```
SELECT collation_name, character_set_name as cs_name, id, is_default AS def, is_compiled AS com,
sortlen, comment FROM information_schema.collations ORDER BY collation_name;
```

collation_name	cs_name	id	def	com	sortlen	comment

550 rows in set (0.005 sec)

The UCA-14.0.0 collations were added in [MariaDB 10.10.1](#).

Before [MariaDB 10.6.1](#), the `utf8mb3*` collations listed above were named `utf8*`.

[MariaDB 11.4.5](#) added UCA-9.0.0 collations, as well as a `Comment` column to `information_schema.collations`, to make it clear that the UCA-9.0.0 collations are mapped to the UCA-14.0.0 collations. The UCA-9.0.0 collations have mainly been added to make it easy to replicate from MySQL 8.0 to [MariaDB 11.4.5](#) and newer.

Note that some of the collations are used with several different character sets. In this case the `Charset` and `Id` columns are `NULL`.

You can find all combinations of supported character set and collation in the [information_schema.COLLATION_CHARACTER_SET_APPLICABILITY](#) table.

Case Sensitivity

A `'ci'` at the end of a collation name indicates the collation is case insensitive. A `'cs'` at the end of a collation name indicates the collation is case sensitive.

NO PAD Collations

`NO PAD` collations regard trailing spaces as normal characters. You can get a list of all of these by querying the [Information Schema COLLATIONS Table](#) as follows:

```
SELECT collation_name FROM information_schema.COLLATIONS
WHERE collation_name LIKE "%nopad%";
+-----+
| collation_name |
+-----+
| big5_chinese_nopad_ci |
| big5_nopad_bin |
...

```

Accent Insensitivity

An accent insensitive collation is one where the accented and unaccented versions of a letter are considered to be identical for sorting purposes.

[MariaDB 10.10](#) added the accent insensitivity flag, and new collations are marked with `'_ai'` or `'_as'` in the name to indicate this, for example:

```

```

Changes

- [MariaDB 10.10](#) added 184 UCA-14.0.0 collations. Unicode-14.0.0 was released in September 2021. They contain 939 [built-in contractions](#). Old collations based on UCA-4.0.0 and UCA-5.2.0 did not support built-in contractions. This is a step towards better Unicode Collation Algorithm compliance. With built-in contractions, some languages (e.g. Thai) won't need specific collations and will just work with the default "root" collation.
- [MariaDB 10.6.1](#) changed the `utf8` character set by default to be an alias for `utf8mb3` rather than the other way around. It can be set to imply `utf8mb4` by changing the value of the `old_mode` system variable.
- [MariaDB 10.2.2](#) added 88 `NO PAD` collations.
- [MariaDB 10.1.15](#) added the `utf8_thai_520_w2`, `utf8mb4_thai_520_w2`, `ucs2_thai_520_w2`, `utf16_thai_520_w2` and `utf32_thai_520_w2` collations.
- [MariaDB 10.0.7](#) added the `utf8_myanmar_ci`, `ucs2_myanmar_ci`, `utf8mb4_myanmar_ci`, `utf16_myanmar_ci` and `utf32_myanmar_ci` collations.
- [MariaDB 10.0.5](#) added the `utf8_german2_ci`, `utf8mb4_german2_ci`, `ucs2_german2_ci`, `utf16_german2_ci` and `utf32_german2_ci` collations.
- [MariaDB 5.1.41](#) added a Croatian collation patch from [Alexander Barkov](#) to fix some problems with the Croatian character set and `LIKE` queries. This patch added `utf8_croatian_ci` and `ucs2_croatian_ci` collations to MariaDB.

5.2 Character Sets and Collations

5.1.3 Date and Time Data Types

DATE

The date type `YYYY-MM-DD`.

TIME

Time format `HH:MM:SS.ssssss`

DATETIME

Date and time combination displayed as `YYYY-MM-DD HH:MM:SS`.

TIMESTAMP

`YYYY-MM-DD HH:MM:SS`

YEAR Data Type

A four-digit year.

There are [3 related questions](#).

5.1.3.1 DATE

Contents

1. [Syntax](#)
2. [Description](#)
 1. [Oracle Mode](#)
3. [Examples](#)

Syntax

```
DATE
```

Description

A date. The supported range is '1000-01-01' to '9999-12-31'. MariaDB displays `DATE` values in 'YYYY-MM-DD' format, but can be assigned dates in looser formats, including strings or numbers, as long as they make sense. These include a short year, `YY-MM-DD`, no delimiters, `YYMMDD`, or any other acceptable delimiter, for example `YYYY/MM/DD`. For details, see [date and time literals](#).

'0000-00-00' is a permitted special value (zero-date), unless the `NO_ZERO_DATE SQL_MODE` is used. Also, individual components of a date can be set to 0 (for example: '2015-00-12'), unless the `NO_ZERO_IN_DATE SQL_MODE` is used. In many cases, the result of an expression involving a zero-date, or a date with zero-parts, is `NULL`. If the `ALLOW_INVALID_DATES SQL_MODE` is enabled, if the day part is in the range between 1 and 31, the date does not produce any error, even for months that have less than 31 days.

Oracle Mode

In [Oracle mode](#), `DATE` with a time portion is a synonym for `DATETIME`. See also [mariadb_schema](#).

Examples

```
CREATE TABLE t1 (d DATE);

INSERT INTO t1 VALUES ("2010-01-12"), ("2011-2-28"), ('120314'), ('13*04*21');

SELECT * FROM t1;
+-----+
| d      |
+-----+
| 2010-01-12 |
| 2011-02-28 |
| 2012-03-14 |
| 2013-04-21 |
+-----+
```

5.1.3.2 TIME

Syntax

```
TIME [(<microsecond precision>)]
```

Contents

1. [Syntax](#)
2. [Description](#)
 1. [Internal Format](#)
3. [Examples](#)

Description

A time. The range is '-838:59:59.999999' to '838:59:59.999999'. [Microsecond precision](#) can be from 0-6; if not specified 0 is used. Microseconds have been available since [MariaDB 5.3](#).

MariaDB displays `TIME` values in 'HH:MM:SS.ssssss' format, but allows assignment of times in looser formats, including 'D HH:MM:SS', 'HH:MM:SS', 'HH:MM', 'D HH:MM', 'D HH', 'SS', or 'HHMMSS', as well as permitting dropping of any leading zeros when a delimiter is provided, for example '3:9:10'. For details, see [date and time literals](#).

[MariaDB 10.1.2](#) introduced the `--mysql56-temporal-format` option, on by default, which allows MariaDB to store `TIMES` using the same low-level format MySQL 5.6 uses.

Internal Format

In [MariaDB 10.1.2](#) a new temporal format was introduced from MySQL 5.6 that alters how the `TIME`, `DATETIME` and `TIMESTAMP` columns operate at lower levels. These changes allow these temporal data types to have fractional parts and negative values. You can disable this feature using the `mysql56_temporal_format` system variable.

Tables that include `TIMESTAMP` values that were created on an older version of MariaDB or that were created while the `mysql56_temporal_format` system variable was disabled continue to store data using the older data type format.

In order to update table columns from the older format to the newer format, execute an `ALTER TABLE... MODIFY COLUMN` statement that changes the column to the *same* data type. This change may be needed if you want to export the table's tablespace and import it onto a server that has `mysql56_temporal_format=ON` set (see [MDEV-15225](#)).

For instance, if you have a `TIME` column in your table:

```
SHOW VARIABLES LIKE 'mysql56_temporal_format';

+-----+-----+
| Variable_name          | Value |
+-----+-----+
| mysql56_temporal_format | ON    |
+-----+-----+

ALTER TABLE example_table MODIFY ts_col TIME;
```

When MariaDB executes the `ALTER TABLE` statement, it converts the data from the older temporal format to the newer one.

In the event that you have several tables and columns using temporal data types that you want to switch over to the new format, make sure the system variable is enabled, then perform a dump and restore using `mariadb-dump`. The columns using relevant temporal data types are restored using the new temporal format.

Starting from [MariaDB 10.5.1](#) columns with old temporal formats are marked with a `/* mariadb-5.3 */` comment in the output of [SHOW CREATE TABLE](#), [SHOW COLUMNS](#), [DESCRIBE](#) statements, as well as in the `COLUMN_TYPE` column of the [INFORMATION_SCHEMA.COLUMNS](#) Table.

```
SHOW CREATE TABLE mariadb5312_time\G
***** 1. row *****
      Table: mariadb5312_time
Create Table: CREATE TABLE `mariadb5312_time` (
  `t0` time /* mariadb-5.3 */ DEFAULT NULL,
  `t6` time(6) /* mariadb-5.3 */ DEFAULT NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
```

Note, columns with the current format are not marked with a comment.

Examples

```
INSERT INTO time VALUES ('90:00:00'), ('800:00:00'), (800), (22), (151413), ('9:6:3'), ('12 09');

SELECT * FROM time;
+-----+
| t      |
+-----+
| 90:00:00 |
| 800:00:00 |
| 00:08:00 |
| 00:00:22 |
| 15:14:13 |
| 09:06:03 |
| 297:00:00 |
+-----+
```

5.1.3.3 DATETIME

Contents

1. [Syntax](#)
2. [Description](#)
3. [Supported Values](#)
4. [Oracle Mode](#)
5. [Internal Format](#)
6. [Examples](#)

Syntax

```
DATETIME [(microsecond precision)]
```

Description

A date and time combination.

MariaDB displays `DATETIME` values in `'YYYY-MM-DD HH:MM:SS.ffffff'` format, but allows assignment of values to `DATETIME` columns using either strings or numbers. For details, see [date and time literals](#).

`DATETIME` columns also accept `CURRENT_TIMESTAMP` as the default value.

[MariaDB 10.1.2](#) introduced the `--mysql56-temporal-format` option, on by default, which allows MariaDB to store `DATETIME`s using the same low-level format MySQL 5.6 uses. For more information, see [Internal Format](#), below.

For storage requirements, see [Data Type Storage Requirements](#).

Supported Values

MariaDB stores values that use the `DATETIME` data type in a format that supports values between `1000-01-01 00:00:00.000000` and `9999-12-31 23:59:59.999999`.

MariaDB can also store [microseconds](#) with a precision between 0 and 6. If no microsecond precision is specified, then 0 is used by default.

MariaDB also supports `'0000-00-00'` as a special *zero-date* value, unless `NO_ZERO_DATE` is specified in the `SQL_MODE`. Similarly, individual components of a date can be set to `0` (for example: `'2015-00-12'`), unless `NO_ZERO_IN_DATE` is specified in the `SQL_MODE`. In many cases, the result of an expression involving a zero-date, or a date with zero-parts, is `NULL`. If the `ALLOW_INVALID_DATES` `SQL_MODE` is enabled, if the day part is in the range between 1 and 31, the date does not produce any error, even for months that have less than 31 days.

Oracle Mode

In [Oracle mode](#), `DATE` with a time portion is a synonym for `DATETIME`. See also [mariadb_schema](#).

Internal Format

In [MariaDB 10.1.2](#) a new temporal format was introduced from MySQL 5.6 that alters how the `TIME`, `DATETIME` and `TIMESTAMP` columns operate at lower levels. These changes allow these temporal data types to have fractional parts and negative values. You can disable this feature using the `mysql56_temporal_format` system variable.

Tables that include `TIMESTAMP` values that were created on an older version of MariaDB or that were created while the `mysql56_temporal_format` system variable was disabled continue to store data using the older data type format.

In order to update table columns from the older format to the newer format, execute an `ALTER TABLE... MODIFY COLUMN` statement that changes the column to the *same* data type. This change may be needed if you want to export the table's tablespace and import it onto a server that has `mysql56_temporal_format=ON` set (see [MDEV-15225](#)).

For instance, if you have a `DATETIME` column in your table:

```
SHOW VARIABLES LIKE 'mysql56_temporal_format';

+-----+-----+
| Variable_name | Value |
+-----+-----+
| mysql56_temporal_format | ON |
+-----+-----+

ALTER TABLE example_table MODIFY ts_col DATETIME;
```

When MariaDB executes the `ALTER TABLE` statement, it converts the data from the older temporal format to the newer one.

In the event that you have several tables and columns using temporal data types that you want to switch over to the new format, make sure the system variable is enabled, then perform a dump and restore using `mysqldump`. The columns using relevant temporal data types are restored using the new temporal format.

Starting from [MariaDB 10.5.1](#) columns with old temporal formats are marked with a `/* mariadb-5.3 */` comment in the output of `SHOW CREATE TABLE`, `SHOW COLUMNS`, `DESCRIBE` statements, as well as in the `COLUMN_TYPE` column of the `INFORMATION_SCHEMA.COLUMNS` Table.

```
SHOW CREATE TABLE mariadb5312_datetime\G
***** 1. row *****
      Table: mariadb5312_datetime
Create Table: CREATE TABLE `mariadb5312_datetime` (
  `dt0` datetime /* mariadb-5.3 */ DEFAULT NULL,
  `dt6` datetime(6) /* mariadb-5.3 */ DEFAULT NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
```

Examples

```

CREATE TABLE t1 (d DATETIME);

INSERT INTO t1 VALUES ("2011-03-11"), ("2012-04-19 13:08:22"),
("2013-07-18 13:44:22.123456");

SELECT * FROM t1;
+-----+
| d                |
+-----+
| 2011-03-11 00:00:00 |
| 2012-04-19 13:08:22 |
| 2013-07-18 13:44:22 |
+-----+

```

```

CREATE TABLE t2 (d DATETIME(6));

INSERT INTO t2 VALUES ("2011-03-11"), ("2012-04-19 13:08:22"),
("2013-07-18 13:44:22.123456");

SELECT * FROM t2;
+-----+
| d                |
+-----+
| 2011-03-11 00:00:00.000000 |
| 2012-04-19 13:08:22.000000 |
| 2013-07-18 13:44:22.123456 |
+-----+

```

Strings used in datetime context are automatically converted to datetime(6). If you want to have a datetime without seconds, you should use [CONVERT\(..,datetime\)](#).

```

SELECT CONVERT('2007-11-30 10:30:19',datetime);
+-----+
| CONVERT('2007-11-30 10:30:19',datetime) |
+-----+
| 2007-11-30 10:30:19                        |
+-----+

SELECT CONVERT('2007-11-30 10:30:19',datetime(6));
+-----+
| CONVERT('2007-11-30 10:30:19',datetime(6)) |
+-----+
| 2007-11-30 10:30:19.000000                |
+-----+

```

5.1.3.4 TIMESTAMP

This page is about the **TIMESTAMP** data type. For the timestamp function, see [TIMESTAMP FUNCTION](#).

Syntax

```
TIMESTAMP [( <microsecond precision > )]
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Supported Values](#)
4. [Automatic Values](#)
5. [Time Zones](#)
6. [Limitations](#)
7. [SQL_MODE=MAXDB](#)
8. [Internal Format](#)
9. [Examples](#)

Description

A timestamp in the format `YYYY-MM-DD HH:MM:SS.ffffff`.

The timestamp field is generally used to define at which moment in time a row was added or updated and by default will automatically be assigned the current datetime when a record is inserted or updated. The automatic properties only apply to the first `TIMESTAMP` in the record; subsequent `TIMESTAMP` columns will not be changed.

MariaDB includes the `--mysql56-temporal-format` option, on by default, which allows MariaDB to store `TIMESTAMPS` using the same low-level format MySQL 5.6 uses.

For more information, see [Internal Format](#).

Supported Values

MariaDB stores values that use the `TIMESTAMP` data type as the number of seconds since '1970-01-01 00:00:00' ([UTC](#)). This means that the `TIMESTAMP` data type can hold values between '1970-01-01 00:00:01' ([UTC](#)) and '2038-01-19 03:14:07' ([UTC](#)) ([MariaDB 11.4](#) and earlier, 32-bit platforms) or '2106-02-07 06:28:15 UTC' (from [MariaDB 11.5](#), 64-bit platforms only).

MariaDB can also store [microseconds](#) with a precision between 0 and 6. If no microsecond precision is specified, then 0 is used by default.

Automatic Values

MariaDB has special behavior for the first column that uses the `TIMESTAMP` data type in a specific table when the system variable [explicit_defaults_for_timestamp](#) is not set (which is the default until [MariaDB 10.10](#)). For the first column that uses the `TIMESTAMP` data type in a specific table, MariaDB automatically assigns the following properties to the column:

- `DEFAULT CURRENT_TIMESTAMP`
- `ON UPDATE CURRENT_TIMESTAMP`

This means that if the column is not explicitly assigned a value in an `INSERT` or `UPDATE` query, then MariaDB will automatically initialize the column's value with the current date and time.

This automatic initialization for `INSERT` and `UPDATE` queries can also be **explicitly enabled** for a column that uses the `TIMESTAMP` data type by specifying the `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` clauses for the column. In these clauses, any synonym of [CURRENT_TIMESTAMP](#) is accepted, including `CURRENT_TIMESTAMP()`, `NOW()`, `LOCALTIME`, `LOCALTIME()`, `LOCALTIMESTAMP`, and `LOCALTIMESTAMP()`.

This automatic initialization for `INSERT` queries can also be **explicitly disabled** for a column that uses the `TIMESTAMP` data type by specifying a constant `DEFAULT` value. For example, `DEFAULT 0`.

This automatic initialization for `UPDATE` queries can also be **explicitly disabled** for a column that uses the `TIMESTAMP` data type by specifying a `DEFAULT` clause for the column, but no `ON UPDATE` clause. If a `DEFAULT` clause is explicitly specified for a column that uses the `TIMESTAMP` data type, but an `ON UPDATE` clause is not specified for the column, then the timestamp value will not automatically change when an `UPDATE` statement is executed.

MariaDB also has special behavior if `NULL` is assigned to column that uses the `TIMESTAMP` data type. If the column is assigned the `NULL` value in an `INSERT` or `UPDATE` query, then MariaDB will automatically initialize the column's value with the current date and time. For details, see [NULL values in MariaDB](#).

This automatic initialization for `NULL` values can also be **explicitly disabled** for a column that uses the `TIMESTAMP` data type by specifying the `NULL` attribute for the column. In this case, if the column's value is set to `NULL`, then the column's value will actually be set to `NULL`.

Time Zones

If a column uses the `TIMESTAMP` data type, then any inserted values are converted from the session's time zone to [Coordinated Universal Time \(UTC\)](#) when stored, and converted back to the session's time zone when retrieved.

MariaDB validates `TIMESTAMP` literals against the session's time zone. For example, if a specific time range never occurred in a specific time zone due to daylight savings time, then `TIMESTAMP` values within that range would be invalid for that time zone.

MariaDB does not currently store any time zone identifier with the value of the `TIMESTAMP` data type. See [MDEV-10018](#) for more information.

MariaDB does not currently support time zone literals that contain time zone identifiers. See [MDEV-11829](#) for more

information.

Limitations

- Because the `TIMESTAMP` value is stored as Epoch Seconds, the timestamp value '1970-01-01 00:00:00' (UTC) is reserved since the second #0 is used to represent '0000-00-00 00:00:00'.
- In [MariaDB 5.5](#) and before there could only be one `TIMESTAMP` column per table that had `CURRENT_TIMESTAMP` defined as its default value. This limit has no longer applied since [MariaDB 10.0](#).

SQL_MODE=MAXDB

If the `SQL_MODE` is set to `MAXDB`, `TIMESTAMP` fields will be silently converted to `DATETIME`.

Internal Format

In [MariaDB 10.1.2](#) a new temporal format was introduced from MySQL 5.6 that alters how the `TIME`, `DATETIME` and `TIMESTAMP` columns operate at lower levels. These changes allow these temporal data types to have fractional parts and negative values. You can disable this feature using the `mysql56_temporal_format` system variable.

Tables that include `TIMESTAMP` values that were created on an older version of MariaDB or that were created while the `mysql56_temporal_format` system variable was disabled continue to store data using the older data type format.

In order to update table columns from the older format to the newer format, execute an `ALTER TABLE... MODIFY COLUMN` statement that changes the column to the *same* data type. This change may be needed if you want to export the table's tablespace and import it onto a server that has `mysql56_temporal_format=ON` set (see [MDEV-15225](#)).

For instance, if you have a `TIMESTAMP` column in your table:

```
SHOW VARIABLES LIKE 'mysql56_temporal_format';

+-----+-----+
| Variable_name | Value |
+-----+-----+
| mysql56_temporal_format | ON |
+-----+-----+

ALTER TABLE example_table MODIFY ts_col TIMESTAMP;
```

When MariaDB executes the `ALTER TABLE` statement, it converts the data from the older temporal format to the newer one.

In the event that you have several tables and columns using temporal data types that you want to switch over to the new format, make sure the system variable is enabled, then perform a dump and restore using `mariadb-dump`. The columns using relevant temporal data types are restored using the new temporal format.

Starting from [MariaDB 10.5.1](#) columns with old temporal formats are marked with a `/* mariadb-5.3 */` comment in the output of `SHOW CREATE TABLE`, `SHOW COLUMNS`, `DESCRIBE` statements, as well as in the `COLUMN_TYPE` column of the `INFORMATION_SCHEMA.COLUMNS` Table.

```
SHOW CREATE TABLE mariadb5312_timestamp\G
***** 1. row *****
      Table: mariadb5312_timestamp
Create Table: CREATE TABLE `mariadb5312_timestamp` (
  `ts0` timestamp /* mariadb-5.3 */ NOT NULL DEFAULT current_timestamp() ON UPDATE current_timestamp()
  `ts6` timestamp(6) /* mariadb-5.3 */ NOT NULL DEFAULT '0000-00-00 00:00:00.000000'
) ENGINE=MyISAM DEFAULT CHARSET=latin1
```

Note: Prior to MySQL 4.1 a different format for the `TIMESTAMP` datatype was used. This format is unsupported in [MariaDB 5.1](#) and upwards.

Examples

```
CREATE TABLE t (id INT, ts TIMESTAMP);
```

```
DESC t;
```

```
+-----+-----+-----+-----+-----+-----+
| Field | Type      | Null | Key | Default          | Extra          |
+-----+-----+-----+-----+-----+-----+
| id    | int(11)   | YES  |     | NULL             |               |
| ts    | timestamp | NO   |     | CURRENT_TIMESTAMP | on update CURRENT_TIMESTAMP |
+-----+-----+-----+-----+-----+-----+
```

```
INSERT INTO t(id) VALUES (1),(2);
```

```
SELECT * FROM t;
```

```
+-----+-----+
| id  | ts                |
+-----+-----+
|  1  | 2013-07-22 12:50:05 |
|  2  | 2013-07-22 12:50:05 |
+-----+-----+
```

```
INSERT INTO t VALUES (3,NULL),(4,'2001-07-22 12:12:12');
```

```
SELECT * FROM t;
```

```
+-----+-----+
| id  | ts                |
+-----+-----+
|  1  | 2013-07-22 12:50:05 |
|  2  | 2013-07-22 12:50:05 |
|  3  | 2013-07-22 12:51:56 |
|  4  | 2001-07-22 12:12:12 |
+-----+-----+
```

Converting to Unix epoch:

```
SELECT ts, UNIX_TIMESTAMP(ts) FROM t;
```

```
+-----+-----+-----+
| ts                | UNIX_TIMESTAMP(ts) |
+-----+-----+-----+
| 2013-07-22 12:50:05 | 1374490205         |
| 2013-07-22 12:50:05 | 1374490205         |
| 2013-07-22 12:51:56 | 1374490316         |
| 2001-07-22 12:12:12 | 995796732          |
+-----+-----+-----+
```

Update also changes the timestamp:

```
UPDATE t set id=5 WHERE id=1;
```

```
SELECT * FROM t;
```

```
+-----+-----+
| id  | ts                |
+-----+-----+
|  5  | 2013-07-22 14:52:33 |
|  2  | 2013-07-22 12:50:05 |
|  3  | 2013-07-22 12:51:56 |
|  4  | 2001-07-22 12:12:12 |
+-----+-----+
```

Default NULL:

```

CREATE TABLE t2 (id INT, ts TIMESTAMP NULL ON UPDATE CURRENT_TIMESTAMP);

INSERT INTO t(id) VALUES (1),(2);

SELECT * FROM t2;

INSERT INTO t2(id) VALUES (1),(2);

SELECT * FROM t2;
+-----+-----+
| id  | ts  |
+-----+-----+
|  1  | NULL |
|  2  | NULL |
+-----+-----+

UPDATE t2 SET id=3 WHERE id=1;

SELECT * FROM t2;
+-----+-----+
| id  | ts                |
+-----+-----+
|  3  | 2013-07-22 15:32:22 |
|  2  | NULL                |
+-----+-----+

```

Only the first timestamp is automatically inserted and updated:

```

CREATE TABLE t3 (id INT, ts1 TIMESTAMP, ts2 TIMESTAMP);

INSERT INTO t3(id) VALUES (1),(2);

SELECT * FROM t3;
+-----+-----+-----+
| id  | ts1                | ts2                |
+-----+-----+-----+
|  1  | 2013-07-22 15:35:07 | 0000-00-00 00:00:00 |
|  2  | 2013-07-22 15:35:07 | 0000-00-00 00:00:00 |
+-----+-----+-----+

DESC t3;
+-----+-----+-----+-----+-----+-----+
| Field | Type      | Null | Key | Default          | Extra          |
+-----+-----+-----+-----+-----+-----+
| id    | int(11)  | YES  |     | NULL             |               |
| ts1   | timestamp | NO   |     | CURRENT_TIMESTAMP | on update CURRENT_TIMESTAMP |
| ts2   | timestamp | NO   |     | 0000-00-00 00:00:00 |               |
+-----+-----+-----+-----+-----+-----+

```

Explicitly setting a timestamp with the [CURRENT_TIMESTAMP](#) function:

```

INSERT INTO t3(id,ts2) VALUES (3,CURRENT_TIMESTAMP());

SELECT * FROM t3;
+-----+-----+-----+
| id  | ts1                | ts2                |
+-----+-----+-----+
|  1  | 2013-07-22 15:35:07 | 0000-00-00 00:00:00 |
|  2  | 2013-07-22 15:35:07 | 0000-00-00 00:00:00 |
|  3  | 2013-07-22 15:38:52 | 2013-07-22 15:38:52 |
+-----+-----+-----+

```

Specifying the timestamp as NOT NULL:

```

CREATE TABLE t4 (id INT, ts TIMESTAMP NOT NULL);

INSERT INTO t4(id) VALUES (1);
SELECT SLEEP(1);
INSERT INTO t4(id,ts) VALUES (2,NULL);

SELECT * FROM t4;

```

5.1.3.5 YEAR Data Type

Syntax

```
YEAR [ (4) ]
```

Description

A year in two-digit or four-digit format. The default is four-digit format. Note that the two-digit format has been deprecated since [MariaDB 5.5.27](#).

In four-digit format, the allowable values are 1901 to 2155, and 0000. In two-digit format, the allowable values are 70 to 69, representing years from 1970 to 2069. MariaDB displays YEAR values in YYYY format, but allows you to assign values to YEAR columns using either strings or numbers.

Inserting numeric zero has a different result for YEAR(4) and YEAR(2). For YEAR(2), the value 00 reflects the year 2000. For YEAR(4), the value 0000 reflects the year zero. This only applies to numeric zero. String zero always reflects the year 2000.

Examples

Accepting a string or a number:

```
CREATE TABLE y(y YEAR);  
  
INSERT INTO y VALUES (1990), ('2012');  
  
SELECT * FROM y;  
+-----+  
| y      |  
+-----+  
| 1990  |  
| 2012  |  
+-----+
```

With `strict_mode` set, the default from [MariaDB 10.2.4](#):

Out of range:

```
INSERT INTO y VALUES (1005), ('3080');  
ERROR 1264 (22003): Out of range value for column 'y' at row 1  
  
INSERT INTO y VALUES ('2013-12-12');  
ERROR 1265 (01000): Data truncated for column 'y' at row 1  
  
SELECT * FROM y;  
+-----+  
| y      |  
+-----+  
| 1990  |  
| 2012  |  
+-----+
```

With `strict_mode` unset, the default until [MariaDB 10.2.3](#):

Out of range:

```
INSERT INTO y VALUES (1005),('3080');
Query OK, 2 rows affected, 2 warnings (0.05 sec)
Records: 2 Duplicates: 0 Warnings: 2
```

```
SHOW WARNINGS;
```

```
+-----+-----+
| Level | Code | Message |
+-----+-----+
| Warning | 1264 | Out of range value for column 'y' at row 1 |
| Warning | 1264 | Out of range value for column 'y' at row 2 |
+-----+-----+
```

```
SELECT * FROM y;
```

```
+-----+
| y |
+-----+
| 1990 |
| 2012 |
| 0000 |
| 0000 |
+-----+
```

Truncating:

```
INSERT INTO y VALUES ('2013-12-12');
Query OK, 1 row affected, 1 warning (0.05 sec)
```

```
SHOW WARNINGS;
```

```
+-----+-----+
| Level | Code | Message |
+-----+-----+
| Warning | 1265 | Data truncated for column 'y' at row 1 |
+-----+-----+
```

```
SELECT * FROM y;
```

```
+-----+
| y |
+-----+
| 1990 |
| 2012 |
| 0000 |
| 0000 |
| 2013 |
+-----+
```

Difference between YEAR(2) and YEAR(4), and string and numeric zero:

```
CREATE TABLE y2(y YEAR(4), y2 YEAR(2));
Query OK, 0 rows affected, 1 warning (0.40 sec)
```

Note (Code 1287): 'YEAR(2)' is deprecated and will be removed in a future release.
Please use YEAR(4) instead

```
INSERT INTO y2 VALUES (0,0),('0','0');
```

```
SELECT YEAR(y), YEAR(y2) FROM y2;
```

```
+-----+-----+
| YEAR(y) | YEAR(y2) |
+-----+-----+
| 0 | 2000 |
| 2000 | 2000 |
+-----+-----+
```

1.1.3.3 Geometry Types

5.1.5 AUTO_INCREMENT

Contents

1. [Description](#)
2. [Setting or Changing the Auto_Increment Value](#)
3. [InnoDB](#)
4. [Setting Explicit Values](#)
5. [Missing Values](#)
6. [Replication](#)
7. [CHECK Constraints, DEFAULT Values and Virtual Columns](#)
8. [Generating Auto_Increment Values When Adding the Attribute](#)

Description

The `AUTO_INCREMENT` attribute can be used to generate a unique identity for new rows. When you insert a new record to the table (or upon adding an `AUTO_INCREMENT` attribute with the `ALTER TABLE` statement), and the `auto_increment` field is `NULL` or `DEFAULT` (in the case of an `INSERT`), the value will automatically be incremented. This also applies to 0, unless the `NO_AUTO_VALUE_ON_ZERO SQL_MODE` is enabled.

`AUTO_INCREMENT` columns start from 1 by default. The automatically generated value can never be lower than 0.

Each table can have only one `AUTO_INCREMENT` column. It must be defined as a key (not necessarily the `PRIMARY KEY` or `UNIQUE` key). In some storage engines (including the default `InnoDB`), if the key consists of multiple columns, the `AUTO_INCREMENT` column must be the first column. Storage engines that permit the column to be placed elsewhere are [Aria](#), [MyISAM](#), [MERGE](#), [Spider](#), [TokuDB](#), [BLACKHOLE](#), [FederatedX](#) and [Federated](#).

```
CREATE TABLE animals (  
  id MEDIUMINT NOT NULL AUTO_INCREMENT,  
  name CHAR(30) NOT NULL,  
  PRIMARY KEY (id)  
);  
  
INSERT INTO animals (name) VALUES  
  ('dog'), ('cat'), ('penguin'),  
  ('fox'), ('whale'), ('ostrich');
```

```
SELECT * FROM animals;  
+----+-----+  
| id | name  |  
+----+-----+  
|  1 | dog   |  
|  2 | cat   |  
|  3 | penguin |  
|  4 | fox   |  
|  5 | whale |  
|  6 | ostrich |  
+----+-----+
```

`SERIAL` is an alias for `BIGINT UNSIGNED NOT NULL AUTO_INCREMENT UNIQUE`.

```
CREATE TABLE t (id SERIAL, c CHAR(1)) ENGINE=InnoDB;  
  
SHOW CREATE TABLE t   
***** 1. row *****  
      Table: t  
Create Table: CREATE TABLE `t` (  
  `id` bigint(20) unsigned NOT NULL AUTO_INCREMENT,  
  `c` char(1) DEFAULT NULL,  
  UNIQUE KEY `id` (`id`)  
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

Setting or Changing the Auto_Increment Value

You can use an `ALTER TABLE` statement to assign a new value to the `auto_increment` table option, or set the `insert_id` server system variable to change the next `AUTO_INCREMENT` value inserted by the current session.

`LAST_INSERT_ID()` can be used to see the last `AUTO_INCREMENT` value inserted by the current session.

```

ALTER TABLE animals AUTO_INCREMENT=8;

INSERT INTO animals (name) VALUES ('aardvark');

SELECT * FROM animals;
+----+-----+
| id | name   |
+----+-----+
| 1  | dog    |
| 2  | cat    |
| 3  | penguin|
| 4  | fox    |
| 5  | whale  |
| 6  | ostrich|
| 8  | aardvark|
+----+-----+

SET insert_id=12;

INSERT INTO animals (name) VALUES ('gorilla');

SELECT * FROM animals;
+----+-----+
| id | name   |
+----+-----+
| 1  | dog    |
| 2  | cat    |
| 3  | penguin|
| 4  | fox    |
| 5  | whale  |
| 6  | ostrich|
| 8  | aardvark|
| 12 | gorilla|
+----+-----+

```

InnoDB

`AUTO_INCREMENT` is persistent in InnoDB. Prior to [MariaDB 10.2.3](#), InnoDB used an auto-increment counter that was stored in memory. When the server restarted, the counter was re-initialized to the highest value used in the table, which canceled the effects of any `AUTO_INCREMENT = N` option in the table statements).

See also [AUTO_INCREMENT Handling in InnoDB](#).

Setting Explicit Values

It is possible to specify a value for an `AUTO_INCREMENT` column. If the key is primary or unique, the value must not already exist in the key.

If the new value is higher than the current maximum value, the `AUTO_INCREMENT` value is updated, so the next value will be higher. If the new value is lower than the current maximum value, the `AUTO_INCREMENT` value remains unchanged.

The following example demonstrates these behaviors:

```

CREATE TABLE t (id INTEGER UNSIGNED AUTO_INCREMENT PRIMARY KEY) ENGINE = InnoDB;

INSERT INTO t VALUES (NULL);
SELECT id FROM t;
+-----+
| id |
+-----+
| 1 |
+-----+

INSERT INTO t VALUES (10); -- higher value
SELECT id FROM t;
+-----+
| id |
+-----+
| 1 |
| 10 |
+-----+

INSERT INTO t VALUES (2); -- lower value
INSERT INTO t VALUES (NULL); -- auto value
SELECT id FROM t;
+-----+
| id |
+-----+
| 1 |
| 2 |
| 10 |
| 11 |
+-----+

```

The [ARCHIVE](#) storage engine does not allow to insert a value that is lower than the current maximum.

Missing Values

An `AUTO_INCREMENT` column normally has missing values. This happens because if a row is deleted, or an `AUTO_INCREMENT` value is explicitly updated, old values are never re-used. The `REPLACE` statement also deletes a row, and its value is wasted. With InnoDB, values can be reserved by a transaction; but if the transaction fails (for example, because of a `ROLLBACK`) the reserved value will be lost.

Thus `AUTO_INCREMENT` values can be used to sort results in a chronological order, but not to create a numeric sequence.

Replication

To make master-master or Galera safe to use `AUTO_INCREMENT` one should use the system variables [auto_increment_increment](#) and [auto_increment_offset](#) to generate unique values for each server.

```

SET @@auto_increment_increment=3;

SHOW VARIABLES LIKE 'auto_inc%';
+-----+-----+
| Variable_name          | Value |
+-----+-----+
| auto_increment_increment | 3     |
| auto_increment_offset   | 1     |
+-----+-----+

CREATE TABLE t (c INT NOT NULL AUTO_INCREMENT PRIMARY KEY);

INSERT INTO t VALUES (NULL), (NULL), (NULL);

SELECT * FROM t;
+----+
| c  |
+----+
| 1  |
| 4  |
| 7  |
+----+

CREATE TABLE t2 (c INT NOT NULL AUTO_INCREMENT PRIMARY KEY);

SET @@auto_increment_offset=2;

SHOW VARIABLES LIKE 'auto_inc%';
+-----+-----+
| Variable_name          | Value |
+-----+-----+
| auto_increment_increment | 3     |
| auto_increment_offset   | 2     |
+-----+-----+

INSERT INTO t2 VALUES (NULL), (NULL), (NULL);

SELECT * FROM t2;
+----+
| c  |
+----+
| 2  |
| 5  |
| 8  |
+----+

```

If `auto_increment_offset` is larger than `auto_increment_increment`, the value of `auto_increment_offset` is ignored, and the offset reverts to the default of 1 instead:

```

SET @@auto_increment_offset=5;

SHOW VARIABLES LIKE 'auto_inc%';
+-----+
| Variable_name          | Value |
+-----+
| auto_increment_increment | 3     |
| auto_increment_offset   | 5     |
+-----+

CREATE TABLE t3 (c INT NOT NULL AUTO_INCREMENT PRIMARY KEY);

INSERT INTO t3 VALUES (NULL), (NULL), (NULL);

SELECT * FROM t3;
+----+
| c |
+----+
| 1 |
| 4 |
| 5 |
+----+

+-----+
| Variable_name          | Value |
+-----+
| auto_increment_increment | 3     |
| auto_increment_offset   | 3     |
+-----+

INSERT INTO t4 VALUES (NULL), (NULL), (NULL);

SELECT * FROM t4;
+----+
| c |
+----+
| 3 |
| 6 |
| 9 |
+----+

```

CHECK Constraints, DEFAULT Values and Virtual Columns

auto_increment columns are not permitted in [CHECK constraints](#), [DEFAULT value expressions](#) and [virtual columns](#). They were permitted until [MariaDB 10.2.6](#), but did not work correctly. See [MDEV-11117](#).

Generating Auto_Increment Values When Adding the Attribute

```

CREATE OR REPLACE TABLE t1 (a INT);
INSERT t1 VALUES (0), (0), (0);
ALTER TABLE t1 MODIFY a INT NOT NULL AUTO_INCREMENT PRIMARY KEY;
SELECT * FROM t1;
+----+
| a |
+----+
| 1 |
| 2 |
| 3 |
+----+

```

```

CREATE OR REPLACE TABLE t1 (a INT);
INSERT t1 VALUES (5), (0), (8), (0);
ALTER TABLE t1 MODIFY a INT NOT NULL AUTO_INCREMENT PRIMARY KEY;
SELECT * FROM t1;
+----+
| a |
+----+
| 5 |
| 6 |
| 8 |
| 9 |
+----+

```

If the `NO_AUTO_VALUE_ON_ZERO SQL_MODE` is set, zero values will not be automatically incremented:

```

SET SQL_MODE='no_auto_value_on_zero';
CREATE OR REPLACE TABLE t1 (a INT);
INSERT t1 VALUES (3), (0);
ALTER TABLE t1 MODIFY a INT NOT NULL AUTO_INCREMENT PRIMARY KEY;
SELECT * FROM t1;
+----+
| a |
+----+
| 0 |
| 3 |
+----+

```

5.1.2.24 Data Type Storage Requirements

10. [InnoDB and AUTO_INCREMENT](#)
11. [General Information To Read](#)
12. [Manual Notes](#)
13. [How to start a table with a set AUTO_INCREMENT value?](#)

How do I get the last inserted auto_increment value?

Use the `LAST_INSERT_ID()` function:

```

SELECT LAST_INSERT_ID();

```

What if someone else inserts before I select my id?

`LAST_INSERT_ID()` is connection specific, so there is no problem from race conditions.

How do I get the next value to be inserted?

You don't. Insert, then find out what you did with `LAST_INSERT_ID()`.

How do I change what number auto_increment starts

with?

`ALTER TABLE yourTable AUTO_INCREMENT = x; — Next insert will contain x or MAX(autoField) + 1, whichever is higher`

or

`INSERT INTO yourTable (autoField) VALUES (x); — Next insert will contain x+1 or MAX(autoField) + 1, whichever is higher`

Issuing [TRUNCATE TABLE](#) will delete all the rows in the table, and will reset the `auto_increment` value to 0 in most cases (some earlier versions mapped TRUNCATE to DELETE for InnoDB tables, meaning the `auto_increment` value would not be reset).

How do I renumber rows once I've deleted some in the middle?

Typically, you don't want to. Gaps are hardly ever a problem; if your application can't handle gaps in the sequence, you probably should rethink your application.

Can I do group-wise `auto_increment`?

Yes, if you use the [MyISAM engine](#).

How do I get the `auto_increment` value in a BEFORE INSERT trigger?

You don't. It's only available after insert.

How do I assign two fields the same `auto_increment` value in one query?

You can't, not even with an AFTER INSERT trigger. Insert, then go back and update using `LAST_INSERT_ID()`. Those two statements could be wrapped into one stored procedure if you wish.

However, you can mimic this behavior with a BEFORE INSERT trigger and a second table to store the sequence position:

```
CREATE TABLE sequence (table_name VARCHAR(255), position INT UNSIGNED);
INSERT INTO sequence VALUES ('testTable', 0);
CREATE TABLE testTable (firstAuto INT UNSIGNED, secondAuto INT UNSIGNED);
DELIMITER //
CREATE TRIGGER testTable_BI BEFORE INSERT ON testTable FOR EACH ROW BEGIN
    UPDATE sequence SET position = LAST_INSERT_ID(position + 1) WHERE table_name = 'testTable';
    SET NEW.firstAuto = LAST_INSERT_ID();
    SET NEW.secondAuto = LAST_INSERT_ID();
END//
DELIMITER ;
INSERT INTO testTable VALUES (NULL, NULL), (NULL, NULL);
SELECT * FROM testTable;
```

```
+-----+-----+
| firstAuto | secondAuto |
+-----+-----+
|          1 |           1 |
|          2 |           2 |
+-----+-----+
```

The same sequence table can maintain separate sequences for multiple tables (or separate sequences for different fields in the same table) by adding extra rows.

Does the `auto_increment` field have to be primary key?

No, it only has to be indexed. It doesn't even have to be unique.

InnoDB and AUTO_INCREMENT

See [AUTO_INCREMENT handling in InnoDB](#)

General Information To Read

[AUTO_INCREMENT](#)

Manual Notes

There can be only one `AUTO_INCREMENT` column per table, it must be indexed, and it cannot have a `DEFAULT` value. An `AUTO_INCREMENT` column works properly only if it contains only positive values. Inserting a negative number is regarded as inserting a very large positive number. This is done to avoid precision problems when numbers wrap over from positive to negative and also to ensure that you do not accidentally get an `AUTO_INCREMENT` column that contains 0.

How to start a table with a set `AUTO_INCREMENT` value?

```
CREATE TABLE autoinc_test (
  h INT UNSIGNED PRIMARY KEY AUTO_INCREMENT,
  m INT UNSIGNED
) AUTO_INCREMENT = 100;

INSERT INTO autoinc_test ( m ) VALUES ( 1 );

SELECT * FROM autoinc_test;
+-----+-----+
| h   | m   |
+-----+-----+
| 100 | 1   |
+-----+-----+
```

5.1.8 NULL Values

Contents

- [Syntax](#)
- [Comparison Operators](#)
- [Ordering](#)
- [Functions](#)
- [AUTO_INCREMENT, TIMESTAMP and Virtual Columns](#)
- [Inserting](#)
 - [Examples](#)
- [Primary Keys and UNIQUE Indexes](#)
- [Oracle Compatibility](#)

NULL represents an unknown value. It is *not* an empty string (by default), or a zero value. These are all valid values, and are not NULLs.

When a table is [created](#) or the format [altered](#), columns can be specified as accepting NULL values, or not accepting them, with the `NULL` and `NOT NULL` clauses respectively.

For example, a customer table could contain dates of birth. For some customers, this information is unknown, so the value could be NULL.

The same system could allocate a customer ID for each customer record, and in this case a NULL value would not be permitted.

```
CREATE TABLE customer (
  id INT NOT NULL,
  date_of_birth DATE NULL
  ...
)
```

User-defined variables are NULL until a value is explicitly assigned.

Stored routines parameters and local variables can always be set to NULL. If no DEFAULT value is specified for a local variable, its initial value will be NULL. If no value is assigned to an OUT parameter in a stored procedure, NULL is assigned at the end of the procedure.

Syntax

The case of NULL is not relevant. \N (uppercase) is an alias for NULL.

The IS operator accepts UNKNOWN as an alias for NULL, which is meant for boolean contexts.

Comparison Operators

NULL values cannot be used with most comparison operators. For example, =, >, >=, <=, <, or != cannot be used, as any comparison with a NULL always returns a NULL value, never true (1) or false (0).

```
SELECT NULL = NULL;
+-----+
| NULL = NULL |
+-----+
|          NULL |
+-----+

SELECT 99 = NULL;
+-----+
| 99 = NULL |
+-----+
|          NULL |
+-----+
```

To overcome this, certain operators are specifically designed for use with NULL values. To cater for testing equality between two values that may contain NULLs, there's <=>, NULL-safe equal.

```
SELECT 99 <=> NULL, NULL <=> NULL;
+-----+-----+
| 99 <=> NULL | NULL <=> NULL |
+-----+-----+
|          0 |          1 |
+-----+-----+
```

Other operators for working with NULLs include IS NULL and IS NOT NULL, ISNULL (for testing an expression) and COALESCE (for returning the first non-NULL parameter).

Ordering

When you order by a field that may contain NULL values, any NULLs are considered to have the lowest value. So ordering in DESC order will see the NULLs appearing last. To force NULLs to be regarded as highest values, one can add another column which has a higher value when the main field is NULL. Example:

```
SELECT col1 FROM tab ORDER BY ISNULL(col1), col1;
```

Descending order, with NULLs first:

```
SELECT col1 FROM tab ORDER BY IF(col1 IS NULL, 0, 1), col1 DESC;
```

All NULL values are also regarded as equivalent for the purposes of the DISTINCT and GROUP BY clauses.

Functions

In most cases, functions will return NULL if any of the parameters are NULL. There are also functions specifically for handling NULLs. These include IFNULL(), NULLIF() and COALESCE().

```

SELECT IFNULL(1,0);
+-----+
| IFNULL(1,0) |
+-----+
|           1 |
+-----+

SELECT IFNULL(NULL,10);
+-----+
| IFNULL(NULL,10) |
+-----+
|              10 |
+-----+

SELECT COALESCE(NULL,NULL,1);
+-----+
| COALESCE(NULL,NULL,1) |
+-----+
|                   1 |
+-----+

```

Aggregate functions, such as [SUM](#) and [AVG](#) ignore NULLs.

```

CREATE TABLE t(x INT);

INSERT INTO t VALUES (1), (9), (NULL);

SELECT SUM(x) FROM t;
+-----+
| SUM(x) |
+-----+
|      10 |
+-----+

SELECT AVG(x) FROM t;
+-----+
| AVG(x) |
+-----+
| 5.0000 |
+-----+

```

The one exception is [COUNT\(*\)](#), which counts rows, and doesn't look at whether a value is NULL or not. Compare for example, [COUNT\(x\)](#), which ignores the NULL, and [COUNT\(*\)](#), which counts it:

```

SELECT COUNT(x) FROM t;
+-----+
| COUNT(x) |
+-----+
|         2 |
+-----+

SELECT COUNT(*) FROM t;
+-----+
| COUNT(*) |
+-----+
|         3 |
+-----+

```

AUTO_INCREMENT, TIMESTAMP and Virtual Columns

MariaDB handles NULL values in a special way if the field is an [AUTO_INCREMENT](#), a [TIMESTAMP](#) or a [virtual column](#). Inserting a NULL value into a numeric AUTO_INCREMENT column will result in the next number in the auto increment sequence being inserted instead. This technique is frequently used with AUTO_INCREMENT fields, which are left to take care of themselves.

```
CREATE TABLE t2(id INT PRIMARY KEY AUTO_INCREMENT, letter CHAR(1));

INSERT INTO t2(letter) VALUES ('a'),('b');

SELECT * FROM t2;
+-----+-----+
| id | letter |
+-----+-----+
| 1 | a      |
| 2 | b      |
+-----+-----+
```

Similarly, if a NULL value is assigned to a `TIMESTAMP` field, the current date and time is assigned instead.

```
CREATE TABLE t3 (x INT, ts TIMESTAMP);

INSERT INTO t3(x) VALUES (1), (2);
```

After a pause,

```
INSERT INTO t3(x) VALUES (3);

SELECT* FROM t3;
+-----+-----+
| x   | ts                |
+-----+-----+
| 1   | 2013-09-05 10:14:18 |
| 2   | 2013-09-05 10:14:18 |
| 3   | 2013-09-05 10:14:29 |
+-----+-----+
```

If a `NULL` is assigned to a `VIRTUAL` or `PERSISTENT` column, the default value is assigned instead.

```
CREATE TABLE virt (c INT, v INT AS (c+10) PERSISTENT) ENGINE=InnoDB;

INSERT INTO virt VALUES (1, NULL);

SELECT c, v FROM virt;
+-----+-----+
| c   | v   |
+-----+-----+
| 1   | 11  |
+-----+-----+
```

In all these special cases, `NULL` is equivalent to the `DEFAULT` keyword.

Inserting

If a `NULL` value is single-row inserted into a column declared as `NOT NULL`, an error will be returned. However, if the [SQL mode](#) is not `strict` (`strict` is the default), if a `NULL` value is multi-row inserted into a column declared as `NOT NULL`, the implicit default for the column type will be inserted (and `NOT` the default value in the table definition). The implicit defaults are an empty string for string types, and the zero value for numeric, date and time types.

By default both cases will result in an error.

Examples

```
CREATE TABLE nulltest (
  a INT(11),
  x VARCHAR(10) NOT NULL DEFAULT 'a',
  y INT(11) NOT NULL DEFAULT 23
);
```

Single-row insert:

```
INSERT INTO nulltest (a,x,y) VALUES (1,NULL,NULL);
ERROR 1048 (23000): Column 'x' cannot be null
```

Multi-row insert with [SQL mode not strict](#):

```
show variables like 'sql_mode%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| sql_mode      | NO_AUTO_CREATE_USER,NO_ENGINE_SUBSTITUTION |
+-----+-----+

INSERT INTO nulltest (a,x,y) VALUES (1,NULL,NULL), (2,NULL,NULL);
Query OK, 2 rows affected, 4 warnings (0.08 sec)
Records: 2 Duplicates: 0 Warnings: 4
```

The specified defaults have not been used; rather, the implicit column type defaults have been inserted

```
SELECT * FROM nulltest;
+-----+-----+
| a    | x  | y  |
+-----+-----+
| 1   | 0  | 0  |
| 2   | 0  | 0  |
+-----+-----+
```

Primary Keys and UNIQUE Indexes

UNIQUE indexes can contain multiple NULL values.

Primary keys are never nullable.

Oracle Compatibility

In [Oracle mode](#), NULL can be used as a statement:

```
IF a=10 THEN NULL; ELSE NULL; END IF
```

In [Oracle mode](#), [CONCAT](#) and the [Logical OR operator ||](#) ignore NULL.

When setting [sql_mode=EMPTY_STRING_IS_NULL](#), empty strings and NULLs are the same thing. For example:

```
SET sql_mode=EMPTY_STRING_IS_NULL;
SELECT '' IS NULL; -- returns TRUE
INSERT INTO t1 VALUES (''); -- inserts NULL
```

5.2 Character Sets and Collations

Simply put, a character set defines how and which characters are stored to support a particular language or languages. A collation, on the other hand, defines the order used when comparing strings (i.e. the position of any given character within the alphabet of that language)

Character Set and Collation Overview

5.2.1 Character Set and Collation Overview

Contents

- [1. What Are Character Sets and Collations](#)
- [2. Viewing Character Sets and Collations](#)
- [3. Changing Character Sets and Collations](#)

What Are Character Sets and Collations

A character set is a set of characters while a collation is the rules for comparing and sorting a particular character set.

For example, a subset of a character set could consist of the letters `A`, `B` and `C`. A default collation could define these as appearing in an ascending order of `A`, `B`, `C`.

If we consider different case characters, more complexity is added. A binary collation would evaluate the characters `A` and `a` differently, ordering them in a particular way. A case-insensitive collation would evaluate `A` and `a` equivalently, while the German phone book collation evaluates the characters `ue` and `ü` equivalently.

A character set can have many collations associated with it, while each collation is only associated with one character set. In MariaDB, the character set name is always part of the collation name. For example, the `latin1_german1_ci` collation applies only to the `latin1` character set. Each character set also has one default collation. The `latin1` default collation is `latin1_swedish_ci`.

As an example, by default, the character `y` comes between `x` and `z`, while in Lithuanian, it's sorted between `i` and `k`. Similarly, the German phone book order is different to the German dictionary order, so while they share the same character set, the collation is different.

Viewing Character Sets and Collations

Prior to [MariaDB 11.6.0](#), the default [character set](#) is `latin1` and the default collation is `latin1_swedish_ci`. In [MariaDB 11.6](#) the default character set is `utf8mb4` and the default collation is `utf8mb4_uca1400_ai_ci`. This may differ in some distros, see for example [Differences in MariaDB in Debian](#).

You can view a full list of character sets and collations supported by MariaDB at [Supported Character Sets and Collations](#),

or see what's supported on your server with the [SHOW CHARACTER SET](#) and [SHOW COLLATION](#) commands.

By default, `A` comes before `Z`, so the following evaluates to true:

```
SELECT "A" < "Z";
+-----+
| "A" < "Z" |
+-----+
|          1 |
+-----+
```

By default, comparisons are case-insensitive:

```
SELECT "A" < "a", "A" = "a";
+-----+-----+
| "A" < "a" | "A" = "a" |
+-----+-----+
|          0 |          1 |
+-----+-----+
```

Changing Character Sets and Collations

Character sets and collations can be set from the server level right down to the column level, as well as for client-server communication.

For example, `ue` and `ü` are by default evaluated differently.

```
SELECT 'Mueller' = 'Müller';
+-----+
| 'Müller' = 'Mueller' |
+-----+
|                      0 |
+-----+
```

By using the [collation_connection](#) system variable to change the connection character set to `latin1_german2_ci`, or German phone book, the same two characters will evaluate as equivalent.

```
SET collation_connection = latin1_german2_ci;

SELECT 'Mueller' = 'Müller';
+-----+
| 'Mueller' = 'Müller' |
+-----+
|                      1 |
+-----+
```

See [Setting Character Sets and Collations](#) for more.

5.1.2.25 Supported Character Sets and Collations

5.2.3 Setting Character Sets and Collations

Contents

1. [Server Level](#)
2. [Database Level](#)
3. [Table Level](#)
4. [Column Level](#)
5. [Filenames](#)
6. [Literals](#)
 1. [Examples](#)
 2. [N](#)
7. [Stored Programs and Views](#)
8. [Changing Default Collation](#)
9. [Example: Changing the Default Character Set To UTF-8](#)

Prior to [MariaDB 11.6.0](#), the default [character set](#) is `latin1` and the default collation is `latin1_swedish_ci`. From [MariaDB 11.6](#), the default character set is `utf8mb4` and the default collation is `utf8mb4_uca1400_ai_ci`. This may differ in some distros, see for example [Differences in MariaDB in Debian](#).

The character sets and the collations can be specified from the server right down to the column level, as well as for client-server connections. When changing a character set and not specifying a collation, the default collation for the new character set is always used.

Character sets and collations always cascade down, so a column without a specified collation will look for the table default, the table for the database, and the database for the server. It's therefore possible to have extremely fine-grained control over all the character sets and collations used in your data.

Default collations for each character set can be viewed with the [SHOW COLLATION](#) statement, for example, to find the default collation for the `latin2` character set:

```
SHOW COLLATION LIKE 'latin2%';
+-----+-----+-----+-----+-----+-----+
| Collation          | Charset | Id | Default | Compiled | Sortlen |
+-----+-----+-----+-----+-----+-----+
| latin2_czech_cs    | latin2  | 2  |         | Yes      | 4       |
| latin2_general_ci  | latin2  | 9  | Yes     | Yes      | 1       |
| latin2_hungarian_ci | latin2  | 21 |         | Yes      | 1       |
| latin2_croatian_ci | latin2  | 27 |         | Yes      | 1       |
| latin2_bin         | latin2  | 77 |         | Yes      | 1       |
+-----+-----+-----+-----+-----+-----+
```

Server Level

The [character_set_server](#) system variable can be used to change the default server character set. It can be set both on startup or dynamically, with the [SET](#) command:

```
SET character_set_server = 'latin2';
```

Similarly, the [collation_server](#) variable is used for setting the default server collation.

```
SET collation_server = 'latin2_czech_cs';
```

Database Level

The [CREATE DATABASE](#) and [ALTER DATABASE](#) statements have optional character set and collation clauses. If these are left out, the server defaults are used.

```
CREATE DATABASE czech_slovak_names
  CHARACTER SET = 'keybcs2'
  COLLATE = 'keybcs2_bin';
```

```
ALTER DATABASE czech_slovak_names COLLATE = 'keybcs2_general_ci';
```

To determine the default character set used by a database, use:

```
SHOW CREATE DATABASE czech_slovak_names;
+-----+-----+-----+-----+-----+-----+
| Database          | Create Database
+-----+-----+-----+-----+-----+-----+
| czech_slovak_names | CREATE DATABASE `czech_slovak_names` /*!40100 DEFAULT CHARACTER SET
keybcs2 */ |
+-----+-----+-----+-----+-----+-----+
```

or alternatively, for the character set and collation:

```

SELECT * FROM INFORMATION_SCHEMA.SCHEMATA;
+-----+-----+-----+-----+
| CATALOG_NAME | SCHEMA_NAME          | DEFAULT_CHARACTER_SET_NAME | DEFAULT_COLLATION_NAME |
SQL_PATH |
+-----+-----+-----+-----+
| def          | czech_slovak_names  | keybcs2                    | keybcs2_general_ci    |
NULL |
| def          | information_schema   | utf8                       | utf8_general_ci       |
NULL |
| def          | mysql                | latin1                     | latin1_swedish_ci     |
NULL |
| def          | performance_schema  | utf8                       | utf8_general_ci       |
NULL |
| def          | test                 | latin1                     | latin1_swedish_ci     |
NULL |
+-----+-----+-----+-----+
-----+

```

It is also possible to specify only the collation, and, since each collation only applies to one character set, the associated character set will automatically be specified.

```

CREATE DATABASE danish_names COLLATE 'utf8_danish_ci';

SHOW CREATE DATABASE danish_names;
+-----+-----+
| Database      | Create Database
|
+-----+-----+
| danish_names | CREATE DATABASE `danish_names` /*!40100 DEFAULT CHARACTER SET utf8 COLLATE
utf8_danish_ci */ |
+-----+-----+
-----+

```

Although there are [character_set_database](#) and [collation_database](#) system variables which can be set dynamically, these are used for determining the character set and collation for the default database, and should only be set by the server.

Table Level

The [CREATE TABLE](#) and [ALTER TABLE](#) statements support optional character set and collation clauses, a MariaDB and MySQL extension to standard SQL.

```

CREATE TABLE english_names (id INT, name VARCHAR(40))
CHARACTER SET 'utf8'
COLLATE 'utf8_icelandic_ci';

```

If neither character set nor collation is provided, the database default will be used. If only the character set is provided, the default collation for that character set will be used. If only the collation is provided, the associated character set will be used. See [Supported Character Sets and Collations](#).

```

ALTER TABLE table_name
CONVERT TO CHARACTER SET charset_name [COLLATE collation_name];

```

If no collation is provided, the collation will be set to the default collation for that character set. See [Supported Character Sets and Collations](#).

For [VARCHAR](#) or [TEXT](#) columns, [CONVERT TO CHARACTER SET](#) changes the data type if needed to ensure the new column is long enough to store as many characters as the original column.

For example, an [ascii](#) [TEXT](#) column requires a single byte per character, so the column can hold up to 65,535 characters. If the column is converted to [utf8mb4](#) (default from [MariaDB 11.6](#)), 4 bytes can be required for each character, so the column will be converted to [MEDIUMTEXT](#) to be able to hold the same number of characters.

[CONVERT TO CHARACTER SET binary](#) will convert [CHAR](#), [VARCHAR](#) and [TEXT](#) columns to [BINARY](#), [VARBINARY](#) and [BLOB](#) respectively, and from that point will no longer have a character set, or be affected by future [CONVERT TO CHARACTER SET](#) statements.

To avoid data type changes resulting from `CONVERT TO CHARACTER SET`, use `MODIFY` on the individual columns instead. For example:

```
ALTER TABLE table_name MODIFY ascii_text_column TEXT CHARACTER SET utf8;
ALTER TABLE table_name MODIFY ascii_varchar_column VARCHAR(M) CHARACTER SET utf8;
```

Column Level

Character sets and collations can also be specified for columns that are character types `CHAR`, `TEXT` or `VARCHAR`. The `CREATE TABLE` and `ALTER TABLE` statements support optional character set and collation clauses for this purpose - unlike those at the table level, the column level definitions are standard SQL.

```
CREATE TABLE european_names (
  croatian_names VARCHAR(40) COLLATE 'cp1250_croatian_ci',
  greek_names VARCHAR(40) CHARACTER SET 'greek');
```

If neither collation nor character set is provided, the table default is used. If only the character set is specified, that character set's default collation is used, while if only the collation is specified, the associated character set is used.

When using `ALTER TABLE` to change a column's character set, you need to ensure the character sets are compatible with your data. MariaDB will map the data as best it can, but it's possible to lose data if care is not taken.

The `SHOW CREATE TABLE` statement or `INFORMATION SCHEMA` database can be used to determine column character sets and collations.

```
SHOW CREATE TABLE european_names\G
***** 1. row *****
      Table: european_names
Create Table: CREATE TABLE `european_names` (
  `croatian_names` varchar(40) CHARACTER SET cp1250 COLLATE cp1250_croatian_ci DEFAULT NULL,
  `greek_names` varchar(40) CHARACTER SET greek DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=utf8 COLLATE=utf8_danish_ci
```

```

SELECT * FROM INFORMATION_SCHEMA.COLUMNS WHERE TABLE_NAME LIKE 'european%\G
***** 1. row *****
    TABLE_CATALOG: def

    COLUMN_COMMENT:

```

Filenames

Since [MariaDB 5.1](#), the [character_set_filesystem](#) system variable has controlled interpretation of file names that are given as literal strings. This affects the following statements and functions:

- [SELECT INTO DUMPFILE](#)
- [SELECT INTO OUTFILE](#)
- [LOAD DATA INFILE](#)
- [LOAD XML](#)
- [LOAD_FILE\(\)](#)

Literals

By default, the character set and collation used for literals is determined by the [character_set_connection](#) and [collation_connection](#) system variables. However, they can also be specified explicitly:

```
[_charset_name]'string' [COLLATE collation_name]
```

The character set of string literals that do not have a character set introducer is determined by the [character_set_connection](#) system variable.

This query:

```
SELECT CHARSET('a'), @@character_set_connection;
```

always returns the same character set name in both columns.

`character_set_client` and `character_set_connection` are normally (e.g. during handshake, or after a SET NAMES query) are set to equal values. However, it's possible to set to different values.

Examples

Examples when setting `@@character_set_client` and `@@character_set_connection` to different values can be useful:

Example 1:

Suppose, we have a utf8 database with this table:

```
CREATE TABLE t1 (a VARCHAR(10)) CHARACTER SET utf8 COLLATE utf8_general_ci;
INSERT INTO t1 VALUES ('oe'), ('ö');
```

Now we connect to it using "mysql.exe", which uses the DOS character set (cp850 on a West European machine), and want to fetch all records that are equal to 'ö' according to the German phonebook rules.

It's possible with the following:

```
SET @@character_set_client=cp850, @@character_set_connection=utf8;
SELECT a FROM t1 WHERE a='ö' COLLATE utf8_german2_ci;
```

This will return:

```
+-----+
| a     |
+-----+
| oe    |
| ö     |
+-----+
```

It works as follows:

1. The client sends the query using cp850.
2. The server, when parsing the query, creates a utf8 string literal by converting 'ö' from `@@character_set_client` (cp850) to `@@character_set_connection` (utf8)
3. The server applies the collation "utf8_german2_ci" to this string literal.
4. The server uses utf8_german2_ci for comparison.

Note, if we rewrite the script like this:

```
SET NAMES cp850;
SELECT a FROM t1 WHERE a='ö' COLLATE utf8_german2_ci;
```

we'll get an error:

```
ERROR 1253 (42000): COLLATION 'utf8_german2_ci' is not valid for CHARACTER SET 'cp850'
```

because:

- on step #2, the literal is not converted to utf8 any more and is created using cp850.
- on step #3, the server fails to apply utf8_german2_ci to an cp850 string literal.

Example 2:

Suppose we have a utf8 database and use "mysql.exe" from a West European machine again.

We can do this:

```
SET @@character_set_client=cp850, @@character_set_connection=utf8;
CREATE TABLE t2 AS SELECT 'ö';
```

It will create a table with a column of the type `VARCHAR(1) CHARACTER SET utf8`.

Note, if we rewrite the query like this:

```
SET NAMES cp850;
CREATE TABLE t2 AS SELECT 'ö';
```

It will create a table with a column of the type `VARCHAR(1) CHARACTER SET cp850`, which is probably not a good idea.

N

Also, `N` or `n` can be used as prefix to convert a literal into the National Character set (which in MariaDB is always utf8).

For example:

```
SELECT _latin2 'Müller';
+-----+
| MĂźller |
+-----+
| MĂźller |
+-----+
```

Prior to [MariaDB 10.6](#):

```
SELECT CHARSET(N'a string');
+-----+
| CHARSET(N'a string') |
+-----+
| utf8                  |
+-----+
```

From [MariaDB 10.6](#):

```
SELECT CHARSET(N'a string');
+-----+
| CHARSET(N'a string') |
+-----+
| utf8mb3              |
+-----+
```

```
SELECT 'Mueller' = 'Müller' COLLATE 'latin1_german2_ci';
+-----+
| 'Mueller' = 'Müller' COLLATE 'latin1_german2_ci' |
+-----+
|                                                    1 |
+-----+
```

Stored Programs and Views

The literals which occur in stored programs and views, by default, use the character set and collation which was specified by the [character_set_connection](#) and [collation_connection](#) system variables when the stored program was created. These values can be seen using the `SHOW CREATE` statements. To change the character sets used for literals in an existing stored program, it is necessary to drop and recreate the stored program.

For stored routines parameters and return values, a character set and a collation can be specified via the `CHARACTER SET` and `COLLATE` clauses. Before 5.5, specifying a collation was not supported.

The following example shows that the character set and collation are determined at the time of creation:

```

SET @@local.character_set_connection='latin1';

DELIMITER ||
CREATE PROCEDURE `test`.`x`()
BEGIN
  SELECT CHARSET('x');
END;
||
Query OK, 0 rows affected (0.00 sec)

DELIMITER ;
SET @@local.character_set_connection='utf8';

CALL `test`.`x`();
+-----+
| CHARSET('x') |
+-----+
| latin1       |
+-----+

```

The following example shows how to specify a function parameters character set and collation:

```

CREATE FUNCTION `test`.`y`()(`str` TEXT CHARACTER SET utf8 COLLATE utf8_bin)
  RETURNS TEXT CHARACTER SET latin1 COLLATE latin1_bin
BEGIN
  SET @param_coll = COLLATION(`str`);
  RETURN `str`;
END;

-- return value's collation:
SELECT COLLATION(`test`.`y`()('Hello, planet!'));
+-----+
| COLLATION(`test`.`y`()('Hello, planet!')) |
+-----+
| latin1_bin                               |
+-----+

-- parameter's collation:
SELECT @param_coll;
+-----+
| @param_coll |
+-----+
| utf8_bin    |
+-----+

```

Changing Default Collation

MariaDB starting with [11.2.1](#) 

From [MariaDB 11.2](#), it is possible to change the default collation associated with a particular character set. The [character_set_collations](#) system variable accepts a comma-delimited list of character sets and new default collations, for example:

```
SET @@character_set_collations = 'utf8mb4=ucal1400_ai_ci, latin2=latin2_hungarian_ci';
```

The new variable will take effect in all cases where a character set is explicitly or implicitly specified without an explicit COLLATE clause, including but not limited to:

- Column collation
- Table collation
- Database collation
- CHAR(expr USING csname)
- CONVERT(expr USING csname)
- CAST(expr AS CHAR CHARACTER SET csname)
- " - character string literal
- `_utf8mb3'text'` - a character string literal with an introducer
- `_utf8mb3 X'61'` - a character string literal with an introducer with hex notation
- `_utf8mb3 0x61` - a character string literal with an introducer with hex hybrid notation
- `@@collation_connection` after a SET NAMES without COLLATE

Example: Changing the Default Character Set To UTF-8

To change the default character set from latin1 (prior to [MariaDB 11.6.0](#)) to UTF-8, the following settings should be specified in the my.cnf configuration file.

```
[mysql]
...
default-character-set=utf8mb4
...
[mysqld]
...
collation-server = utf8mb4_unicode_ci
init-connect='SET NAMES utf8mb4'
character-set-server = utf8mb4
...
```

Note that the `default-character-set` option is a client option, not a server option.

5.2.4 Unicode

Unicode is a standard for encoding text across multiple writing systems. MariaDB supports a number of [character sets](#) for storing Unicode data:

Character Set	Description
ucs2	UCS-2, each character is represented by a 2-byte code with the most significant byte first. Fixed-length 16-bit encoding.
utf8	Until MariaDB 10.5 , this was a UTF-8 encoding using one to three bytes per character. Basic Latin letters, numbers and punctuation use one byte. European and Middle East letters mostly fit into 2 bytes. Korean, Chinese, and Japanese ideographs use 3-bytes. No supplementary characters are stored. From MariaDB 10.6 , <code>utf8</code> is an alias for <code>utf8mb3</code> , but this can be changed to <code>utf8mb4</code> by changing the default value of the <code>old_mode</code> system variable. From MariaDB 11.8 , <code>utf8</code> is an alias for <code>utf8mb4</code> .
utf8mb3	UTF-8 encoding using one to three bytes per character. Basic Latin letters, numbers and punctuation use one byte. European and Middle East letters mostly fit into 2 bytes. Korean, Chinese, and Japanese ideographs use 3-bytes. No supplementary characters are stored. Until MariaDB 10.5 , this was an alias for <code>utf8</code> . From MariaDB 10.6 , <code>utf8</code> is by default an alias for <code>utf8mb3</code> , but this can be changed to <code>utf8mb4</code> by changing the default value of the <code>old_mode</code> system variable.
utf8mb4	UTF-8 encoding the same as <code>utf8mb3</code> but which stores supplementary characters in four bytes.
utf16	UTF-16, same as <code>ucs2</code> , but stores supplementary characters in 32 bits. 16 or 32-bits.
utf32	UTF-32, fixed-length 32-bit encoding.

Support for the UCA-14.0.0 collations was added in [MariaDB 10.10](#) ([MDEV-27009](#)).

Support for the MySQL 8.0 UCA-9-0-0 (`utf8mb4_0900_...`) collations will be added to [MariaDB 11.4.5](#).

1.1.1.2.8.7 SHOW CHARACTER SET

5.2.6 SHOW COLLATION

Syntax

```
SHOW COLLATION
  [LIKE 'pattern' | WHERE expr]
```

Contents

- [Syntax](#)
- [Description](#)
- [Examples](#)

Description

The output from `SHOW COLLATION` includes all available [collations](#). The `LIKE` clause, if present on its own, indicates which collation names to match. The `WHERE` and `LIKE` clauses can be given to select rows using more general conditions, as discussed in [Extended SHOW](#).

Similar information, including some extra information (such as, from [MariaDB 11.4](#),.5, which collation an alias refers to), can be queried from the [Information Schema COLLATIONS](#) table.

See [Setting Character Sets and Collations](#) for details on specifying the collation at the server, database, table and column levels.

Examples

```
SHOW COLLATION LIKE 'latin1%';
```

Collation	Charset	Id	Default	Compiled	Sortlen
latin1_german1_ci	latin1	5		Yes	1
latin1_swedish_ci	latin1	8	Yes	Yes	1
latin1_danish_ci	latin1	15		Yes	1
latin1_german2_ci	latin1	31		Yes	2
latin1_bin	latin1	47		Yes	1
latin1_general_ci	latin1	48		Yes	1
latin1_general_cs	latin1	49		Yes	1
latin1_spanish_ci	latin1	94		Yes	1
latin1_swedish_nopad_ci	latin1	1032		Yes	1
latin1_nopad_bin	latin1	1071		Yes	1

```

5.3 Storage Engines

Information on storage engines available for MariaDB.

Choosing the Right Storage Engine

[Quickly choose the most suitable storage engine for your needs.](#)

InnoDB

[The general-purpose InnoDB storage engine.](#)

MariaDB ColumnStore

[Uses a massively parallel architecture, ideal for systems that scale to petabytes of data.](#)

Aria

[Aria is a crash safe MyISAM and more.](#)

Archive

[Stores data in compressed \(gzip\) format.](#)

BLACKHOLE

[Storage engine that accepts data without storing it.](#)

CONNECT

[The CONNECT storage engine enables MariaDB to access external local or remote data.](#)

CSV

Works with files stored in CSV (comma-separated-values) format.

FederatedX

Allows you to access tables in other MariaDB or MySQL servers.

MEMORY Storage Engine

Storage engine stored in memory rather than on disk.

MERGE

Allows you to access a collection of identical MyISAM tables as one.

Mroonga

Provides fast CJK-ready full text searching using column store.

MyISAM

Non-transactional storage engine with good performance and small data footprint.

MyRocks

Adds RocksDB, an LSM database with a great compression ratio that is optimized for flash storage.

OQGRAPH

Open Query GRAPH computation engine for handling hierarchies (tree structures) and complex graphs.

S3 Storage Engine

A read-only storage engine that stores its data in Amazon S3.

Sequence Storage Engine

Allows ascending or descending sequences of numbers.

SphinxSE

Storage engine that talks to searchd to enable text searching.

Spider

Supports partitioning and xa transactions and allows tables of different in...

TokuDB

For use in high-performance and write-intensive environments. [🔗](#)

Information Schema ENGINES Table

Storage engine information.

PERFORMANCE_SCHEMA Storage Engine

PERFORMANCE_SCHEMA storage engine, a mechanism for implementing the feature.

Legacy Storage Engines

Storage engines that are no longer maintained. [🔗](#)

Storage Engine Development

Storage Engine Development.

Converting Tables from MyISAM to InnoDB

Issues when converting tables from MyISAM to InnoDB.

Machine Learning with MindsDB

A 3rd-party tool interfacing with MariaDB Server to provide Machine Learning capabilities.

There are [5 related questions](#) [🔗](#).

5.3.1 Choosing the Right Storage Engine

Contents

1. [Topic List](#)
 1. [General Purpose](#)
 2. [Scaling, Partitioning](#)
 3. [Compression / Archive](#)
 4. [Connecting to Other Data Sources](#)
 5. [Search Optimized](#)
 6. [Cache, Read-only](#)
 7. [Other Specialized Storage Engines](#)
2. [Alphabetical List](#)

A high-level overview of the main reasons for choosing a particular storage engine:

Topic List

General Purpose

- [InnoDB](#) is a good general transaction storage engine, and the best choice in most cases. It is the default storage engine.
- [Aria](#), MariaDB's more modern improvement on [MyISAM](#), has a small footprint and allows for easy copying between systems.
- [MyISAM](#) has a small footprint and allows for easy copying between systems. MyISAM is MySQL's oldest storage engine. There is usually little reason to use it except for legacy purposes. Aria is MariaDB's more modern improvement.
- [XtraDB](#) is no longer available. It was a performance-enhanced fork of InnoDB and was MariaDB's default engine until [MariaDB 10.1](#).

Scaling, Partitioning

When you want to split your database load on several servers or optimize for scaling. We also suggest looking at [Galera](#), a synchronous multi-master cluster.

- [Spider](#) uses partitioning to provide data sharding through multiple servers.
- [ColumnStore](#) [↗](#) utilizes a massively parallel distributed data architecture and is designed for big data scaling to process petabytes of data.
- The [MERGE](#) storage engine is a collection of identical [MyISAM](#) tables that can be used as one. "Identical" means that all tables have identical column and index information.
- [TokuDB](#) [↗](#) is a transactional storage engine which is optimized for workloads that do not fit in memory, and provides a good compression ratio. TokuDB has been deprecated by its upstream developers, and is disabled in [MariaDB 10.5](#), and removed in [MariaDB 10.6](#).

Compression / Archive

- [MyRocks](#) enables greater compression than InnoDB, as well as less write amplification giving better endurance of flash storage and improving overall throughput.
- The [Archive](#) storage engine is, unsurprisingly, best used for archiving.
- [TokuDB](#) [↗](#) is a transactional storage engine which is optimized for workloads that do not fit in memory, and provides a good compression ratio. TokuDB has been deprecated by its upstream developers, and is disabled in [MariaDB 10.5](#), and removed in [MariaDB 10.6](#).

Connecting to Other Data Sources

When you want to use data not stored in a MariaDB database.

- [CONNECT](#) allows access to different kinds of text files and remote resources as if they were regular MariaDB tables.
- The [CSV](#) storage engine can read and append to files stored in CSV (comma-separated-values) format. However, since [MariaDB 10.0](#), [CONNECT](#) is a better choice and is more flexibly able to read and write such files.
- [FederatedX](#) [↗](#) uses libmysql to talk to the data source, the data source being a remote RDBMS. Currently, since FederatedX only uses libmysql, it can only talk to another MySQL RDBMS.
- [CassandraSE](#) [↗](#) is a storage engine allowing access to an older version of Apache Cassandra NoSQL DBMS. It was relatively experimental, is no longer being actively developed and has been removed in [MariaDB 10.6](#).

Search Optimized

Search engines optimized for search.

- [SphinxSE](#) is used as a proxy to run statements on a remote Sphinx database server (mainly useful for advanced fulltext searches).
- [Mroonga](#) provides fast CJK-ready full text searching using column store.

Cache, Read-only

- [MEMORY](#) does not write data on-disk (all rows are lost on crash) and is best-used for read-only caches of data from other tables, or for temporary work areas. With the default [InnoDB](#) and other storage engines having good caching, there is less need for this engine than in the past.

Other Specialized Storage Engines

- [S3 Storage Engine](#) is a read-only storage engine that stores its data in Amazon S3.
- [Sequence](#) allows the creation of ascending or descending sequences of numbers (positive integers) with a given starting value, ending value and increment, creating virtual, ephemeral tables automatically when you need them.
- The [BLACKHOLE](#) storage engine accepts data but does not store it and always returns an empty result. This can be useful in [replication](#) environments, for example, if you want to run complex filtering rules on a slave without incurring any overhead on a master.
- [OQGRAPH](#) allows you to handle hierarchies (tree structures) and complex graphs (nodes having many connections in several directions).

Alphabetical List

- The [Archive](#) storage engine is, unsurprisingly, best used for archiving.
- [Aria](#), MariaDB's more modern improvement on MyISAM, has a small footprint and allows for easy copy between systems.
- The [BLACKHOLE](#) storage engine accepts data but does not store it and always returns an empty result. This can be useful in [replication](#) environments, for example, if you want to run complex filtering rules on a slave without incurring any overhead on a master.
- [CassandraSE](#) [↗](#) is a storage engine allowing access to an older version of Apache Cassandra NoSQL DBMS. It was relatively experimental, is no longer being actively developed and has been removed in [MariaDB 10.6](#).
- [ColumnStore](#) [↗](#) utilizes a massively parallel distributed data architecture and is designed for big data scaling to process petabytes of data.
- [CONNECT](#) allows access to different kinds of text files and remote resources as if they were regular MariaDB tables.
- The [CSV](#) storage engine can read and append to files stored in CSV (comma-separated-values) format. However, since [MariaDB 10.0](#), [CONNECT](#) is a better choice and is more flexibly able to read and write such files.
- [FederatedX](#) [↗](#) uses libmysql to talk to the data source, the data source being a remote RDBMS. Currently, since FederatedX only uses libmysql, it can only talk to another MySQL RDBMS.
- [InnoDB](#) is a good general transaction storage engine, and the best choice in most cases. It is the default storage engine.
- The [MERGE](#) storage engine is a collection of identical MyISAM tables that can be used as one. "Identical" means that all tables have identical column and index information.
- [MEMORY](#) does not write data on-disk (all rows are lost on crash) and is best-used for read-only caches of data from other tables, or for temporary work areas. With the default [InnoDB](#) and other storage engines having good caching, there is less need for this engine than in the past.
- [Mroonga](#) provides fast CJK-ready full text searching using column store.
- [MyISAM](#) has a small footprint and allows for easy copying between systems. MyISAM is MySQL's oldest storage engine. There is usually little reason to use it except for legacy purposes. Aria is MariaDB's more modern improvement.

- [Spider](#) uses partitioning to provide data sharding through multiple servers.
- [TokuDB](#) [↗](#) is a transactional storage engine which is optimized for workloads that do not fit in memory, and provides a good compression ratio. TokuDB has been deprecated by its upstream developers, and is disabled in [MariaDB 10.5](#), and removed in [MariaDB 10.6](#)
- [XtraDB](#) is no longer available. It was a performance-enhanced fork of InnoDB and was MariaDB's default engine until [MariaDB 10.1](#).

5.3.2 InnoDB

InnoDB is a general-purpose storage engine, and the default in MariaDB.

InnoDB Versions

From MariaDB 10.2, InnoDB is the default storage engine.

InnoDB Limitations

The InnoDB storage engine has the following limitations.

InnoDB Troubleshooting

Guidelines when troubleshooting problems with InnoDB .

InnoDB System Variables

List and description of InnoDB-related server system variables.

InnoDB Server Status Variables

List and description of InnoDB status variables.

AUTO_INCREMENT Handling in InnoDB

AUTO_INCREMENT handling in InnoDB and the lock modes.

InnoDB Buffer Pool

The most important memory buffer used by InnoDB.

InnoDB Change Buffering

Buffering INSERT, UPDATE and DELETE statements for greater efficiency.

InnoDB Doublewrite Buffer

Buffer used for recovering from half-written pages.

InnoDB Tablespaces

Information on tablespaces in InnoDB, including an overview, system tablesp...

InnoDB File Format

Description of the file formats supported by InnoDB.

InnoDB Row Formats

InnoDB's row formats are REDUNDANT, COMPACT, DYNAMIC, and COMPRESSED.

InnoDB Strict Mode

InnoDB strict mode makes InnoDB more reliable.

InnoDB Redo Log

The redo log is used by InnoDB during crash recovery.

InnoDB Undo Log

InnoDB Undo log.

InnoDB Page Flushing

Configuring when and how InnoDB flushes dirty pages to disk.

InnoDB Purge

Purge process to remove old versions of a row from the undo log.

Information Schema InnoDB Tables

All InnoDB-specific Information Schema tables.

InnoDB Online DDL

InnoDB tables support online DDL in certain circumstances.

Binary Log Group Commit and InnoDB Flushing Performance

Improvement for group commit for InnoDB transactions with the binary log enabled.

InnoDB Page Compression

InnoDB page compression, which is more sophisticated than the COMPRESSED row format.

InnoDB Data Scrubbing

Ensuring data is completely removed when deleted.

InnoDB Lock Modes

InnoDB supports a number of lock modes to ensure that concurrent write operations never collide.

InnoDB Monitors

Standard Monitor, Lock Monitor, Tablespace Monitor and the Table Monitor.

InnoDB Encryption Overview

Data-at-rest encryption for tables that use the InnoDB storage engine.

InnoDB - Unmaintained

Articles that apply only to old, unmaintained versions of MariaDB. [↗](#)

There are [11 related questions](#) [↗](#).

5.3.2.1 InnoDB Versions

MariaDB starting with [10.3.7](#) [↗](#)

In [MariaDB 10.3.7](#) [↗](#) and later, the InnoDB implementation has diverged substantially from the InnoDB in MySQL. Therefore, in these versions, the InnoDB version is no longer associated with a MySQL release version.

MariaDB starting with [10.2](#)

In [MariaDB 10.2](#) and later, the default InnoDB implementation is based on InnoDB from MySQL 5.7. See [Why MariaDB uses InnoDB instead of XtraDB from MariaDB 10.2](#) [↗](#) for more information.

MariaDB until [10.1](#)

In [MariaDB 10.1](#) and before, the default InnoDB implementation is based on Percona's XtraDB. XtraDB is a performance enhanced fork of InnoDB. For compatibility reasons, the [system variables](#) still retain their original `innodb` prefixes. If the documentation says that something applies to InnoDB, then it usually also applies to the XtraDB fork, unless explicitly stated otherwise. In these versions, it is still possible to use InnoDB instead of XtraDB. See [Using InnoDB instead of XtraDB](#) [↗](#) for more information.

Divergences

Some examples of divergences between MariaDB's InnoDB and MySQL's InnoDB are:

- [MariaDB 10.1](#) (which is based on MySQL 5.6) included encryption and variable-size page compression before MySQL 5.7 introduced them.
- [MariaDB 10.2](#) (based on MySQL 5.7) introduced persistent AUTO_INCREMENT ([MDEV-6076](#) [↗](#)) in a GA release before MySQL 8.0.
- [MariaDB 10.3](#) (based on MySQL 5.7) introduced instant ADD COLUMN ([MDEV-11369](#) [↗](#)) before MySQL.

InnoDB Versions Included in MariaDB Releases

MariaDB 10.3

5.3.2.2 InnoDB Limitations

Contents

1. [Limitations on Schema](#)
2. [Limitations on Size](#)
 1. [Page Sizes](#)
3. [Limitations on Tables](#)
 1. [Table Analysis](#)
 2. [Table Status](#)
 3. [Auto-incrementing Columns](#)
4. [Transactions and Locks](#)

The [InnoDB storage engine](#) has the following limitations.

Limitations on Schema

- InnoDB tables can have a maximum of 1,017 columns. This includes [virtual generated columns](#).
- InnoDB tables can have a maximum of 64 secondary indexes.
- A multicolumn index on InnoDB can use a maximum of 32 columns. If you attempt to create a multicolumn index that uses more than 32 columns, MariaDB returns an Error 1070.

Limitations on Size

- With the exception of variable-length columns (that is, [VARBINARY](#), [VARCHAR](#), [BLOB](#) and [TEXT](#)), rows in InnoDB have a maximum length of roughly half the page size for 4KB, 8KB, 16KB and 32KB page sizes.
- The maximum size for [BLOB](#) and [TEXT](#) columns is 4GB. This also applies to [LONGBLOB](#) and [LONGTEXT](#).
- MariaDB imposes a row-size limit of 65,535 bytes for the combined sizes of all columns. If the table contains [BLOB](#) or [TEXT](#) columns, these only count for 9 - 12 bytes in this calculation, given that their content is stored separately.
- 32-bit operating systems have a maximum file size limit of 2GB. When working with large tables using this architecture, configure InnoDB to use smaller data files.
- The maximum size for the combined InnoDB log files is 512GB.
- With tablespaces, the minimum size is 10MB, the maximum varies depending on the InnoDB Page Size.

InnoDB Page Size	Maximum Tablespace Size
4KB	16TB
8KB	32TB
16KB	64TB
32KB	128TB

64KB	256TB
------	-------

Page Sizes

Using the `innodb_page_size` system variable, you can configure the size in bytes for InnoDB pages. Pages default to 16KB. There are certain limitations on how you use this variable.

- MariaDB instances using one page size cannot use data files or log files from an instance using a different page size.
- When using a Page Size of 4KB or 8KB, the maximum index key length is lowered proportionately.

InnoDB Page Size	Index Key Length
4KB	768B
8KB	1536B
16KB	3072B

Limitations on Tables

InnoDB has the following table-specific limitations.

- When you issue a `DELETE` statement, InnoDB doesn't regenerate the table, rather it deletes each row from the table one by one.
- When running MariaDB on Windows, InnoDB stores databases and tables in lowercase. When moving databases and tables in a binary format from Windows to a Unix-like system or from a Unix system to Windows, you need to rename these to use lowercase.
- When using cascading `foreign keys`, operations in the cascade don't activate triggers.

Table Analysis

When running `ANALYZE TABLE` twice on a table in which statements or transactions are running, MariaDB blocks the second `ANALYZE TABLE` until the statement or transaction is complete. This occurs because the statement or transaction blocks the second `ANALYZE TABLE` statement from reloading the table definition, which it must do since the old one was marked as obsolete after the first statement.

Table Status

`SHOW TABLE STATUS` statements do not provide accurate statistics for InnoDB, except for the physical table size.

The InnoDB storage engine does not maintain internal row counts. Transactions isolate writes, which means that concurrent transactions will not have the same row counts.

Auto-incrementing Columns

- When defining an index on an auto-incrementing column, it must be defined in a way that allows the equivalent of `SELECT MAX(col)` lookups on the table.
- Restarting MariaDB may cause InnoDB to reuse old auto-increment values, such as in the case of a transaction that was rolled back.
- When auto-incrementing columns run out of values, `INSERT` statements generate duplicate-key errors.

Transactions and Locks

- You can modify data on a maximum of $96 * 1023$ concurrent transactions that generate undo records.
- Of the 128 rollback segments, InnoDB assigns 32 to non-redo logs for transactions that modify temporary tables and related objects, reducing the maximum number of concurrent data-modifying transactions to 96,000, from 128,000.
- The limit is 32,000 concurrent transactions when all data-modifying transactions also modify temporary tables.
- Issuing a `LOCK TABLES` statement sets two locks on each table when the `innodb_table_locks` system variable is enabled (the default).
- When you commit or roll back a transaction, any locks set in the transaction are released. You don't need to issue `LOCK TABLES` statements when the `autocommit` variable is enabled, as InnoDB would immediately release the table locks.

5.3.2.3 InnoDB Troubleshooting

Guidelines when troubleshooting problems with InnoDB.

InnoDB Troubleshooting Overview

Overview of InnoDB errors experienced and steps to take.

InnoDB Data Dictionary Troubleshooting

Troubleshooting the InnoDB Data Dictionary.

InnoDB Recovery Modes

Modes for recovering from emergency situations in InnoDB.

Troubleshooting Row Size Too Large Errors with InnoDB

Fixing "Row size too large (> 8126). Changing some columns to TEXT or BLOB may help."

There are [1 related questions](#).

5.3.2.3.1 InnoDB Troubleshooting Overview

Contents

As with most errors, first take a look at the contents of the [MariaDB error log](#). If dealing with a deadlock, setting the `innodb_print_all_deadlocks` option (off by default) will output details of all deadlocks to the error log.

It can also help to enable the various [InnoDB Monitors](#) relating to the problem you are experiencing. There are four types: the standard InnoDB monitor, the InnoDB Lock Monitor, InnoDB Tablespace Monitor and the InnoDB Table Monitor.

Running `CHECK TABLE` will help determine whether there are errors in the table.

For problems with the InnoDB Data Dictionary, see [InnoDB Data Dictionary Troubleshooting](#).

5.3.2.3.2 InnoDB Data Dictionary Troubleshooting

Contents

- [1. Can't Open File](#)
- [2. Could not find a valid tablespace file](#)
- [3. Removing Orphan Intermediate Tables](#)

Can't Open File

If InnoDB returns something like the following error:

```
ERROR 1016: Can't open file: 'x.ibd'. (errno: 1)
```

it may be that an orphan `.frm` file exists. Something like the following may also appear in the [error log](#):

```
InnoDB: Cannot find table test/x from the internal data dictionary
InnoDB: of InnoDB though the .frm file for the table exists. Maybe you
InnoDB: have deleted and recreated InnoDB data files but have forgotten
InnoDB: to delete the corresponding .frm files of InnoDB tables?
```

If this is the case, as the text describes, delete the orphan `.frm` file on the filesystem.

Could not find a valid tablespace file

In this case the table definition, the `.frm` file, is missing and the InnoDB dictionary expects it to be there. To remove the InnoDB dictionary entry, the existence of the file needs to be faked and then dropped. The existence of the file is faked by creating the `tablename.frm` and potential the database directory if it is missing. Then a `DROP TABLE` or `DROP DATABASE` can be executed which will remove the InnoDB dictionary entry.

Use the query to identify potentially other tablespaces that are known but missing with:

```
SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME LIKE 'dbname/%';
```

Removing Orphan Intermediate Tables

An orphan intermediate table may prevent you from dropping the tablespace even if it is otherwise empty, and generally takes up unnecessary space.

It may come about if MariaDB exits in the middle of an [ALTER TABLE ... ALGORITHM=INPLACE](#) operation. They will be listed in the `INFORMATION_SCHEMA.INNODB_SYS_TABLES` table, and always start with an `#sql-ib` prefix. The accompanying `.frm` file also begins with `#sql-`, but has a different name.

To identify orphan tables, run:

```
SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME LIKE '%#sql%';
```

When `innodb_file_per_table` is set, the `#sql-*.ibd` file will also be visible in the database directory.

To remove an orphan intermediate table:

- Rename the `#sql-*.frm` file (in the database directory) to match the base name of the orphan intermediate table, for example:

```
mv #sql-36ab_2.frm #sql-ib87-856498050.frm
```

- Drop the table, for example:

```
DROP TABLE `#mysql50##sql-ib87-856498050`;
```

5.3.2.3.3 InnoDB Recovery Modes

The InnoDB recovery mode is a mode used for recovering from emergency situations. You should ensure you have a backup of your database before making changes in case you need to restore it. The `innodb_force_recovery` server system variable sets the recovery mode. A mode of 0 is normal use, while the higher the mode, the more stringent the restrictions. Higher modes incorporate all limitations of the lower modes.

The recovery mode should never be set to a value other than zero except in an emergency situation.

Please note that recovery mode does not repair corruption. The corrupted files remain corrupted regardless of recovery mode. The sole purpose of recovery mode is to allow read access to the data, if at all possible.

Generally, it is best to start with a recovery mode of 1, and increase in single increments if needs be. With a recovery mode < 4, only corrupted pages should be lost. With 4, secondary indexes could be corrupted. With 5, results could be inconsistent and secondary indexes could be corrupted (even if they were not with 4). A value of 6 leaves pages in an obsolete state, which might cause more corruption.

Until [MariaDB 10.2.7](#), mode 0 was the only mode permitting changes to the data. From [MariaDB 10.2.7](#), write transactions are permitted with mode 3 or less.

To recover the tables, you can execute [SELECTs](#) to dump data, and [DROP TABLE](#) (when write transactions are permitted) to remove corrupted tables.

The following modes are available:

Recovery Modes

Recovery mode behaviour differs per version (`server/storage/innobase/include/srv0srv.h`)

[MariaDB 10.4](#) and before:

Mode	Description
0	The default mode while InnoDB is running normally. Until MariaDB 10.2.7 , it was the only mode permitting changes to the data. From MariaDB 10.2.7 , write transactions are permitted with <code>innodb_force_recovery<=3</code> .

1	(SRV_FORCE_IGNORE_CORRUPT) allows the the server to keep running even if corrupt pages are detected. It does so by making redo log based recovery ignore certain errors, such as missing data files or corrupted data pages. Any redo log for affected files or pages will be skipped. You can facilitate dumping tables by getting the <code>SELECT * FROM table_name</code> statement to jump over corrupt indexes and pages.
2	(SRV_FORCE_NO_BACKGROUND) stops the master thread from running, preventing a crash that occurs during a purge. No purge will be performed, so the undo logs will keep growing.
3	(SRV_FORCE_NO_TRX_UNDO) does not roll back transactions after the crash recovery. Does not affect rollback of currently active transactions. Starting with MariaDB 10.2.7 , will also prevent some undo-generating background tasks from running. These tasks could hit a lock wait due to the recovered incomplete transactions whose rollback is being prevented.
4	(SRV_FORCE_NO_IBUF_MERGE) does not calculate tables statistics and prevents insert buffer merges.
5	(SRV_FORCE_NO_UNDO_LOG_SCAN) treats incomplete transactions as committed, and does not look at the undo logs when starting.
6	(SRV_FORCE_NO_LOG_REDO) does not perform redo log roll-forward as part of recovery. Running queries that require indexes are likely to fail with this mode active. However, if a table dump still causes a crash, you can try using a <code>SELECT * FROM tab ORDER BY primary_key DESC</code> to dump all the data portion after the corrupted part.

From [MariaDB 10.5](#) to [MariaDB 10.6.4](#):

Mode	Description
0	The default mode while InnoDB is running normally. Write transactions are permitted with <code>innodb_force_recovery<=4</code> .
1	(SRV_FORCE_IGNORE_CORRUPT) allows the the server to keep running even if corrupt pages are detected. It does so by making redo log based recovery ignore certain errors, such as missing data files or corrupted data pages. Any redo log for affected files or pages will be skipped. You can facilitate dumping tables by getting the <code>SELECT * FROM table_name</code> statement to jump over corrupt indexes and pages.
2	(SRV_FORCE_NO_BACKGROUND) stops the master thread from running, preventing a crash that occurs during a purge. No purge will be performed, so the undo logs will keep growing.
3	(SRV_FORCE_NO_TRX_UNDO) does not roll back transactions after the crash recovery. Does not affect rollback of currently active transactions. Will also prevent some undo-generating background tasks from running. These tasks could hit a lock wait due to the recovered incomplete transactions whose rollback is being prevented.

5	(SRV_FORCE_NO_UNDO_LOG_SCAN) treats incomplete transactions as committed, and does not look at the undo logs when starting.
6	(SRV_FORCE_NO_LOG_REDO) does not perform redo log roll-forward as part of recovery. Running queries that require indexes are likely to fail with this mode active. However, if a table dump still causes a crash, you can try using a <code>SELECT * FROM tab ORDER BY primary_key DESC</code> to dump all the data portion after the corrupted part.

From [MariaDB 10.6.5](#)

Mode	Description
0	The default mode while InnoDB is running normally. Write transactions are permitted with <code>innodb_force_recovery<=4</code> .
1	(SRV_FORCE_IGNORE_CORRUPT) allows the the server to keep running even if corrupt pages are detected. It does so by making redo log based recovery ignore certain errors, such as missing data files or corrupted data pages. Any redo log for affected files or pages will be skipped. You can facilitate dumping tables by getting the <code>SELECT * FROM table_name</code> statement to jump over corrupt indexes and pages.
2	(SRV_FORCE_NO_BACKGROUND) stops the master thread from running, preventing a crash that occurs during a purge. No purge will be performed, so the undo logs will keep growing.
3	(SRV_FORCE_NO_TRX_UNDO) does not roll back DML transactions after the crash recovery. Does not affect rollback of currently active DML transactions. Will also prevent some undo-generating background tasks from running. These tasks could hit a lock wait due to the recovered incomplete transactions whose rollback is being prevented.

4	(SRV_FORCE_NO_DDL_UNDO) does not roll back transactions after the crash recovery. Does not affect rollback of currently active transactions. Will also prevent some undo-generating background tasks from running. These tasks could hit a lock wait due to the recovered incomplete transactions whose rollback is being prevented.
5	(SRV_FORCE_NO_UNDO_LOG_SCAN) treats incomplete transactions as committed, and does not look at the undo logs when starting. Any DDL log for InnoDB tables will be essentially ignored by InnoDB, but the server will start up
6	(SRV_FORCE_NO_LOG_REDO) does not perform redo log roll-forward as part of recovery. Running queries that require indexes are likely to fail with this mode active. However, if a table dump still causes a crash, you can try using a <code>SELECT * FROM tab ORDER BY primary_key DESC</code> to dump all the data portion after the corrupted part.

Note also that XtraDB (<= [MariaDB 10.2.6](#)) by default will crash the server when it detects corrupted data in a single-table tablespace. This behaviour can be changed - see the [innodb_corrupt_table_action](#) system variable.

Fixing Things

Try to set `innodb_force_recovery` to 1 and start `mariadb`. If that fails, try a value of "2". If a value of 2 works, then there is a chance the only corruption you have experienced is within the `innodb` "undo logs". If that gets `mariadb` started, you should be able to dump your database with `mariadb-dump`. You can verify any other issues with any tables by running `mariadb-check --all-databases`.

If you were able to successfully dump your databases, or had previously known good backups, drop your database(s) from the `mariadb` command line like `"DROP DATABASE yourdatabase"`. Stop `mariadb`. Go to `/var/lib/mysql` (or wherever your `mysql` data directory is located) and `"rm -i ib*"`. Start `mariadb`, create the database(s) you dropped (`"CREATE DATABASE yourdatabase"`), and then import your most recent dumps: `"mysql < mydatabasedump.sql"`

5.3.2.3.4 Troubleshooting Row Size Too Large Errors with InnoDB

Need additional support? We're here to help!

[Contact Us](#)

With InnoDB, users can see the following message as an error or warning:

```
ERROR 1118 (42000): Row size too large (> 8126). Changing some columns to
TEXT or BLOB may help. In current row format, BLOB prefix of 0 bytes is stored
inline.
```

And they can also see the following message as an error or warning in the [error log](#):

```
[Warning] InnoDB: Cannot add field col in table db1.tab because after adding it,
the row size is 8478 which is greater than maximum allowed size (8126) for a
record on index leaf page.
```

2. Root Cause of the Problem
3. Checking Existing Tables for the Problem
4. Finding All Tables That Currently Have the Problem
5. Solving the Problem
 1. Converting the Table to the DYNAMIC Row Format
 2. Fitting More Columns on Overflow Pages
 1. Converting Some Columns to BLOB or TEXT
 2. Increasing the Length of VARBINARY Columns
 3. Increasing the Length of VARCHAR Columns
6. Working Around the Problem
 1. Refactoring the Table into Multiple Tables
 2. Refactoring Some Columns into JSON
 3. Disabling InnoDB Strict Mode

These messages indicate that the table's definition allows rows that the table's InnoDB row format can't actually store.

These messages are raised in the following cases:

- If **InnoDB strict mode** is **enabled** and if a **DDL** statement is executed that touches the table, such as **CREATE TABLE** or **ALTER TABLE**, then InnoDB will raise an **error** with this message
- If **InnoDB strict mode** is **disabled** and if a **DDL** statement is executed that touches the table, such as **CREATE TABLE** or **ALTER TABLE**, then InnoDB will raise a **warning** with this message.
- Regardless of whether **InnoDB strict mode** is enabled, if a **DML** statement is executed that attempts to write a row that the table's InnoDB row format can't store, then InnoDB will raise an **error** with this message.

Example of the Problem

Here is an example of the problem:

```
SET GLOBAL innodb_default_row_format='dynamic';

SET SESSION innodb_strict_mode=ON;

CREATE OR REPLACE TABLE tab (
  col1 varchar(40) NOT NULL,
  col2 varchar(40) NOT NULL,
  col3 varchar(40) NOT NULL,
  col4 varchar(40) NOT NULL,
  col5 varchar(40) NOT NULL,
  col6 varchar(40) NOT NULL,
  col7 varchar(40) NOT NULL,

col194 varchar(40) NOT NULL,
col195 varchar(40) NOT NULL,
col196 varchar(40) NOT NULL,
col197 varchar(40) NOT NULL,
col198 varchar(40) NOT NULL,
PRIMARY KEY (col1)
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4;
ERROR 1118 (42000): Row size too large (> 8126). Changing some columns to
TEXT or BLOB may help. In current row format, BLOB prefix of 0 bytes is stored inline.

```

Root Cause of the Problem

The root cause is that InnoDB has a maximum row size that is roughly equivalent to half of the value of the `innodb_page_size` system variable. See [InnoDB Row Formats Overview: Maximum Row Size](#) for more information.

InnoDB's row formats work around this limit by storing certain kinds of variable-length columns on overflow pages. However, different row formats can store different types of data on overflow pages. Some row formats can store more data in overflow pages than others. For example, the `DYNAMIC` and `COMPRESSED` row formats can store the most data in overflow pages. To learn how the various InnoDB row formats use overflow pages, see the following pages:

- [InnoDB REDUNDANT Row Format: Overflow Pages with the REDUNDANT Row Format](#)
- [InnoDB COMPACT Row Format: Overflow Pages with the COMPACT Row Format](#)
- [InnoDB DYNAMIC Row Format: Overflow Pages with the DYNAMIC Row Format](#)
- [InnoDB COMPRESSED Row Format: Overflow Pages with the COMPRESSED Row Format](#)

Checking Existing Tables for the Problem

InnoDB does not currently have an easy way to check all existing tables to determine which tables have this problem. See [MDEV-20400](#) for more information.

One method to check a single existing table for this problem is to enable `InnoDB strict mode`, and then try to create a duplicate of the table with `CREATE TABLE ... LIKE`. If the table has this problem, then the operation will fail. For example:

```

SET SESSION innodb_strict_mode=ON;

CREATE TABLE tab_dup LIKE tab;
ERROR 1118 (42000): Row size too large (> 8126). Changing some columns to
TEXT or BLOB may help. In current row format, BLOB prefix of 0 bytes is stored inline.

```

Finding All Tables That Currently Have the Problem

The following shell script will read through a MariaDB server to identify every table that has a row size definition that is too large for its row format and the server's page size. It runs on most common distributions of Linux.

To run the script, copy the code below to a shell-script named `rowsize.sh`, make it executable with the command `chmod 755 ./rowsize.sh`, and invoke it with the following parameters:

```
./rowsize.sh host user password
```

When the script runs, it displays the name of the temporary database it creates, so that if the script is interrupted before cleaning up, the database can be easily identified and removed manually.

As the script runs it will output one line reporting the database and tablename for each table it finds that has the oversize row problem. If it finds none, it will print the following message: "No tables with rows size too big found."

In either case, the script prints one final line to announce when it's done: `./rowsize.sh done`.

```
#!/bin/bash

[ -z "$3" ] && echo "Usage: $0 host user password" >&2 && exit 1

dt="tmp_$$RANDOM$$RANDOM"

mysql -h $1 -u $2 -p$3 -ABNe "create database $dt;"
[ $? -ne 0 ] && echo "Error: $0 terminating" >&2 exit 1

echo
echo "Created temporary database ${dt} on host $1"
echo

c=0
for d in $(mysql -h $1 -u $2 -p$3 -ABNe "show databases;" | egrep -iv
"information_schema|mysql|performance_schema|$dt")
do
for t in $(mysql -h $1 -u $2 -p$3 -ABNe "show tables;" $d)
do
tc=$(mysql -h $1 -u $2 -p$3 -ABNe "show create table $t\G" $d | egrep -iv "^\|^$t")

echo $tc | grep -iq "ROW_FORMAT"
if [ $? -ne 0 ]
then
tf=$(mysql -h $1 -u $2 -p$3 -ABNe "select row_format from
information_schema.innodb_sys_tables where name = '${d}/${t}';")
tc="$tc ROW_FORMAT=$tf"
fi

ef="/tmp/e$$RANDOM$$RANDOM"
mysql -h $1 -u $2 -p$3 -ABNe "set innodb_strict_mode=1; set foreign_key_checks=0; ${tc};" $dt
>/dev/null 2>$ef
[ $? -ne 0 ] && cat $ef | grep -q "Row size too large" && echo "${d}.${t}" && let c++ ||
mysql -h $1 -u $2 -p$3 -ABNe "drop table if exists ${t};" $dt
rm -f $ef
done
done
mysql -h $1 -u $2 -p$3 -ABNe "set innodb_strict_mode=1; drop database $dt;"
[ $c -eq 0 ] && echo "No tables with rows size too large found." || echo && echo "$c tables
found with row size too large."
echo
echo "$0 done."
```

Solving the Problem

There are several potential solutions available to solve this problem.

Converting the Table to the DYNAMIC Row Format

If the table is using either the [REDUNDANT](#) or the [COMPACT](#) row format, then one potential solution to this problem is to convert the table to use the [DYNAMIC](#) row format instead.

If your tables were originally created on an older version of MariaDB or MySQL, then your table may be using one of InnoDB's older row formats:

- In [MariaDB 10.1](#) and before, and in MySQL 5.6 and before, the [COMPACT](#) row format was the default row format.
- In MySQL 4.1 and before, the [REDUNDANT](#) row format was the default row format.

The [DYNAMIC](#) row format can store more data on overflow pages than these older row formats, so this row format may actually be able to store the table's data safely. See [InnoDB DYNAMIC Row Format: Overflow Pages with the DYNAMIC Row Format](#) for more information.

Therefore, a potential solution to the *Row size too large* error is to convert the table to use the [DYNAMIC](#) row format. For example:

```
ALTER TABLE tab ROW_FORMAT=DYNAMIC;
```

You can use the [INNODB_SYS_TABLES](#) table in the [information_schema](#) database to find all tables that use the [REDUNDANT](#) or the [COMPACT](#) row formats. This is helpful if you would like to convert all of your tables that you still use the older row formats to the [DYNAMIC](#) row format. For example, the following query can find those tables, while excluding [InnoDB's internal system tables](#):

```

SELECT NAME, ROW_FORMAT
FROM information_schema.INNODB_SYS_TABLES
WHERE ROW_FORMAT IN ('Redundant', 'Compact')
AND NAME NOT IN ('SYS_DATAFILES', 'SYS_FOREIGN', 'SYS_FOREIGN_COLS', 'SYS_TABLESPACES', 'SYS_VIRTU

```

In [MariaDB 10.2](#) and later, the [DYNAMIC](#) row format is the default row format. If your tables were originally created on one of these newer versions, then they may already be using this row format. In that case, you may need to try the next solution.

Fitting More Columns on Overflow Pages

If the table is already using the [DYNAMIC](#) row format, then another potential solution to this problem is to change the table schema, so that the row format can store more columns on overflow pages.

In order for InnoDB to store some variable-length columns on overflow pages, the length of those columns may need to be increased.

Therefore, a counter-intuitive solution to the *Row size too large* error in a lot of cases is actually to **increase** the length of some variable-length columns, so that InnoDB's row format can store them on overflow pages.

Some possible ways to change the table schema are listed below.

Converting Some Columns to `BLOB` or `TEXT`

For [BLOB](#) and [TEXT](#) columns, the [DYNAMIC](#) row format can store these columns on overflow pages. See [InnoDB DYNAMIC Row Format: Overflow Pages with the DYNAMIC Row Format](#) for more information.

Therefore, a potential solution to the *Row size too large* error is to convert some columns to the [BLOB](#) or [TEXT](#) data types.

Increasing the Length of `VARBINARY` Columns

For [VARBINARY](#) columns, the [DYNAMIC](#) row format can only store these columns on overflow pages if the maximum length of the column is 256 bytes or longer. See [InnoDB DYNAMIC Row Format: Overflow Pages with the DYNAMIC Row Format](#) for more information.

Therefore, a potential solution to the *Row size too large* error is to ensure that all [VARBINARY](#) columns are at least as long as `varbinary(256)`.

Increasing the Length of `VARCHAR` Columns

For [VARCHAR](#) columns, the [DYNAMIC](#) row format can only store these columns on overflow pages if the maximum length of the column is 256 bytes or longer. See [InnoDB DYNAMIC Row Format: Overflow Pages with the DYNAMIC Row Format](#) for more information.

The original table schema shown earlier on this page causes the *Row size too large* error, because all of the table's [VARCHAR](#) columns are smaller than 256 bytes, which means that they have to be stored on the row's main data page.

Therefore, a potential solution to the *Row size too large* error is to ensure that all [VARCHAR](#) columns are at least as long as 256 bytes. The number of characters required to reach the 256 byte limit depends on the [character set](#) used by the column.

For example, when using InnoDB's [DYNAMIC](#) row format and a default character set of [latin1](#) (which requires up to 1 byte per character), the 256 byte limit means that a [VARCHAR](#) column will only be stored on overflow pages if it is at least as large as a `varchar(256)` :

```

SET GLOBAL innodb_default_row_format='dynamic';
SET SESSION innodb_strict_mode=ON;
CREATE OR REPLACE TABLE tab (
  col1 varchar(256) NOT NULL,
  col2 varchar(256) NOT NULL,
  col3 varchar(256) NOT NULL,
  col4 varchar(256) NOT NULL,
  col5 varchar(256) NOT NULL,
  col6 varchar(256) NOT NULL,
  col7 varchar(256) NOT NULL,
  col8 varchar(256) NOT NULL,
  col9 varchar(256) NOT NULL,
  col10 varchar(256) NOT NULL,

) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4;
```

Working Around the Problem

There are a few ways to work around this problem.

If you would like a solution for the problem instead of just working around it, then see the solutions mentioned in the previous section.

Refactoring the Table into Multiple Tables

A *safe* workaround is to refactor the single wide table, so that its columns are spread among multiple tables.

This workaround can even work if your table is so wide that the previous solutions have failed to solve them problem for your table.

Refactoring Some Columns into JSON

A *safe* workaround is to refactor some of the columns into a JSON document.

The JSON document can be queried and manipulated using MariaDB's [JSON functions](#).

The JSON document can be stored in a column that uses one of the following data types:

- **TEXT**: The maximum size of a **TEXT** column is 64 KB.
- **MEDIUMTEXT**: The maximum size of a **MEDIUMTEXT** column is 16 MB.
- **LONGTEXT**: The maximum size of a **LONGTEXT** column is 4 GB.
- **JSON**: This is just an alias for the **LONGTEXT** data type.

This workaround can even work if your table is so wide that the previous solutions have failed to solve them problem for your table.

Disabling InnoDB Strict Mode

An *unsafe* workaround is to disable **InnoDB strict mode**. **InnoDB strict mode** can be disabled by setting the **innodb_strict_mode** system variable to **OFF**.

For example, even though the following table schema is too large for most InnoDB row formats to store, it can still be created when **InnoDB strict mode** is disabled:

```
SET GLOBAL innodb_default_row_format='dynamic';  
SET SESSION innodb_strict_mode=OFF;  
CREATE OR REPLACE TABLE tab (  
  col1 varchar(40) NOT NULL,  
  col2 varchar(40) NOT NULL,  
  col3 varchar(40) NOT NULL,  
  col4 varchar(40) NOT NULL,  
  col5 varchar(40) NOT NULL,  
  col6 varchar(40) NOT NULL,  
  col7 varchar(40) NOT NULL,  
  col8 varchar(40) NOT NULL,  
  col9 varchar(40) NOT NULL,  
  col10 varchar(40) NOT NULL,  
  col11 varchar(40) NOT NULL,  
  col12 varchar(40) NOT NULL,  
  col13 varchar(40) NOT NULL,  
  col14 varchar(40) NOT NULL,  
  col15 varchar(40) NOT NULL,  
  col16 varchar(40) NOT NULL,  
  col17 varchar(40) NOT NULL,  
  col18 varchar(40) NOT NULL,  
  col19 varchar(40) NOT NULL,  
  col20 varchar(40) NOT NULL,  
  col21 varchar(40) NOT NULL,  
  col22 varchar(40) NOT NULL,  
  col23 varchar(40) NOT NULL,  
  col24 varchar(40) NOT NULL,

PRIMARY KEY (col1)
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4;

```

But as mentioned above, if [InnoDB strict mode](#) is **disabled** and if a [DDL](#) statement is executed, then InnoDB will still raise a **warning** with this message. The [SHOW WARNINGS](#) statement can be used to view the warning. For example:

```

SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 139 | Row size too large (> 8126). Changing some columns to TEXT or BLOB may help. In current row format, BLOB prefix of 0 bytes is stored inline. |
+-----+-----+-----+
1 row in set (0.000 sec)

```

As mentioned above, even though InnoDB is allowing the table to be created, there is still an opportunity for errors. Regardless of whether [InnoDB strict mode](#) is enabled, if a [DML](#) statement is executed that attempts to write a row that the table's InnoDB row format can't store, then InnoDB will raise an **error** with this message. This creates a somewhat *unsafe* situation, because it means that the application has the chance to encounter an additional error while executing [DML](#).

This page documents system variables related to the [InnoDB storage engine](#). For options that are not system variables, see [InnoDB Options](#).

See [Server System Variables](#) for a complete list of system variables and instructions on setting them.

Also see the [Full list of MariaDB options, system and status variables](#).

have_innodb

- **Description:** If the server supports [InnoDB tables](#), will be set to `YES`, otherwise will be set to `NO`. Removed in [MariaDB 10.0](#), use the [Information Schema PLUGINS](#) table or [SHOW ENGINES](#) instead.
- **Scope:** Global
- **Dynamic:** No
- **Removed:** [MariaDB 10.0](#)

ignore_builtin_innodb

- **Description:** Setting this to `1` results in the built-in InnoDB storage engine being ignored. In some versions of MariaDB, XtraDB is the default and is always present, so this variable is ignored and setting it results in a warning. From [MariaDB 10.0.1](#) to [MariaDB 10.0.8](#), when InnoDB was the default instead of XtraDB, this variable needed to be set. Usually used in conjunction with the [plugin-load=innodb=ha_innodb](#) option to use the InnoDB plugin.
- **Commandline:** `--ignore-builtin-innodb`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `boolean`
- **Default Value:** `OFF`

innodb_adaptive_checkpoint

- **Description:** Replaced with [innodb_adaptive_flushing_method](#). Controls adaptive checkpointing. InnoDB's fuzzy checkpointing can cause stalls, as many dirty blocks are flushed at once as the checkpoint age nears the maximum. Adaptive checkpointing aims for more consistent flushing, approximately `modified age / maximum checkpoint age`. Can result in larger transaction log files
 - `reflex` Similar to [innodb_max_dirty_pages_pct](#) flushing but flushes blocks constantly and contiguously

based on the oldest modified age. If the age exceeds 1/2 of the maximum age capacity, flushing will be weak contiguous. If the age exceeds 3/4, flushing will be strong. Strength can be adjusted by the variable [innodb_io_capacity](#).

- `estimate` The default, and independent of [innodb_io_capacity](#). If the oldest modified age exceeds 1/2 of the maximum age capacity, blocks will be flushed every second at a rate determined by the number of modified blocks, LSN progress speed and the average age of all modified blocks.
- `keep_average` Attempts to keep the I/O rate constant by using a shorter loop cycle of one tenth of a second. Designed for SSD cards.

- **Commandline:** `--innodb-adaptive-checkpoint=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `string`
- **Default Value:** `estimate`
- **Valid Values:** `none` or `0`, `reflex` or `1`, `estimate` or `2`, `keep_average` or `3`
- **Removed:** XtraDB 5.5 - replaced with [innodb_adaptive_flushing_method](#)

`innodb_adaptive_flushing`

- **Description:** If set to `1`, the default, the server will dynamically adjust the flush rate of dirty pages in the [InnoDB buffer pool](#). This assists to reduce brief bursts of I/O activity. If set to `0`, adaptive flushing will only take place when the limit specified by [innodb_adaptive_flushing_lwm](#) is reached.
- **Commandline:** `--innodb-adaptive-flushing={0|1}`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `ON`

`innodb_adaptive_flushing_lwm`

- **Description:** Adaptive flushing is enabled when this low water mark percentage of the [InnoDB redo log](#) capacity is reached. Takes effect even if [innodb_adaptive_flushing](#) is disabled.
- **Commandline:** `--innodb-adaptive-flushing-lwm=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `double`
- **Default Value:** `10.000000`
- **Range:** `0` to `70`

`innodb_adaptive_flushing_method`

- **Description:** Determines the method of flushing dirty blocks from the [InnoDB buffer pool](#). If set to `native` or `0`, the original InnoDB method is used. The maximum checkpoint age is determined by the total length of all transaction log files. When the checkpoint age reaches the maximum checkpoint age, blocks are flushed. This can cause lag if there are many updates per second and many blocks with an almost identical age need to be flushed. If set to `estimate` or `1`, the default, the oldest modified age will be compared with the maximum age capacity. If it's more than 1/4 of this age, blocks are flushed every second. The number of blocks flushed is determined by the number of modified blocks, the LSN progress speed and the average age of all modified blocks. It's therefore independent of the [innodb_io_capacity](#) for the 1-second loop, but not entirely so for the 10-second loop. If set to `keep_average` or `2`, designed specifically for SSD cards, a shorter loop cycle is used in an attempt to keep the I/O rate constant. Removed in [MariaDB 10.0/XtraDB 5.6](#) and replaced with InnoDB flushing method from MySQL 5.6.
- **Commandline:** `innodb-adaptive-flushing-method=value`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `enumeration`
- **Default Value:** `estimate`
- **Valid Values:** `native` or `0`, `estimate` or `1`, `keep_average` or `2`
- **Removed:** [MariaDB 10.0](#) - replaced with InnoDB flushing method from MySQL 5.6

`innodb_adaptive_hash_index`

- **Description:** If set to `1`, the default until [MariaDB 10.5](#), the [InnoDB](#) hash index is enabled. Based on performance

testing ([MDEV-17492](#)), the InnoDB adaptive hash index helps performance in mostly read-only workloads, and could slow down performance in other environments, especially [DROP TABLE](#), [TRUNCATE TABLE](#), [ALTER TABLE](#), or [DROP INDEX](#) operations.

- **Commandline:** `--innodb-adaptive-hash-index={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF` (`>= MariaDB 10.5`), `ON` (`<= MariaDB 10.4`)
-

`innodb_adaptive_hash_index_partitions`

- **Description:** Specifies the number of partitions for use in adaptive searching. If set to `1`, no extra partitions are created. XtraDB-only. From [MariaDB 10.2.6](#) (which uses InnoDB as default instead of XtraDB), this is an alias for [innodb_adaptive_hash_index_parts](#) to allow for easier upgrades.
 - **Commandline:** `innodb-adaptive-hash-index-partitions=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:** `1`
 - **Range:** `1` to `64`
-

`innodb_adaptive_hash_index_parts`

- **Description:** Specifies the number of partitions for use in adaptive searching. If set to `1`, no extra partitions are created.
 - **Commandline:** `innodb-adaptive-hash-index-parts=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:** `8`
 - **Range:** `1` to `512`
-

`innodb_adaptive_max_sleep_delay`

- **Description:** Maximum time in microseconds to automatically adjust the [innodb_thread_sleep_delay](#) value to, based on the workload. Useful in extremely busy systems with hundreds of thousands of simultaneous connections. `0` disables any limit. Deprecated and ignored from [MariaDB 10.5.5](#).
 - **Commandline:** `--innodb-adaptive-max-sleep-delay=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:**
 - `0` (`>= MariaDB 10.5.5`)
 - `150000` (`<= MariaDB 10.5.4`)
 - **Range:** `0` to `1000000`
 - **Introduced:** [MariaDB 10.0](#)
 - **Deprecated:** [MariaDB 10.5.5](#)
 - **Removed:** [MariaDB 10.6.0](#)
-

`innodb_additional_mem_pool_size`

- **Description:** Size in bytes of the InnoDB memory pool used for storing information about internal data structures. Defaults to 8MB, if your application has many tables and a large structure, and this is exceeded, operating system memory will be allocated and warning messages written to the error log, in which case you should increase this value. Deprecated in [MariaDB 10.0](#) and removed in [MariaDB 10.2](#) along with InnoDB's internal memory allocator.
 - **Commandline:** `--innodb-additional-mem-pool-size=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:** `8388608`
 - **Range:** `2097152` to `4294967295`
-

- **Deprecated:** [MariaDB 10.0](#)
 - **Removed:** [MariaDB 10.2.2](#) 
-

`innodb_alter_copy_bulk`

- **Description:** Allow bulk insert operation for copy alter operation.
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `ON`
 - **Introduced:** [MariaDB 10.11.9](#), [MariaDB 11.1.6](#) , [MariaDB 11.2.5](#) , [MariaDB 11.4.3](#), [MariaDB 11.5.2](#) , [MariaDB 11.6.1](#) 
-

`innodb_api_bk_commit_interval`

- **Description:** Time in seconds between auto-commits for idle connections using the InnoDB memcached interface (not implemented in MariaDB).
 - **Commandline:** `--innodb-api-bk-commit-interval=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `5`
 - **Range:** `1` to `1073741824`
 - **Introduced:** [MariaDB 10.0](#)
 - **Removed:** [MariaDB 10.2.4](#) 
-

`innodb_api_disable_rowlock`

- **Description:** For use with MySQL's memcached (not implemented in MariaDB)
 - **Commandline:** `--innodb-api-disable-rowlock={0|1}`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
 - **Introduced:** [MariaDB 10.0](#)
 - **Removed:** [MariaDB 10.2.4](#) 
-

`innodb_api_enable_binlog`

- **Description:** For use with MySQL's memcached (not implemented in MariaDB)
 - **Commandline:** `--innodb-api-enable-binlog={0|1}`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
 - **Introduced:** [MariaDB 10.0](#)
 - **Removed:** [MariaDB 10.2.4](#) 
-

`innodb_api_enable_md1`

- **Description:** For use with MySQL's memcached (not implemented in MariaDB)
 - **Commandline:** `--innodb-api-enable-md1={0|1}`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
 - **Introduced:** [MariaDB 10.0](#)
 - **Removed:** [MariaDB 10.2.4](#) 
-

innodb_api_trx_level

- **Description:** For use with MySQL's memcached (not implemented in MariaDB)
 - **Commandline:** `--innodb-api-trx-level=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `0`
 - **Introduced:** [MariaDB 10.0](#)
 - **Removed:** [MariaDB 10.2.4](#) 
-

innodb_auto_lru_dump

- **Description:** Renamed [innodb_buffer_pool_restore_at_startup](#) since XtraDB 5.5.10-20.1, which was in turn replaced by [innodb_buffer_pool_load_at_startup](#) in [MariaDB 10.0](#).
 - **Commandline:** `--innodb-auto-lru-dump=#`
 - **Removed:** XtraDB 5.5.10-20.1
-

innodb_autoextend_increment

- **Description:** Size in MB to increment an auto-extending shared tablespace file when it becomes full. If [innodb_file_per_table](#) was set to `1`, this setting does not apply to the resulting per-table tablespace files, which are automatically extended in their own way.
 - **Commandline:** `--innodb-autoextend-increment=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `64` (from [MariaDB 10.0](#)) `8` (before [MariaDB 10.0](#)),
 - **Range:** `1` to `1000`
-

innodb_autoinc_lock_mode

- **Description:** The lock mode that is used when generating [AUTO_INCREMENT](#) values for InnoDB tables.
 - Valid values are:
 - `0` is the traditional lock mode.
 - `1` is the consecutive lock mode.
 - `2` is the interleaved lock mode.
 - In order to use [Galera Cluster](#), the lock mode needs to be set to `2`.
 - See [AUTO_INCREMENT Handling in InnoDB: AUTO_INCREMENT Lock Modes](#) for more information.
 - **Commandline:** `--innodb-autoinc-lock-mode=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:** `1`
 - **Range:** `0` to `2`
-

innodb_background_scrub_data_check_interval

- **Description:** Check if spaces needs scrubbing every [innodb_background_scrub_data_check_interval](#) seconds. See [Data Scrubbing](#). Deprecated and ignored from [MariaDB 10.5.2](#).
 - **Commandline:** `--innodb-background-scrub-data-check-interval=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `3600`
 - **Range:** `1` to `4294967295`
 - **Deprecated:** [MariaDB 10.5.2](#)
 - **Removed:** [MariaDB 10.6.0](#)
-

innodb_background_scrub_data_compressed

- **Description:** Enable scrubbing of compressed data by background threads (same as `encryption_threads`). See [Data Scrubbing](#). Deprecated and ignored from [MariaDB 10.5.2](#).
 - **Commandline:** `--innodb-background-scrub-data-compressed={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `0`
 - **Deprecated:** [MariaDB 10.5.2](#)
 - **Removed:** [MariaDB 10.6.0](#)
-

`innodb_background_scrub_data_interval`

- **Description:** Scrub spaces that were last scrubbed longer than this number of seconds ago. See [Data Scrubbing](#). Deprecated and ignored from [MariaDB 10.5.2](#).
 - **Commandline:** `--innodb-background-scrub-data-interval=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `604800`
 - **Range:** `1` to `4294967295`
 - **Deprecated:** [MariaDB 10.5.2](#)
 - **Removed:** [MariaDB 10.6.0](#)
-

`innodb_background_scrub_data_uncompressed`

- **Description:** Enable scrubbing of uncompressed data by background threads (same as `encryption_threads`). See [Data Scrubbing](#). Deprecated and ignored from [MariaDB 10.5.2](#).
 - **Commandline:** `--innodb-background-scrub-data-uncompressed={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `0`
 - **Deprecated:** [MariaDB 10.5.2](#)
 - **Removed:** [MariaDB 10.6.0](#)
-

`innodb_blocking_buffer_pool_restore`

- **Description:** If set to `1` (`0` is default), XtraDB will wait until the least-recently used (LRU) dump is completely restored upon restart before reporting back to the server that it has successfully started up. Available with XtraDB only, not InnoDB.
 - **Commandline:** `innodb-blocking-buffer-pool-restore={0|1}`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
 - **Removed:** [MariaDB 10.0.0](#) 
-

`innodb_buf_dump_status_frequency`

- **Description:** Determines how often (as a percent) the buffer pool dump status should be printed in the logs. For example, `10` means that the buffer pool dump status is printed when every 10% of the number of buffer pool pages are dumped. The default is `0` (only start and end status is printed).
 - **Commandline:** `--innodb-buf-dump-status-frequency=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `0`
 - **Range:** `0` to `100`
-

`innodb_buffer_pool_chunk_size`

- **Description:** Chunk size used for dynamically resizing the [buffer pool](#). Note that changing this setting can change the size of the buffer pool. When [large-pages](#) is used this value is effectively rounded up to the next multiple of [large-page-size](#). See [Setting InnoDB Buffer Pool Size Dynamically](#). From [MariaDB 10.8.0](#), the variable is autosized based on the [buffer pool size](#).
 - **Commandline:** `--innodb-buffer-pool-chunk-size=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:**
 - `autosize (0)`, resulting in `innodb_buffer_pool_size/64`, if [large_pages](#) round down to multiple of largest page size, with 1MiB minimum (\geq [MariaDB 10.8.1](#))
 - `134217728` (\leq [MariaDB 10.8.0](#))
 - **Range:**
 - `0`, as `autosize`, and then `1048576` to `18446744073709551615` (\geq [MariaDB 10.8](#))
 - `1048576` to `innodb_buffer_pool_size/innodb_buffer_pool_instances` (\leq [MariaDB 10.7](#))
 - **Block size:** `1048576`
-

`innodb_buffer_pool_dump_at_shutdown`

- **Description:** Whether to record pages cached in the [buffer pool](#) on server shutdown, which reduces the length of the warmup the next time the server starts. The related [innodb_buffer_pool_load_at_startup](#) specifies whether the buffer pool is automatically warmed up at startup.
 - **Commandline:** `--innodb-buffer-pool-dump-at-shutdown={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `ON`
-

`innodb_buffer_pool_dump_now`

- **Description:** Immediately records pages stored in the [buffer pool](#). The related [innodb_buffer_pool_load_now](#) does the reverse, and will immediately warm up the buffer pool.
 - **Commandline:** `--innodb-buffer-pool-dump-now={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
 - **Introduced:** [MariaDB 10.0](#)
-

`innodb_buffer_pool_dump_pct`

- **Description:** Dump only the hottest N% of each [buffer pool](#).
 - **Commandline:** `--innodb-buffer-pool-dump-pct={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:**
 - `25`
 - **Range:** `1` to `100`
-

`innodb_buffer_pool_evict`

- **Description:** Evict pages from the buffer pool. If set to "uncompressed" then all uncompressed pages are evicted from the buffer pool. Variable to be used only for testing. Only exists in DEBUG builds.
 - **Commandline:** `--innodb-buffer-pool-evict=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `string`
 - **Default Value:** `""`
 - **Valid Values:** `""` or `"uncompressed"`
-

innodb_buffer_pool_filename

- **Description:** The file that holds the [buffer pool](#) list of page numbers set by [innodb_buffer_pool_dump_at_shutdown](#) and [innodb_buffer_pool_dump_now](#).
 - **Commandline:** `--innodb-buffer-pool-filename=file`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `string`
 - **Default Value:** `ib_buffer_pool`
 - **Introduced:** [MariaDB 10.0](#)
-

innodb_buffer_pool_instances

- **Description:** If [innodb_buffer_pool_size](#) is set to more than 1GB, `innodb_buffer_pool_instances` divides the [InnoDB](#) buffer pool into the specified number of instances. The default was 1 in [MariaDB 5.5](#), but for large systems with buffer pools of many gigabytes, many instances could help reduce contention concurrency through [MariaDB 10.2](#). The default is 8 in [MariaDB 10](#) (except on Windows 32-bit, where it varies according to [innodb_buffer_pool_size](#), or from [MariaDB 10.2.2](#) [↗](#), where it is set to 1 if [innodb_buffer_pool_size](#) < 1GB). Each instance manages its own data structures and takes an equal portion of the total buffer pool size, so for example if [innodb_buffer_pool_size](#) is 4GB and `innodb_buffer_pool_instances` is set to 4, each instance will be 1GB. Each instance should ideally be at least 1GB in size. Starting with [MariaDB 10.3](#), performance improvements intended to reduce the overhead of context-switching between buffer pools changed the recommended number of `innodb_buffer_pool_instances` to one for every 128GB of buffer pool size. Based on these changes, the variable is deprecated and ignored from [MariaDB 10.5.1](#), where the buffer pool runs in a single instance regardless of size.
 - **Commandline:** `--innodb-buffer-pool-instances=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:** `>= MariaDB 10.0.4` [↗](#): 8, 1 (`>= MariaDB 10.2.2` [↗](#) if [innodb_buffer_pool_size](#) < 1GB), or dependent on [innodb_buffer_pool_size](#) (Windows 32-bit)
 - **Deprecated:** [MariaDB 10.5.1](#)
 - **Removed:** [MariaDB 10.6.0](#)
-

innodb_buffer_pool_load_abort

- **Description:** Aborts the process of restoring [buffer pool](#) contents started by [innodb_buffer_pool_load_at_startup](#) or [innodb_buffer_pool_load_now](#).
 - **Commandline:** `--innodb-buffer-pool-load-abort={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
-

innodb_buffer_pool_load_at_startup

- **Description:** Specifies whether the [buffer pool](#) is automatically warmed up when the server starts by loading the pages held earlier. The related [innodb_buffer_pool_dump_at_shutdown](#) specifies whether pages are saved at shutdown. If the buffer pool is large and taking a long time to load, increasing [innodb_io_capacity](#) at startup may help.
 - **Commandline:** `--innodb-buffer-pool-load-at-startup={0|1}`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `ON`
-

innodb_buffer_pool_load_now

- **Description:** Immediately warms up the [buffer pool](#) by loading the stored data pages. The related [innodb_buffer_pool_dump_now](#) does the reverse, and immediately records pages stored in the buffer pool.
 - **Commandline:** `--innodb-buffer-pool-load-now={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
-

- **Default Value:** OFF
-

innodb_buffer_pool_load_pages_abort

- **Description:** Number of pages during a buffer pool load to process before signaling [innodb_buffer_pool_load_abort=1](#). Debug builds only.
 - **Commandline:** `--innodb-buffer-pool-load-pages-abort=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** numeric
 - **Default Value:** 9223372036854775807
 - **Range:** 1 to 9223372036854775807
-

innodb_buffer_pool_populate

- **Description:** When set to 1 (0 is default), XtraDB will preallocate pages in the buffer pool on starting up so that NUMA allocation decisions are made while the buffer cache is still clean. XtraDB only. This option was made ineffective in [MariaDB 10.0.23](#). Added as a deprecated and ignored option in [MariaDB 10.2.6](#) (which uses InnoDB as default instead of XtraDB) to allow for easier upgrades.
 - **Commandline:** `innodb-buffer-pool-populate={0|1}`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** boolean
 - **Default Value:** OFF
 - **Deprecated:** [MariaDB 10.0.23](#)
 - **Removed:** [MariaDB 10.3.0](#)
-

innodb_buffer_pool_restore_at_startup

- **Description:** Time in seconds between automatic buffer pool dumps. If set to a non-zero value, XtraDB will also perform an automatic restore of the [buffer pool](#) at startup. If set to 0, automatic dumps are not performed, nor automatic restores on startup. Replaced by [innodb_buffer_pool_load_at_startup](#) in [MariaDB 10.0](#).
 - **Commandline:** `innodb-buffer-pool-restore-at-startup`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** numeric
 - **Default Value:** 0
 - **Range - 32 bit:** 0 to 4294967295
 - **Range - 64 bit:** 0 to 18446744073709547520
 - **Removed:** [MariaDB 10.0](#) - replaced by [innodb_buffer_pool_load_at_startup](#)
-

innodb_buffer_pool_shm_checksum

- **Description:** Used with Percona's SHM buffer pool patch in XtraDB 5.5. Was shortly deprecated and removed in XtraDB 5.6. XtraDB only.
 - **Commandline:** `innodb-buffer-pool-shm-checksum={0|1}`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** boolean
 - **Default Value:** ON
 - **Removed:** [MariaDB 10.0](#)
-

innodb_buffer_pool_shm_key

- **Description:** Used with Percona's SHM buffer pool patch in XtraDB 5.5. Later deprecated in XtraDB 5.5, and removed in XtraDB 5.6.
- **Commandline:** `innodb-buffer-pool-shm-key={0|1}`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** boolean

- **Default Value:** 0
 - **Removed:** [MariaDB 10.0](#)
-

`innodb_buffer_pool_size`

- **Description:** InnoDB buffer pool size in bytes. The primary value to adjust on a database server with entirely/primarily [InnoDB](#) tables, can be set up to 80% of the total memory in these environments. See the [InnoDB Buffer Pool](#) for more on setting this variable, and also [Setting InnoDB Buffer Pool Size Dynamically](#) if doing so dynamically.
 - **Commandline:** `--innodb-buffer-pool-size=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** 134217728 (128MiB)
 - **Range:**
 - Minimum: 5242880 (5MiB) for [InnoDB Page Size](#) <= 16k otherwise 25165824 (24MiB) for [InnoDB Page Size](#) > 16k (for versions less than next line)
 - Minimum: 2MiB [InnoDB Page Size](#) = 4k, 3MiB [InnoDB Page Size](#) = 8k, 5MiB [InnoDB Page Size](#) = 16k, 10MiB [InnoDB Page Size](#) = 32k, 20MiB [InnoDB Page Size](#) = 64k, (>= [MariaDB 10.2.42](#) [↗](#), >= [MariaDB 10.3.33](#) [↗](#), >= [MariaDB 10.4.23](#) [↗](#), >= [MariaDB 10.5.14](#), >= [MariaDB 10.6.6](#), >= [MariaDB 10.7.2](#) [↗](#))
 - Minimum: 1GiB for [innodb_buffer_pool_instances](#) > 1 (<= [MariaDB 10.7](#))
 - Maximum: 9223372036854775807 (8192PB) (all versions)
 - **Block size:** 1048576
-

`innodb_change_buffer_dump`

- **Description:** If set, causes the contents of the InnoDB change buffer to be dumped to the server error log at startup. Only available in debug builds.
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** OFF
 - **Introduced:** [MariaDB 10.2.28](#) [↗](#), [MariaDB 10.3.19](#) [↗](#), [MariaDB 10.4.9](#) [↗](#)
-

`innodb_change_buffer_max_size`

- **Description:** Maximum size of the [InnoDB Change Buffer](#) as a percentage of the total buffer pool. The default is 25%, and this can be increased up to 50% for servers with high write activity, and lowered down to 0 for servers used exclusively for reporting.
 - **Commandline:** `--innodb-change-buffer-max-size=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** 25
 - **Range:** 0 to 50
 - **Introduced:** [MariaDB 10.0](#)
 - **Deprecated:** [MariaDB 10.9.0](#) [↗](#)
 - **Removed:** [MariaDB 11.0.0](#) [↗](#)
-

`innodb_change_buffering`

- **Description:** Sets how [InnoDB](#) change buffering is performed. See [InnoDB Change Buffering](#) for details on the settings. Deprecated and ignored from [MariaDB 10.9.0](#) [↗](#).
 - **Commandline:** `--innodb-change-buffering=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `enumeration` (>= [MariaDB 10.3.7](#) [↗](#)), `string` (<= [MariaDB 10.3.6](#) [↗](#))
 - **Default Value:**
 - >= [MariaDB 10.5.15](#), [MariaDB 10.6.7](#), [MariaDB 10.7.3](#) [↗](#), [MariaDB 10.8.2](#) [↗](#): none
 - <= [MariaDB 10.5.14](#), [MariaDB 10.6.6](#), [MariaDB 10.7.2](#) [↗](#), [MariaDB 10.8.1](#) [↗](#): all
 - **Valid Values:** `inserts`, `none`, `deletes`, `purges`, `changes`, `all`
-

- **Deprecated:** [MariaDB 10.9.0](#)
- **Removed:** [MariaDB 11.0.0](#)

`innodb_change_buffering_debug`

- **Description:** If set to `1`, an [InnoDB Change Buffering](#) debug flag is set. `1` forces all changes to the change buffer, while `2` causes a crash at merge. `0`, the default, indicates no flag is set. Only available in debug builds.
- **Commandline:** `--innodb-change-buffering-debug=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `0`
- **Range:** `0` to `2`

`innodb_checkpoint_age_target`

- **Description:** The maximum value of the checkpoint age. If set to `0`, has no effect. Removed in [MariaDB 10.0/XtraDB 5.6](#) and replaced with InnoDB flushing method from MySQL 5.6.
- **Commandline:** `innodb-checkpoint-age-target=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `0`
- **Range:** `0` upwards
- **Removed:** [MariaDB 10.0](#) - replaced with InnoDB flushing method from MySQL 5.6.

`innodb_checksum_algorithm`

- **Description:** Specifies how the InnoDB tablespace checksum is generated and verified.
 - `innodb` : Backwards compatible with earlier versions (\leq [MariaDB 5.5](#)). Deprecated in [MariaDB 10.3.29](#), [MariaDB 10.4.19](#), [MariaDB 10.5.10](#) and removed in [MariaDB 10.6](#). If really needed, data files can still be converted with [innochecksum](#).
 - `crc32` : A newer, faster algorithm, but incompatible with earlier versions. Tablespace blocks will be converted to the new format over time, meaning that a mix of checksums may be present.
 - `full_crc32` and `strict_full_crc32` : From [MariaDB 10.4.3](#). Permits encryption to be supported over a [SPATIAL INDEX](#), which `crc32` does not support. Newly-created data files will carry a flag that indicates that all pages of the file will use a full CRC-32C checksum over the entire page contents (excluding the bytes where the checksum is stored, at the very end of the page). Such files will always use that checksum, no matter what parameter `innodb_checksum_algorithm` is assigned to. Even if `innodb_checksum_algorithm` is modified later, the same checksum will continue to be used. A special flag will be set in the `FSP_SPACE_FLAGS` in the first data page to indicate the new format of checksum and encryption/page_compressed. `ROW_FORMAT=COMPRESSED` tables will only use the old format. These tables do not support new features, such as larger `innodb_page_size` or instant `ADD/DROP COLUMN`. Also cleans up the MariaDB tablespace flags - flags are reserved to store the `page_compressed` compression algorithm, and to store the compressed payload length, so that checksum can be computed over the compressed (and possibly encrypted) stream and can be validated without decrypting or decompressing the page. In the `full_crc32` format, there no longer are separate before-encryption and after-encryption checksums for pages. The single checksum is computed on the page contents that is written to the file. See [MDEV-12026](#) for details.
 - `none` : Writes a constant rather than calculate a checksum. Deprecated in [MariaDB 10.3.29](#), [MariaDB 10.4.19](#), [MariaDB 10.5.10](#) and removed in [MariaDB 10.6](#) as was mostly used to disable the original, slow, page checksum for benchmarking purposes.
 - `strict_crc32`, `strict_innodb` and `strict_none` : The options are the same as the regular options, but InnoDB will halt if it comes across a mix of checksum values. These are faster, as both new and old checksum values are not required, but can only be used when setting up tablespaces for the first time.
- **Commandline:** `--innodb-checksum-algorithm=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `enumeration`
- **Default Value:**
 - `full_crc32` (\geq [MariaDB 10.5.0](#))
 - `crc32` (\geq [MariaDB 10.2.2](#) to \leq [MariaDB 10.4](#))

- `innodb` ([<= MariaDB 10.2.1](#))
- **Valid Values:**
 - [>= MariaDB 10.6.0](#): `crc32`, `full_crc32`, `strict_crc32`, `strict_full_crc32`
 - [MariaDB 10.5](#), [>= MariaDB 10.4.3](#): `innodb`, `crc32`, `full_crc32`, `none`, `strict_innodb`, `strict_crc32`, `strict_none`, `strict_full_crc32`
 - [<= MariaDB 10.4.2](#): `innodb`, `crc32`, `none`, `strict_innodb`, `strict_crc32`, `strict_none`

`innodb_checksums`

- **Description:** By default, **InnoDB** performs checksum validation on all pages read from disk, which provides extra fault tolerance. You would usually want this set to `1` in production environments, although setting it to `0` can provide marginal performance improvements. Deprecated and functionality replaced by `innodb_checksum_algorithm` in [MariaDB 10.0](#), and should be removed to avoid conflicts. `ON` is equivalent to `--innodb_checksum_algorithm=innodb` and `OFF` to `--innodb_checksum_algorithm=none`.
- **Commandline:** `--innodb-checksums`, `--skip-innodb-checksums`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `boolean`
- **Default Value:** `ON`
- **Deprecated:** [MariaDB 10.0](#)
- **Removed:** [MariaDB 10.5.0](#)

`innodb_cleaner_lsn_age_factor`

- **Description:** XtraDB has enhanced page cleaner heuristics, and with these in place, the default InnoDB adaptive flushing may be too aggressive. As a result, a new LSN age factor formula has been introduced, controlled by this variable. The default setting, `high_checkpoint`, uses the new formula, while the alternative, `legacy`, uses the original algorithm. XtraDB only. Added as a deprecated and ignored option in [MariaDB 10.2.6](#) (which uses InnoDB as default instead of XtraDB) to allow for easier upgrades.
- **Commandline:** `--innodb-cleaner-lsn-age-factor=value`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `enum`
- **Default Value:**
 - `deprecated`
- **Valid Values:**
 - `deprecated`, `high_checkpoint`, `legacy`
- **Deprecated:** [MariaDB 10.2.6](#)
- **Removed:** [MariaDB 10.3.0](#)

`innodb_cmp_per_index_enabled`

- **Description:** If set to `ON` (`OFF` is default), per-index compression statistics are stored in the `INFORMATION_SCHEMA.INNODB_CMP_PER_INDEX` table. These are expensive to record, so this setting should only be changed with care, such as for performance tuning on development or replica servers.
- **Commandline:** `--innodb-cmp-per-index-enabled={0|1}`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `OFF`
- **Introduced:** [MariaDB 10.0](#)

`innodb_commit_concurrency`

- **Description:** Limit to the number of transaction threads that can can commit simultaneously. `0`, the default, imposes no limit. While you can change from one positive limit to another at runtime, you cannot set this variable to `0`, or change it from `0`, while the server is running. Deprecated and ignored from [MariaDB 10.5.5](#).
- **Commandline:** `--innodb-commit-concurrency=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`

- **Default Value:** 0
 - **Range:** 0 to 1000
 - **Deprecated:** [MariaDB 10.5.5](#)
 - **Removed:** [MariaDB 10.6.0](#)
-

`innodb_compression_algorithm`

- **Description:** Compression algorithm used for [InnoDB page compression](#). The supported values are:
 - `none`: Pages are not compressed.
 - `zlib`: Pages are compressed using the bundled [zlib](#)  compression algorithm.
 - `lz4`: Pages are compressed using the [lz4](#)  compression algorithm.
 - `lzo`: Pages are compressed using the [lzo](#)  compression algorithm.
 - `lzma`: Pages are compressed using the [lzma](#)  compression algorithm.
 - `bzip2`: Pages are compressed using the [bzip2](#)  compression algorithm.
 - `snappy`: Pages are compressed using the [snappy](#)  algorithm.
 - On many distributions, MariaDB may not support all page compression algorithms by default. From [MariaDB 10.7](#), libraries can be installed as a plugin. See [Compression Plugins](#).
 - See [InnoDB Page Compression: Configuring the InnoDB Page Compression Algorithm](#) for more information.
 - **Commandline:** `--innodb-compression-algorithm=value`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `enum`
 - **Default Value:** `zlib`
 - **Valid Values:** `none`, `zlib`, `lz4`, `lzo`, `lzma`, `bzip2` or `snappy`
-

`innodb_compression_default`

- **Description:** Whether or not [InnoDB page compression](#) is enabled by default for new tables.
 - The default value is `OFF`, which means new tables are not compressed.
 - See [InnoDB Page Compression: Enabling InnoDB Page Compression by Default](#) for more information.
 - **Commandline:** `--innodb-compression-default={0|1}`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
-

`innodb_compression_failure_threshold_pct`

- **Description:** Specifies the percentage cutoff for expensive compression failures during updates to a table that uses [InnoDB page compression](#), after which free space is added to each new compressed page, dynamically adjusted up to the level set by `innodb_compression_pad_pct_max`. Zero disables checking of compression efficiency and adjusting padding.
 - See [InnoDB Page Compression: Configuring the Failure Threshold and Padding](#) for more information.
 - **Commandline:** `--innodb-compression-failure-threshold-pct=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** 5
 - **Range:** 0 to 100
 - **Introduced:** [MariaDB 10.0](#)
-

`innodb_compression_level`

- **Description:** Specifies the default level of compression for tables that use [InnoDB page compression](#).
 - Only a subset of InnoDB page compression algorithms support compression levels. If an InnoDB page compression algorithm does not support compression levels, then the compression level value is ignored.
 - The compression level can be set to any value between 1 and 9. The default compression level is 6. The range goes from the fastest to the most compact, which means that 1 is the fastest and 9 is the most compact.
 - See [InnoDB Page Compression: Configuring the Default Compression Level](#) for more information.
 - **Commandline:** `--innodb-compression-level=#`
-

- **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** 6
 - **Range:** 1 to 9
 - **Introduced:** [MariaDB 10.0](#)
-

`innodb_compression_pad_pct_max`

- **Description:** The maximum percentage of reserved free space within each compressed page for tables that use [InnoDB page compression](#). Reserved free space is used when the page's data is reorganized and might be recompressed. Only used when `innodb_compression_failure_threshold_pct` is not zero, and the rate of compression failures exceeds its setting.
 - See [InnoDB Page Compression: Configuring the Failure Threshold and Padding](#) for more information.
 - **Commandline:** `--innodb-compression-pad-pct-max=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** 50
 - **Range:** 0 to 75
 - **Introduced:** [MariaDB 10.0](#)
-

`innodb_concurrency_tickets`

- **Description:** Number of times a newly-entered thread can enter and leave [InnoDB](#) until it is again subject to the limitations of `innodb_thread_concurrency` and may possibly be queued. Deprecated and ignored from [MariaDB 10.5.5](#).
 - **Commandline:** `--innodb-concurrency-tickets=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:**
 - 0 ([>= MariaDB 10.5.5](#))
 - 5000 ([<= MariaDB 10.5.4](#))
 - **Range:** 1 to 18446744073709551615
 - **Deprecated:** [MariaDB 10.5.5](#)
 - **Removed:** [MariaDB 10.6.0](#)
-

`innodb_corrupt_table_action`

- **Description:** What action to perform when a corrupt table is found. XtraDB only.
 - When set to `assert`, the default, XtraDB will intentionally crash the server when it detects corrupted data in a single-table tablespace, with an assertion failure.
 - When set to `warn`, it will pass corruption as corrupt table instead of crashing, and disable all further I/O (except for deletion) on the table file.
 - If set to `salvage`, read access is permitted, but corrupted pages are ignored. `innodb_file_per_table` must be enabled for this option. Previously named `innodb_pass_corrupt_table`.
 - Added as a deprecated and ignored option in [MariaDB 10.2.6](#) (which uses InnoDB as default instead of XtraDB) to allow for easier upgrades.
 - **Commandline:** `innodb-corrupt-table-action=value`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `enumeration`
 - **Default Value:**
 - `assert` ([<= MariaDB 10.1](#))
 - `deprecated` ([<= MariaDB 10.2.6](#))
 - **Valid Values:**
 - `deprecated`, `assert`, `warn`, `salvage`
 - **Deprecated:** [MariaDB 10.2.6](#)
 - **Removed:** [MariaDB 10.3.0](#)
-

innodb_data_file_buffering

- **Description:** Whether to enable the file system cache for data files. Set to `OFF` by default, will be set to `ON` if [innodb_flush_method](#) is set to `fsync`, `littlesync`, `nosync`, or (Windows specific) `normal`.
 - **Commandline:** `--innodb-data-file-buffering={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
 - **Introduced:** [MariaDB 11.0.0](#) 
-

innodb_data_file_path

- **Description:** Individual [InnoDB](#) data files, paths and sizes. The value of [innodb_data_home_dir](#) is joined to each path specified by `innodb_data_file_path` to get the full directory path. If `innodb_data_home_dir` is an empty string, absolute paths can be specified here. A file size is specified (with K for kilobytes, M for megabytes and G for gigabytes). Also whether or not to `autoextend` the data file, and whether or not to `autoshrink` on startup may also be specified.
 - **Commandline:** `--innodb-data-file-path=name`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:** `ibdata1:12M:autoextend` (from [MariaDB 10.0](#)), `ibdata1:10M:autoextend` (before [MariaDB 10.0](#))
-

innodb_data_file_write_through

- **Description:** Whether writes to InnoDB data files (including the temporary tablespace) are write through. Set to `OFF` by default, will be set to `ON` if [innodb_flush_method](#) is set to `O_DSYNC`. On systems that support FUA it may make sense to enable write-through, to avoid extra system calls.
 - **Commandline:** `--innodb-data-file-write-through={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
 - **Introduced:** [MariaDB 11.0.0](#) 
-

innodb_data_home_dir

- **Description:** Directory path for all [InnoDB](#) data files in the shared tablespace (assuming [innodb_file_per_table](#) is not enabled). File-specific information can be added in [innodb_data_file_path](#), as well as absolute paths if `innodb_data_home_dir` is set to an empty string.
 - **Commandline:** `--innodb-data-home-dir=path`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `directory name`
 - **Default Value:** The MariaDB data directory
-

innodb_deadlock_detect

- **Description:** By default, the InnoDB deadlock detector is enabled. If set to off, deadlock detection is disabled and MariaDB will rely on [innodb_lock_wait_timeout](#) instead. This may be more efficient in systems with high concurrency as deadlock detection can cause a bottleneck when a number of threads have to wait for the same lock.
 - **Commandline:** `--innodb-deadlock-detect`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `1`
-

innodb_deadlock_report

- **Description:** How to report deadlocks (if `innodb_deadlock_detect=ON`).
 - `off`: Do not report any details of deadlocks.
 - `basic`: Report transactions and waiting locks.
 - `full`: Default. Report transactions, waiting locks and blocking locks.
 - **Commandline:** `--innodb-deadlock-report=val`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `enum`
 - **Default Value:** `full`
 - **Valid Values:** `off`, `basic`, `full`
 - **Introduced:** [MariaDB 10.6.0](#)
-

`innodb_default_page_encryption_key`

- **Description:** Encryption key used for page encryption.
 - See [Data-at-Rest Encryption](#) and [InnoDB Encryption Keys](#) for more information.
 - **Commandline:** `--innodb-default-page-encryption-key=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `1`
 - **Range:** `1` to `255`
 - **Introduced:** [MariaDB 10.1.3](#)
 - **Removed:** [MariaDB 10.1.4](#)
-

`innodb_default_encryption_key_id`

- **Description:** ID of encryption key used by default to encrypt InnoDB tablespaces.
 - See [Data-at-Rest Encryption](#) and [InnoDB Encryption Keys](#) for more information.
 - **Commandline:** `--innodb-default-encryption-key-id=#`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `1`
 - **Range:** `1` to `4294967295`
-

`innodb_default_row_format`

- **Description:** Specifies the default [row format](#) to be used for InnoDB tables. The compressed row format cannot be set as the default.
 - See [InnoDB Row Formats Overview: Default Row Format](#) for more information.
 - **Commandline:** `--innodb-default-row-format=value`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `enum`
 - **Default Value:** `dynamic`
 - **Valid Values:** `redundant`, `compact` or `dynamic`
-

`innodb_defragment`

- **Description:** When set to `1` (the default is `0`), InnoDB defragmentation is enabled. When set to `FALSE`, all existing defragmentation will be paused and new defragmentation commands will fail. Paused defragmentation commands will resume when this variable is set to true again. See [Defragmenting InnoDB Tablespaces](#).
 - **Commandline:** `--innodb-defragment={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
 - **Deprecated:** [MariaDB 11.0.1](#)
 - **Removed:** [MariaDB 11.1.0](#)
-

innodb_defragment_fill_factor

- **Description:** Indicates how full defragmentation should fill a page. Together with [innodb_defragment_fill_factor_n_recs](#) ensures defragmentation won't pack the page too full and cause page split on the next insert on every page. The variable indicating more defragmentation gain is the one effective. See [Defragmenting InnoDB Tablespaces](#).
 - **Commandline:** `--innodb-defragment-fill-factor=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `double`
 - **Default Value:** `0.9`
 - **Range:** `0.7` to `1`
 - **Deprecated:** [MariaDB 11.0.1](#) 
 - **Removed:** [MariaDB 11.1.0](#) 
-

innodb_defragment_fill_factor_n_recs

- **Description:** Number of records of space that defragmentation should leave on the page. This variable, together with [innodb_defragment_fill_factor](#), is introduced so defragmentation won't pack the page too full and cause page split on the next insert on every page. The variable indicating more defragmentation gain is the one effective. See [Defragmenting InnoDB Tablespaces](#).
 - **Commandline:** `--innodb-defragment-fill-factor-n-recs=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `20`
 - **Range:** `1` to `100`
 - **Deprecated:** [MariaDB 11.0.1](#) 
 - **Removed:** [MariaDB 11.1.0](#) 
-

innodb_defragment_frequency

- **Description:** Maximum times per second for defragmenting a single index. This controls the number of times the defragmentation thread can request `X_LOCK` on an index. The defragmentation thread will check whether `1/defragment_frequency` (s) has passed since it last worked on this index, and put the index back in the queue if not enough time has passed. The actual frequency can only be lower than this given number. See [Defragmenting InnoDB Tablespaces](#).
 - **Commandline:** `--innodb-defragment-frequency=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `integer`
 - **Default Value:** `40`
 - **Range:** `1` to `1000`
 - **Deprecated:** [MariaDB 11.0.1](#) 
 - **Removed:** [MariaDB 11.1.0](#) 
-

innodb_defragment_n_pages

- **Description:** Number of pages considered at once when merging multiple pages to defragment. See [Defragmenting InnoDB Tablespaces](#).
 - **Commandline:** `--innodb-defragment-n-pages=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `7`
 - **Range:** `2` to `32`
 - **Deprecated:** [MariaDB 11.0.1](#) 
 - **Removed:** [MariaDB 11.1.0](#) 
-

innodb_defragment_stats_accuracy

- **Description:** Number of defragment stats changes there are before the stats are written to persistent storage.

Defaults to zero, meaning disable defragment stats tracking. See [Defragmenting InnoDB Tablespaces](#).

- **Commandline:** `--innodb-defragment-stats-accuracy=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `0`
- **Range:** `0` to `4294967295`
- **Deprecated:** [MariaDB 11.0.1](#) 
- **Removed:** [MariaDB 11.1.0](#) 

`innodb_dict_size_limit`

- **Description:** Size in bytes of a soft limit the memory used by tables in the data dictionary. Once this limit is reached, XtraDB will attempt to remove unused entries. If set to `0`, the default and standard InnoDB behavior, there is no limit to memory usage. Removed in [MariaDB 10.0/XtraDB 5.6](#) and replaced by MySQL 5.6's new [table_definition_cache](#) implementation.
- **Commandline:** `innodb-dict-size-limit=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `0`
- **Default Value - 32 bit:** `2147483648`
- **Default Value - 64 bit:** `9223372036854775807`
- **Removed:** [MariaDB 10.0](#) - replaced by MySQL 5.6's [table_definition_cache](#) implementation.

`innodb_disable_sort_file_cache`

- **Description:** If set to `1` (`0` is default), the operating system file system cache for merge-sort temporary files is disabled.
- **Commandline:** `--innodb-disable-sort-file-cache={0|1}`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `OFF`

`innodb_disallow_writes`

- **Description:** Tell InnoDB to stop any writes to disk.
- **Commandline:** None
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `OFF`
- **Removed:** [MariaDB 10.3.35](#) , [MariaDB 10.4.25](#) , [MariaDB 10.5.16](#), [MariaDB 10.6.8](#), [MariaDB 10.7.4](#) 

`innodb_doublewrite`

- **Description:** If set to `1`, the default, to improve fault tolerance InnoDB first stores data to a [doublewrite buffer](#) before writing it to data file. Disabling will provide a marginal performance improvement.
- **Commandline:** `--innodb-doublewrite`, `--skip-innodb-doublewrite`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `boolean`
- **Default Value:** `ON`

`innodb_doublewrite_file`

- **Description:** The absolute or relative path and filename to a dedicated tablespace for the [doublewrite buffer](#). In heavy workloads, the doublewrite buffer can impact heavily on the server, and moving it to a different drive will reduce contention on random reads. Since the doublewrite buffer is mostly sequential writes, a traditional HDD is a better

choice than SSD. This Percona XtraDB variable has not been ported to XtraDB 5.6.

- **Commandline:** `innodb-doublewrite-file=filename`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `filename`
 - **Default Value:** `NULL`
 - **Removed:** [MariaDB 10.0](#)
-

`innodb_empty_free_list_algorithm`

- **Description:** XtraDB 5.6.13-61 introduced an algorithm to assist with reducing mutex contention when the buffer pool free list is empty, controlled by this variable. If set to `backoff`, the default until [MariaDB 10.1.24](#), the new algorithm will be used. If set to `legacy`, the original InnoDB algorithm will be used. XtraDB only. Added as a deprecated and ignored option in [MariaDB 10.2.6](#) (which uses InnoDB as default instead of XtraDB) to allow for easier upgrades. See [#1651657](#) for the reasons this was changed back to `legacy` in XtraDB 5.6.36-82.0. When upgrading from 10.0 to 10.1 ($\geq 10.1.24$), for large buffer pools the default will remain `backoff`, while for small ones it will be changed to `legacy`.
 - **Commandline:** `innodb-empty-free-list-algorithm=value`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `enum`
 - **Default Value:**
 - `deprecated`
 - **Valid Values:**
 - `deprecated`, `backoff`, `legacy`
 - **Deprecated:** [MariaDB 10.2.6](#)
 - **Removed:** [MariaDB 10.3.0](#)
-

`innodb_enable_unsafe_group_commit`

- **Description:** Unneeded after XtraDB 1.0.5. If set to `0`, the default, InnoDB will keep transactions between the transaction log and [binary logs](#) in the same order. Safer, but slower. If set to `1`, transactions can be group-committed, but there is no guarantee of the order being kept, and a small risk of the two logs getting out of sync. In write-intensive environments, can lead to a significant improvement in performance.
 - **Commandline:** `--innodb-enable-unsafe-group-commit`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `0`
 - **Range:** `0` to `1`
 - **Removed:** Not needed after XtraDB 1.0.5
-

`innodb_encrypt_log`

- **Description:** Enables encryption of the [InnoDB redo log](#). This also enables encryption of some temporary files created internally by InnoDB, such as those used for merge sorts and row logs.
 - See [Data-at-Rest Encryption](#) and [Enabling InnoDB Encryption: Enabling Encryption for the Redo Log](#) for more information.
 - **Commandline:** `--innodb-encrypt-log`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
-

`innodb_encrypt_tables`

- **Description:** Enables automatic encryption of all InnoDB tablespaces.
 - `OFF` - Disables table encryption for all new and existing tables that have the `ENCRYPTED` table option set to `DEFAULT`.
 - `ON` - Enables table encryption for all new and existing tables that have the `ENCRYPTED` table option set to `DEFAULT`, but allows unencrypted tables to be created.
-

- **FORCE** - Enables table encryption for all new and existing tables that have the `ENCRYPTED` table option set to `DEFAULT`, and doesn't allow unencrypted tables to be created (`CREATE TABLE ... ENCRYPTED=NO` will fail).
 - See [Data-at-Rest Encryption](#) and [Enabling InnoDB Encryption: Enabling Encryption for Automatically Encrypted Tablespaces](#) for more information.
 - **Commandline:** `--innodb-encrypt-tables={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
 - **Valid Values:** `ON`, `OFF`, `FORCE`
-

`innodb_encrypt_temporary_tables`

- **Description:** Enables automatic encryption of the InnoDB [temporary tablespace](#).
 - See [Data-at-Rest Encryption](#) and [InnoDB Enabling Encryption: Enabling Encryption for Temporary Tablespaces](#) for more information.
 - **Commandline:** `--innodb-encrypt-temporary-tables={0|1}`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
 - **Valid Values:** `ON`, `OFF`
 - **Introduced:** [MariaDB 10.2.26](#), [MariaDB 10.3.17](#), [MariaDB 10.4.7](#)
-

`innodb_encryption_rotate_key_age`

- **Description:** Re-encrypt in background any page having a key older than this number of key versions. When setting up encryption, this variable must be set to a non-zero value. Otherwise, when you enable encryption through `innodb_encrypt_tables` MariaDB won't be able to automatically encrypt any unencrypted tables.
 - See [Data-at-Rest Encryption](#) and [InnoDB Encryption Keys: Key Rotation](#) for more information.
 - **Commandline:** `--innodb-encryption-rotate-key-age=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `1`
 - **Range:** `0` to `4294967295`
-

`innodb_encryption_rotation_iops`

- **Description:** Use this many iops for background key rotation operations performed by the background encryption threads.
 - See [Data-at-Rest Encryption](#) and [InnoDB Encryption Keys: Key Rotation](#) for more information.
 - **Commandline:** `--innodb-encryption-rotation_iops=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `100`
 - **Range:** `0` to `4294967295`
-

`innodb_encryption_threads`

- **Description:** Number of background encryption threads performing background key rotation and [scrubbing](#). When setting up encryption, this variable must be set to a non-zero value. Otherwise, when you enable encryption through `innodb_encrypt_tables` MariaDB won't be able to automatically encrypt any unencrypted tables. Recommended never be set higher than 255.
 - See [Data-at-Rest Encryption](#) and [InnoDB Background Encryption Threads](#) for more information.
 - **Commandline:** `--innodb-encryption-threads=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `0`
-

- **Range:**
 - 0 to 4294967295 ([=< MariaDB 10.1.45](#), [=< MariaDB 10.2.32](#), [=< MariaDB 10.3.23](#), [=< MariaDB 10.4.13](#), [=< MariaDB 10.5.3](#))
 - 0 to 255 ([=> MariaDB 10.1.46](#), [=> MariaDB 10.2.33](#), [=> MariaDB 10.3.24](#), [=> MariaDB 10.4.14](#), [=> MariaDB 10.5.4](#))
-

`innodb_extra_rsegments`

- **Description:** Removed in XtraDB 5.5 and replaced by [innodb_rollback_segments](#). Usually there is one rollback segment protected by single mutex, a source of contention in high write environments. This option specifies a number of extra user rollback segments. Changing the default will make the data readable by XtraDB only, and is incompatible with InnoDB. After modifying, the server must be slow-shutdown. If there is existing data, it must be dumped before changing, and re-imported after the change has taken effect.
 - **Commandline:** `--innodb-extra-rsegments=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:** 0
 - **Range:** 0 to 126
 - **Removed:** XtraDB 5.5 - replaced by [innodb_rollback_segments](#)
-

`innodb_extra_undoslots`

- **Description:** Usually, InnoDB has 1024 undo slots in its rollback segment, so 1024 transactions can run in parallel. New transactions will fail if all slots are used. Setting this variable to 1 expands the available undo slots to 4072. Not recommended unless you get the `Warning: cannot find a free slot for an undo log` error in the error log, as it makes data files unusable for `ibbackup`, or MariaDB servers not run with this option. See also [undo log](#).
 - **Commandline:** `--innodb-extra-undoslots={0|1}`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
 - **Removed:** XtraDB 5.5
-

`innodb_fake_changes`

- **Description:** From [MariaDB 5.5](#) until [MariaDB 10.1](#), XtraDB-only option that enables the fake changes feature. In [replication](#), setting up or restarting a replica can cause a replication reads to perform more slowly, as MariaDB is single-threaded and needs to read the data before it can execute the queries. This can be speeded up by prefetching threads to warm the server, replaying the statements and then rolling back at commit. This however has an overhead from locking rows only then to undo changes at rollback. Fake changes attempts to reduce this overhead by reading the rows for INSERT, UPDATE and DELETE statements but not updating them. The rollback is then very fast with little or nothing to do. Added as a deprecated and ignored option in [MariaDB 10.2.6](#) (which uses InnoDB as default instead of XtraDB) to allow for easier upgrades. Not present in [MariaDB 10.3](#) and beyond.
 - **Commandline:** `--innodb-fake-changes={0|1}`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
 - **Deprecated:** [MariaDB 10.2.6](#)
 - **Removed:** [MariaDB 10.3.0](#)
-

`innodb_fast_checksum`

- **Description:** Implements a more CPU efficient XtraDB checksum algorithm, useful for write-heavy loads with high I/O. If set to 1 on a server with tables that have been created with it set to 0, reads will be slower, so tables should be recreated (dumped and reloaded). XtraDB will fail to start if set to 0 and there are tables created while set to 1. Replaced with [innodb_checksum_algorithm](#) in [MariaDB 10.0/XtraDB 5.6](#).
 - **Commandline:** `--innodb-fast-checksum={0|1}`
 - **Scope:** Global
 - **Dynamic:** No
-

- **Data Type:** `boolean`
 - **Default Value:** `OFF`
 - **Removed:** [MariaDB 10.0/XtraDB 5.6](#) - replaced with [innodb_checksum_algorithm](#)
-

`innodb_fast_shutdown`

- **Description:** The shutdown mode.
 - `0` - InnoDB performs a slow shutdown, including full purge (before [MariaDB 10.3.6](#), not always, due to [MDEV-13603](#)) and change buffer merge. Can be very slow, even taking hours in extreme cases.
 - `1` - the default, InnoDB performs a fast shutdown, not performing a full purge or an insert buffer merge.
 - `2`, the [InnoDB redo log](#) is flushed and a cold shutdown takes place, similar to a crash. The resulting startup then performs crash recovery. Extremely fast, in cases of emergency, but risks corruption. Not suitable for upgrades between major versions!
 - `3` (from [MariaDB 10.3.6](#)) - active transactions will not be rolled back, but all changed pages will be written to data files. The active transactions will be rolled back by a background thread on a subsequent startup. The fastest option that will not involve [InnoDB redo log](#) apply on subsequent startup. See [MDEV-15832](#).
 - **Commandline:** `--innodb-fast-shutdown[=#]`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `1`
 - **Range:** `0` to `3` ([>= MariaDB 10.3.6](#)), `0` to `2` ([<= MariaDB 10.3.5](#))
-

`innodb_fatal_semaphore_wait_threshold`

- **Description:** In MariaDB, the fatal semaphore timeout is configurable. This variable sets the maximum number of seconds for semaphores to time out in InnoDB.
 - **Commandline:** `--innodb-fatal-semaphore-wait-threshold=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:** `600`
 - **Range:** `1` to `4294967295`
-

`innodb_file_format`

- **Description:** File format for new InnoDB tables. Can either be `Antelope`, the default and the original format, or `Barracuda`, which supports [compression](#). Note that this value is also used when a table is re-created with an `ALTER TABLE` which requires a table copy. See [XtraDB/InnoDB File Format](#) for more on the file formats. Removed in 10.3.1 and restored as a deprecated and unused variable in 10.4.3 for compatibility purposes.
 - **Commandline:** `--innodb-file-format=value`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `string`
 - **Default Value:**
 - `Barracuda`
 - **Valid Values:** `Antelope`, `Barracuda`
 - **Deprecated:** [MariaDB 10.2](#)
 - **Removed:** [MariaDB 10.3.1](#)
 - **Re-introduced:** [MariaDB 10.4.3](#) (for compatibility purposes)
 - **Removed:** [MariaDB 10.6.0](#)
-

`innodb_file_format_check`

- **Description:** If set to `1`, the default, InnoDB checks the shared tablespace file format tag. If this is higher than the current version supported by XtraDB/InnoDB (for example `Barracuda` when only `Antelope` is supported), XtraDB/InnoDB will not start. If the value is not higher, XtraDB/InnoDB starts correctly and the [innodb_file_format_max](#) value is set to this value. If `innodb_file_format_check` is set to `0`, no checking is performed. See [XtraDB/InnoDB File Format](#) for more on the file formats.
 - **Commandline:** `--innodb-file-format-check={0|1}`
 - **Scope:** Global
-

- **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `ON`
 - **Deprecated:** [MariaDB 10.2](#)
 - **Removed:** [MariaDB 10.3.1](#) 
-

`innodb_file_format_max`

- **Description:** The highest [XtraDB/InnoDB](#) file format. This is set to the value of the file format tag in the shared tablespace on startup (see [innodb_file_format_check](#)). If the server later creates a higher table format, `innodb_file_format_max` is set to that value. See [XtraDB/InnoDB File Format](#) for more on the file formats.
 - **Commandline:** `--innodb-file-format-max=value`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `string`
 - **Default Value:** `Antelope`
 - **Valid Values:** `Antelope`, `Barracuda`
 - **Deprecated:** [MariaDB 10.2](#)
 - **Removed:** [MariaDB 10.3.1](#) 
-

`innodb_file_per_table`

- **Description:** If set to `ON`, then new [InnoDB](#) tables are created with their own [InnoDB file-per-table tablespaces](#). If set to `OFF`, then new tables are created in the [InnoDB system tablespace](#) instead. [Page compression](#) is only available with file-per-table tablespaces. Note that this value is also used when a table is re-created with an [ALTER TABLE](#) which requires a table copy. Deprecated in [MariaDB 11.0](#) as there's no benefit to setting to `OFF`, the original InnoDB default.
 - **Commandline:** `--innodb-file-per-table`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `ON`
 - **Deprecated:** [MariaDB 11.0.1](#) 
-

`innodb_fill_factor`

- **Description:** Percentage of B-tree page filled during bulk insert (sorted index build). Used as a hint rather than an absolute value. Setting to `70`, for example, reserves 30% of the space on each B-tree page for the index to grow in future.
 - **Commandline:** `--innodb-fill-factor=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `100`
 - **Range:** `10` to `100`
-

`innodb_flush_log_at_timeout`

- **Description:** Interval in seconds to write and flush the [InnoDB redo log](#). Before [MariaDB 10](#), this was fixed at one second, which is still the default, but this can now be changed. It's usually increased to reduce flushing and avoid impacting performance of binary log group commit.
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `1`
 - **Range:** `0` to `2700`
-

`innodb_flush_log_at_trx_commit`

- **Description:** Set to `1`, along with [sync_binlog=1](#) for the greatest level of fault tolerance. The value of

`innodb_use_global_flush_log_at_trx_commit` determines whether this variable can be reset with a SET statement or not.

- 1 The default, the log buffer is written to the [InnoDB redo log](#) file and a flush to disk performed after each transaction. This is required for full ACID compliance.
 - 0 Nothing is done on commit; rather the log buffer is written and flushed to the [InnoDB redo log](#) once a second. This gives better performance, but a server crash can erase the last second of transactions.
 - 2 The log buffer is written to the [InnoDB redo log](#) after each commit, but flushing takes place every `innodb_flush_log_at_timeout` seconds (by default once a second). Performance is slightly better, but a OS or power outage can cause the last second's transactions to be lost.
 - 3 Emulates [MariaDB 5.5 group commit](#) (3 syncs per group commit). See [Binlog group commit and innodb_flush_log_at_trx_commit](#). This option has not been working correctly since 10.2 and may be removed in future, see <https://github.com/MariaDB/server/pull/1873>
- **Commandline:** `--innodb-flush-log-at-trx-commit[=#]`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** enumeration
 - **Default Value:** 1
 - **Valid Values:** 0, 1, 2 or 3

`innodb_flush_method`

- **Description:** [InnoDB](#) flushing method. Windows always uses `async_unbuffered` and this variable then has no effect. On Unix, before [MariaDB 10.6.0](#), by default `fsync()` is used to flush data and logs. Adjusting this variable can give performance improvements, but behavior differs widely on different filesystems, and changing from the default has caused problems in some situations, so test and benchmark carefully before adjusting. In [MariaDB](#), Windows recognises and correctly handles the Unix methods, but if none are specified it uses own default - unbuffered write (analog of `O_DIRECT`) + syncs (e.g `FileFlushBuffers()`) for all files.
 - `O_DSYNC` - `O_DSYNC` is used to open and flush logs, and `fsync()` to flush the data files.
 - `O_DIRECT` - `O_DIRECT` or `directio()`, is used to open data files, and `fsync()` to flush data and logs. Default on Unix from [MariaDB 10.6.0](#).
 - `fsync` - Default on Unix until [MariaDB 10.5](#). Can be specified directly, but if the variable is unset on Unix, `fsync()` will be used by default.
 - `O_DIRECT_NO_FSYNC` - introduced in [MariaDB 10.0](#). Uses `O_DIRECT` during flushing I/O, but skips `fsync()` afterwards. Not suitable for XFS filesystems. Generally not recommended over `O_DIRECT`, as does not get the benefit of `innodb_use_native_aio=ON`.
 - `ALL_O_DIRECT` - introduced in [MariaDB 5.5](#) and available with XtraDB only. Uses `O_DIRECT` for opening both data and logs and `fsync()` to flush data but not logs. Use with large InnoDB files only, otherwise may cause a performance degradation. Set `innodb_log_block_size` to 4096 on ext4 filesystems. This is the default log block size on ext4 and will avoid unaligned AIO/DIO warnings.
 - `unbuffered` - Windows-only default
 - `async_unbuffered` - Windows-only, alias for `unbuffered`
 - `normal` - Windows-only, alias for `fsync`
 - `littlesync` - for internal testing only
 - `nosync` - for internal testing only
- Deprecated in [MariaDB 11.0](#) and replaced by four boolean dynamic variables that can be changed while the server is running: `innodb_log_file_buffering` (disable `O_DIRECT`, added by [MDEV-28766](#) in 10.8.4, 10.9.2), `innodb_data_file_buffering` (disable `O_DIRECT` on data files), `innodb_log_file_write_through` (enable `O_DSYNC` on the log), `innodb_data_file_write_through` (enable `O_DSYNC` on persistent data files)

From [MariaDB 11.0](#), if set to one of the following values, then the values of the four boolean flags will be set as follows:

- `O_DSYNC` : `innodb_log_file_write_through=ON`, `innodb_data_file_write_through=ON`, `innodb_data_file_buffering=OFF`, and (if supported) `innodb_log_file_buffering=OFF`.
 - `fsync`, `littlesync`, `nosync`, or (Microsoft Windows specific) `normal` : `innodb_log_file_write_through=OFF`, `innodb_data_file_write_through=OFF`, and `innodb_data_file_buffering=ON`.
- **Commandline:** `--innodb-flush-method=name`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** enumeration (`>= MariaDB 10.3.7`), string (`<= MariaDB 10.3.6`)
 - **Default Value:**
 - `O_DIRECT` (Unix, `>= MariaDB 10.6.0`)
 - `fsync` (Unix, `>= MariaDB 10.3.7`, `<= MariaDB 10.5`)
 - Not set (`<= MariaDB 10.3.6`)
 - **Valid Values:**

- Unix: `fsync`, `O_DSYNC`, `littlesync`, `nosync`.`O_DIRECT`, `O_DIRECT_NO_FSYNC`
 - Windows: `unbuffered`, `async_unbuffered`, `normal`
 - **Deprecated:** [MariaDB 11.0](#)
-

`innodb_flush_neighbor_pages`

- **Description:** Determines whether, when dirty pages are flushed to the data file, neighboring pages in the data file are flushed at the same time. If set to `none`, the feature is disabled. If set to `area`, the default, the standard InnoDB behavior is used. For each page to be flushed, dirty neighboring pages are flushed too. If there's little head seek delay, such as SSD or large enough write buffer, one of the other two options may be more efficient. If set to `cont`, for each page to be flushed, neighboring contiguous blocks are flushed at the same time. Being contiguous, a sequential I/O is used, unlike the random I/O used in `area`. Replaced by `innodb_flush_neighbors` in [MariaDB 10.0/XtraDB 5.6](#).
 - **Commandline:** `innodb-flush-neighbor-pages=value`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `enumeration`
 - **Default Value:** `area`
 - **Valid Values:** `none` or `0`, `area` or `1`, `cont` or `2`
 - **Removed:** [MariaDB 10.0/XtraDB 5.6](#) - replaced by `innodb_flush_neighbors`
-

`innodb_flush_neighbors`

- **Description:** Determines whether flushing a page from the [buffer pool](#) will flush other dirty pages in the same group of pages (extent). In high write environments, if flushing is not aggressive enough, it can fall behind resulting in higher memory usage, or if flushing is too aggressive, cause excess I/O activity. SSD devices, with low seek times, would be less likely to require dirty neighbor flushing to be set. Since [MariaDB 10.4.4](#) an attempt is made under Windows and Linux to determine SSD status which was exposed in [information_schema.innodb_tablespace_scrubbing_table](#). This variable is ignored for table spaces that are detected as stored on SSD (and the `0` behavior applies).
 - `1`: The default, flushes contiguous dirty pages in the same extent from the buffer pool.
 - `0`: No other dirty pages are flushed.
 - `2`: Flushes dirty pages in the same extent from the buffer pool.
 - **Commandline:** `--innodb-flush-neighbors=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `enumeration`
 - **Default Value:** `1`
 - **Valid Values:** `0`, `1`, `2`
-

`innodb_flush_sync`

- **Description:** If set to `ON`, the default, the [innodb_io_capacity](#) setting is ignored for I/O bursts occurring at checkpoints.
 - **Commandline:** `--innodb-flush-sync={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `ON`
-

`innodb_flushing_avg_loops`

- **Description:** Determines how quickly adaptive flushing will respond to changing workloads. The value is the number of iterations that a previously calculated flushing state snapshot is kept. Increasing the value smooths and slows the rate that the flushing operations change, while decreasing it causes flushing activity to spike quickly in response to workload changes.
 - **Commandline:** `--innodb-flushing-avg-loops=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `30`
 - **Range:** `1` to `1000`
-

innodb_force_load_corrupted

- **Description:** Set to `0` by default, if set to `1`, [InnoDB](#) will be permitted to load tables marked as corrupt. Only use this to recover data you can't recover any other way, or in troubleshooting. Always restore to `0` when the returning to regular use. Given that [MDEV-11412](#) in [MariaDB 10.5.4](#) aims to allow any metadata for a missing or corrupted table to be dropped, and given that [MDEV-17567](#) and [MDEV-25506](#) and related tasks made DDL operations crash-safe, the parameter no longer serves any purpose and was removed in [MariaDB 10.6.6](#).
 - **Commandline:** `--innodb-force-load-corrupted`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
 - **Removed:** [MariaDB 10.6.6](#)
-

innodb_force_primary_key

- **Description:** If set to `1` (`0` is default) CREATE TABLEs without a primary or unique key where all keyparts are NOT NULL will not be accepted, and will return an error.
 - **Commandline:** `--innodb-force-primary-key`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
-

innodb_force_recovery

- **Description:** [InnoDB](#) crash recovery mode. `0` is the default. The other modes are for recovery purposes only, and no data can be changed while another mode is active. Some queries relying on indexes are also blocked. See [InnoDB Recovery Modes](#) for more on mode specifics.
 - **Commandline:** `--innodb-force-recovery=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `enumeration`
 - **Default Value:** `0`
 - **Range:** `0` to `6`
-

innodb_foreground_preflush

- **Description:** Before XtraDB 5.6.13-61.0, if the checkpoint age is in the sync preflush zone while a thread is writing to the [XtraDB redo log](#), it will try to advance the checkpoint by issuing a flush list flush batch if this is not already being done. XtraDB has enhanced page cleaner tuning, and may already be performing furious flushing, resulting in the flush simply adding unneeded mutex pressure. Instead, the thread now waits for the flushes to finish, and then has two options, controlled by this variable. XtraDB only. Added as a deprecated and ignored option in [MariaDB 10.2.6](#) (which uses InnoDB as default instead of XtraDB) to allow for easier upgrades.
 - `exponential_backoff` - thread sleeps while it waits for the flush list flush to occur. The sleep time randomly progressively increases, periodically reset to avoid runaway sleeps.
 - `sync_preflush` - thread issues a flush list batch, and waits for it to complete. This is the same as is used when the page cleaner thread is not running.
 - **Commandline:** `innodb-foreground-preflush=value`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `enum`
 - **Default Value:**
 - `deprecated`
 - **Valid Values:**
 - `deprecated`, `exponential_backoff`, `sync_preflush`
 - **Deprecated:** [MariaDB 10.2.6](#)
 - **Removed:** [MariaDB 10.3.0](#)
-

innodb_ft_aux_table

- **Description:** Diagnostic variable intended only to be set at runtime. It specifies the qualified name (for example `test/ft_innodb`) of an InnoDB table that has a [FULLTEXT index](#), and after being set the `INFORMATION_SCHEMA` tables [INNODB_FT_INDEX_TABLE](#), [INNODB_FT_INDEX_CACHE](#), [INNODB_FT_CONFIG](#), [INNODB_FT_DELETED](#), and [INNODB_FT_BEING_DELETED](#) will contain search index information for the specified table.
 - **Commandline:** `--innodb-ft-aux-table=value`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `string`
-

`innodb_ft_cache_size`

- **Description:** Cache size available for a parsed document while creating an InnoDB [FULLTEXT index](#).
 - **Commandline:** `--innodb-ft-cache-size=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:** `8000000`
-

`innodb_ft_enable_diag_print`

- **Description:** If set to `1`, additional [full-text](#) search diagnostic output is enabled.
 - **Commandline:** `--innodb-ft-enable-diag-print={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
-

`innodb_ft_enable_stopword`

- **Description:** If set to `1`, the default, a set of [stopwords](#) is associated with an InnoDB [FULLTEXT index](#) when it is created. The stopword list comes from the table set by the session variable [innodb_ft_user_stopword_table](#), if set, otherwise the global variable [innodb_ft_server_stopword_table](#), if that is set, or the [built-in list](#) if neither variable is set.
 - **Commandline:** `--innodb-ft-enable-stopword={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `ON`
-

`innodb_ft_max_token_size`

- **Description:** Maximum length of words stored in an InnoDB [FULLTEXT index](#). A larger limit will increase the size of the index, slowing down queries, but permit longer words to be searched for. In most normal situations, longer words are unlikely search terms.
 - **Commandline:** `--innodb-ft-max-token-size=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:** `84`
 - **Range:** `10` to `84`
-

`innodb_ft_min_token_size`

- **Description:** Minimum length of words stored in an InnoDB [FULLTEXT index](#). A smaller limit will increase the size of the index, slowing down queries, but permit shorter words to be searched for. For data stored in a Chinese, Japanese or Korean [character set](#), a value of `1` should be specified to preserve functionality.
- **Commandline:** `--innodb-ft-min-token-size=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`

- **Default Value:** 3
 - **Range:** 0 to 16
-

`innodb_ft_num_word_optimize`

- **Description:** Number of words processed during each [OPTIMIZE TABLE](#) on an InnoDB [FULLTEXT index](#). To ensure all changes are incorporated, multiple `OPTIMIZE TABLE` statements could be run in case of a substantial change to the index.
 - **Commandline:** `--innodb-ft-num-word-optimize=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** 2000
 - **Range:** 1000 to 10000
-

`innodb_ft_result_cache_limit`

- **Description:** Limit in bytes of the InnoDB [FULLTEXT index](#) query result cache per fulltext query. The latter stages of the full-text search are handled in memory, and limiting this prevents excess memory usage. If the limit is exceeded, the query returns an error.
 - **Commandline:** `--innodb-ft-result-cache-limit=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** 2000000000
 - **Range:** 1000000 to 18446744073709551615
-

`innodb_ft_server_stopword_table`

- **Description:** Table name containing a list of stopwords to ignore when creating an InnoDB [FULLTEXT index](#), in the format `db_name/table_name`. The specified table must exist before this option is set, and must be an InnoDB table with a single column, a [VARCHAR](#) named `VALUE`. See also [innodb_ft_enable_stopword](#).
 - **Commandline:** `--innodb-ft-server-stopword-table=db_name/table_name`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `string`
 - **Default Value:** Empty
-

`innodb_ft_sort_pll_degree`

- **Description:** Number of parallel threads used when building an InnoDB [FULLTEXT index](#). See also [innodb_sort_buffer_size](#).
 - **Commandline:** `--innodb-ft-sort-pll-degree=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:** 2
 - **Range:** 1 to 32
-

`innodb_ft_total_cache_size`

- **Description:** Total memory allocated for the cache for all InnoDB [FULLTEXT index](#) tables. A force sync is triggered if this limit is exceeded.
 - **Commandline:** `--innodb-ft-total-cache-size=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:** 640000000
 - **Range:** 32000000 to 1600000000
 - **Introduced:** [MariaDB 10.0.9](#) 
-

innodb_ft_user_stopword_table

- **Description:** Table name containing a list of stopwords to ignore when creating an InnoDB [FULLTEXT index](#), in the format `db_name/table_name`. The specified table must exist before this option is set, and must be an InnoDB table with a single column, a [VARCHAR](#) named `VALUE`. See also [innodb_ft_enable_stopword](#).
 - **Commandline:** `--innodb-ft-user-stopword-table=db_name/table_name`
 - **Scope:** Session
 - **Dynamic:** Yes
 - **Data Type:** `string`
 - **Default Value:** Empty
-

innodb_ibuf_accel_rate

- **Description:** Allows the insert buffer activity to be adjusted. The following formula is used: $[\text{real activity}] = [\text{default activity}] * (\text{innodb_io_capacity}/100) * (\text{innodb_ibuf_accel_rate}/100)$. As `innodb_ibuf_accel_rate` is increased from its default value of `100`, the lowest setting, insert buffer activity is increased. See also [innodb_io_capacity](#). This Percona XtraDB variable has not been ported to XtraDB 5.6.
 - **Commandline:** `innodb-ibuf-accel-rate=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `100`
 - **Range:** `100` to `9999999999`
 - **Removed:** [MariaDB 10.0](#)
-

innodb_ibuf_active_contract

- **Description:** Specifies whether the insert buffer can be processed before it's full. If set to `0`, the standard InnoDB method is used, and the buffer is not processed until it's full. If set to `1`, the default, the insert buffer can be processed before it is full. This Percona XtraDB variable has not been ported to XtraDB 5.6.
 - **Commandline:** `innodb-ibuf-active-contract=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `1`
 - **Range:** `0` to `1`
 - **Removed:** [MariaDB 10.0](#)
-

innodb_ibuf_max_size

- **Description:** Maximum size in bytes of the insert buffer. Defaults to half the size of the [buffer pool](#) so you may want to reduce if you have a very large buffer pool. If set to `0`, the insert buffer is disabled, which will cause all secondary index updates to be performed synchronously, usually at a cost to performance. This Percona XtraDB variable has not been ported to XtraDB 5.6.
 - **Commandline:** `innodb-ibuf-max-size=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:** 1/2 the size of the InnoDB buffer pool
 - **Range:** `0` to 1/2 the size of the InnoDB buffer pool
 - **Removed:** [MariaDB 10.0](#)
-

innodb_idle_flush_pct

- **Description:** Up to what percentage of dirty pages should be flushed when innodb finds it has spare resources to do so. Has had no effect since merging InnoDB 5.7 from mysql-5.7.9 ([MariaDB 10.2.2](#) [↗](#)). Deprecated in [MariaDB 10.2.37](#) [↗](#), [MariaDB 10.3.28](#) [↗](#), [MariaDB 10.4.18](#) [↗](#) and removed in [MariaDB 10.5.9](#).
 - **Commandline:** `--innodb-idle-flush-pct=#`
 - **Scope:** Global
 - **Dynamic:** Yes
-

- **Data Type:** numeric
 - **Default Value:** 100
 - **Range:** 0 to 100
 - **Deprecated:** [MariaDB 10.2.37](#), [MariaDB 10.3.28](#), [MariaDB 10.4.18](#)
 - **Removed:** [MariaDB 10.5.9](#)
-

innodb_immediate_scrub_data_uncompressed

- **Description:** Enable scrubbing of data. See [Data Scrubbing](#).
 - **Commandline:** `--innodb-immediate-scrub-data-uncompressed={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** boolean
 - **Default Value:** OFF
-

innodb_import_table_from_xtrabackup

- **Description:** If set to 1, permits importing of .ibd files exported with the [XtraBackup](#) `--export` option. Previously named `innodb_expand_import`. Removed in [MariaDB 10.0/XtraDB 5.6](#) and replaced with MySQL 5.6's transportable tablespaces.
 - **Commandline:** `innodb-import-table-from-xtrabackup=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** numeric
 - **Default Value:** 0
 - **Range:** 0 to 1
 - **Removed:** [MariaDB 10.0](#)
-

innodb_instant_alter_column_allowed

- **Description:**
 - If a table is altered using `ALGORITHM=INSTANT`, it can force the table to use a non-canonical format: A hidden metadata record at the start of the clustered index is used to store each column's `DEFAULT` value. This makes it possible to add new columns that have default values without rebuilding the table. Starting with [MariaDB 10.4](#), a BLOB in the hidden metadata record is used to store column mappings. This makes it possible to drop or reorder columns without rebuilding the table. This also makes it possible to add columns to any position or drop columns from any position in the table without rebuilding the table. If a column is dropped without rebuilding the table, old records will contain garbage in that column's former position, and new records will be written with `NULL` values, empty strings, or dummy values.
 - This is generally not a problem. However, there may be cases where you want to avoid putting a table into this format. For example, to ensure that future `UPDATE` operations after an `ADD COLUMN` will be performed in-place, to reduce write amplification. (Instantly added columns are essentially always variable-length.) Also avoid bugs similar to [MDEV-19916](#), or to be able to export tables to older versions of the server.
 - This variable has been introduced as a result, with the following values:
 - `never` (0): Do not allow instant add/drop/reorder, to maintain format compatibility with MariaDB 10.x and MySQL 5.x. If the table (or partition) is not in the canonical format, then any `ALTER TABLE` (even one that does not involve instant column operations) will force a table rebuild.
 - `add_last` (1, default in 10.3): Store a hidden metadata record that allows columns to be appended to the table instantly ([MDEV-11369](#)). In 10.4 or later, if the table (or partition) is not in this format, then any `ALTER TABLE` (even one that does not involve column changes) will force a table rebuild.
 - `add_drop_reorder` (2, default): From [MariaDB 10.4](#) only. Like 'add_last', but allow the metadata record to store a column map, to support instant add/drop/reorder of columns.
- **Commandline:** `--innodb-instant-alter-column-allowed=value`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** enum
- **Valid Values:**
 - `<= MariaDB 10.3:` `never`, `add_last`
 - `>= MariaDB 10.4:` `never`, `add_last`, `add_drop_reorder`
- **Default Value:**
 - `<= MariaDB 10.3:` `add_last`
 - `>= MariaDB 10.4:` `add_drop_reorder`

- **Introduced:** [MariaDB 10.3.23](#), [MariaDB 10.4.13](#), [MariaDB 10.5.3](#)

`innodb_instrument_semaphores`

- **Description:** Enable semaphore request instrumentation. This could have some effect on performance but allows better information on long semaphore wait problems.
- **Commandline:** `--innodb-instrument-semaphores={0|1}`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `OFF`
- **Deprecated:** [MariaDB 10.2.5](#) (treated as if `OFF`)
- **Removed:** [MariaDB 10.3.0](#)

`innodb_io_capacity`

- **Description:** Limit on I/O activity for InnoDB background tasks, including merging data from the insert buffer and flushing pages. Should be set to around the number of I/O operations per second that system can handle, based on the type of drive/s being used. You can also set it higher when the server starts to help with the extra workload at that time, and then reduce for normal use. Ideally, opt for a lower setting, as at higher value data is removed from the buffers too quickly, reducing the effectiveness of caching. See also [innodb_flush_sync](#).
 - See [InnoDB Page Flushing: Configuring the InnoDB I/O Capacity](#) for more information.
- **Commandline:** `--innodb-io-capacity=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `200`
- **Range:** `100` to `18446744073709551615` ($2^{64}-1$)

`innodb_io_capacity_max`

- **Description:** Upper limit to which InnoDB can extend [innodb_io_capacity](#) in case of emergency. See [InnoDB Page Flushing: Configuring the InnoDB I/O Capacity](#) for more information.
- **Commandline:** `--innodb-io-capacity-max=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `2000` or twice [innodb_io_capacity](#), whichever is higher.
- **Range :** `100` to `18446744073709551615` ($2^{64}-1$)

`innodb_kill_idle_transaction`

- **Description:** Time in seconds before killing an idle XtraDB transaction. If set to `0` (the default), the feature is disabled. Used to prevent accidental user locks. XtraDB only. Added as a deprecated and ignored option in [MariaDB 10.2.6](#) (which uses InnoDB as default instead of XtraDB) to allow for easier upgrades.
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `0`
- **Range:** `0` to `9223372036854775807`
- **Deprecated:** [MariaDB 10.2.6](#)
- **Removed:** [MariaDB 10.3.0](#)

`innodb_large_prefix`

- **Description:** If set to `1`, tables that use specific [row formats](#) are permitted to have index key prefixes up to 3072 bytes (for 16k pages, [smaller otherwise](#)). If not set, the limit is 767 bytes.
 - This applies to the `DYNAMIC` and `COMPRESSED` row formats.
 - Removed in 10.3.1 and restored as a deprecated and unused variable in 10.4.3 for compatibility purposes.
- **Commandline:** `--innodb-large-prefix`

- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:**
 - ON
- **Deprecated:** [MariaDB 10.2](#)
- **Removed:** [MariaDB 10.3.1](#) [↗](#)
- **Re-introduced:** [MariaDB 10.4.3](#) [↗](#) (for compatibility purposes)
- **Removed:** [MariaDB 10.6.0](#)

`innodb_lazy_drop_table`

- **Description:** Deprecated and removed in XtraDB 5.6. [DROP TABLE](#) processing can take a long time when [innodb_file_per_table](#) is set to 1 and there's a large [buffer pool](#). If `innodb_lazy_drop_table` is set to 1 (0 is default), XtraDB attempts to optimize [DROP TABLE](#) processing by deferring the dropping of related pages from the [buffer pool](#) until there is time, only initially marking them.
- **Commandline:** `innodb-lazy-drop-table={0|1}`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** 0
- **Deprecated:** XtraDB 5.5.30-30.2
- **Removed:** [MariaDB 10.0.0](#) [↗](#)

`innodb_lock_schedule_algorithm`

- **Description:** Removed in [MariaDB 10.6.0](#) due to problems with the VATS implementation ([MDEV-16664](#) [↗](#)). Specifies the algorithm that InnoDB uses to decide which of the waiting transactions should be granted the lock once it has been released. The possible values are: `FCFS` (First-Come-First-Served) where locks are granted in the order they appear in the lock queue and `VATS` (Variance-Aware-Transaction-Scheduling) where locks are granted based on the Eldest-Transaction-First heuristic. Note that `VATS` should not be used with [Galera](#), and InnoDB will refuse to start if `VATS` is used with Galera. It is also not recommended to set to `VATS` even in the general case ([MDEV-16664](#) [↗](#)). From [MariaDB 10.2.12](#) [↗](#), the value was changed to `FCFS` and a warning produced when using Galera.
- **Commandline:** `--innodb-lock-schedule-algorithm=#`
- **Scope:** Global
- **Dynamic:** No (\geq [MariaDB 10.2.12](#) [↗](#), [MariaDB 10.1.30](#) [↗](#)), Yes (\leq [MariaDB 10.2.11](#) [↗](#), [MariaDB 10.1.29](#) [↗](#))
- **Data Type:** `enum`
- **Valid Values:** `FCFS`, `VATS`
- **Default Value:** `FCFS` ([MariaDB 10.3.9](#) [↗](#), [MariaDB 10.2.17](#) [↗](#)), `VATS` ([MariaDB 10.2.3](#) [↗](#)), `FCFS` ([MariaDB 10.1](#))
- **Deprecated:** [MariaDB 10.5.7](#), [MariaDB 10.4.16](#) [↗](#), [MariaDB 10.3.26](#) [↗](#), [MariaDB 10.2.35](#) [↗](#)
- **Removed:** [MariaDB 10.6.0](#)

`innodb_lock_wait_timeout`

- **Description:** Time in seconds that an InnoDB transaction waits for an InnoDB record lock (or table lock) before giving up with the error `ERROR 1205 (HY000): Lock wait timeout exceeded; try restarting transaction`. When this occurs, the statement (not transaction) is rolled back. The whole transaction can be rolled back if the [innodb_rollback_on_timeout](#) option is used. Increase this for data warehousing applications or where other long-running operations are common, or decrease for OLTP and other highly interactive applications. This setting does not apply to deadlocks, which InnoDB detects immediately, rolling back a deadlocked transaction. 0 means no wait. See [WAIT and NOWAIT](#). Setting to 100000000 or more (from [MariaDB 10.6.3](#), 100000000 is the maximum) means the timeout is infinite.
- **Commandline:** `--innodb-lock-wait-timeout=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `INT UNSIGNED` (\geq [MariaDB 10.6.3](#)), `BIGINT UNSIGNED` (\leq [MariaDB 10.6.2](#))
- **Default Value:** 50
- **Range:**
 - 0 to 100000000 (\geq [MariaDB 10.6.3](#))
 - 0 to 1073741824 (\geq [MariaDB 10.3](#) to \leq [MariaDB 10.6.2](#))

innodb_locking_fake_changes

- **Description:** From [MariaDB 5.5](#) to [MariaDB 10.1](#), XtraDB-only option that if set to `OFF`, fake transactions (see [innodb_fake_changes](#)) don't take row locks. This is an experimental feature to attempt to deal with drawbacks in fake changes blocking real locks. It is not safe for use in all environments. Added as a deprecated and ignored option in [MariaDB 10.2.6](#) (which uses InnoDB as default instead of XtraDB) to allow for easier upgrades.
 - **Commandline:** `--innodb-locking-fake-changes`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `ON`
 - **Deprecated:** [MariaDB 10.2.6](#)
 - **Removed:** [MariaDB 10.3.0](#)
-

innodb_locks_unsafe_for_binlog

- **Description:** Set to `0` by default, in which case XtraDB/InnoDB uses [gap locking](#). If set to `1`, gap locking is disabled for searches and index scans. Deprecated in [MariaDB 10.0](#), and removed in [MariaDB 10.5](#), use [READ COMMITTED transaction isolation level](#) instead.
 - **Commandline:** `--innodb-locks-unsafe-for-binlog`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
 - **Deprecated:** [MariaDB 10.0](#)
 - **Removed:** [MariaDB 10.5.0](#)
-

innodb_log_arch_dir

- **Description:** The directory for [XtraDB redo log](#) archiving. XtraDB only. Added as a deprecated and ignored option in [MariaDB 10.2.6](#) (which uses InnoDB as default instead of XtraDB) to allow for easier upgrades.
 - **Commandline:** `--innodb-log-arch-dir=name`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `string`
 - **Default Value:** `./`
 - **Deprecated:** [MariaDB 10.2.6](#)
 - **Removed:** [MariaDB 10.3.0](#)
-

innodb_log_arch_expire_sec

- **Description:** Time in seconds since the last change after which the archived [XtraDB redo log](#) should be deleted. XtraDB only. Added as a deprecated and ignored option in [MariaDB 10.2.6](#) (which uses InnoDB as default instead of XtraDB) to allow for easier upgrades.
 - **Commandline:** `--innodb-log-arch-expire-sec=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `0`
 - **Deprecated:** [MariaDB 10.2.6](#)
 - **Removed:** [MariaDB 10.3.0](#)
-

innodb_log_archive

- **Description:** Whether or not [XtraDB redo log](#) archiving is enabled. XtraDB only. Added as a deprecated and ignored option in [MariaDB 10.2.6](#) (which uses InnoDB as default instead of XtraDB) to allow for easier upgrades.
 - **Commandline:** `--innodb-log-archive={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
-

- **Deprecated:** [MariaDB 10.2.6](#)
- **Removed:** [MariaDB 10.3.0](#)

innodb_log_block_size

- **Description:** Size in bytes of the [XtraDB redo log](#) records. Generally `512`, the default, or `4096`, are the only two useful values. If the server is restarted and this value is changed, all old log files need to be removed. Should be set to `4096` for SSD cards or if `innodb_flush_method` is set to `ALL_O_DIRECT` on ext4 filesystems. XtraDB only. Added as a deprecated and ignored option in [MariaDB 10.2.6](#) (which uses InnoDB as default instead of XtraDB) to allow for easier upgrades.
- **Commandline:** `innodb-log-block-size=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `512`
- **Deprecated:** [MariaDB 10.2.6](#)
- **Removed:** [MariaDB 10.3.0](#)

innodb_log_buffer_size

- **Description:** Size in bytes of the buffer for writing [InnoDB redo log](#) files to disk. Increasing this means larger transactions can run without needing to perform disk I/O before committing.
- **Commandline:** `--innodb-log-buffer-size=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `16777216` (16MB)
- **Range:** `262144` to `2147479552` (256KB to 2GB - 4K) (`>=` [MariaDB 10.11.8](#))
- **Range:** `262144` to `18446744073709551615` (`<=` [MariaDB 10.11.7](#)) - limit to the above maximum because this is an operating system limit.
- **Block size:** `4096`

innodb_log_checksum_algorithm

- **Description:** Experimental feature (as of [MariaDB 10.0.9](#)), this variable specifies how to generate and verify [XtraDB redo log](#) checksums. XtraDB only. Added as a deprecated and ignored option in [MariaDB 10.2.6](#) (which uses InnoDB as default instead of XtraDB) to allow for easier upgrades.
 - `none` - No checksum. A constant value is instead written to logs, and no checksum validation is performed.
 - `innodb` - The default, and the original InnoDB algorithm. This is inefficient, but compatible with all MySQL, MariaDB and Percona versions that don't support other checksum algorithms.
 - `crc32` - CRC32© is used for log block checksums, which also permits recent CPUs to use hardware acceleration (on SSE4.2 x86 machines and Power8 or later) for the checksums.
 - `strict_*` - Whether or not to accept checksums from other algorithms. If strict mode is used, checksums blocks will be considered corrupt if they don't match the specified algorithm. Normally they are considered corrupt only if no other algorithm matches.
- **Commandline:** `innodb-log-checksum-algorithm=value`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `enum`
- **Default Value:**
 - `deprecated` (`>=` [MariaDB 10.2.6](#))
 - `innodb` (`<=` [MariaDB 10.1](#))
- **Valid Values:**
 - `deprecated`, `innodb`, `none`, `crc32`, `strict_none`, `strict_innodb`, `strict_crc32` (`>=` [MariaDB 10.2.6](#))
 - `innodb`, `none`, `crc32`, `strict_none`, `strict_innodb`, `strict_crc32` (`<=` [MariaDB 10.1](#))
- **Deprecated:** [MariaDB 10.2.6](#)
- **Removed:** [MariaDB 10.3.0](#)

innodb_log_checksums

- **Description:** If set to `1`, the CRC32C for InnoDB or `innodb_log_checksum_algorithm` for XtraDB algorithm is used for [InnoDB redo log](#) pages. If disabled, the checksum field contents are ignored. From [MariaDB 10.5.0](#), the variable is deprecated, and checksums are always calculated, as previously, the InnoDB redo log used the slow `innodb` algorithm, but with hardware or SIMD assisted CRC-32C computation being available, there is no reason to allow checksums to be disabled on the redo log.
 - **Commandline:** `innodb-log-checksums={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `ON`
 - **Deprecated:** [MariaDB 10.5.0](#)
 - **Removed:** [MariaDB 10.6.0](#)
-

`innodb_log_compressed_pages`

- **Description:** Whether or not images of recompressed pages are stored in the [InnoDB redo log](#). Deprecated and ignored from [MariaDB 10.5.3](#).
 - **Commandline:** `--innodb-log-compressed-pages={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:**
 - `ON`
 - **Deprecated:** [MariaDB 10.5.3](#)
 - **Removed:** [MariaDB 10.6.0](#)
-

`innodb_log_file_buffering`

- **Description:** Whether the file system cache for `ib_logfile0` is enabled. In [MariaDB 10.8.3](#), MariaDB disabled the file system cache on the InnoDB write-ahead log file (`ib_logfile0`) by default on Linux. With `innodb_flush_trx_log_at_commit=2` in particular, writing to the log via the file system cache typically improves throughput, especially on slow storage or at a small number of concurrent transactions. For other values of `innodb_flush_log_at_trx_commit`, direct writes were observed to be mostly but not always faster. Whether it pays off to disable the file system cache on the log may depend on the type of storage, the workload, and the operating system kernel version. If the server is started up with `innodb_flush_log_at_trx_commit=2`, the value will be changed to `ON`. Will be set to `OFF` if `innodb_flush_method` is set to `O_DSYNC`. On Linux, when the physical block size cannot be determined to be a power of 2 between 64 and 4096 bytes, the file system cache cannot be disabled, and `innodb_log_file_buffering=ON` cannot be changed. Linux and Windows only.
 - **Commandline:** `--innodb-log-file-buffering={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
 - **Introduced:** [MariaDB 10.8.4](#), [MariaDB 10.9.2](#)
-

`innodb_log_file_mmap`

- **Description:** Whether `ib_logfile0` resides in persistent memory or should initially be memory-mapped. When using the default `innodb_log_buffer_size=2m`, `mariadb-backup --backup` would spend a lot of time re-reading and re-parsing the log. For reading the log file during `mariadb-backup --backup`, it is beneficial to memory-map the entire `ib_logfile0` to the address space (typically 48 bits or 256 TiB) and read it from there, both during `--backup` and `--prepare`. `OFF` by default on most platforms, to avoid aggressive read-ahead of the entire `ib_logfile0` in when only a tiny portion would be accessed. On Linux and FreeBSD the default is `innodb_log_file_mmap=ON`, because those platforms define a specific `mmap(2)` option for enabling such read-ahead and therefore it can be assumed that the default would be on-demand paging. This parameter will only have impact on the initial InnoDB startup and recovery. Any writes to the log will use regular I/O, except when the `ib_logfile0` is stored in a specially configured file system that is backed by persistent memory (Linux "mount -o dax").
- **Commandline:** `--innodb-log-file-mmap={0|1}`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `boolean`
- **Default Value:** `ON` (Linux, FreeBSD), `OFF` (Other platforms)
- **Introduced:** [MariaDB 10.11.10](#), [MariaDB 11.2.6](#), [MariaDB 11.4.4](#), [MariaDB 11.6.2](#), [MariaDB 11.7.1](#)

innodb_log_file_size

- **Description:** Size in bytes of each [InnoDB redo log](#) file in the log group. The combined size can be no more than 512GB. Larger values mean less disk I/O due to less flushing checkpoint activity, but also slower recovery from a crash. In [MariaDB 10.5](#), crash recovery has been improved and shouldn't run out of memory, so the default has been increased. It can safely be set higher to reduce checkpoint flushing, even larger than [innodb_buffer_pool_size](#). From [MariaDB 10.9](#) the variable is dynamic, and the server no longer needs to be restarted for the resizing to take place. Unless the log is located in a persistent memory file system (PMEM), an attempt to [SET GLOBAL innodb_log_file_size](#) to less than [innodb_log_buffer_size](#) will be refused. Log resizing can be aborted by killing the connection that is executing the SET GLOBAL statement.
 - **Commandline:** `--innodb-log-file-size=#`
 - **Scope:** Global
 - **Dynamic:** Yes ([>= MariaDB 10.9](#)), No ([<= MariaDB 10.8](#))
 - **Data Type:** `numeric`
 - **Default Value:** `100663296` (96MB) ([>= MariaDB 10.5](#)), `50331648` (48MB) ([<= MariaDB 10.4](#))
 - **Range:**
 - [>= MariaDB 10.8.3](#): `4194304` to `512GB` (4MB to 512GB)
 - [<= MariaDB 10.8.2](#): `1048576` to `512GB` (1MB to 512GB)
 - **Block size:** `4096`
-

innodb_log_file_write_through

- **Description:** Whether each write to `ib_logfile0` is write through (disabling any caching, as in `O_SYNC` or `O_DSYNC`). Set to `OFF` by default, will be set to `ON` if [innodb_flush_method](#) is set to `O_DSYNC`. On systems that support FUA it may make sense to enable write-through, to avoid extra system calls.
 - **Commandline:** `--innodb-log-file-write-through={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
 - **Introduced:** [MariaDB 11.0.0](#)
-

innodb_log_files_in_group

- **Description:** Number of physical files in the [InnoDB redo log](#). Deprecated and ignored from [MariaDB 10.5.2](#)
 - **Commandline:** `--innodb-log-files-in-group=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:** `1` ([>= MariaDB 10.5](#)), `2` ([<= MariaDB 10.4](#))
 - **Range:** `1` to `100` ([>= MariaDB 10.2.4](#))
 - **Deprecated:** [MariaDB 10.5.2](#)
 - **Removed:** [MariaDB 10.6.0](#)
-

innodb_log_group_home_dir

- **Description:** Path to the [InnoDB redo log](#) files. If none is specified, [innodb_log_files_in_group](#) files named `ib_logfile0` and so on, with a size of [innodb_log_file_size](#) are created in the data directory.
 - **Commandline:** `--innodb-log-group-home-dir=path`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `directory name`
-

innodb_log_optimize_ddl

- **Description:** Whether [InnoDB redo log](#) activity should be reduced when natively creating indexes or rebuilding tables. Reduced logging requires additional page flushing and interferes with [Mariabackup](#). Enabling this may slow down backup and cause delay due to page flushing. Deprecated and ignored from [MariaDB 10.5.1](#). Deprecated (but not ignored) from [MariaDB 10.4.16](#), [MariaDB 10.3.26](#) and [MariaDB 10.2.35](#).
 - **Commandline:** `--innodb-log-optimize-ddl={0|1}`
-

- **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:**
 - OFF (\geq [MariaDB 10.5.1](#), [MariaDB 10.4.16](#), [MariaDB 10.3.26](#), [MariaDB 10.2.35](#))
 - ON (\leq [MariaDB 10.5.0](#), [MariaDB 10.4.15](#), [MariaDB 10.3.25](#), [MariaDB 10.2.34](#))
 - **Introduced:** [MariaDB 10.2.17](#), [MariaDB 10.3.9](#)
 - **Deprecated:** [MariaDB 10.5.1](#), [MariaDB 10.4.16](#), [MariaDB 10.3.26](#), [MariaDB 10.2.35](#)
 - **Removed:** [MariaDB 10.6.0](#)
-

`innodb_log_spin_wait_delay`

- **Description:** Delay between log buffer spin lock polls (0 to use a blocking latch). Specifically, enables a spin lock that will execute that many `MY_RELAX_CPU()` operations (such as the x86 `PAUSE` instruction) between successive attempts of acquiring the spin lock. On some hardware with certain workloads (observed on write intensive workloads on NUMA systems), the default setting results in a significant amount of time being spent in `native_queued_spin_lock_slowpath()` in the Linux kernel, plus context switching between user and kernel address space, in which case changing from the default (for example, setting to `50`), may result in a performance improvement.
 - **Commandline:** `--innodb-log-spin-wait-delay=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `0`
 - **Range:** `0` to `6000`
 - **Introduced:** [MariaDB 10.11.8](#), [MariaDB 11.0.6](#), [MariaDB 11.1.5](#), [MariaDB 11.2.4](#), [MariaDB 11.4.2](#), [MariaDB 11.5.1](#)
-

`innodb_log_write_ahead_size`

- **Description:** [InnoDB redo log](#) write ahead unit size to avoid read-on-write. Should match the OS cache block IO size. Removed in [MariaDB 10.8](#), and instead on Linux and Windows, the physical block size of the underlying storage is detected and used. Reintroduced in [MariaDB 10.11.9](#) and later versions. On Linux and Windows, the default or the specified `innodb_log_write_ahead_size` will be automatically adjusted to not be less than the physical block size (if it can be determined).
 - **Commandline:** `--innodb-log-write-ahead-size=#`
 - **Scope:** Global
 - **Dynamic:** No (\geq [MariaDB 10.11.9](#)), Yes (\leq [MariaDB 10.7](#))
 - **Data Type:** `numeric`
 - **Default Value:** `512` (\geq [MariaDB 10.11.9](#)), `8192` (\leq [MariaDB 10.7](#))
 - **Range:**
 - `512` to `4096` (\geq [MariaDB 10.11.9](#))
 - `512` to `innodb_page_size` (\leq [MariaDB 10.7](#))
 - **Removed:** [MariaDB 10.8](#)
 - **Re-introduced:** [MariaDB 10.11.9](#), [MariaDB 11.1.6](#), [MariaDB 11.2.5](#), [MariaDB 11.4.3](#), [MariaDB 11.5.2](#)
-

`innodb_lru_flush_size`

- **Description:** Number of pages to flush on LRU eviction. Changes in [MariaDB 10.6.18](#), [MariaDB 10.11.8](#), [MariaDB 11.0.6](#), [MariaDB 11.1.5](#), [MariaDB 11.2.4](#) and [MariaDB 11.4.2](#) made this setting superfluous, and it is no longer used.
 - **Commandline:** `--innodb-lru-flush-size=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `32`
 - **Range:** `1` to `18446744073709551615`
 - **Introduced:** [MariaDB 10.5.7](#)
 - **Deprecated:** [MariaDB 10.6.20](#), [MariaDB 10.11.10](#), [MariaDB 11.2.6](#) and [MariaDB 11.4.4](#). [MariaDB 11.6.1](#), [MariaDB 11.7.1](#)
-

innodb_lru_scan_depth

- **Description:** Specifies how far down the buffer pool least-recently used (LRU) list the cleaning thread should look for dirty pages to flush. This process is performed once a second. In an I/O intensive-workload, can be increased if there is spare I/O capacity, or decreased if in a write-intensive workload with little spare I/O capacity.
 - See [InnoDB Page Flushing](#) for more information.
 - **Commandline:** `--innodb-lru-scan-depth=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:**
 - 1536 ([>= MariaDB 10.5.7](#))
 - 1024 ([<= MariaDB 10.5.6](#))
 - **Range - 32bit:** 100 to $2^{32}-1$
 - **Range - 64bit:** 100 to $2^{64}-1$
-

innodb_max_bitmap_file_size

- **Description:** Limit in bytes of the changed page bitmap files. For faster incremental backup with [Xtrabackup](#), XtraDB tracks pages with changes written to them according to the [XtraDB redo log](#) and writes the information to special changed page bitmap files. These files are rotated when the server restarts or when this limit is reached. XtraDB only. See also [innodb_track_changed_pages](#) and [innodb_max_changed_pages](#).
 - Deprecated and ignored in [MariaDB 10.2.6](#) (which uses InnoDB as default instead of XtraDB) to allow for easier upgrades.
 - **Commandline:** `innodb-max-bitmap-file-size=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** 4096 (4KB)
 - **Range:** 4096 (4KB) to 18446744073709551615 (16EB)
 - **Deprecated:** [MariaDB 10.2.6](#)
-

innodb_max_changed_pages

- **Description:** Limit to the number of changed page bitmap files (stored in the [Information Schema INNODB_CHANGED_PAGES table](#)). Zero is unlimited. See [innodb_max_bitmap_file_size](#) and [innodb_track_changed_pages](#). Previously named `innodb_changed_pages_limit`. XtraDB only.
 - Deprecated and ignored in [MariaDB 10.2.6](#) (which uses InnoDB as default instead of XtraDB) to allow for easier upgrades.
 - **Commandline:** `innodb-max-changed-pages=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** 1000000
 - **Range:** 0 to 18446744073709551615
 - **Deprecated:** [MariaDB 10.2.6](#)
-

innodb_max_dirty_pages_pct

- **Description:** Maximum percentage of unwritten (dirty) pages in the buffer pool.
 - See [InnoDB Page Flushing](#) for more information.
 - **Commandline:** `--innodb-max-dirty-pages-pct=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:**
 - 90.000000 ([>= MariaDB 10.5.7](#))
 - 75.000000 ([<= MariaDB 10.5.6](#))
 - **Range:** 0 to 99.999
-

innodb_max_dirty_pages_pct_lwm

- **Description:** Low water mark percentage of dirty pages that will enable preflushing to lower the dirty page ratio. The value 0 (default) means 'refer to [innodb_max_dirty_pages_pct](#)'. (Note that 0 meant 0 in 10.5.7 to 10.5.8, but was then reverted back to "same as [innodb_max_dirty_pages_pct](#)" again in 10.5.9)
 - See [InnoDB Page Flushing](#) for more information.
 - **Commandline:** `--innodb-max-dirty-pages-pct-lwm=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:**
 - 0 ([>= MariaDB 10.2.1](#))
 - 0.001 ([<= MariaDB 10.2.0](#))
 - **Range:** 0 to 99.999
-

`innodb_max_purge_lag`

- **Description:** When purge operations are lagging on a busy server, setting `innodb_max_purge_lag` can help. By default set to 0, no lag, the figure is used to calculate a time lag for each INSERT, UPDATE, and DELETE when the system is lagging. InnoDB keeps a list of transactions with delete-marked index records due to UPDATE and DELETE statements. The length of this list is `purge_lag`, and the calculation, performed every ten seconds, is as follows: $((\text{purge_lag}/\text{innodb_max_purge_lag}) \times 10) - 5$ microseconds.
 - **Commandline:** `--innodb-max-purge-lag=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** 0
 - **Range:** 0 to 4294967295
-

`innodb_max_purge_lag_delay`

- **Description:** Maximum delay in milliseconds imposed by the `innodb_max_purge_lag` setting. If set to 0, the default, there is no maximum.
 - **Commandline:** `--innodb-max-purge-lag-delay=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** 0
-

`innodb_max_purge_lag_wait`

- **Description:** Wait until History list length is below the specified limit.
 - **Commandline:** `--innodb-max-purge-wait=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** 4294967295
 - **Range:** 0 to 4294967295
 - **Introduced:** [MariaDB 10.5.7](#), [MariaDB 10.4.16](#), [MariaDB 10.3.26](#), [MariaDB 10.2.35](#)
-

`innodb_max_undo_log_size`

- **Description:** If an undo tablespace is larger than this, it will be marked for truncation if `innodb_undo_log_truncate` is set.
 - **Commandline:** `--innodb-max-undo-log-size=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:**
 - 10485760
 - **Range:** 10485760 to 18446744073709551615
-

innodb_merge_sort_block_size

- **Description:** Size in bytes of the block used for merge sorting in fast index creation. Replaced in [MariaDB 10.0/XtraDB 5.6](#) by [innodb_sort_buffer_size](#).
 - **Commandline:** `innodb-merge-sort-block-size=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `1048576` (1M)
 - **Range:** `1048576` (1M) to `1073741824` (1G)
 - **Removed:** [MariaDB 10.0](#) - replaced by [innodb_sort_buffer_size](#)
-

innodb_mirrored_log_groups

- **Description:** Unused. Restored as a deprecated and ignored option in [MariaDB 10.2.6](#) (which uses InnoDB as default instead of XtraDB) to allow for easier upgrades.
 - **Deprecated:** [MariaDB 10.0](#)
 - **Removed:** [MariaDB 10.2.2](#) - [MariaDB 10.2.5](#)
-

innodb_mtflush_threads

- **Description:** Sets the number of threads to use in Multi-Threaded Flush operations. For more information, see [Fusion-io Multi-threaded Flush](#).
 - InnoDB's multi-thread flush feature was deprecated in [MariaDB 10.2.9](#) and removed from [MariaDB 10.3.2](#). In later versions of MariaDB, use `innodb_page_cleaners` system variable instead.
 - See [InnoDB Page Flushing: Page Flushing with Multi-threaded Flush Threads](#) for more information.
 - **Commandline:** `--innodb-mtflush-threads=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:** `8`
 - **Range:** `1` to `64`
 - **Deprecated:** [MariaDB 10.2.9](#)
 - **Removed:** [MariaDB 10.3.2](#)
-

innodb_monitor_disable

- **Description:** Disables the specified counters in the `INFORMATION_SCHEMA.INNODB_METRICS` table.
 - **Commandline:** `--innodb-monitor-disable=string`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `string`
-

innodb_monitor_enable

- **Description:** Enables the specified counters in the `INFORMATION_SCHEMA.INNODB_METRICS` table.
 - **Commandline:** `--innodb-monitor-enable=string`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `string`
-

innodb_monitor_reset

- **Description:** Resets the count value of the specified counters in the `INFORMATION_SCHEMA.INNODB_METRICS` table to zero.
 - **Commandline:** `--innodb-monitor-reset=string`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `string`
-

innodb_monitor_reset_all

- **Description:** Resets all values for the specified counters in the [INFORMATION_SCHEMA.INNODB_METRICS](#) table.
 - **Commandline:** `---innodb-monitor-reset-all=string`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `string`
-

innodb_numa_interleave

- **Description:** Whether or not to use the NUMA interleave memory policy to allocate the [InnoDB buffer pool](#). Before [MariaDB 10.2.4](#), required that MariaDB be compiled on a NUMA-enabled Linux system.
 - **Commandline:** `innodb-numa-interleave={0|1}`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
 - **Removed:** [MariaDB 10.2.23](#), [MariaDB 10.3.14](#), [MariaDB 10.4.4](#)
-

innodb_old_blocks_pct

- **Description:** Percentage of the [buffer pool](#) to use for the old block sublist.
 - **Commandline:** `--innodb-old-blocks-pct=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `37`
 - **Range:** `5` to `95`
-

innodb_old_blocks_time

- **Description:** Time in milliseconds an inserted block must stay in the old sublist after its first access before it can be moved to the new sublist. '0' means "no delay". Setting a non-zero value can help prevent full table scans clogging the [buffer pool](#). See also [innodb_old_blocks_pct](#).
 - **Commandline:** `--innodb-old-blocks-time=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `1000`
 - **Range:** `0` to `232-1`
-

innodb_online_alter_log_max_size

- **Description:** The maximum size for temporary log files during online DDL (data and index structure changes). The temporary log file is used for each table being altered, or index being created, to store data changes to the table while the process is underway. The table is extended by [innodb_sort_buffer_size](#) up to the limit set by this variable. If this limit is exceeded, the online DDL operation fails and all uncommitted changes are rolled back. A lower value reduces the time a table could lock at the end of the operation to apply all the log's changes, but also increases the chance of the online DDL changes failing.
 - **Commandline:** `--innodb-online-alter-log-max-size=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `134217728`
 - **Range:** `65536` to `264-1`
-

innodb_open_files

- **Description:** Maximum `.ibd` files MariaDB can have open at the same time. Only applies to systems with multiple XtraDB/InnoDB tablespaces, and is separate to the table cache and [open_files_limit](#). The default, if

`innodb_file_per_table` is disabled, is 300 or the value of `table_open_cache`, whichever is higher. It will also auto-size up to the default value if it is set to a value less than 10 .

- **Commandline:** `--innodb-open-files=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:** `autosized`
 - **Range:** 10 to 4294967295
-

`innodb_optimize_fulltext_only`

- **Description:** When set to 1 (0 is default), `OPTIMIZE TABLE` will only process InnoDB `FULLTEXT` index data. Only intended for use during fulltext index maintenance.
 - **Commandline:** `--innodb-optimize-fulltext-only={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
-

`innodb_page_cleaners`

- **Description:** Number of page cleaner threads. The default is 4 , but the value will be set to the number of `innodb_buffer_pool_instances` if this is lower. If set to 1 , only a single cleaner thread is used, as was the case until [MariaDB 10.2.1](#) . Cleaner threads flush dirty pages from the `buffer pool`, performing flush list and least-recently used (LRU) flushing. Deprecated and ignored from [MariaDB 10.5.1](#), as the original reasons for for splitting the buffer pool have mostly gone away.
 - See [InnoDB Page Flushing: Page Flushing with Multiple InnoDB Page Cleaner Threads](#) for more information.
 - **Commandline:** `--innodb-page-cleaners=#`
 - **Scope:** Global
 - **Dynamic:** Yes (\geq [MariaDB 10.3.3](#)), No (\leq [MariaDB 10.3.2](#))
 - **Data Type:** `numeric`
 - **Default Value:** 4 (or set to `innodb_buffer_pool_instances` if lower)
 - **Range:** 1 to 64
 - **Deprecated:** [MariaDB 10.5.1](#)
 - **Removed:** [MariaDB 10.6.0](#)
-

`innodb_page_size`

- **Description:** Specifies the page size in bytes for all InnoDB tablespaces. The default, 16k , is suitable for most uses.
 - A smaller InnoDB page size might work more effectively in a situation with many small writes (OLTP), or with SSD storage, which usually has smaller block sizes.
 - A larger InnoDB page size can provide a larger `maximum row size`.
 - InnoDB's page size can be as large as 64k for tables using the following `row formats`: `DYNAMIC`, `COMPACT`, and `REDUNDANT`.
 - InnoDB's page size must still be 16k or less for tables using the `COMPRESSED` row format.
 - This system variable's value cannot be changed after the `datadir` has been initialized. InnoDB's page size is set when a MariaDB instance starts, and it remains constant afterwards.
 - **Commandline:** `--innodb-page-size=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `enumeration`
 - **Default Value:** 16384
 - **Valid Values:** 4k or 4096 , 8k or 8192 , 16k or 16384 , 32k and 64k .
-

`innodb_pass_corrupt_table`

- **Removed:** XtraDB 5.5 - renamed `innodb_corrupt_table_action`.
-

`innodb_prefix_index_cluster_optimization`

- **Description:** Enable prefix optimization to sometimes avoid cluster index lookups. Deprecated and ignored from [MariaDB 10.10](#), as the optimization is now always enabled.
 - **Commandline:** `--innodb-prefix-index-cluster-optimization={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
 - **Deprecated:** [MariaDB 10.10.1](#) 
-

`innodb_print_all_deadlocks`

- **Description:** If set to `1` (`0` is default), all InnoDB transaction deadlock information is written to the [error log](#).
 - **Commandline:** `--innodb-print-all-deadlocks={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
-

`innodb_purge_batch_size`

- **Description:** Number of [InnoDB undo log](#) pages to purge in one batch from the history list. Together with [innodb_purge_threads](#) has a small effect on tuning.
 - **Commandline:** `--innodb-purge-batch-size=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:**
 - `127` (`>=` [MariaDB 10.6.20](#), [MariaDB 10.11.10](#), [MariaDB 11.2.6](#) , [MariaDB 11.4.4](#), [MariaDB 11.6.2](#) )
 - `1000` (`>=` [MariaDB 10.6.16](#), [MariaDB 10.10.7](#) , [MariaDB 10.11.6](#), [MariaDB 11.0.4](#) , [MariaDB 11.1.3](#) , [MariaDB 11.2.2](#) )
 - `300` (`<=` [MariaDB 10.6.15](#), [MariaDB 10.10.6](#) , [MariaDB 10.11.5](#), [MariaDB 11.0.3](#) , [MariaDB 11.1.2](#) , [MariaDB 11.2.1](#) )
 - **Range:** `1` to `5000`
-

`innodb_purge_rseg_truncate_frequency`

- **Description:** Frequency with which undo records are purged. Set by default to every 128 times, reducing this increases the frequency at which rollback segments are freed. See also [innodb_undo_log_truncate](#). The motivation for introducing this in MySQL seems to have been to avoid stalls due to freeing undo log pages or truncating undo log tablespaces. In MariaDB, [innodb_undo_log_truncate=ON](#) should be a much lighter operation because it will not involve any log checkpoint, hence this is deprecated and ignored from [MariaDB 10.6.16](#), [MariaDB 10.10.7](#) , [MariaDB 10.11.6](#), [MariaDB 11.0.4](#) , [MariaDB 11.1.3](#)  and [MariaDB 11.2.2](#) . ([MDEV-32050](#) )
 - **Commandline:** `--innodb-purge-rseg-truncate-frequency=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `128`
 - **Range:** `1` to `128`
 - **Deprecated:** [MariaDB 10.6.16](#), [MariaDB 10.10.7](#) , [MariaDB 10.11.6](#), [MariaDB 11.0.4](#) , [MariaDB 11.1.3](#) , [MariaDB 11.2.2](#) 
-

`innodb_purge_threads`

- **Description:** Number of background threads dedicated to InnoDB purge operations. The range is `1` to `32`. At least one background thread is always used. Setting to a value greater than 1 creates that many separate purge threads. This can improve efficiency in some cases, such as when performing DML operations on many tables. See also [innodb_purge_batch_size](#).
 - **Commandline:** `--innodb-purge-threads=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
-

- **Default Value:** 4
 - **Range:** 1 to 32
-

`innodb_random_read_ahead`

- **Description:** Originally, random read-ahead was always set as an optimization technique, but was removed in [MariaDB 5.5](#). `innodb_random_read_ahead` permits it to be re-instated if set to 1 (0 is default).
 - **Commandline:** `--innodb-random-read-ahead={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
-

`innodb_read_ahead`

- **Description:** If set to `linear`, the default, XtraDB/InnoDB will automatically fetch remaining pages if there are enough within the same extent that can be accessed sequentially. If set to `none`, read-ahead is disabled. `random` has been removed and is now ignored, while `both` sets to both `linear` and `random`. Also see [innodb_read_ahead_threshold](#) for more control on read-aheads. Removed in [MariaDB 10.0/XtraDB 5.6](#) and replaced by MySQL 5.6's [innodb_random_read_ahead](#).
 - **Commandline:** `innodb-read-ahead=value`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `enumeration`
 - **Default Value:** `linear`
 - **Valid Values:** `none`, `random`, `linear`, `both`
 - **Removed:** [MariaDB 10.0/XtraDB 5.6](#) - replaced by MySQL 5.6's [innodb_random_read_ahead](#)
-

`innodb_read_ahead_threshold`

- **Description:** Minimum number of pages InnoDB must read sequentially from an extent of 64 before initiating an asynchronous read for the following extent.
 - **Commandline:** `--innodb-read-ahead-threshold=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** 56
 - **Range:** 0 to 64
-

`innodb_read_io_threads`

- **Description:** Prior to [MariaDB 10.5](#), this was simply the number of I/O threads for InnoDB reads. From [MariaDB 10.5](#), asynchronous I/O functionality in the InnoDB Background Thread Pool replaces the old InnoDB I/O Threads. This variable is now multiplied by 256 to determine the maximum number of concurrent asynchronous I/O read requests that can be completed by the Background Thread Pool. The default is therefore $4 * 256 = 1024$ concurrent asynchronous read requests. You may on rare occasions need to reduce this default on Linux systems running multiple MariaDB servers to avoid exceeding system limits, or increase if spending too much time waiting on I/O requests.
 - **Commandline:** `--innodb-read-io-threads=#`
 - **Scope:** Global
 - **Dynamic:** Yes (\geq [MariaDB 10.11](#)), No (\leq [MariaDB 10.10](#))
 - **Data Type:** `numeric`
 - **Default Value:** 4
 - **Range:** 1 to 64
-

`innodb_read_only`

- **Description:** If set to 1 (0 is default), the server will be read-only. For use in distributed applications, data warehouses or read-only media.
- **Commandline:** `--innodb-read-only={0|1}`

- **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
-

`innodb_read_only_compressed`

- **Description:** If set (the default before [MariaDB 10.6.6](#)), `ROW_FORMAT=COMPRESSED` tables will be read-only. This was intended to be the first step towards removing write support and deprecating the feature, but this plan has been abandoned.
 - **Commandline:** `--innodb-read-only-compressed`, `--skip-innodb-read-only-compressed`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF` (\geq [MariaDB 10.6.6](#)), `ON` (\leq [MariaDB 10.6.5](#))
 - **Introduced:** [MariaDB 10.6.0](#)
-

`innodb_recovery_stats`

- **Description:** If set to `1` (`0` is default) and recovery is necessary on startup, the server will write detailed recovery statistics to the error log at the end of the recovery process. This Percona XtraDB variable has not been ported to XtraDB 5.6.
 - **Commandline:** No
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
 - **Removed:** [MariaDB 10.0](#)
-

`innodb_recovery_update_relay_log`

- **Description:** If set to `1` (`0` is default), the relay log info file will be overwritten on crash recovery if the information differs from the InnoDB record. Should not be used if multiple storage engine types are being replicated. Previously named `innodb_overwrite_relay_log_info`. Removed in [MariaDB 10.0/XtraDB 5.6](#) and replaced by MySQL 5.6's `relay-log-recovery`
 - **Commandline:** `innodb-recovery-update-relay-log={0|1}`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
 - **Removed:** [MariaDB 10.0](#) - replaced by MySQL 5.6's `relay-log-recovery`
-

`innodb_replication_delay`

- **Description:** Time in milliseconds for the replica server to delay the replication thread if `innodb_thread_concurrency` is reached. Deprecated and ignored from [MariaDB 10.5.5](#).
 - **Commandline:** `--innodb-replication-delay=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `0`
 - **Range:** `0` to `4294967295`
 - **Deprecated:** [MariaDB 10.5.5](#)
 - **Removed:** [MariaDB 10.6.0](#)
-

`innodb_rollback_on_timeout`

- **Description:** InnoDB usually rolls back the last statement of a transaction that's been timed out (see [innodb_lock_wait_timeout](#)). If `innodb_rollback_on_timeout` is set to `1` (`0` is default), InnoDB will roll back the entire transaction. Before [MariaDB 5.5](#), rolling back the entire transaction was the default behavior.

- **Commandline:** `--innodb-rollback-on-timeout`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `0`
-

`innodb_rollback_segments`

- **Description:** Specifies the number of rollback segments that XtraDB/InnoDB will use within a transaction (see [undo log](#)). Deprecated and replaced by `innodb_undo_logs` in [MariaDB 10.0](#). Removed in [MariaDB 10.5](#) as part of an InnoDB cleanup, as it makes sense to always create and use the maximum number of rollback segments. |
 - **Commandline:** `--innodb-rollback-segments=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `128`
 - **Range:** `1` to `128`
 - **Deprecated:** [MariaDB 10.0](#)
 - **Removed:** [MariaDB 10.5.0](#)
-

`innodb_safe_truncate`

- **Description:** Use a backup-safe `TRUNCATE TABLE` implementation and crash-safe rename operations inside InnoDB. This is not compatible with hot backup tools other than [Mariabackup](#). Users who need to use such tools may set this to `OFF`.
 - **Commandline:** `--innodb-safe-truncate={0|1}`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `ON`
 - **Introduced:** [MariaDB 10.2.19](#) [↗](#)
 - **Removed:** [MariaDB 10.3.0](#) [↗](#)
-

`innodb_scrub_log`

- **Description:** Enable [InnoDB redo log scrubbing](#). See [Data Scrubbing](#). Deprecated and ignored from [MariaDB 10.5.2](#), as never really worked ([MDEV-13019](#) [↗](#) and [MDEV-18370](#) [↗](#)). If old log contents should be kept secret, then enabling [innodb_encrypt_log](#) or setting a smaller `innodb_log_file_size` could help.
 - **Commandline:** `--innodb-scrub-log`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
 - **Deprecated:** [MariaDB 10.5.2](#)
 - **Removed:** [MariaDB 10.6.0](#)
-

`innodb_scrub_log_interval`

- **Description:** Used with [Data Scrubbing](#) in 10.1.3 only - replaced in 10.1.4 by `innodb_scrub_log_speed`. InnoDB redo log scrubbing interval in milliseconds.
 - **Commandline:** `--innodb-scrub-log-interval=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `56`
 - **Range:** `0` to `50000`
 - **Introduced:** [MariaDB 10.1.3](#) [↗](#)
 - **Removed:** [MariaDB 10.1.4](#) [↗](#)
-

`innodb_scrub_log_speed`

- **Description:** [InnoDB redo log](#) scrubbing speed in bytes/sec. See [Data Scrubbing](#). Deprecated and ignored from [MariaDB 10.5.2](#).
 - **Commandline:** `--innodb-scrub-log-speed=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `256`
 - **Range:** `1` to `50000`
 - **Deprecated:** [MariaDB 10.5.2](#)
 - **Removed:** [MariaDB 10.6.0](#)
-

`innodb_sched_priority_cleaner`

- **Description:** Set a thread scheduling priority for cleaner and least-recently used (LRU) manager threads. The range from `0` to `39` corresponds in reverse order to Linux nice values of `-20` to `19`. So `0` is the lowest priority (Linux nice value `19`) and `39` is the highest priority (Linux nice value `-20`). XtraDB only. Added as a deprecated and ignored option in [MariaDB 10.2.6](#) (which uses InnoDB as default instead of XtraDB) to allow for easier upgrades.
 - **Commandline:** `innodb-sched-priority-cleaner=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `19`
 - **Range:** `0` to `39`
 - **Deprecated:** [MariaDB 10.2.6](#)
 - **Removed:** [MariaDB 10.3.0](#)
-

`innodb_show_locks_held`

- **Description:** Specifies the number of locks held for each InnoDB transaction to be displayed in [SHOW ENGINE INNODB STATUS](#) output. XtraDB only. Added as a deprecated and ignored option in [MariaDB 10.2.6](#) (which uses InnoDB as default instead of XtraDB) to allow for easier upgrades.
 - **Commandline:** `innodb-show-locks-held=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `10`
 - **Range:** `0` to `1000`
 - **Deprecated:** [MariaDB 10.2.6](#)
 - **Removed:** [MariaDB 10.3.0](#)
-

`innodb_show_verbose_locks`

- **Description:** If set to `1`, and [innodb_status_output_locks](#) is also ON, the traditional InnoDB behavior is followed and locked records will be shown in [SHOW ENGINE INNODB STATUS](#) output. If set to `0`, the default, only high-level information about the lock is shown. XtraDB only. Added as a deprecated and ignored option in [MariaDB 10.2.6](#) (which uses InnoDB as default instead of XtraDB) to allow for easier upgrades.
 - **Commandline:** `innodb-show-verbose-locks=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `0`
 - **Range:** `0` to `1`
 - **Deprecated:** [MariaDB 10.2.6](#)
 - **Removed:** [MariaDB 10.3.0](#)
-

`innodb_simulate_comp_failures`

- **Description:** Simulate compression failures. Used for testing robustness against random compression failures. XtraDB only.
- **Commandline:** None
- **Scope:** Global

- **Dynamic:** Yes
 - **Data Type:** numeric
 - **Default Value:** 0
 - **Range:** 0 to 99
-

innodb_snapshot_isolation

- **Description:** Use snapshot isolation (write-write conflict detection). If set, if an attempt to acquire a lock on a record that does not exist in the current read view is made, an error DB_RECORD_CHANGED (HA_ERR_RECORD_CHANGED, ER_CHECKREAD) will be raised. This error will be treated in the same way as a deadlock and the transaction will be rolled back. When set, the default isolation level, [REPEATABLE READ](#) will become Snapshot Isolation. Prior to [MariaDB 11.6.2](#), the default is OFF for backwards compatibility.
 - **Commandline:** `--innodb-snapshot-isolation={0|1}`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** boolean
 - **Default Value:** ON (\geq [MariaDB 11.6.2](#)), OFF (\leq [MariaDB 11.6.1](#))
 - **Introduced:** [MariaDB 10.6.18](#), [MariaDB 10.11.8](#), [MariaDB 11.0.6](#), [MariaDB 11.1.5](#), [MariaDB 11.2.4](#), [MariaDB 11.4.2](#)
-

innodb_sort_buffer_size

- **Description:** Size of the sort buffers used for sorting data when an InnoDB index is created, as well as the amount by which the temporary log file is extended during online DDL operations to record concurrent writes. The larger the setting, the fewer merge phases are required between buffers while sorting. When a [CREATE TABLE](#) or [ALTER TABLE](#) creates a new index, three buffers of this size are allocated, as well as pointers for the rows in the buffer.
 - **Commandline:** `--innodb-sort-buffer-size=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** numeric
 - **Default Value:** 1048576 (1M)
 - **Range:** 65536 to 67108864
-

innodb_log_spin_wait_delay

- **Description:** Maximum delay (not strictly corresponding to a time unit) between spin lock polls. Default changed from 6 to 4 in [MariaDB 10.3.5](#), as this was verified to give the best throughput by OLTP update index and read-write benchmarks on Intel Broadwell (2/20/40) and ARM (1/46/46).
 - **Commandline:** `--innodb-log-spin-wait-delay=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** numeric
 - **Default Value:** 4 (\geq [MariaDB 10.3.5](#)), 6 (\leq [MariaDB 10.3.4](#))
 - **Range:** 0 to 4294967295
-

innodb_stats_auto_recalc

- **Description:** If set to 1 (the default), persistent statistics are automatically recalculated when the table changes significantly (more than 10% of the rows). Affects tables created or altered with `STATS_PERSISTENT=1` (see [CREATE TABLE](#)), or when `innodb_stats_persistent` is enabled. `innodb_stats_persistent_sample_pages` determines how much data to sample when recalculating. See [InnoDB Persistent Statistics](#).
 - **Commandline:** `--innodb-stats-auto-recalc={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** boolean
 - **Default Value:** ON
-

innodb_stats_auto_update

- **Description:** If set to 0 (1 is default), index statistics will not be automatically calculated except when an [ANALYZE](#)

[TABLE](#) is run, or the table is first opened. Replaced by [innodb_stats_auto_recalc](#) in [MariaDB 10.0/XtraDB 5.6](#).

- **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `1`
 - **Removed:** [MariaDB 10.0](#) - replaced by [innodb_stats_auto_recalc](#).
-

`innodb_stats_include_delete_marked`

- **Description:** Include delete marked records when calculating persistent statistics.
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
-

`innodb_stats_method`

- **Description:** Determines how NULLs are treated for InnoDB index statistics purposes.
 - `nulls_equal`: The default, all NULL index values are treated as a single group. This is usually fine, but if you have large numbers of NULLs the average group size is slanted higher, and the optimizer may miss using the index for ref accesses when it would be useful.
 - `nulls_unequal`: The opposite approach to `nulls_equal` is taken, with each NULL forming its own group of one. Conversely, the average group size is slanted lower, and the optimizer may use the index for ref accesses when not suitable.
 - `nulls_ignored`: Ignore NULLs altogether from index group calculations.
 - See also [Index Statistics](#), [aria_stats_method](#) and [myisam_stats_method](#).
 - **Commandline:** `--innodb-stats-method=name`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `enumeration`
 - **Default Value:** `nulls_equal`
 - **Valid Values:** `nulls_equal`, `nulls_unequal`, `nulls_ignored`
-

`innodb_stats_modified_counter`

- **Description:** The number of rows modified before we calculate new statistics. If set to `0`, the default, current limits are used.
 - **Commandline:** `--innodb-stats-modified-counter=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `0`
 - **Range:** `0` to `18446744073709551615`
-

`innodb_stats_on_metadata`

- **Description:** If set to `1`, the default, XtraDB/InnoDB updates statistics when accessing the `INFORMATION_SCHEMA.TABLES` or `INFORMATION_SCHEMA.STATISTICS` tables, and when running metadata statements such as [SHOW INDEX](#) or [SHOW TABLE STATUS](#). If set to `0`, statistics are not updated at those times, which can reduce the access time for large schemas, as well as make execution plans more stable.
 - **Commandline:** `--innodb-stats-on-metadata`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
-

`innodb_stats_persistent`

- **Description:** [ANALYZE TABLE](#) produces index statistics, and this setting determines whether they will be stored on disk, or be required to be recalculated more frequently, such as when the server restarts. This information is stored for

each table, and can be set with the `STATS_PERSISTENT` clause when creating or altering tables (see [CREATE TABLE](#)). See [InnoDB Persistent Statistics](#).

- **Commandline:** `--innodb-stats-persistent={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `ON`
-

`innodb_stats_persistent_sample_pages`

- **Description:** Number of index pages sampled when estimating cardinality and statistics for indexed columns. Increasing this value will increase index statistics accuracy, but use more I/O resources when running [ANALYZE TABLE](#). See [InnoDB Persistent Statistics](#).
 - **Commandline:** `--innodb-stats-persistent-sample-pages=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `20`
-

`innodb_stats_sample_pages`

- **Description:** Gives control over the index distribution statistics by determining the number of index pages to sample. Higher values produce more disk I/O, but, especially for large tables, produce more accurate statistics and therefore make more effective use of the query optimizer. Lower values than the default are not recommended, as the statistics can be quite inaccurate.
 - If [innodb_stats_traditional](#) is enabled, then the exact number of pages configured by this system variable will be sampled for statistics.
 - If [innodb_stats_traditional](#) is disabled, then the number of pages to sample for statistics is calculated using a logarithmic algorithm, so the exact number can change depending on the size of the table. This means that more samples may be used for larger tables.
 - If [persistent statistics](#) are enabled, then the [innodb_stats_persistent_sample_pages](#) system variable applies instead. [persistent statistics](#) are enabled with the [innodb_stats_persistent](#) system variable.
 - This system variable has been **deprecated**. The [innodb_stats_transient_sample_pages](#) system variable should be used instead.
 - **Commandline:** `--innodb-stats-sample-pages=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `8`
 - **Range:** `1` to `264-1`
 - **Deprecated:** [MariaDB 10.0](#)
 - **Removed:** [MariaDB 10.5.0](#)
-

`innodb_stats_traditional`

- **Description:** This system variable affects how the number of pages to sample for transient statistics is determined, in particular how [innodb_stats_transient_sample_pages](#) is used.
 - If [innodb_stats_traditional](#) is enabled, then the exact number of pages configured by the system variable will be sampled for statistics.
 - If [innodb_stats_traditional](#) is disabled, then the number of pages to sample for statistics is calculated using a logarithmic algorithm, so the exact number can change depending on the size of the table. This means that more samples may be used for larger tables.
 - This system variable does not affect the calculation of [persistent statistics](#).
 - **Commandline:** `--innodb-stats-traditional={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `ON`
-

`innodb_stats_transient_sample_pages`

- **Description:** Gives control over the index distribution statistics by determining the number of index pages to sample.

Higher values produce more disk I/O, but, especially for large tables, produce more accurate statistics and therefore make more effective use of the query optimizer. Lower values than the default are not recommended, as the statistics can be quite inaccurate.

- If `innodb_stats_traditional` is enabled, then the exact number of pages configured by this system variable will be sampled for statistics.
 - If `innodb_stats_traditional` is disabled, then the number of pages to sample for statistics is calculated using a logarithmic algorithm, so the exact number can change depending on the size of the table. This means that more samples may be used for larger tables.
 - If `persistent statistics` are enabled, then the `innodb_stats_persistent_sample_pages` system variable applies instead. `persistent statistics` are enabled with the `innodb_stats_persistent` system variable.
- **Commandline:** `--innodb-stats-transient-sample-pages=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** 8
 - **Range:** 1 to $2^{64}-1$
-

`innodb_stats_update_need_lock`

- **Description:** Setting to 0 (1 is default) may help reduce contention of the `&dict_operation_lock`, but also disables the `Data_free` option in `SHOW TABLE STATUS`. This Percona XtraDB variable has not been ported to XtraDB 5.6.
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** 1
 - **Removed:** MariaDB 10.0/XtraDB 5.6
-

`innodb_status_output`

- **Description:** Enable `InnoDB monitor` output to the `error log`.
 - **Commandline:** `--innodb-status-output={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
-

`innodb_status_output_locks`

- **Description:** Enable `InnoDB lock monitor` output to the `error log` and `SHOW ENGINE INNODB STATUS`. Also requires `innodb_status_output=ON` to enable output to the error log.
 - **Commandline:** `--innodb-status-output-lock={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
-

`innodb_strict_mode`

- **Description:** If set to 1 (the default), InnoDB will return errors instead of warnings in certain cases, similar to strict SQL mode. See `InnoDB Strict Mode` for details.
 - **Commandline:** `--innodb-strict-mode={0|1}`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `ON`
-

`innodb_support_xa`

- **Description:** If set to 1, the default, `XA transactions` are supported. XA support ensures data is written to the `binary`

log in the same order to the actual database, which is critical for [replication](#) and disaster recovery, but comes at a small performance cost. If your database is set up to only permit one thread to change data (for example, on a replication replica with only the replication thread writing), it is safe to turn this option off. Removed in [MariaDB 10.3](#), XA transactions are always supported.

- **Commandline:** `--innodb-support-xa`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `ON`
- **Deprecated:** [MariaDB 10.2](#)
- **Removed:** [MariaDB 10.3.0](#) 

`innodb_sync_array_size`

- **Description:** By default `1`, can be increased to split internal thread co-ordinating, giving higher concurrency when there are many waiting threads.
- **Commandline:** `--innodb-sync-array-size=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `1`
- **Range:** `1` to `1024`
- **Removed:** [MariaDB 10.6.0](#)

`innodb_sync_spin_loops`

- **Description:** The number of times a thread waits for an InnoDB mutex to be freed before the thread is suspended.
- **Commandline:** `--innodb-sync-spin-loops=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `30`
- **Range:** `0` to `4294967295`

`innodb_table_locks`

- **Description:** If [autocommit](#) is set to `0` (`1` is default), setting `innodb_table_locks` to `1`, the default, will cause InnoDB to lock a table internally upon a [LOCK TABLE](#).
- **Commandline:** `--innodb-table-locks`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `ON`

`innodb_thread_concurrency`

- **Description:** Once this number of threads is reached (excluding threads waiting for locks), XtraDB/InnoDB will place new threads in a wait state in a first-in, first-out queue for execution, in order to limit the number of threads running concurrently. A setting of `0`, the default, permits as many threads as necessary. A suggested setting is twice the number of CPU's plus the number of disks. Deprecated and ignored from [MariaDB 10.5.5](#).
- **Commandline:** `--innodb-thread-concurrency=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `0`
- **Range:** `0` to `1000`
- **Deprecated:** [MariaDB 10.5.5](#)
- **Removed:** [MariaDB 10.6.0](#)

`innodb_thread_concurrency_timer_based`

- **Description:** If set to `1`, thread concurrency will be handled in a lock-free timer-based manner rather than the default mutex-based method. Depends on atomic op builtins being available. This Percona XtraDB variable has not been ported to XtraDB 5.6.
 - **Commandline:** `innodb-thread-concurrency-timer-based={0|1}`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
 - **Removed:** [MariaDB 10.0/XtraDB 5.6](#)
-

`innodb_thread_sleep_delay`

- **Description:** Time in microseconds that InnoDB threads sleep before joining the queue. Setting to `0` disables sleep. Deprecated and ignored from [MariaDB 10.5.5](#)
 - **Commandline:** `--innodb-thread-sleep-delay=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:**
 - `0` (\geq [MariaDB 10.5.5](#).)
 - `10000` (\leq [MariaDB 10.5.4](#))
 - **Range:** `0` to `1000000`
 - **Deprecated:** [MariaDB 10.5.5](#)
 - **Removed:** [MariaDB 10.6.0](#)
-

`innodb_temp_data_file_path`

- **Description:** Path where to store data for InnoDB temporary tables. Argument is `filename:size` followed by options separated by `!`. Multiple paths can be given separated by `;`. A file size is specified (with K for kilobytes, M for megabytes and G for gigabytes). Also whether or not to `autoextend` the data file, `max` size and whether or not to `autoshrink` on startup may also be specified.
 - **Commandline:** `--innodb-temp-data-file-path=path`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `string`
 - **Default Value:** `ibtmp1:12M:autoextend`
 - **Documentation & examples:** [innodb-temporary-tablespaces](#)
-

`innodb_tmpdir`

- **Description:** Allows an alternate location to be set for temporary non-tablespace files. If not set (the default), files will be created in the usual `tmpdir` location. Alternate location must be outside of `datadir`
 - **Commandline:** `--innodb-tmpdir=path`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `string`
 - **Default Value:** `Empty`
-

`innodb_track_changed_pages`

- **Description:** For faster incremental backup with [Xtrabackup](#), XtraDB tracks pages with changes written to them according to the [XtraDB redo log](#) and writes the information to special changed page bitmap files. This read-only variable is used for controlling this feature. See also [innodb_max_changed_pages](#) and [innodb_max_bitmap_file_size](#). XtraDB only. Added as a deprecated and ignored option in [MariaDB 10.2.6](#) (which uses InnoDB as default instead of XtraDB) to allow for easier upgrades.
 - **Commandline:** `innodb-track-changed-pages={0|1}`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
 - **Deprecated:** [MariaDB 10.2.6](#)
-

innodb_track_redo_log_now

- **Description:** Available on debug builds only. XtraDB only. Added as a deprecated and ignored option in [MariaDB 10.2.6](#) (which uses InnoDB as default instead of XtraDB) to allow for easier upgrades.
 - **Commandline:** `innodb-track-redo-log-now={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
 - **Deprecated:** [MariaDB 10.2.6](#)
-

innodb_truncate_temporary_tablespace_now

- **Description:** Set to ON to shrink the temporary tablespace.
 - **Commandline:** `innodb-truncate-temporary-tablespace-now={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
 - **Introduced:** [MariaDB 11.3.0](#)
-

innodb_undo_directory

- **Description:** Path to the directory (relative or absolute) that InnoDB uses to create separate tablespaces for the [undo logs](#). `.` (the default value before 10.2.2) leaves the undo logs in the same directory as the other log files. From [MariaDB 10.2.2](#), the default value is `NULL`, and if no path is specified, undo tablespaces will be created in the directory defined by `datadir`. Use together with [innodb_undo_logs](#) and [innodb_undo_tablespaces](#). Undo logs are most usefully placed on a separate storage device.
 - **Commandline:** `--innodb-undo-directory=name`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `string`
 - **Default Value:** `NULL`
-

innodb_undo_log_truncate

- **Description:** When enabled, [innodb_undo_tablespaces](#) that are larger than [innodb_max_undo_log_size](#) will be marked for truncation. See also [innodb_purge_rseg_truncate_frequency](#). **Enabling this setting may cause stalls during heavy write workloads.**
 - **Commandline:** `--innodb-undo-log-truncate[={0|1}]`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
-

innodb_undo_logs

- **Description:** Specifies the number of rollback segments that XtraDB/InnoDB will use within a transaction (or the number of active [undo logs](#)). By default set to the maximum, `128`, it can be reduced to avoid allocating unneeded rollback segments. See the [innodb_available_undo_logs](#) status variable for the number of undo logs available. See also [innodb_undo_directory](#) and [innodb_undo_tablespaces](#). Replaced [innodb_rollback_segments](#) in [MariaDB 10.0](#). The [Information Schema XTRADB_RSEG Table](#) contains information about the XtraDB rollback segments. Deprecated and ignored in [MariaDB 10.5.0](#), as it always makes sense to use the maximum number of rollback segments.
 - **Commandline:** `--innodb-undo-logs=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `128`
 - **Range:** `0` to `128`
-

- **Deprecated:** [MariaDB 10.5.0](#)
- **Removed:** [MariaDB 10.6.0](#)

innodb_undo_tablespaces

- **Description:** Number of tablespaces files used for dividing up the [undo logs](#). Zero (the default before [MariaDB 11.0](#)) means that undo logs are all part of the system tablespace, which contains one undo tablespace more than the `innodb_undo_tablespaces` setting. A value of 1 is reset to 0 as 2 or more are needed for separate tablespaces. When the undo logs can grow large, splitting them over multiple tablespaces will reduce the size of any single tablespace. Until [MariaDB 10.11.1](#), must be set before InnoDB is initialized, or else MariaDB will fail to start, with an error saying that InnoDB did not find the expected number of undo tablespaces. The files are created in the directory specified by [innodb_undo_directory](#), and are named `undoN`, N being an integer. The default size of an undo tablespace is 10MB.
From [MariaDB 11.0](#), multiple undo tablespaces are enabled by default, and the default is changed to 3 so that the space occupied by possible bursts of undo log records can be reclaimed after [innodb_undo_log_truncate](#) is set. Before [MariaDB 10.6](#), [innodb_undo_logs](#) must have a non-zero setting for `innodb_undo_tablespaces` to take effect.
- **Commandline:** `--innodb-undo-tablespaces=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** 3 (\geq [MariaDB 11.0](#)), 0 (\leq [MariaDB 10.11](#))
- **Range:** 0, or 2 to 95

innodb_use_atomic_writes

- **Description:** Implement atomic writes on supported SSD devices. See [atomic write support](#) for other variables affected when this is set.
- **Commandline:** `innodb-use-atomic-writes={0|1}`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `boolean`
- **Default Value:** ON

innodb_use_fallocate

- **Description:** Preallocate files fast, using operating system functionality. On POSIX systems, `posix_fallocate` system call is used.
 - Automatically set to 1 when [innodb_use_atomic_writes](#) is set - see [FusionIO DirectFS atomic write support](#) [↗](#).
 - See [InnoDB Page Compression: Saving Storage Space with Sparse Files](#) for more information.
- **Commandline:** `innodb-use-fallocate={0|1}`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `boolean`
- **Default Value:** OFF
- **Deprecated:** [MariaDB 10.2.5](#) [↗](#) (treated as if ON)
- **Removed:** [MariaDB 10.3.0](#) [↗](#)

innodb_use_global_flush_log_at_trx_commit

- **Description:** Determines whether a user can set the variable [innodb_flush_log_at_trx_commit](#). If set to 1, a user cannot reset the value with a SET command, while if set to 0, a user can reset the value of `innodb_flush_log_at_trx_commit`. XtraDB only. Added as a deprecated and ignored option in [MariaDB 10.2.6](#) [↗](#) (which uses InnoDB as default instead of XtraDB) to allow for easier upgrades.
- **Commandline:** `innodb-use-global-flush-log-at-trx_commit={0|1}`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** ON
- **Deprecated:** [MariaDB 10.2.6](#) [↗](#)
- **Removed:** [MariaDB 10.3.0](#) [↗](#)

innodb_use_mtflush

- **Description:** Whether to enable Multi-Threaded Flush operations. For more information, see Fusion.
 - InnoDB's multi-thread flush feature was deprecated in [MariaDB 10.2.9](#) and removed from [MariaDB 10.3.2](#). In later versions of MariaDB, use `innodb_page_cleaners` system variable instead.
 - See [InnoDB Page Flushing: Page Flushing with Multi-threaded Flush Threads](#) for more information.
 - **Commandline:** `--innodb-use-mtflush={0|1}`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
 - **Deprecated:** [MariaDB 10.2.9](#)
 - **Removed:** [MariaDB 10.3.2](#)
-

innodb_use_native_aio

- **Description:** For Linux systems only, specified whether to use Linux's asynchronous I/O subsystem. Set to `ON` by default, it may be changed to `0` at startup if InnoDB detects a problem, or from [MariaDB 10.6.5/MariaDB 10.7.1](#), if a 5.11 - 5.15 Linux kernel is detected, to avoid an io-uring bug/incompatibility ([MDEV-26674](#)). MariaDB-10.6.6/MariaDB-10.7.2 and later also consider 5.15.3+ as a fixed kernel and default to `ON`. To really benefit from the setting, the files should be opened in `O_DIRECT` mode (`innodb_flush_method=O_DIRECT`, default from [MariaDB 10.6](#)), to bypass the file system cache. In this way, the reads and writes can be submitted with DMA, using the InnoDB buffer pool directly, and no processor cycles need to be used for copying data.
 - **Commandline:** `--innodb-use-native-aio={0|1}`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `ON`
-

innodb_use_purge_thread

- **Description:** Usually with InnoDB, data changed by a transaction is written to an undo space to permit read consistency, and freed when the transaction is complete. Many, or large, transactions, can cause the main tablespace to grow dramatically, reducing performance. This option, introduced in XtraDB 5.1 and removed for 5.5, allows multiple threads to perform the purging, resulting in slower, but much more stable performance.
 - **Commandline:** `--innodb-use-purge-thread=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:** `1`
 - **Range:** `0` to `32`
 - **Removed:** XtraDB 5.5
-

innodb_use_stacktrace

- **Description:** If set to `ON` (`OFF` is default), a signal handler for `SIGUSR2` is installed when the InnoDB server starts. When a long semaphore wait is detected at `sync/sync0array.c`, a `SIGUSR2` signal is sent to the waiting thread and thread that has acquired the `RW-latch`. For both threads a full stacktrace is produced as well as if possible. XtraDB only. Added as a deprecated and ignored option in [MariaDB 10.2.6](#) (which uses InnoDB as default instead of XtraDB) to allow for easier upgrades.
 - **Commandline:** `--innodb-use-stacktrace={0|1}`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
 - **Deprecated:** [MariaDB 10.2.6](#)
 - **Removed:** [MariaDB 10.3.0](#)
-

innodb_use_sys_malloc

- **Description:** If set the `1`, the default, XtraDB/InnoDB will use the operating system's memory allocator. If set to `0` it will use its own. Deprecated in [MariaDB 10.0](#) and removed in [MariaDB 10.2](#) along with InnoDB's internal memory allocator.
 - **Commandline:** `--innodb-use-sys-malloc={0|1}`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `ON`
 - **Deprecated:** [MariaDB 10.0](#)
 - **Removed:** [MariaDB 10.2.2](#)
-

`innodb_use_sys_stats_table`

- **Description:** If set to `1` (`0` is default), XtraDB will use the `SYS_STATS` system table for extra table index statistics. When a table is opened for the first time, statistics will then be loaded from `SYS_STATS` instead of sampling the index pages. Statistics are designed to be maintained only by running an [ANALYZE TABLE](#). Replaced by MySQL 5.6's Persistent Optimizer Statistics.
 - **Commandline:** `innodb-use-sys-stats-table={0|1}`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `0`
 - **Removed:** [MariaDB 10.0/XtraDB 5.6](#)
-

`innodb_use_trim`

- **Description:** Use trim to free up space of compressed blocks.
 - See [InnoDB Page Compression: Saving Storage Space with Sparse Files](#) for more information.
 - **Commandline:** `--innodb-use-trim={0|1}`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `ON`
 - **Deprecated:** [MariaDB 10.2.4](#)
 - **Removed:** [MariaDB 10.3.0](#)
-

`innodb_version`

- **Description:** InnoDB version number. From [MariaDB 10.3.7](#), as the InnoDB implementation in MariaDB has diverged from MySQL, the MariaDB version is instead reported. For example, the InnoDB version reported in [MariaDB 10.1](#) (which is based on MySQL 5.6) included encryption and variable-size page compression before MySQL 5.7 introduced them. [MariaDB 10.2](#) (based on MySQL 5.7) introduced persistent `AUTO_INCREMENT` ([MDEV-6076](#)) in a GA release before MySQL 8.0. [MariaDB 10.3](#) (based on MySQL 5.7) introduced instant `ADD COLUMN` ([MDEV-11369](#)) before MySQL.
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `string`
 - **Removed:** [MariaDB 10.10](#)
-

`innodb_write_io_threads`

- **Description:** Prior to [MariaDB 10.5](#), this was simply the number of I/O threads for InnoDB writes. From [MariaDB 10.5](#), asynchronous I/O functionality in the InnoDB Background Thread Pool replaces the old InnoDB I/O Threads. This variable is now multiplied by 256 to determine the maximum number of concurrent asynchronous I/O write requests that can be completed by the Background Thread Pool. The default is therefore $4 * 256 = 1024$ concurrent asynchronous write requests. You may on rare occasions need to reduce this default on Linux systems running multiple MariaDB servers to avoid exceeding system limits, or increase if spending too much time waiting on I/O requests.
 - **Commandline:** `--innodb-write-io-threads=#`
 - **Scope:** Global
 - **Dynamic:** Yes (\geq [MariaDB 10.11](#)), No (\leq [MariaDB 10.10](#))
-

- **Data Type:** numeric
- **Default Value:** 4
- **Range:** 1 to 64

See [Server Status Variables](#) for a complete list of status variables that can be viewed with `SHOW STATUS`.

Much of the `InnoDB` information here can also be seen with a `SHOW ENGINE INNODB STATUS` statement.

See also the [Full list of MariaDB options, system and status variables](#).

`InnoDB_adaptive_hash_cells`

- **Description:** As shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the `SHOW ENGINE INNODB STATUS` output.
 - In [MariaDB 5.5](#), this status variable is present in XtraDB.
 - In [MariaDB 10.1](#) and later, this status variable is not present.

- **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 5.5](#)
 - **Removed:** [MariaDB 10.0.0](#) [↗](#)
-

`InnoDB_adaptive_hash_hash_searches`

- **Description:** Hash searches as shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the [SHOW ENGINE INNODB STATUS](#) output.
 - Before the variable was introduced in [MariaDB 10.5.0](#), use the `adaptive_hash_searches` counter in the `information_schema.INNODB_METRICS` table instead.
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 10.5.0](#)
-

`InnoDB_adaptive_hash_heap_buffers`

- **Description:** As shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the [SHOW ENGINE INNODB STATUS](#) output.
 - In [MariaDB 5.5](#), this status variable is present in XtraDB.
 - In [MariaDB 10.1](#) and later, this status variable is not present.
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 5.5](#)
 - **Removed:** [MariaDB 10.0.0](#) [↗](#)
-

`InnoDB_adaptive_hash_non_hash_searches`

- **Description:** Non-hash searches as shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the [SHOW ENGINE INNODB STATUS](#) output. From [MariaDB 10.6.2](#), not updated if `innodb_adaptive_hash_index` is not enabled (the default).
 - In [MariaDB 10.1](#), [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this status variable is not present. Use the `adaptive_hash_searches_btree` counter in the `information_schema.INNODB_METRICS` table instead.
 - From [MariaDB 10.5](#), this status variable is present.
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 5.5](#), [MariaDB 10.5.0](#)
 - **Removed:** [MariaDB 10.0.0](#) [↗](#)
-

`InnoDB_async_reads_pending`

- **Description:** Number of async read I/O operations currently in progress (from SUBMITTED to COMPLETED). See [InnoDB Asynchronous I/O](#) [↗](#).
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 11.5](#)
-

`InnoDB_async_reads_queue_size`

- **Description:** Current size of the async I/O read queue. See [InnoDB Asynchronous I/O Queuing Mechanism](#).
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 11.5](#)
-

`InnoDB_async_reads_tasks_running`

- **Description:** Number of async read I/O operations currently in the EXECUTING_COMPLETION_TASK state. See [InnoDB Asynchronous I/O](#) [↗](#).
- **Scope:** Global

- **Data Type:** `numeric`
 - **Introduced:** [MariaDB 11.5](#)
-

`InnoDB_async_reads_total_count`

- **Description:** Total number of async read completion tasks that have finished execution. See [InnoDB Asynchronous I/O](#).
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 11.5](#)
-

`InnoDB_async_reads_total_enqueues`

- **Description:** Total number of async read operations that were queued. Includes those still waiting and making up `innodb_async_reads_queue_size`. See [InnoDB Asynchronous I/O](#).
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 11.5](#)
-

`InnoDB_async_reads_wait_slot_sec`

- **Description:** Total wait time for a free I/O slot (see [Waiting for IO Slots](#)). See [InnoDB Asynchronous I/O Waiting for IO Slots](#).
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 11.5](#)
-

`InnoDB_async_writes_pending`

- **Description:** Number of async write I/O operations currently in progress (from SUBMITTED to COMPLETED). See [InnoDB Asynchronous I/O](#).
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 11.5](#)
-

`InnoDB_async_writes_queue_size`

- **Description:** Current size of the async I/O write queue. See [InnoDB Asynchronous I/O Queuing Mechanism](#).
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 11.5](#)
-

`InnoDB_async_writes_tasks_running`

- **Description:** Number of async write I/O operations currently in the EXECUTING_COMPLETION_TASK state. See [InnoDB Asynchronous I/O](#).
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 11.5](#)
-

`InnoDB_async_writes_total_count`

- **Description:** Total number of async write completion tasks that have finished execution. See [InnoDB Asynchronous I/O](#).
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 11.5](#)
-

InnoDB_async_writes_total_enqueues

- **Description:** Total number of async write operations that were queued. Includes those still waiting and making up [innodb_async_writes_queue_size](#). See [InnoDB Asynchronous I/O](#).
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 11.5](#)
-

InnoDB_async_writes_wait_slot_sec

- **Description:** See [InnoDB Asynchronous I/O](#).
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 11.5](#)
-

InnoDB_available_undo_logs

- **Description:** Total number available InnoDB [undo logs](#). Differs from the [innodb_undo_logs](#) system variable, which specifies the number of *active* undo logs.
 - **Scope:** Global
 - **Data Type:** `numeric`
-

InnoDB_background_log_sync

- **Description:** As shown in the BACKGROUND THREAD section of the [SHOW ENGINE INNODB STATUS](#) output.
 - In [MariaDB 5.5](#), this status variable is present in XtraDB.
 - In [MariaDB 10.1](#), [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this status variable is not present.
 - In [MariaDB 10.5](#), this status variable was reintroduced.
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 5.5](#) (XtraDB only), [MariaDB 10.5.0](#)
-

InnoDB_buffer_pool_bytes_data

- **Description:** Number of bytes contained in the [InnoDB buffer pool](#), both dirty (modified) and clean (unmodified). See also [InnoDB_buffer_pool_pages_data](#), which can contain pages of different sizes in the case of compression.
 - **Scope:** Global
 - **Data Type:** `numeric`
-

InnoDB_buffer_pool_bytes_dirty

- **Description:** Number of dirty (modified) bytes contained in the [InnoDB buffer pool](#). See also [InnoDB_buffer_pool_pages_dirty](#), which can contain pages of different sizes in the case of compression.
 - **Scope:** Global
 - **Data Type:** `numeric`
-

InnoDB_buffer_pool_dump_status

- **Description:** A text description of the progress or final status of the last InnoDB buffer pool dump.
 - **Scope:** Global
 - **Data Type:** `string`
 - **Introduced:** [MariaDB 10.0.0](#)
-

InnoDB_buffer_pool_load_incomplete

- **Description:** Whether or not the loaded buffer pool is incomplete, for example after a shutdown or abort during InnoDB buffer pool load from file caused an incomplete save.
- **Scope:** Global

- **Data Type:** `boolean`
- **Introduced:** [MariaDB 10.3.5](#) 

InnoDB_buffer_pool_load_status

- **Description:** A text description of the progress or final status of the last InnoDB buffer pool load.
- **Scope:** Global
- **Data Type:** `string`
- **Introduced:** [MariaDB 10.0.0](#) 

InnoDB_buffer_pool_pages_data

- **Description:** Number of [InnoDB buffer pool](#) pages which contain data, both dirty (modified) and clean (unmodified). See also [InnoDB_buffer_pool_bytes_data](#).
- **Scope:** Global
- **Data Type:** `numeric`

InnoDB_buffer_pool_pages_dirty

- **Description:** Number of [InnoDB buffer pool](#) pages which contain dirty (modified) data. See also [InnoDB_buffer_pool_bytes_dirty](#).
- **Scope:** Global
- **Data Type:** `numeric`

InnoDB_buffer_pool_pages_flushed

- **Description:** Number of [InnoDB buffer pool](#) pages which have been flushed.
- **Scope:** Global
- **Data Type:** `numeric`

InnoDB_buffer_pool_pages_LRU_flushed

- **Description:** Flush list as shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the [SHOW ENGINE INNODB STATUS](#) output.
 - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this status variable is present in XtraDB.
 - In [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this status variable is not present.
 - In [MariaDB 10.5](#), this status variable was reintroduced.
- **Scope:** Global
- **Data Type:** `numeric`
- **Introduced:** [MariaDB 5.5](#) (XtraDB-only), [MariaDB 10.5.0](#)

InnoDB_buffer_pool_pages_LRU_freed

- **Description:** Monitor the number of pages that were freed by a buffer pool LRU eviction scan, without flushing.
- **Scope:** Global
- **Data Type:** `numeric`
- **Introduced:** [MariaDB 10.6.0](#)

InnoDB_buffer_pool_pages_free

- **Description:** Number of free [InnoDB buffer pool](#) pages.
- **Scope:** Global
- **Data Type:** `numeric`

InnoDB_buffer_pool_pages_made_not_young

- **Description:** Pages not young as shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the

[SHOW ENGINE INNODB STATUS](#) output.

- In [MariaDB 5.5](#) and [MariaDB 10.1](#), this status variable is present in XtraDB.
- In [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this status variable is not present.
- In [MariaDB 10.5](#), this status variable was reintroduced.

- **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 5.5](#) (XtraDB-only), [MariaDB 10.5.0](#)
-

`Innodb_buffer_pool_pages_made_young`

- **Description:** Pages made young as shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the [SHOW ENGINE INNODB STATUS](#) output.
 - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this status variable is present in XtraDB.
 - In [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this status variable is not present.
 - In [MariaDB 10.5](#), this status variable was reintroduced.
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 5.5](#) (XtraDB-only), [MariaDB 10.5.0](#)
-

`Innodb_buffer_pool_pages_misc`

- **Description:** Number of [InnoDB buffer pool](#) pages set aside for internal use.
 - **Scope:** Global
 - **Data Type:** `numeric`
-

`Innodb_buffer_pool_pages_old`

- **Description:** Old database page, as shown in the BUFFER POOL AND MEMORY section of the [SHOW ENGINE INNODB STATUS](#) output.
 - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this status variable is present for XtraDB.
 - In [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this status variable is not present.
 - In [MariaDB 10.5](#), this status variable was reintroduced.
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 5.5](#) (XtraDB-only), [MariaDB 10.5.0](#)
-

`Innodb_buffer_pool_pages_total`

- **Description:** Total number of [InnoDB buffer pool](#) pages.
 - **Scope:** Global
 - **Data Type:** `numeric`
-

`Innodb_buffer_pool_read_ahead`

- **Description:** Number of pages read into the [InnoDB buffer pool](#) by the read-ahead background thread.
 - **Scope:** Global
 - **Data Type:** `numeric`
-

`Innodb_buffer_pool_read_ahead_evicted`

- **Description:** Number of pages read into the [InnoDB buffer pool](#) by the read-ahead background thread that were evicted without having been accessed by queries.
 - **Scope:** Global
 - **Data Type:** `numeric`
-

`Innodb_buffer_pool_read_ahead_rnd`

- **Description:** Number of random read-aheads.

- **Scope:** Global
 - **Data Type:** numeric
-

InnoDB_buffer_pool_read_requests

- **Description:** Number of requests to read from the [InnoDB buffer pool](#).
 - **Scope:** Global
 - **Data Type:** numeric
-

InnoDB_buffer_pool_reads

- **Description:** Number of reads that could not be satisfied by the [InnoDB buffer pool](#) and had to be read from disk.
 - **Scope:** Global
 - **Data Type:** numeric
-

InnoDB_buffer_pool_resize_status

- **Description:** Progress of the dynamic [InnoDB buffer pool](#) resizing operation. See [Setting InnoDB Buffer Pool Size Dynamically](#).
 - **Scope:** Global
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 10.2.2](#) 
-

InnoDB_buffer_pool_wait_free

- **Description:** Number of times InnoDB waited for a free page before reading or creating a page. Normally, writes to the [InnoDB buffer pool](#) happen in the background. When no clean pages are available, dirty pages are flushed first in order to free some up. This counts the numbers of wait for this operation to finish. If this value is not small, look at increasing [innodb_buffer_pool_size](#).
 - **Scope:** Global
 - **Data Type:** numeric
-

InnoDB_buffer_pool_write_requests

- **Description:** Number of requests to write to the [InnoDB buffer pool](#).
 - **Scope:** Global
 - **Data Type:** numeric
-

InnoDB_buffered_aio_submitted

- **Description:**
 - **Scope:** Global
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 10.5.0](#)
-

InnoDB_bulk_operations

- **Description:** Number of bulk insert operations to InnoDB tables.
 - **Scope:** Global
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 10.6.19](#), [MariaDB 10.11.9](#), [MariaDB 11.1.6](#) , [MariaDB 11.2.5](#) , [MariaDB 11.4.3](#)
-

InnoDB_checkpoint_age

- **Description:** The amount of data written to the InnoDB redo log since the last checkpoint, as shown in the LOG section of the [SHOW ENGINE INNODB STATUS](#) output. (This is equivalent to subtracting "Last checkpoint at" from "Log sequence number", cf the [RedoLog details](#)). Despite the name ("age"), the value is not a duration, but really an

amount of data (in bytes) !

- In [MariaDB 5.5](#) and [MariaDB 10.1](#), this status variable is present in XtraDB.
 - In [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this status variable is not present.
 - In [MariaDB 10.5](#), this status variable was reintroduced.
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 5.5](#) (XtraDB-only), [MariaDB 10.5.0](#)
-

InnoDB_checkpoint_max_age

- **Description:** Max checkpoint age, as shown in the LOG section of the [SHOW ENGINE INNODB STATUS](#) output.
 - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this status variable is present in XtraDB.
 - In [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this status variable is not present.
 - In [MariaDB 10.5](#), this status variable was reintroduced.
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 5.5](#) (XtraDB-only), [MariaDB 10.5.0](#)
-

InnoDB_checkpoint_target_age

- **Description:** Checkpoint age target, as shown in the LOG section of the [SHOW ENGINE INNODB STATUS](#) output. XtraDB only. Removed in [MariaDB 10.0](#) and replaced with MySQL 5.6's flushing implementation.
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 5.5](#)
 - **Removed:** [MariaDB 10.0](#)
-

InnoDB_current_row_locks

- **Description:** Number of current row locks on InnoDB tables as shown in the TRANSACTIONS section of the [SHOW ENGINE INNODB STATUS](#) output. Renamed from [InnoDB_row_lock_numbers](#) in XtraDB 5.5.8-20.1.
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 5.5](#)
-

InnoDB_data_fsyncs

- **Description:** Number of InnoDB fsync (sync-to-disk) calls. fsync call frequency can be influenced by the [innodb_flush_method](#) configuration option.
 - **Scope:** Global
 - **Data Type:** `numeric`
-

InnoDB_data_pending_fsyncs

- **Description:** Number of pending InnoDB fsync (sync-to-disk) calls. fsync call frequency can be influenced by the [innodb_flush_method](#) configuration option.
 - **Scope:** Global
 - **Data Type:** `numeric`
-

InnoDB_data_pending_reads

- **Description:** Number of pending InnoDB reads.
 - **Scope:** Global
 - **Data Type:** `numeric`
-

InnoDB_data_pending_writes

- **Description:** Number of pending InnoDB writes.

- **Scope:** Global
 - **Data Type:** numeric
-

InnoDB_data_read

- **Description:** Number of InnoDB bytes read since server startup (not to be confused with [InnoDB_data_reads](#)).
 - **Scope:** Global
 - **Data Type:** numeric
-

InnoDB_data_reads

- **Description:** Number of InnoDB read operations (not to be confused with [InnoDB_data_read](#)).
 - **Scope:** Global
 - **Data Type:** numeric
-

InnoDB_data_writes

- **Description:** Number of InnoDB write operations.
 - **Scope:** Global
 - **Data Type:** numeric
-

InnoDB_data_written

- **Description:** Number of InnoDB bytes written since server startup. From [MariaDB 10.5.1](#), no longer includes writes to the redo log file `ib_logfile0`, which continue to be counted by [InnoDB_os_log_written](#). An error in counting was introduced in [MariaDB 10.5.7](#) until [MariaDB 10.5.20](#), [MariaDB 10.6.13](#), [MariaDB 10.8.8](#), [MariaDB 10.9.6](#), [MariaDB 10.10.4](#) and [MariaDB 10.11.3 \(MDEV-31124\)](#) in which writes via the doublewrite buffer started to be counted incorrectly, without multiplying them by `innodb_page_size`. A workaround for the error could be the following formulae:
$$\text{real_data_written} = \text{InnoDB_data_written} + (\text{innodb_page_size} - 1) * \text{InnoDB_dblwr_pages_written}$$
$$\text{innodb_written} = \text{real_data_written} + \text{InnoDB_os_log_written}$$
 - **Scope:** Global
 - **Data Type:** numeric
-

InnoDB_dblwr_pages_written

- **Description:** Number of pages written to the [InnoDB doublewrite buffer](#).
 - **Scope:** Global
 - **Data Type:** numeric
-

InnoDB_dblwr_writes

- **Description:** Number of writes to the [InnoDB doublewrite buffer](#).
 - **Scope:** Global
 - **Data Type:** numeric
-

InnoDB_deadlocks

- **Description:** Total number of InnoDB deadlocks. Deadlocks occur when at least two transactions are waiting for the other to finish, creating a circular dependency. InnoDB usually detects these quickly, returning an error.
 - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this status variable is present in XtraDB.
 - In [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this status variable is not present.
 - In [MariaDB 10.5](#), this status variable was reintroduced.
 - **Scope:** Global
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 5.5](#) (XtraDB-only), [MariaDB 10.5.0](#)
-

InnoDB_defragment_compression_failures

- **Description:** Number of defragment re-compression failures. See [Defragmenting InnoDB Tablespace](#).
 - **Scope:** Global
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 10.1.1](#) 
-

InnoDB_defragment_count

- **Description:** Number of defragment operations. See [Defragmenting InnoDB Tablespace](#).
 - **Scope:** Global
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 10.1.1](#) 
-

InnoDB_defragment_failures

- **Description:** Number of defragment failures. See [Defragmenting InnoDB Tablespace](#).
 - **Scope:** Global
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 10.1.1](#) 
-

InnoDB_dict_tables

- **Description:** Number of entries in the XtraDB data dictionary cache. This Percona XtraDB variable was removed in MariaDB 10/XtraDB 5.6 as it was replaced with MySQL 5.6's [table_definition_cache](#) implementation.
 - **Scope:** Global
 - **Data Type:** numeric
 - **Introduced:** XtraDB 5.0.77-b13
 - **Removed:** [MariaDB 10.0](#)
-

InnoDB_encryption_n_merge_blocks_decrypted

- **Description:**
 - **Scope:** Global
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 10.1.28](#) , [MariaDB 10.2.9](#) , [MariaDB 10.3.2](#) 
-

InnoDB_encryption_n_merge_blocks_encrypted

- **Description:**
 - **Scope:** Global
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 10.1.28](#) , [MariaDB 10.2.9](#) , [MariaDB 10.3.2](#) 
-

InnoDB_encryption_n_rowlog_blocks_decrypted

- **Description:**
 - **Scope:** Global
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 10.1.28](#) , [MariaDB 10.2.9](#) , [MariaDB 10.3.2](#) 
-

InnoDB_encryption_n_rowlog_blocks_encrypted

- **Description:**
 - **Scope:** Global
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 10.1.28](#) , [MariaDB 10.2.9](#) , [MariaDB 10.3.2](#) 
-

InnoDB_encryption_n_temp_blocks_decrypted

- **Description:**
 - **Scope:** Global
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 10.2.26](#), [MariaDB 10.3.17](#), [MariaDB 10.4.7](#)
-

InnoDB_encryption_n_temp_blocks_encrypted

- **Description:**
 - **Scope:** Global
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 10.2.26](#), [MariaDB 10.3.17](#), [MariaDB 10.4.7](#)
-

InnoDB_encryption_num_key_requests

- **Description:** Was not present in [MariaDB 10.5.2](#).
 - **Scope:** Global
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 10.2.4](#)
-

InnoDB_encryption_rotation_estimated_iops

- **Description:** See [Table and Tablespace Encryption](#).
 - **Scope:** Global
 - **Data Type:** numeric
 - **Removed:** [MariaDB 10.1.3](#)
-

InnoDB_encryption_rotation_pages_flushed

- **Description:** See [Table and Tablespace Encryption](#).
 - **Scope:** Global
 - **Data Type:** numeric
 - **Removed:** [MariaDB 10.1.3](#)
-

InnoDB_encryption_rotation_pages_modified

- **Description:** See [Table and Tablespace Encryption](#).
 - **Scope:** Global
 - **Data Type:** numeric
 - **Removed:** [MariaDB 10.1.3](#)
-

InnoDB_encryption_rotation_pages_read_from_cache

- **Description:** See [Table and Tablespace Encryption](#).
 - **Scope:** Global
 - **Data Type:** numeric
 - **Removed:** [MariaDB 10.1.3](#)
-

InnoDB_encryption_rotation_pages_read_from_disk

- **Description:** See [Table and Tablespace Encryption](#).
 - **Scope:** Global
 - **Data Type:** numeric
 - **Removed:** [MariaDB 10.1.3](#)
-

InnoDB_have_atomic_builtins

- **Description:** Whether the server has been built with atomic instructions, provided by the CPU ensuring that critical low-level operations can't be interrupted. XtraDB only.
 - **Scope:** Global
 - **Data Type:** `boolean`
-

InnoDB_have_bzip2

- **Description:** Whether the server has the bzip2 compression method available. See [InnoDB/XtraDB Page Compression](#).
 - **Scope:** Global
 - **Data Type:** `boolean`
 - **Introduced:** [MariaDB 10.1.0](#) 
-

InnoDB_have_lz4

- **Description:** Whether the server has the lz4 compression method available. See [InnoDB/XtraDB Page Compression](#).
 - **Scope:** Global
 - **Data Type:** `boolean`
 - **Introduced:** [MariaDB 10.1.0](#) 
-

InnoDB_have_lzma

- **Description:** Whether the server has the lzma compression method available. See [InnoDB/XtraDB Page Compression](#).
 - **Scope:** Global
 - **Data Type:** `boolean`
 - **Introduced:** [MariaDB 10.1.0](#) 
-

InnoDB_have_lzo

- **Description:** Whether the server has the lzo compression method available. See [InnoDB/XtraDB Page Compression](#).
 - **Scope:** Global
 - **Data Type:** `boolean`
 - **Introduced:** [MariaDB 10.1.0](#) 
-

InnoDB_have_punch_hole

- **Description:**
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 10.2.4](#) 
-

InnoDB_have_snappy

- **Description:** Whether the server has the snappy compression method available. See [InnoDB/XtraDB Page Compression](#).
 - **Scope:** Global
 - **Data Type:** `boolean`
 - **Introduced:** [MariaDB 10.1.3](#) 
-

InnoDB_history_list_length

- **Description:** History list length as shown in the TRANSACTIONS section of the [SHOW ENGINE INNODB STATUS](#) output. XtraDB only until introduced in [MariaDB 10.5.0](#).
- **Scope:** Global
- **Data Type:** `numeric`

- **Introduced:** [MariaDB 5.5](#) (XtraDB-only), [MariaDB 10.5.0](#)
-

InnoDB_ibuf_discarded_delete_marks

- **Description:** As shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the [SHOW ENGINE INNODB STATUS](#) output.
 - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this status variable is present in XtraDB.
 - In [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this status variable is not present.
 - In [MariaDB 10.5](#), this status variable was reintroduced.
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 5.5](#) (XtraDB-only), [MariaDB 10.5.0](#)
-

InnoDB_ibuf_discarded_deletes

- **Description:** As shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the [SHOW ENGINE INNODB STATUS](#) output.
 - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this status variable is present in XtraDB.
 - In [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this status variable is not present.
 - In [MariaDB 10.5](#), this status variable was reintroduced.
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 5.5](#) (XtraDB-only), [MariaDB 10.5.0](#)
-

InnoDB_ibuf_discarded_inserts

- **Description:** As shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the [SHOW ENGINE INNODB STATUS](#) output.
 - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this status variable is present in XtraDB.
 - In [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this status variable is not present.
 - In [MariaDB 10.5](#), this status variable was reintroduced.
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 5.5](#) (XtraDB-only), [MariaDB 10.5.0](#)
-

InnoDB_ibuf_free_list

- **Description:** As shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the [SHOW ENGINE INNODB STATUS](#) output.
 - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this status variable is present in XtraDB.
 - In [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this status variable is not present.
 - In [MariaDB 10.5](#), this status variable was reintroduced.
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 5.5](#) (XtraDB-only), [MariaDB 10.5.0](#)
-

InnoDB_ibuf_merged_delete_marks

- **Description:** As shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the [SHOW ENGINE INNODB STATUS](#) output.
 - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this status variable is present in XtraDB.
 - In [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this status variable is not present.
 - In [MariaDB 10.5](#), this status variable was reintroduced.
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 5.5](#) (XtraDB-only), [MariaDB 10.5.0](#)
-

InnoDB_ibuf_merged_deletes

- **Description:** As shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the [SHOW ENGINE](#)

[INNODB STATUS](#) output.

- In [MariaDB 5.5](#) and [MariaDB 10.1](#), this status variable is present in XtraDB.
 - In [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this status variable is not present.
 - In [MariaDB 10.5](#), this status variable was reintroduced.
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 5.5](#) (XtraDB-only), [MariaDB 10.5.0](#)
-

`InnoDB_ibuf_merged_inserts`

- **Description:** As shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the [SHOW ENGINE INNODB STATUS](#) output.
 - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this status variable is present in XtraDB.
 - In [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this status variable is not present.
 - In [MariaDB 10.5](#), this status variable was reintroduced.
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 5.5](#) (XtraDB-only), [MariaDB 10.5.0](#)
-

`InnoDB_ibuf_merges`

- **Description:** As shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the [SHOW ENGINE INNODB STATUS](#) output.
 - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this status variable is present in XtraDB.
 - In [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this status variable is not present.
 - In [MariaDB 10.5](#), this status variable was reintroduced.
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 5.5](#) (XtraDB-only), [MariaDB 10.5.0](#)
-

`InnoDB_ibuf_segment_size`

- **Description:** As shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the [SHOW ENGINE INNODB STATUS](#) output.
 - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this status variable is present in XtraDB.
 - In [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this status variable is not present.
 - In [MariaDB 10.5](#), this status variable was reintroduced.
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 5.5](#) (XtraDB-only), [MariaDB 10.5.0](#)
-

`InnoDB_ibuf_size`

- **Description:** As shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the [SHOW ENGINE INNODB STATUS](#) output.
 - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this status variable is present in XtraDB.
 - In [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this status variable is not present.
 - In [MariaDB 10.5](#), this status variable was reintroduced.
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 5.5](#) (XtraDB-only), [MariaDB 10.5.0](#)
-

`InnoDB_instant_alter_column`

- **Description:** See [Instant ADD COLUMN for InnoDB](#).
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 10.3.2](#) [↗](#)
-

InnoDB_log_waits

- **Description:** Number of times InnoDB was forced to wait for log writes to be flushed due to the log buffer being too small.
 - **Scope:** Global
 - **Data Type:** numeric
-

InnoDB_log_write_requests

- **Description:** Number of requests to write to the InnoDB redo log.
 - **Scope:** Global
 - **Data Type:** numeric
-

InnoDB_log_writes

- **Description:** Number of writes to the InnoDB redo log.
 - **Scope:** Global
 - **Data Type:** numeric
-

InnoDB_lsn_current

- **Description:** Log sequence number as shown in the LOG section of the [SHOW ENGINE INNODB STATUS](#) output.
 - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this status variable is present in XtraDB.
 - In [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this status variable is not present.
 - In [MariaDB 10.5](#), this status variable was reintroduced.
 - **Scope:** Global
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 5.5](#) (XtraDB-only), [MariaDB 10.5.0](#)
-

InnoDB_lsn_flushed

- **Description:** Flushed up to log sequence number as shown in the LOG section of the [SHOW ENGINE INNODB STATUS](#) output.
 - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this status variable is present in XtraDB.
 - In [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this status variable is not present.
 - In [MariaDB 10.5](#), this status variable was reintroduced.
 - **Scope:** Global
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 5.5](#) (XtraDB-only), [MariaDB 10.5.0](#)
-

InnoDB_lsn_last_checkpoint

- **Description:** Log sequence number last checkpoint as shown in the LOG section of the [SHOW ENGINE INNODB STATUS](#) output.
 - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this status variable is present in XtraDB.
 - In [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this status variable is not present.
 - In [MariaDB 10.5](#), this status variable was reintroduced.
 - **Scope:** Global
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 5.5](#) (XtraDB-only), [MariaDB 10.5.0](#)
-

InnoDB_master_thread_1_second_loops

- **Description:** As shown in the BACKGROUND THREAD section of the [SHOW ENGINE INNODB STATUS](#) output.
 - In [MariaDB 5.5](#), this status variable is present in XtraDB.
 - In [MariaDB 10.1](#) and later, this status variable is not present.
- **Scope:** Global
- **Data Type:** numeric
- **Introduced:** [MariaDB 5.5](#)
- **Removed:** [MariaDB 10.0](#)

InnoDB_master_thread_10_second_loops

- **Description:** As shown in the BACKGROUND THREAD section of the [SHOW ENGINE INNODB STATUS](#) output.
 - In [MariaDB 5.5](#), this status variable is present in XtraDB.
 - In [MariaDB 10.1](#) and later, this status variable is not present
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 5.5](#)
 - **Removed:** [MariaDB 10.0](#)
-

InnoDB_master_thread_active_loops

- **Description:** As shown in the BACKGROUND THREAD section of the [SHOW ENGINE INNODB STATUS](#) output.
 - In [MariaDB 10.1](#), this status variable is present in XtraDB.
 - In [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this status variable is not present.
 - In [MariaDB 10.5](#), this status variable was reintroduced.
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 10.0.9](#) [🔗](#) (XtraDB-only), [MariaDB 10.5.0](#):
-

InnoDB_master_thread_background_loops

- **Description:** As shown in the BACKGROUND THREAD section of the [SHOW ENGINE INNODB STATUS](#) output.
 - In [MariaDB 5.5](#), this status variable is present in XtraDB.
 - In [MariaDB 10.1](#) and later, this status variable is not present
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 5.5](#)
 - **Removed:** [MariaDB 10.0](#)
-

InnoDB_master_thread_idle_loops

- **Description:** As shown in the BACKGROUND THREAD section of the [SHOW ENGINE INNODB STATUS](#) output.
 - In [MariaDB 10.1](#), this status variable is present in XtraDB.
 - In [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this status variable is not present.
 - In [MariaDB 10.5](#), this status variable was reintroduced.
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 10.0.9](#) [🔗](#) (XtraDB-only), [MariaDB 10.5.0](#):
-

InnoDB_master_thread_main_flush_loops

- **Description:** As shown in the BACKGROUND THREAD section of the [SHOW ENGINE INNODB STATUS](#) output.
 - In [MariaDB 5.5](#), this status variable is present in XtraDB.
 - In [MariaDB 10.1](#) and later, this status variable is not present
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 5.5](#)
 - **Removed:** [MariaDB 10.0](#)
-

InnoDB_master_thread_sleeps

- **Description:** As shown in the BACKGROUND THREAD section of the [SHOW ENGINE INNODB STATUS](#) output. XtraDB only.
 - In [MariaDB 5.5](#), this status variable is present in XtraDB.
 - In [MariaDB 10.1](#), [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this status variable is not present. Use the `innodb_master_thread_sleeps` counter in the `information_schema.INNODB_METRICS` table instead.
 - In [MariaDB 10.5](#), this status variable was reintroduced.

- **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 5.5](#)
 - **Removed:** [MariaDB 10.0](#)
-

InnoDB_max_trx_id

- **Description:** As shown in the TRANSACTIONS section of the [SHOW ENGINE INNODB STATUS](#) output.
 - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this status variable is present in XtraDB.
 - In [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this status variable is not present.
 - In [MariaDB 10.5](#), this status variable was reintroduced.
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 5.5](#) (XtraDB-only), [MariaDB 10.5.0](#)
-

InnoDB_mem_adaptive_hash

- **Description:** As shown in the BUFFER POOL AND MEMORY section of the [SHOW ENGINE INNODB STATUS](#) output.
 - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this status variable is present in XtraDB.
 - In [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this status variable is not present.
 - In [MariaDB 10.5](#), this status variable was reintroduced.
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 5.5](#) (XtraDB-only), [MariaDB 10.5.0](#)
-

InnoDB_mem_dictionary

- **Description:** As shown in the BUFFER POOL AND MEMORY section of the [SHOW ENGINE INNODB STATUS](#) output.
 - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this status variable is present in XtraDB.
 - In [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this status variable is not present.
 - In [MariaDB 10.5](#), this status variable was reintroduced.
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 5.5](#) (XtraDB-only), [MariaDB 10.5.0](#)
-

InnoDB_mem_total

- **Description:** As shown in the BUFFER POOL AND MEMORY section of the [SHOW ENGINE INNODB STATUS](#) output.
 - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this status variable is present in XtraDB.
 - In [MariaDB 10.2](#) and later, this status variable is not present.
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 5.5](#)
-

InnoDB_mutex_os_waits

- **Description:** Mutex OS waits as shown in the SEMAPHORES section of the [SHOW ENGINE INNODB STATUS](#) output.
 - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this status variable is present in XtraDB.
 - In [MariaDB 10.2](#) and later, this status variable is not present.
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 5.5](#)
-

InnoDB_mutex_spin_rounds

- **Description:** Mutex spin rounds as shown in the SEMAPHORES section of the [SHOW ENGINE INNODB STATUS](#) output.
 - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this status variable is present in XtraDB.
 - In [MariaDB 10.2](#) and later, this status variable is not present.
 - **Scope:** Global
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 5.5](#)
-

Innodb_mutex_spin_waits

- **Description:** Mutex spin waits as shown in the SEMAPHORES section of the [SHOW ENGINE INNODB STATUS](#) output.
 - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this status variable is present in XtraDB.
 - In [MariaDB 10.2](#) and later, this status variable is not present.
 - **Scope:** Global
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 5.5](#)
-

Innodb_num_index_pages_written

- **Description:**
 - **Scope:**
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 10.1.0](#) 
-

Innodb_num_non_index_pages_written

- **Description:**
 - **Scope:**
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 10.1.0](#) 
-

Innodb_num_open_files

- **Description:** Number of open files held by InnoDB. InnoDB only.
 - **Scope:** Global
 - **Data Type:** numeric
-

Innodb_num_page_compressed_trim_op

- **Description:** Number of trim operations performed.
 - **Scope:** Global
 - **Data Type:** numeric
-

Innodb_num_page_compressed_trim_op_saved

- **Description:** Number of trim operations not done because of an earlier trim.
 - **Scope:** Global
 - **Data Type:** numeric
-

Innodb_num_pages_decrypted

- **Description:** Number of pages page decrypted. See [Table and Tablespace Encryption](#).
 - **Scope:** Global
 - **Data Type:** numeric
-

Innodb_num_pages_encrypted

- **Description:** Number of pages page encrypted. See [Table and Tablespace Encryption](#).
 - **Scope:** Global
 - **Data Type:** `numeric`
-

`InnoDB_num_pages_page_compressed`

- **Description:** Number of pages that are page compressed.
 - **Scope:** Global
 - **Data Type:** `numeric`
-

`InnoDB_num_pages_page_compression_error`

- **Description:** Number of compression errors.
 - **Scope:** Global
 - **Data Type:** `numeric`
-

`InnoDB_num_pages_page_decompressed`

- **Description:** Number of pages compressed with page compression that are decompressed.
 - **Scope:** Global
 - **Data Type:** `numeric`
-

`InnoDB_num_pages_page_encryption_error`

- **Description:** Number of page encryption errors. See [Table and Tablespace Encryption](#).
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 10.1.3](#) 
 - **Removed:** [MariaDB 10.1.4](#) 
-

`InnoDB_oldest_view_low_limit_trx_id`

- **Description:** As shown in the TRANSACTIONS section of the [SHOW ENGINE INNODB STATUS](#) output.
 - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this status variable is present in XtraDB.
 - In [MariaDB 10.2](#) and later, this status variable is not present.
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 5.5](#)
 - **Removed:** [MariaDB 10.2](#)
-

`InnoDB_onlineddl_pct_progress`

- **Description:** Shows the progress of in-place alter table. It might be not so accurate because in-place alter is highly dependent on disk and buffer pool status. See [Monitoring progress and temporal memory usage of Online DDL in InnoDB](#) .
 - **Scope:** Global
 - **Data Type:** `numeric`
-

`InnoDB_onlineddl_rowlog_pct_used`

- **Description:** Shows row log buffer usage in 5-digit integer (10000 means 100.00%). See [Monitoring progress and temporal memory usage of Online DDL in InnoDB](#) .
 - **Scope:** Global
 - **Data Type:** `numeric`
-

`InnoDB_onlineddl_rowlog_rows`

- **Description:** Number of rows stored in the row log buffer. See [Monitoring progress and temporal memory usage of Online DDL in InnoDB](#).
 - **Scope:** Global
 - **Data Type:** numeric
-

InnoDB_os_log_fsyncs

- **Description:** Number of InnoDB log fsync (sync-to-disk) requests.
 - **Scope:** Global
 - **Data Type:** numeric
 - **Removed:** [MariaDB 10.8](#)
-

InnoDB_os_log_pending_fsyncs

- **Description:** Number of pending InnoDB log fsync (sync-to-disk) requests.
 - **Scope:** Global
 - **Data Type:** numeric
 - **Removed:** [MariaDB 10.8](#)
-

InnoDB_os_log_pending_writes

- **Description:** Number of pending InnoDB log writes.
 - **Scope:** Global
 - **Data Type:** numeric
 - **Removed:** [MariaDB 10.8](#)
-

InnoDB_os_log_written

- **Description:** Number of bytes written to the InnoDB log.
 - **Scope:** Global
 - **Data Type:** numeric
-

InnoDB_page_compression_saved

- **Description:** Number of bytes saved by page compression.
 - **Scope:**
 - **Data Type:**
-

InnoDB_page_compression_trim_sect512

- **Description:** Number of TRIM operations performed for the page-compression/NVM Compression workload for the 512 byte block-size.
 - **Scope:**
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 10.1.0](#), [MariaDB 10.0.15](#) Fusion-io
 - **Removed:** [MariaDB 10.2.4](#)
-

InnoDB_page_compression_trim_sect1024

- **Description:** Number of TRIM operations performed for the page-compression/NVM Compression workload for the 1K block-size.
 - **Scope:**
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 10.1.2](#), [MariaDB 10.0.15](#) Fusion-io
 - **Removed:** [MariaDB 10.2.4](#)
-

InnoDB_page_compression_trim_sect2048

- **Description:** Number of TRIM operations performed for the page-compression/NVM Compression workload for the 2K block-size.
 - **Scope:**
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 10.1.2](#), [MariaDB 10.0.15](#) Fusion-io
 - **Removed:** [MariaDB 10.2.4](#)
-

InnoDB_page_compression_trim_sect4096

- **Description:** Number of TRIM operations performed for the page-compression/NVM Compression workload for the 4K block-size.
 - **Scope:**
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 10.1.0](#), [MariaDB 10.0.15](#) Fusion-io
 - **Removed:** [MariaDB 10.2.4](#)
-

InnoDB_page_compression_trim_sect8192

- **Description:** Number of TRIM operations performed for the page-compression/NVM Compression workload for the 8K block-size.
 - **Scope:**
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 10.1.2](#), [MariaDB 10.0.15](#) Fusion-io
 - **Removed:** [MariaDB 10.2.4](#)
-

InnoDB_page_compression_trim_sect16384

- **Description:** Number of TRIM operations performed for the page-compression/NVM Compression workload for the 16K block-size.
 - **Scope:**
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 10.1.2](#), [MariaDB 10.0.15](#) Fusion-io
 - **Removed:** [MariaDB 10.2.4](#)
-

InnoDB_page_compression_trim_sect32768

- **Description:** Number of TRIM operations performed for the page-compression/NVM Compression workload for the 32K block-size.
 - **Scope:**
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 10.1.2](#), [MariaDB 10.0.15](#) Fusion-io
 - **Removed:** [MariaDB 10.2.4](#)
-

InnoDB_page_size

- **Description:** Page size used by InnoDB. Defaults to 16KB, can be compiled with a different value.
 - **Scope:** Global
 - **Data Type:** `numeric`
-

InnoDB_pages_created

- **Description:** Number of InnoDB pages created.
 - **Scope:** Global
 - **Data Type:** `numeric`
-

InnoDB_pages_read

- **Description:** Number of InnoDB pages read.

- **Scope:** Global
 - **Data Type:** numeric
-

InnoDB_pages0_read

- **Description:** Counter for keeping track of reads of the first page of InnoDB data files, because the original implementation of data-at-rest-encryption for InnoDB introduced new code paths for reading the pages. Removed in [MariaDB 10.4.0](#) as the extra reads of the first page were removed, and the encryption subsystem will be initialized whenever we first read the first page of each data file, in `fil_node_open_file()`.
 - **Scope:** Global
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 10.2.4](#), [MariaDB 10.1.21](#)
 - **Removed:** [MariaDB 10.4.0](#)
-

InnoDB_pages_written

- **Description:** Number of InnoDB pages written.
 - **Scope:** Global
 - **Data Type:** numeric
-

InnoDB_purge_trx_id

- **Description:** Purge transaction id as shown in the TRANSACTIONS section of the [SHOW ENGINE INNODB STATUS](#) output.
 - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this status variable is present in XtraDB.
 - In [MariaDB 10.2](#) and later, this status variable is not present.
 - **Scope:** Global
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 5.5](#)
 - **Removed:** [MariaDB 10.2](#)
-

InnoDB_purge_undo_no

- **Description:** As shown in the TRANSACTIONS section of the [SHOW ENGINE INNODB STATUS](#) output.
 - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this status variable is present in XtraDB.
 - In [MariaDB 10.2](#) and later, this status variable is not present.
 - **Scope:** Global
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 5.5](#)
 - **Removed:** [MariaDB 10.2](#)
-

InnoDB_read_views_memory

- **Description:** As shown in the BUFFER POOL AND MEMORY section of the [SHOW ENGINE INNODB STATUS](#) output. Shows the total of memory in bytes allocated for the InnoDB read view.
 - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this status variable is present in XtraDB.
 - In [MariaDB 10.2](#) and later, this status variable is not present.
 - **Scope:** Global
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 5.5.32](#)
 - **Removed:** [MariaDB 10.2](#)
-

InnoDB_row_lock_current_waits

- **Description:** Number of pending row lock waits on InnoDB tables.
 - **Scope:** Global
 - **Data Type:** numeric
-

InnoDB_row_lock_numbers

- **Description:** Number of current row locks on InnoDB tables as shown in the TRANSACTIONS section of the [SHOW ENGINE INNODB STATUS](#) output. Renamed to [InnoDB_current_row_locks](#) in XtraDB 5.5.10-20.1.
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 5.5](#) / XtraDB 5.5.8-20
 - **Removed:** [MariaDB 5.5](#) / XtraDB 5.5.10-20.1
-

InnoDB_row_lock_time

- **Description:** Total time in milliseconds spent getting InnoDB row locks.
 - **Scope:** Global
 - **Data Type:** `numeric`
-

InnoDB_row_lock_time_avg

- **Description:** Average time in milliseconds spent getting an InnoDB row lock.
 - **Scope:** Global
 - **Data Type:** `numeric`
-

InnoDB_row_lock_time_max

- **Description:** Maximum time in milliseconds spent getting an InnoDB row lock.
 - **Scope:** Global
 - **Data Type:** `numeric`
-

InnoDB_row_lock_waits

- **Description:** Number of times InnoDB had to wait before getting a row lock.
 - **Scope:** Global
 - **Data Type:** `numeric`
-

InnoDB_rows_deleted

- **Description:** Number of rows deleted from InnoDB tables that were not system tables. Almost equivalent to [Handler_delete](#) which does include system tables.
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Removed:** [MariaDB 10.10](#)
-

InnoDB_rows_inserted

- **Description:** Number of rows inserted into InnoDB tables that were not system tables. No direct equivalent in [Handler](#) status variables.
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Removed:** [MariaDB 10.10](#)
-

InnoDB_rows_read

- **Description:** Number of rows read from InnoDB tables that were not system tables. Almost equivalent to the sum of [Handler_read*](#) status variables which do include system tables.
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Removed:** [MariaDB 10.10](#)
-

InnoDB_rows_updated

- **Description:** Number of rows updated in InnoDB tables that were not system tables. Almost equivalent to [Handler_update](#) which does include system tables.
 - **Scope:** Global
 - **Data Type:** numeric
 - **Removed:** [MariaDB 10.10](#)
-

InnoDB_s_lock_os_waits

- **Description:** As shown in the SEMAPHORES section of the [SHOW ENGINE INNODB STATUS](#) output.
 - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this status variable is present in XtraDB.
 - In [MariaDB 10.2](#) and later, this status variable is not present.
 - **Scope:** Global
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 5.5](#)
 - **Removed:** [MariaDB 10.2](#)
-

InnoDB_s_lock_spin_rounds

- **Description:** As shown in the SEMAPHORES section of the [SHOW ENGINE INNODB STATUS](#) output.
 - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this status variable is present in XtraDB.
 - In [MariaDB 10.2](#) and later, this status variable is not present.
 - **Scope:** Global
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 5.5](#)
 - **Removed:** [MariaDB 10.2](#)
-

InnoDB_s_lock_spin_waits

- **Description:** As shown in the SEMAPHORES section of the [SHOW ENGINE INNODB STATUS](#) output.
 - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this status variable is present in XtraDB.
 - In [MariaDB 10.2](#) and later, this status variable is not present.
 - **Scope:** Global
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 5.5](#)
 - **Removed:** [MariaDB 10.2](#)
-

InnoDB_scrub_background_page_reorganizations

- **Description:** See [Table and Tablespace Encryption](#).
 - **Scope:** Global
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 10.1.3](#) [↗](#)
 - **Removed:** [MariaDB 10.5.2](#)
-

InnoDB_scrub_background_page_split_failures_missing_index

- **Description:** See [Table and Tablespace Encryption](#).
 - **Scope:** Global
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 10.1.3](#) [↗](#)
 - **Removed:** [MariaDB 10.5.2](#)
-

InnoDB_scrub_background_page_split_failures_out_of_filespace

- **Description:** See [Table and Tablespace Encryption](#).
- **Scope:** Global
- **Data Type:** numeric
- **Introduced:** [MariaDB 10.1.3](#) [↗](#)

- **Removed:** [MariaDB 10.5.2](#)
-

InnoDB_scrub_background_page_split_failures_underflow

- **Description:** See [Table and Tablespace Encryption](#).
 - **Scope:** Global
 - **Data Type:** numeric
 - **Removed:** [MariaDB 10.5.2](#)
-

InnoDB_scrub_background_page_split_failures_unknown

- **Description:** See [Table and Tablespace Encryption](#).
 - **Scope:** Global
 - **Data Type:** numeric
 - **Removed:** [MariaDB 10.5.2](#)
-

InnoDB_scrub_background_page_splits

- **Description:** See [Table and Tablespace Encryption](#).
 - **Scope:** Global
 - **Data Type:** numeric
 - **Removed:** [MariaDB 10.5.2](#)
-

InnoDB_scrub_log

- **Description:**

 - **Introduced:** [MariaDB 10.2.4](#) [↗](#)
 - **Removed:** [MariaDB 10.5.2](#)
-

InnoDB_secondary_index_triggered_cluster_reads

- **Description:** Used to track the effectiveness of the Prefix Index Queries Optimization ([MDEV-6929](#) [↗](#)). Removed in [MariaDB 10.10](#) as the optimization is now always enabled.
 - **Scope:** Global
 - **Data Type:** numeric
 - **Removed:** [MariaDB 10.10](#)
-

InnoDB_secondary_index_triggered_cluster_reads_avoided

- **Description:** Used to track the effectiveness of the Prefix Index Queries Optimization ([MDEV-6929](#) [↗](#)). Removed in [MariaDB 10.10](#) as the optimization is now always enabled.
 - **Scope:** Global
 - **Data Type:** numeric
 - **Removed:** [MariaDB 10.10](#)
-

InnoDB_system_rows_deleted

- **Description:** Number of rows deleted on system tables.
 - **Scope:** Global
 - **Data Type:** numeric
 - **Removed:** [MariaDB 10.10](#)
-

InnoDB_system_rows_inserted

- **Description:** Number of rows inserted on system tables.

- **Scope:** Global
 - **Data Type:** `numeric`
 - **Removed:** [MariaDB 10.10](#)
-

InnoDB_system_rows_read

- **Description:** Number of rows read on system tables.
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Removed:** [MariaDB 10.10.0](#) 
-

InnoDB_system_rows_updated

- **Description:** Number of rows updated on system tables.
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Removed:** [MariaDB 10.10.0](#) 
-

InnoDB_truncated_status_writes

- **Description:** Number of times output from [SHOW ENGINE INNODB STATUS](#) has been truncated.
 - **Scope:** Global
 - **Data Type:** `numeric`
-

InnoDB_undo_truncations

- **Description:** Number of undo tablespace truncation operations.
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 10.3.10](#) 
-

InnoDB_x_lock_os_waits

- **Description:** As shown in the SEMAPHORES section of the [SHOW ENGINE INNODB STATUS](#) output.
 - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this status variable is present in XtraDB.
 - In [MariaDB 10.2](#) and later, this status variable is not present.
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 5.5](#)
 - **Removed:** [MariaDB 10.2](#)
-

InnoDB_x_lock_spin_rounds

- **Description:** As shown in the SEMAPHORES section of the [SHOW ENGINE INNODB STATUS](#) output.
 - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this status variable is present in XtraDB.
 - In [MariaDB 10.2](#) and later, this status variable is not present.
 - **Scope:** Global
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 5.5](#)
 - **Removed:** [MariaDB 10.2](#)

InnoDB_x_lock_spin_waits

- **Description:** As shown in the SEMAPHORES section of the [SHOW ENGINE INNODB STATUS](#) output.
 - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this status variable is present in XtraDB.
 - In [MariaDB 10.2](#) and later, this status variable is not present.
- **Scope:** Global
- **Data Type:** `numeric`

- Introduced: [MariaDB 5.5](#)
- Removed: [MariaDB 10.2](#)

5.3.2.6 AUTO_INCREMENT Handling in InnoDB

Contents

1. [AUTO_INCREMENT Lock Modes](#)
 1. [Traditional Lock Mode](#)
 2. [Consecutive Lock Mode](#)
 3. [Interleaved Lock Mode](#)
2. [Setting AUTO_INCREMENT Values](#)

AUTO_INCREMENT Lock Modes

The `innodb_autoinc_lock_mode` system variable determines the lock mode when generating `AUTO_INCREMENT` values for `InnoDB` tables. These modes allow `InnoDB` to make significant performance optimizations in certain circumstances.

The `innodb_autoinc_lock_mode` system variable may be removed in a future release. See [MDEV-19577](#) for more information.

Traditional Lock Mode

When `innodb_autoinc_lock_mode` is set to `0`, `InnoDB` uses the traditional lock mode.

In this mode, `InnoDB` holds a table-level lock for all `INSERT` statements until the statement completes.

Consecutive Lock Mode

When `innodb_autoinc_lock_mode` is set to `1`, `InnoDB` uses the consecutive lock mode.

In this mode, `InnoDB` holds a table-level lock for all bulk `INSERT` statements (such as `LOAD DATA` or `INSERT ... SELECT`) until the end of the statement. For simple `INSERT` statements, no table-level lock is held. Instead, a lightweight mutex is used which scales significantly better. This is the default setting.

Interleaved Lock Mode

When `innodb_autoinc_lock_mode` is set to `2`, `InnoDB` uses the interleaved lock mode.

In this mode, `InnoDB` does not hold any table-level locks at all. This is the fastest and most scalable mode, but is not safe for `statement-based` replication.

Setting AUTO_INCREMENT Values

The `AUTO_INCREMENT` value for an `InnoDB` table can be set for a table by executing the `ALTER TABLE` statement and specifying the `AUTO_INCREMENT` table option. For example:

```
ALTER TABLE tab AUTO_INCREMENT=100;
```

However, in [MariaDB 10.2.3](#) and before, `InnoDB` stores the table's `AUTO_INCREMENT` counter in memory. In these versions, when the server restarts, the counter is re-initialized to the highest value found in the table. This means that the above operation can be undone if the server is restarted before any rows are written to the table.

In [MariaDB 10.2.4](#) and later, the `AUTO_INCREMENT` counter is persistent, so this restriction is no longer present. Persistent, however, does not mean transactional. Gaps may still occur in some cases, such as if a `INSERT IGNORE` statement fails, or if a user executes `ROLLBACK` or `ROLLBACK TO SAVEPOINT`.

For example:

```

CREATE TABLE t1 (pk INT AUTO_INCREMENT PRIMARY KEY, i INT, UNIQUE (i)) ENGINE=InnoDB;

INSERT INTO t1 (i) VALUES (1),(2),(3);
INSERT IGNORE INTO t1 (pk, i) VALUES (100,1);
Query OK, 0 rows affected, 1 warning (0.099 sec)

SELECT * FROM t1;
+----+-----+
| pk | i   |
+----+-----+
|  1 |  1 |
|  2 |  2 |
|  3 |  3 |
+----+-----+

SHOW CREATE TABLE t1\G
***** 1. row *****
      Table: t1
Create Table: CREATE TABLE `t1` (
  `pk` int(11) NOT NULL AUTO_INCREMENT,
  `i` int(11) DEFAULT NULL,
  PRIMARY KEY (`pk`),
  UNIQUE KEY `i` (`i`)
) ENGINE=InnoDB AUTO_INCREMENT=4 DEFAULT CHARSET=latin1

```

If the server is restarted at this point, then the [AUTO_INCREMENT](#) counter will revert to 101, which is the persistent value set as part of the failed [INSERT IGNORE](#).

```

# Restart server
SHOW CREATE TABLE t1\G
***** 1. row *****
      Table: t1
Create Table: CREATE TABLE `t1` (
  `pk` int(11) NOT NULL AUTO_INCREMENT,
  `i` int(11) DEFAULT NULL,
  PRIMARY KEY (`pk`),
  UNIQUE KEY `i` (`i`)
) ENGINE=InnoDB AUTO_INCREMENT=101 DEFAULT CHARSET=latin1

```

5.3.2.7 InnoDB Buffer Pool

Contents

1. [How the Buffer Pool Works](#)
2. [innodb_buffer_pool_size](#)
3. [innodb_buffer_pool_instances](#)
4. [innodb_old_blocks_pct](#) and [innodb_old_blocks_time](#)
5. [Dumping and Restoring the Buffer Pool](#)

The [InnoDB](#) buffer pool is a key component for optimizing MariaDB. It stores data and indexes, and you usually want it as large as possible so as to keep as much of the data and indexes in memory, reducing disk IO, as main bottleneck.

How the Buffer Pool Works

The buffer pool attempts to keep frequently-used blocks in the buffer, and so essentially works as two sublists, a *new* sublist of recently-used information, and an *old* sublist of older information. By default, 37% of the list is reserved for the old list.

When new information is accessed that doesn't appear in the list, it is placed at the top of the old list, the oldest item in the old list is removed, and everything else bumps back one position in the list.

When information is accessed that appears in the *old* list, it is moved to the top the new list, and everything above moves back one position.

innodb_buffer_pool_size

The most important [server system variable](#) is [innodb_buffer_pool_size](#). This size should contain most of the active data set of your server so that SQL request can work directly with information in the buffer pool cache. Starting at several gigabytes of memory is a good starting point if you have that RAM available. Once warmed up to its normal load there should be very

few `innodb_buffer_pool_reads` compared to `innodb_buffer_pool_read_requests`. Look how these values change over a minute. If the change in `innodb_buffer_pool_reads` is less than 1% of the change in `innodb_buffer_pool_read_requests` then you have a good amount of usage. If you are getting the status variable `innodb_buffer_pool_wait_free` increasing then you don't have enough buffer pool (or your flushing isn't occurring frequently enough).

Be aware that before [MariaDB 10.4.4](#) the total memory allocated is about 10% more than the specified size as extra space is also reserved for control structures and buffers.

The larger the size, the longer it will take to initialize. On a modern 64-bit server with a 10GB memory pool, this can take five seconds or more. Increasing `innodb_buffer_pool_chunk_size` by several factors will reduce this significantly. [MariaDB 10.6](#) could start up with a 96GB buffer pool in less than 1 second.

Make sure that the size is not too large, causing swapping. The benefit of a larger buffer pool size is more than undone if your operating system is regularly swapping.

The buffer pool can be set dynamically. See [Setting InnoDB Buffer Pool Size Dynamically](#).

innodb_buffer_pool_instances

The functionality described below was disabled in [MariaDB 10.5](#), and removed in [MariaDB 10.6](#), as the original reasons for splitting the buffer pool have mostly gone away.

If `innodb_buffer_pool_size` is set to more than 1GB, `innodb_buffer_pool_instances` divides the InnoDB buffer pool into a specific number of instances. The default was 1 in [MariaDB 5.5](#), but for large systems with buffer pools of many gigabytes, many instances can help reduce contention concurrency. The default is 8 in [MariaDB 10.0](#), with the exception of 32-bit Windows, where it depends on the value of `innodb_buffer_pool_size`. Each instance manages its own data structures and takes an equal portion of the total buffer pool size, so for example if `innodb_buffer_pool_size` is 4GB and `innodb_buffer_pool_instances` is set to 4, each instance will be 1GB. Each instance should ideally be at least 1GB in size.

innodb_old_blocks_pct and innodb_old_blocks_time

The default 37% reserved for the old list can be adjusted by changing the value of `innodb_old_blocks_pct`. It can accept anything between 5% and 95%.

The `innodb_old_blocks_time` variable specifies the delay before a block can be moved from the old to the new sublist. 0 means no delay, while the default has been set to 1000.

Before changing either of these values from their defaults, make sure you understand the impact and how your system currently uses the buffer. Their main reason for existence is to reduce the impact of full table scans, which are usually infrequent, but large, and previously could clear everything from the buffer. Setting a non-zero delay could help in situations where full table scans are performed in quick succession.

Temporarily changing these values can also be useful to avoid the negative impact of a full table scan, as explained in [InnoDB logical backups](#).

Dumping and Restoring the Buffer Pool

When the server starts, the buffer pool is empty. As it starts to access data, the buffer pool will slowly be populated. As more data will be accessed, the most frequently accessed data will be put into the buffer pool, and old data may be evicted. This means that a certain period of time is necessary before the buffer pool is really useful. This period of time is called the warmup.

Since [MariaDB 10.0](#), InnoDB can dump the buffer pool before the server shuts down, and restore it when it starts again. If this feature is used (default since [MariaDB 10.2](#)), no warmup is necessary. Use the `innodb_buffer_pool_dump_at_shutdown` and `innodb_buffer_pool_load_at_startup` system variables to enable or disable the buffer pool dump at shutdown and the restore at startup respectively.

It is also possible to dump the InnoDB buffer pool at any moment while the server is running, and it is possible to restore the last buffer pool dump at any moment. To do this, the special `innodb_buffer_pool_dump_now` and `innodb_buffer_pool_load_now` system variables can be set to ON. When selected, their value is always OFF.

A buffer pool restore, both at startup or at any other moment, can be aborted by setting `innodb_buffer_pool_load_abort` to ON.

The file which contains the buffer pool dump is specified via the `innodb_buffer_pool_filename` system variable.

5.3.2.8 InnoDB Change Buffering

The change buffer has been disabled by default from [MariaDB 10.5.15](#), [MariaDB 10.6.7](#), [MariaDB 10.7.3](#) and

[MariaDB 10.8.2](#) (MDEV-27734), was deprecated and ignored from [MariaDB 10.9.0](#) (MDEV-27735), and was removed in [MariaDB 11.0.0](#) (MDEV-29694).

Benchmarks attached to [MDEV-19514](#) show that the change buffer sometimes reduces performance, and in the best case seem to bring a few per cent improvement to throughput. However, such improvement could come with a price: If the buffered changes are never merged ([MDEV-19514](#), motivated by the reduction of random crashes and the removal of an `innodb_force_recovery` option that can inflict further corruption), then the InnoDB system tablespace can grow out of control ([MDEV-21952](#)).

Contents

INSERT, UPDATE and DELETE statements can be particularly heavy operations to perform, as all indexes need to be updated after each change. For this reason these changes are often buffered.

Pages are modified in the [buffer pool](#), and not immediately on disk. After all the records that cover the changes to a data page have been written to the InnoDB redo log, the changed page may be written ("flushed") to a data file. Pages that have been modified in memory and not yet flushed are called dirty pages.

The Change Buffer is an optimization that allows some data to be modified even though the data page does not exist in the buffer pool. Instead of modifying the data in its final destination, we would insert a record into a special Change Buffer that resides in the system tablespace. When the page is read into the buffer pool for any reason, the buffered changes will be applied to it.

The Change Buffer only contains changes to secondary index leaf pages.

Before [MariaDB 5.5](#), only inserted rows could be buffered, so this buffer was called Insert Buffer. The old name still appears in several places, for example in the output of [SHOW ENGINE INNODB STATUS](#).

Inserts to UNIQUE secondary indexes cannot be buffered unless `unique_checks=0` is used. This may sometimes allow duplicates to be inserted into the UNIQUE secondary index. Much of the time, the UNIQUE constraint would be checked because the change buffer could only be used if the index page is not located in the buffer pool.

When rows are deleted, a flag is set, thus rows are not immediately deleted. Delete-marked records may be purged after the transaction has been committed and any read views that were created before the commit have been closed. Delete-mark and purge buffering of any secondary indexes is allowed.

ROLLBACK never makes use of the change buffer; it would force a merge of any changes that were buffered during the execution of the transaction.

The Change Buffer is an optimization because:

- Some random-access page reads will be transformed into modifications of change buffer pages.
- A change buffer page can be modified several times in memory and be flushed to disk only once.
- Dirty pages are flushed together, so the number of IO operations is lower.

If the server crashes or is shut down, the Change Buffer might not be empty. The Change Buffer resides in the InnoDB system tablespace, covered by the write-ahead log, so they can be applied at server restart. A shutdown with `innodb_fast_shutdown=0` will merge all buffered changes.

Starting with [MariaDB 10.5](#), there no longer is a background task that would merge the change buffer to the secondary index pages. The changes would only be merged on demand.

The Change Buffer was removed in [MariaDB 11.0](#) because it has been a prominent source of corruption bugs that have been extremely hard to reproduce.

The main server system variable here is `innodb_change_buffering`, which determines which form of change buffering, if any, to use.

The following settings are available:

- inserts
 - Only buffer insert operations
- deletes
 - Only buffer delete operations
- changes
 - Buffer both insert and delete operations
- purges
 - Buffer the actual physical deletes that occur in the background
- all
 - Buffer inserts, deletes and purges. Default setting from [MariaDB 5.5](#) until [MariaDB 10.5.14](#), [MariaDB 10.6.6](#), [MariaDB 10.7.2](#) and [MariaDB 10.8.1](#).
- none
 - Don't buffer any operations. Default from [MariaDB 10.5.15](#), [MariaDB 10.6.7](#), [MariaDB 10.7.3](#) and [MariaDB 10.8.2](#).

Modifying the value of this variable only affects the buffering of new operations. The merging of already buffered changes is not affected.

The `innodb_change_buffer_max_size` system variable determines the maximum size of the change buffer, expressed as a percentage of the buffer pool.

5.3.2.9 InnoDB Doublewrite Buffer

The InnoDB doublewrite buffer was implemented to recover from half-written pages. This can happen when there's a power failure while InnoDB is writing a page to disk. On reading that page, InnoDB can discover the corruption from the mismatch of the page checksum. However, in order to recover, an intact copy of the page would be needed.

The double write buffer provides such a copy.

Whenever InnoDB flushes a page to disk, it is first written to the double write buffer. Only when the buffer is safely flushed to disk will InnoDB write the page to the final destination. When recovering, InnoDB scans the double write buffer and for each valid page in the buffer checks if the page in the data file is valid too.

Doublewrite Buffer Settings

To turn off the doublewrite buffer, set the `innodb_doublewrite` system variable to `0`. This is safe on filesystems that write pages atomically - that is, a page write fully succeeds or fails. But with other filesystems, it is not recommended for production systems. An alternative option is atomic writes. See [atomic write support](#) for more details.

5.3.2.10 InnoDB Tablespaces

Tables that use the InnoDB storage engine are written to disk in data files called tablespaces. An individual tablespace can contain data from one or more InnoDB tables as well as the associated indexes.

InnoDB System Tablespaces

The system tablespace, how to change its size, and the use of raw disk partitions.

5.3.2.10.1 InnoDB System Tablespaces

Contents

- [Changing Sizes](#)
 - [Increasing the Size](#)
 - [Decreasing the Size](#)
- [Using Raw Disk Partitions](#)
 - [Raw Disk Partitions on Windows](#)
- [System Tables within the InnoDB System Tablespace](#)

When InnoDB needs to store general information relating to the system as a whole, rather than a specific table, the specific file it writes to is the system tablespace. By default, this is the `ibdata1` file located in the data directory, (as defined by either the `datadir` or `innodb_data_home_dir` system variables). InnoDB uses the system tablespace to store the data dictionary, change buffer, and undo logs.

You can define the system tablespace filename or filenames, size and other options by setting the `innodb_data_file_path` system variable. This system variable can be specified as a command-line argument to `mariadb` or it can be specified in a relevant server [option group](#) in an [option file](#). For example:

```
[mariadb]
...
innodb_data_file_path=ibdata1:50M:autoextend
```

This system variable defaults to the file `ibdata1`, and it defaults to a minimum size of `12M`, and it defaults with the `autoextend` attribute enabled.

Changing Sizes

InnoDB defaults to allocating `12M` to the `ibdata1` file for the system tablespace. While this is sufficient for most use cases, it may not be for all. You may find after using MariaDB for a while that the allocation is too small for the system tablespace or it grows too large for your disk. Fortunately, you can adjust this size as need later.

Increasing the Size

When setting the `innodb_data_file_path` system variable, you can define a size for each file given. In cases where you need a larger system tablespace, add the `autoextend` option to the last value.

```
[mariadb]
...
innodb_data_file_path=ibdata1:12M;ibdata2:50M:autoextend
```

Under this configuration, when the last system tablespace grows beyond the size allocation, InnoDB increases the size of the file by increments. To control the allocation increment, set the `innodb_autoextend_increment` system variable.

Decreasing the Size

MariaDB starting with [11.2](#)

From [MariaDB 11.2.0](#), when MariaDB starts up, unused InnoDB tablespace can be reclaimed, reducing the file size ([MDEV-14795](#)). This is disabled by default and is enabled by adding the `:autoshrink` attribute to the `innodb_data_file_path` system variable, e.g.:

```
[mariadb]
...
innodb_data_file_path=ibdata1:12M;ibdata2:50M:autoextend:autoshrink
```

Alternatively, starting with [MariaDB 11.2.3](#), the shrinking can be set to happen during a slow shutdown (e.g. after `SET GLOBAL innodb_fast_shutdown=0`) ([MDEV-32452](#)).

Technically, how this works is:

1. Find the last used extent in the system tablespace by iterating through the BITMAP in the extent descriptor page.
2. Check whether the tablespace is being used within fixed size, and if the last used extent is less than the fixed size, then set the desired target size to fixed size.
3. Flush all pages belonging to the system tablespace in flush list.
4. Truncate the truncated pages from `FSP_FREE` and `FSP_FREE_FRAG` list.
5. Reset the bitmap in descriptor pages for the truncated pages.
6. Update the `FSP_SIZE` and `FSP_FREE_LIMIT` in header page.
7. In case of multiple files, calculate the truncated last file size and do the truncation in last file.

MariaDB until [11.2.0](#)

In cases where the InnoDB system tablespace has grown too large, before [MariaDB 11.2](#), the process to reduce it in size is a little more complicated than increasing the size. MariaDB does not allow you to remove data from the tablespace file itself. Instead you need to delete the tablespace files themselves, then restore the database from backups.

The backup utility `mariadb-dump` produces backup files containing the SQL statements needed to recreate the database. As a result, it restores a database with the bare minimum data rather than any additional information that might have built up in the tablespace file.

Use `mariadb-dump` to backup all of your InnoDB database tables, including the system tables in the `mysql` database that use InnoDB. You can find out what they are using the Information Schema.

```
SELECT TABLE_NAME FROM information_schema.TABLES
WHERE TABLE_SCHEMA = 'mysql' AND ENGINE = 'InnoDB';
```

If you only use InnoDB, you may find it easier to back up all databases and tables.

```
$ mariadb-dump -u root -p --all-databases > full-backup.sql
```

Then stop the MariaDB Server and remove the InnoDB tablespace files. In the data directory or the InnoDB data home

directory, delete all the `ibdata` and `ib_log` files as well as any file with an `.ibd` or `.frm` extension.

Once this is done, restart the server and import the dump file:

```
$ mysql -u root -p < full-backup.sql
```

Using Raw Disk Partitions

Instead of having InnoDB write to the file system, you can set it to use raw disk partitions. On Windows and some Linux distributions, this allows you to perform non-buffered I/O without the file system overhead. Note that in many use cases this may not actually improve performance. Run tests to verify if there are any real gains for your application usage.

To enable a raw disk partition, first start MariaDB with the `newraw` option set on the tablespace. For example:

```
[mariadb]
...
innodb_data_file_path=/dev/sdc:10Gnewraw
```

When the MariaDB Server starts, it initializes the partition. Don't create or change any data, (any data written to InnoDB at this stage will be lost on restart). Once the server has successfully started, stop it then edit the configuration file again, changing the `newraw` keyword to `raw`.

```
[mariadb]
...
innodb_data_file_path=/dev/sdc:10Graw
```

When you start MariaDB again, it'll read and write InnoDB data to the given disk partition instead of the file system.

Raw Disk Partitions on Windows

When defining a raw disk partition for InnoDB on the Windows operating system, use the same procedure as defined above, but when defining the path for the `innodb_data_file_path` system variable, use `./` at the start. For example:

```
[mariadb]
...
innodb_data_file_path=//./E::10Graw
```

The given path is synonymous with the Windows syntax for accessing the physical drive.

System Tables within the InnoDB System Tablespace

InnoDB creates some system tables within the InnoDB System Tablespace:

- `SYS_DATAFILES`
- `SYS_FOREIGN`
- `SYS_FOREIGN_COLS`
- `SYS_TABLESPACES`
- `SYS_VIRTUAL`
- `SYS_ZIP_DICT`
- `SYS_ZIP_DICT_COLS`

These tables cannot be queried. However, you might see references to them in some places, such as in the `INNODB_SYS_TABLES` table in the `information_schema` database.

5.3.2.10.2 InnoDB File-Per-Table Tablespaces

Contents

1. [File-Per-Table Tablespace Locations](#)
2. [Copying Transportable Tablespaces](#)
 1. [Copying Transportable Tablespaces for Non-partitioned Tables](#)
 1. [Exporting Transportable Tablespaces for Non-partitioned Tables](#)
 2. [Importing Transportable Tablespaces for Non-partitioned Tables](#)
 2. [Copying Transportable Tablespaces for Partitioned Tables](#)

 1. [Differing Storage Formats for Temporal Columns](#)
 2. [Differing ROW_FORMAT Values](#)
 3. [Foreign Key Constraints](#)
3. [Tablespace Encryption](#)

When you create a table using the [InnoDB storage engine](#), data written to that table is stored on the file system in a data file called a tablespace. Tablespace files contain both the data and indexes.

When `innodb_file_per_table=ON` is set, InnoDB uses one tablespace file per InnoDB table. These tablespace files have the `.ibd` extension. When `innodb_file_per_table=OFF` is set, InnoDB stores all tables in the [InnoDB system tablespace](#).

InnoDB versions in MySQL 5.7 and above also support an additional type of tablespace called [general tablespaces](#) [↗](#) that are created with [CREATE TABLESPACE](#) [↗](#). However, InnoDB versions in MariaDB Server do not support general tablespaces or [CREATE TABLESPACE](#).

File-Per-Table Tablespace Locations

By default, InnoDB's file-per-table tablespaces are created in the system's data directory, which is defined by the `datadir` system variable. The system variable `innodb_data_home_dir` will not change the location of file-per-table tablespaces.

In the event that you have a specific tablespace that you need stored in a dedicated path, you can set the location using the [DATA DIRECTORY](#) table option when you create the table.

For instance,

```
CREATE TABLE test.t1 (  
  id INT PRIMARY KEY AUTO_INCREMENT,  
  name VARCHAR(50)  
) ENGINE=InnoDB  
DATA DIRECTORY = "/data/contact";
```

MariaDB then creates a database directory on the configured path and the file-per-table tablespace will be created inside that directory. On Unix-like operating systems, you can see the file using the `ls` command:

```
# ls -al /data/contact/test  
drwxrwx--- 2 mysql mysql 4096 Dec 8 18:46 .  
drwxr-xr-x 3 mysql mysql 4096 Dec 8 18:46 ..  
-rw-rw---- 1 mysql mysql 98304 Dec 8 20:41 t1.ibd
```

Note, the system user that runs the MariaDB Server process (which is usually `mysql`) must have write permissions on the given path.

Copying Transportable Tablespaces

InnoDB's file-per-table tablespaces are transportable, which means that you can copy a file-per-table tablespace from one MariaDB Server to another server. You may find this useful in cases where you need to transport full tables between servers and don't want to use backup tools like [mariabackup](#) or [mariadb-dump](#). In fact, this process can even be used with [mariabackup](#) in some cases, such as when [restoring partial backups](#) or when [restoring individual tables or partitions from a backup](#).

Copying Transportable Tablespaces for Non-partitioned Tables

You can copy the transportable tablespace of a non-partitioned table from one server to another by exporting the tablespace file from the original server, and then importing the tablespace file into the new server.

MariaDB starting with 11.2.1 [↗](#)

The workflow is simplified starting from [MariaDB 11.2.1](#) [↗](#). On the source server, simply do:

```
FLUSH TABLES t1 FOR EXPORT;
# scp /data/contacts/test/t1.ibd target-server.com:/var/lib/mysql/test/
# scp /data/contacts/test/t1.cfg target-server.com:/var/lib/mysql/test/
# scp /data/contacts/test/t1.frm target-server.com:/var/lib/mysql/test/
UNLOCK TABLES;
```

On the destination server, simply do:

```
ALTER TABLE t1 IMPORT TABLESPACE;
```

Exporting Transportable Tablespaces for Non-partitioned Tables

You can export a non-partitioned table by locking the table and copying the table's `.ibd` and `.cfg` files from the relevant [tablespace location](#) for the table to a backup location. For example, the process would go like this:

- First, use the [FLUSH TABLES ... FOR EXPORT](#) statement on the target table:

```
FLUSH TABLES test.t1 FOR EXPORT;
```

This forces the server to close the table and provides your connection with a read lock on the table.

- Then, while your connection still holds the lock on the table, copy the tablespace file and the metadata file to a safe directory:

```
# cp /data/contacts/test/t1.ibd /data/saved-tablespaces/
# cp /data/contacts/test/t1.cfg /data/saved-tablespaces/
```

- Then, once you've copied the files, you can release the lock with [UNLOCK TABLES](#):

```
UNLOCK TABLES;
```

Importing Transportable Tablespaces for Non-partitioned Tables

You can import a non-partitioned table by discarding the table's original tablespace, copying the table's `.ibd` and `.cfg` files from the backup location to the relevant [tablespace location](#) for the table, and then telling the server to import the tablespace.

For example, the process would go like this:

- First, on the destination server, you need to create a copy of the table. Use the same [CREATE TABLE](#) statement that was used to create the table on the original server.

```
CREATE TABLE test.t1 (
  id INT PRIMARY KEY AUTO_INCREMENT,
  name VARCHAR(50)
) ENGINE=InnoDB;
```

- Then, use [ALTER TABLE ... DISCARD TABLESPACE](#) to discard the new table's tablespace:

```
ALTER TABLE test.t1 DISCARD TABLESPACE;
```

- Then, copy the `.ibd` and `.cfg` files from the original server to the relevant directory on the target MariaDB Server.

```
# scp /data/tablespaces/t1.ibd target-server.com:/var/lib/mysql/test/
# scp /data/tablespaces/t1.cfg target-server.com:/var/lib/mysql/test/
```

File-per-table tablespaces can be imported with just the `.ibd` file in many cases. If you do not have the tablespace's `.cfg` file for whatever reason, then it is usually worth trying to import the tablespace with just the `.ibd` file.

- Then, once the files are in the proper directory on the target server, use [ALTER TABLE ... IMPORT TABLESPACE](#) to

import the new table's tablespace:

```
ALTER TABLE test.t1 IMPORT TABLESPACE;
```

Copying Transportable Tablespaces for Partitioned Tables

Currently, MariaDB does not directly support the transport of tablespaces from partitioned tables. See [MDEV-10568](#) for more information about that. It is still possible to transport partitioned tables if we use a workaround. You can copy the transportable tablespaces of a partitioned table from one server to another by exporting the tablespace file of each partition from the original server, and then importing the tablespace file of each partition into the new server.

Exporting Transportable Tablespaces for Partitioned Tables

You can export a partitioned table by locking the table and copying the `.ibd` and `.cfg` files of each partition from the relevant [tablespace location](#) for the partition to a backup location. For example, the process would go like this:

- First, let's create a test table with some data on the original server:

```
CREATE TABLE test.t2 (  
  employee_id INT,  
  name VARCHAR(50)  
) ENGINE=InnoDB  
PARTITION BY RANGE (employee_id) (  
  PARTITION p0 VALUES LESS THAN (6),  
  PARTITION p1 VALUES LESS THAN (11),  
  PARTITION p2 VALUES LESS THAN (16),  
  PARTITION p3 VALUES LESS THAN MAXVALUE  
);  
  
INSERT INTO test.t2 (name, employee_id) VALUES  
(  
  'Geoff Montee', 1),  
  ('Chris Calendar', 6),  
  ('Kyle Joiner', 11),  
  ('Will Fong', 16);
```

- Then, we need to export the partitioned tablespace from the original server, which follows the same process as exporting non-partitioned tablespaces. That means that we need to use the [FLUSH TABLES ... FOR EXPORT](#) statement on the target table:

```
FLUSH TABLES test.t2 FOR EXPORT;
```

This forces the server to close the table and provides your connection with a read lock on the table.

- Then, if we grep the database directory in the data directory for the newly created `t2` table, we can see a number of `.ibd` and `.cfg` files for the table:

```
# ls -l /var/lib/mysql/test/ | grep t2  
total 428  
-rw-rw---- 1 mysql mysql 827 Dec 5 16:08 t2.frm  
-rw-rw---- 1 mysql mysql 48 Dec 5 16:08 t2.par  
-rw-rw---- 1 mysql mysql 579 Dec 5 18:47 t2#P#p0.cfg  
-rw-r----- 1 mysql mysql 98304 Dec 5 16:43 t2#P#p0.ibd  
-rw-rw---- 1 mysql mysql 579 Dec 5 18:47 t2#P#p1.cfg  
-rw-rw---- 1 mysql mysql 98304 Dec 5 16:08 t2#P#p1.ibd  
-rw-rw---- 1 mysql mysql 579 Dec 5 18:47 t2#P#p2.cfg  
-rw-rw---- 1 mysql mysql 98304 Dec 5 16:08 t2#P#p2.ibd  
-rw-rw---- 1 mysql mysql 579 Dec 5 18:47 t2#P#p3.cfg  
-rw-rw---- 1 mysql mysql 98304 Dec 5 16:08 t2#P#p3.ibd
```

- Then, while our connection still holds the lock on the table, we need to copy the tablespace files and the metadata files to a safe directory:

```
$ mkdir /tmp/backup  
$ sudo cp /var/lib/mysql/test/t2*.ibd /tmp/backup  
$ sudo cp /var/lib/mysql/test/t2*.cfg /tmp/backup
```

- Then, once we've copied the files, we can release the lock with [UNLOCK TABLES](#):

```
UNLOCK TABLES;
```

Importing Transportable Tablespaces for Partitioned Tables

You can import a partitioned table by creating a placeholder table, discarding the placeholder table's original tablespace, copying the partition's `.ibd` and `.cfg` files from the backup location to the relevant [tablespace location](#) for the placeholder table, and then telling the server to import the tablespace. At that point, the server can exchange the tablespace for the placeholder table with the one for the partition. For example, the process would go like this:

- First, we need to copy the saved tablespace files from the original server to the target server:

```
$ scp /tmp/backup/t2* user@target-host:/tmp/backup
```

- Then, we need to import the partitioned tablespaces onto the target server. The import process for partitioned tables is more complicated than the import process for non-partitioned tables. To start with, if it doesn't already exist, then we need to create a partitioned table on the target server that matches the partitioned table on the original server:

```
CREATE TABLE test.t2 (  
  employee_id INT,  
  name VARCHAR(50)  
) ENGINE=InnoDB  
PARTITION BY RANGE (employee_id) (  
  PARTITION p0 VALUES LESS THAN (6),  
  PARTITION p1 VALUES LESS THAN (11),  
  PARTITION p2 VALUES LESS THAN (16),  
  PARTITION p3 VALUES LESS THAN MAXVALUE  
);
```

- Then, using this table as a model, we need to create a placeholder of this table with the same structure that does not use partitioning. This can be done with a [CREATE TABLE... AS SELECT](#) statement:

```
CREATE TABLE test.t2_placeholder LIKE test.t2;  
ALTER TABLE test.t2_placeholder REMOVE PARTITIONING;
```

This statement will create a new table called `t2_placeholder` that has the same schema structure as `t2`, but it does not use partitioning and it contains no rows.

For Each Partition

From this point forward, the rest of our steps need to happen for each individual partition. For each partition, we need to do the following process:

- First, we need to use [ALTER TABLE ... DISCARD TABLESPACE](#) to discard the placeholder table's tablespace:

```
ALTER TABLE test.t2_placeholder DISCARD TABLESPACE;
```

- Then, copy the `.ibd` and `.cfg` files for the next partition to the relevant directory for the `t2_placeholder` table on the target MariaDB Server:

```
# cp /tmp/backup/t2#P#p0.cfg /var/lib/mysql/test/t2_placeholder.cfg  
# cp /tmp/backup/t2#P#p0.ibd /var/lib/mysql/test/t2_placeholder.ibd  
# chown mysql:mysql /var/lib/mysql/test/t2_placeholder*
```

File-per-table tablespaces can be imported with just the `.ibd` file in many cases. If you do not have the tablespace's `.cfg` file for whatever reason, then it is usually worth trying to import the tablespace with just the `.ibd` file.

- Then, once the files are in the proper directory on the target server, we need to use [ALTER TABLE ... IMPORT TABLESPACE](#) to import the new table's tablespace:

```
ALTER TABLE test.t2_placeholder IMPORT TABLESPACE;
```

The placeholder table now contains data from the `p0` partition on the source server.

```
SELECT * FROM test.t2_placeholder;
```

```
+-----+-----+
| employee_id | name          |
+-----+-----+
|           1 | Geoff Montee |
+-----+-----+
```

- Then, it's time to transfer the partition from the placeholder to the target table. This can be done with an [ALTER TABLE... EXCHANGE PARTITION](#) statement:

```
ALTER TABLE test.t2 EXCHANGE PARTITION p0 WITH TABLE test.t2_placeholder;
```

The target table now contains the first partition from the source table.

```
SELECT * FROM test.t2;
```

```
+-----+-----+
| employee_id | name          |
+-----+-----+
|           1 | Geoff Montee |
+-----+-----+
```

- Repeat this procedure for each partition you want to import. For each partition, we need to discard the placeholder table's tablespace, and then import the partitioned table's tablespace into the placeholder table, and then exchange the tablespaces between the placeholder table and the partition of our target table.

When this process is complete for all partitions, the target table will contain the imported data:

```
SELECT * FROM test.t2;
```

```
+-----+-----+
| employee_id | name          |
+-----+-----+
|           1 | Geoff Montee |
|           6 | Chris Calendar |
|          11 | Kyle Joiner   |
|           16 | Will Fong     |
+-----+-----+
```

- Then, we can remove the placeholder table from the database:

```
DROP TABLE test.t2_placeholder;
```

Known Problems with Copying Transportable Tablespaces

Differing Storage Formats for Temporal Columns

[MariaDB 10.1.2](#) added the [mysql56_temporal_format](#) system variable, which enables a new MySQL 5.6-compatible storage format for the [TIME](#), [DATETIME](#) and [TIMESTAMP](#) data types.

If a file-per-tablespace file contains columns that use one or more of these temporal data types and if the tablespace file's original table was created with a certain storage format for these columns, then the tablespace file can only be imported into tables that were also created with the same storage format for these columns as the original table. Otherwise, you will see errors like the following:

```
ALTER TABLE dt_test IMPORT TABLESPACE;
ERROR 1808 (HY000): Schema mismatch (Column dt precise type mismatch.)
```

See [MDEV-15225](#) for more information.

See the pages for the [TIME](#), [DATETIME](#) and [TIMESTAMP](#) data types to determine how to update the storage format for temporal columns in tables that were created before [MariaDB 10.1.2](#) or that were created with [mysql56_temporal_format=OFF](#).

Differing ROW_FORMAT Values

InnoDB file-per-table tablespaces can use different [row formats](#). A specific row format can be specified when creating a table either by setting the `ROW_FORMAT` table option or by the setting the `innodb_default_row_format` system variable. See [Setting a Table's Row Format](#) for more information on how to set an InnoDB table's row format.

If a file-per-tablespace file was created with a certain row format, then the tablespace file can only be imported into tables that were created with the same row format as the original table. Otherwise, you will see errors like the following:

```
ALTER TABLE t0 IMPORT TABLESPACE;
ERROR 1808 (HY000): Schema mismatch (Expected FSP_SPACE_FLAGS=0x21, .ibd file contains 0x0.)
```

The error message is a bit more descriptive in [MariaDB 10.2.17](#) and later:

```
ALTER TABLE t0 IMPORT TABLESPACE;
ERROR 1808 (HY000): Schema mismatch (Table flags don't match, server table has 0x1 and the
meta-data file has 0x0; .cfg file uses ROW_FORMAT=REDUNDANT)
```

Be sure to check a tablespace's row format before moving it from one server to another. Keep in mind that the default row format can change between major versions of MySQL or MariaDB. See [Checking a Table's Row Format](#) for information on how to check an InnoDB table's row format.

See [MDEV-15049](#) and [MDEV-16851](#) for more information.

Foreign Key Constraints

DISCARD on a table with foreign key constraints is only possible after disabling `foreign_key_checks`:

```
SET SESSION foreign_key_checks=0;
ALTER TABLE t0 DISCARD TABLESPACE;
```

IMPORT on the other hand does not enforce foreign key constraints. So when importing tablespaces, referential integrity can only be guaranteed to import all tables bound by foreign key constraint at the same time, from an EXPORT of those tables taken with the same transactional state.

Tablespace Encryption

MariaDB supports data-at-rest encryption for the InnoDB storage engine. When enabled, the Server encrypts data before writing it to the tablespace and decrypts reads from the tablespace before returning result-sets. This means that a malicious user attempting to exfiltrate sensitive data won't be able to import the tablespace onto a different server as shown above without the encryption key.

For more information on data encryption, see [Encrypting Data for InnoDB](#).

5.3.2.10.3 InnoDB Temporary Tablespaces

When the user creates a temporary table using the `CREATE TEMPORARY TABLE` statement and the engine is set as InnoDB, MariaDB creates a temporary tablespace file. When the table is not compressed, MariaDB writes to a shared temporary tablespace as defined by the `innodb_temp_data_file_path` system variable. MariaDB does not allow the creation of `ROW_FORMAT=COMPRESSED` temporary tables. All temporary tables will be uncompressed. MariaDB deletes temporary tablespaces when the server shuts down gracefully and is recreated when it starts again. It cannot be placed on a raw device.

Internal temporary tablespaces, (that is, temporary tables that cannot be kept in memory) use either Aria or MyISAM, depending on the `aria_used_for_temp_tables` system variable. You can set the default storage engine for user-created temporary tables using the `default_tmp_storage_engine` system variable.

Prior to [MariaDB 10.2](#), temporary tablespaces existed as part of the InnoDB `system` tablespace or were file-per-table depending on the configuration of the `innodb_file_per_table` system variable.

Syntax for the value of the `innodb_temp_data_file_path` variable

The options for `innodb_temp_data_file_path` is one path or a set of paths, separated by ';':

The syntax for each path is:

```
path:size[:autoextend][:max:size][:autoshrink]
```

`size` can have extensions 'G' (Gigabytes), 'M' (Megabytes) or 'K' (Kilobytes). If no extension is given, then megabytes is assumed.

- The first `size` argument is the initial size of the temporary table space.
- `autoextend` means that the file size will automatically increase if needed.
- `max` can be used to limit the total size of the temporary file if `autoextend` is used.
- `autoshrink` means that the file will shrink to original size when possible.

Only the last path can have the `autoextend`, `max` and `autoshrink` options.

Sizing Temporary Tablespaces

In order to size temporary tablespaces, use the `innodb_temp_data_file_path` system variable. This system variable can be specified as a command-line argument to `mysqld` or it can be specified in a relevant server [option group](#) in an [option file](#). For example:

```
[mariadb]
...
innodb_temp_data_file_path=ibtmp1:32M:autoextend
```

This system variable's syntax is the same as the `innodb_data_file_path` system variable. That is, a file name, size and option. By default, it writes a 12MB autoextending file to `ibtmp1` in the data directory.

To increase the size of the temporary tablespace, you can add a path to an additional tablespace file to the value of the `innodb_temp_data_file_path` system variable. Providing additional paths allows you to spread the temporary tablespace between multiple tablespace files. The last file can have the `autoextend` attribute, which ensures that you won't run out of space. For example:

```
[mariadb]
...
innodb_temp_data_file_path=ibtmp1:32M;ibtmp2:32M:autoextend
```

Unlike normal tablespaces, temporary tablespaces are deleted when you stop MariaDB. To shrink temporary tablespaces to their minimum sizes, restart the server.

Shrinking the Tablespace

MariaDB starting with [11.3](#)

From [MariaDB 11.3.0](#), the temporary tablespace can be shrunk by setting `innodb_truncate_temporary_tablespace_now` to ON:

```
SET GLOBAL innodb_truncate_temporary_tablespace_now=1;
```

5.3.2.11 InnoDB File Format

Contents

1. [Setting a Table's File Format](#)
2. [Supported File Formats](#)
 1. [Antelope](#)
 2. [Barracuda](#)
 3. [Future Formats](#)
3. [Checking a Table's File Format](#).
4. [Compatibility](#)

Prior to [MariaDB 10.3](#), the [InnoDB](#) storage engine supports two different file formats.

Setting a Table's File Format

In [MariaDB 10.2](#) and before, the default file format for InnoDB tables can be chosen by setting the `innodb_file_format`.

In [MariaDB 10.2.1](#) and before, the default file format is `Antelope`. In [MariaDB 10.2.2](#) and later, the default file format is `Barracuda` and `Antelope` is deprecated.

A table's tablespace is tagged with the lowest InnoDB file format that supports the table's row format. So, even if the Barracuda file format is enabled, tables that use the COMPACT or REDUNDANT row formats will be tagged with the Antelope file format in the information_schema.INNODB_SYS_TABLES table.

Supported File Formats

The InnoDB storage engine supports two different file formats:

- Antelope
- Barracuda

Antelope

In MariaDB 10.2.1 and before, the default file format is Antelope. In MariaDB 10.2.2 and later, the Antelope file format is deprecated.

Antelope is the original InnoDB file format. It supports the COMPACT and REDUNDANT row formats, but not the DYNAMIC or COMPRESSED row formats.

Barracuda

In MariaDB 10.1 and before, the Barracuda file format is only supported if the innodb_file_per_table system variable is set to ON. In MariaDB 10.2.2 and later, the default file format is Barracuda and Antelope is deprecated.

Barracuda is a newer InnoDB file format. It supports the COMPACT, REDUNDANT, DYNAMIC and COMPRESSED row formats. Tables with large BLOB or TEXT columns in particular could benefit from the dynamic row format.

Future Formats

InnoDB might use new file formats in the future. Each format will have an identifier from 0 to 25, and a name. The names have already been decided, and are animal names listed in an alphabetical order: Antelope, Barracuda, Cheetah, Dragon, Elk, Fox, Gazelle, Hornet, Impala, Jaguar, Kangaroo, Leopard, Moose, Nautilus, Ocelot, Porpoise, Quail, Rabbit, Shark, Tiger, Urchin, Viper, Whale, Xenops, Yak and Zebra.

Checking a Table's File Format.

The information_schema.INNODB_SYS_TABLES table can be queried to see the file format used by a table.

A table's tablespace is tagged with the lowest InnoDB file format that supports the table's row format. So, even if the Barracuda file format is enabled, tables that use the COMPACT or REDUNDANT row formats will be tagged with the Antelope file format in the information_schema.INNODB_SYS_TABLES table.

Compatibility

Each tablespace is tagged with the id of the most recent file format used by one of its tables. All versions of InnoDB can read tables that use an older file format. However, it can not read from more recent formats. For this reason, each time InnoDB opens a table it checks the tablespace's format, and returns an error if a newer format is used.

This check can be skipped via the innodb_file_format_check variable. Beware that, if InnoDB tries to repair a table in an unknown format, the table will be corrupted! This happens on restart if innodb_file_format_check is disabled and the server crashed, or it was closed with fast shutdown.

To downgrade a table from the Barracuda format to Antelope, the table's ROW_FORMAT can be set to a value supported by Antelope, via an ALTER TABLE statement. This recreates the indexes.

The Antelope format can be used to make sure that tables work on MariaDB and MySQL servers which are older than 5.5.

5.3.2.12 InnoDB Row Formats

InnoDB Row Formats Overview

InnoDB's row formats are REDUNDANT, COMPACT, DYNAMIC, and COMPRESSED.

InnoDB REDUNDANT Row Format

The REDUNDANT row format is the original non-compacted row format.

InnoDB COMPACT Row Format

Similar to the REDUNDANT row format, but stores data in a more compact manner.

InnoDB DYNAMIC Row Format

Similar to the COMPACT row format, but can store even more data on overflow pages.

InnoDB COMPRESSED Row Format

Similar to the COMPACT row format, but can store even more data on overflow pages.

Troubleshooting Row Size Too Large Errors with InnoDB

Fixing "Row size too large (> 8126). Changing some columns to TEXT or BLOB may help."

5.3.2.12.1 InnoDB Row Formats Overview

Contents

1. Default Row Format
2. Setting a Table's Row Format
3. Checking a Table's Row Format
4. Row Formats
 1. REDUNDANT Row Format
 2. COMPACT Row Format
 3. DYNAMIC Row Format
 4. COMPRESSED Row Format
5. Maximum Row Size
6. Known Issues
 1. Upgrading Causes Row Size Too Large Errors

The InnoDB storage engine supports four different row formats:

- REDUNDANT
- COMPACT
- DYNAMIC
- COMPRESSED

In MariaDB 10.1 and before, the latter two row formats are only supported if the InnoDB file format is Barracuda . Therefore, the `innodb_file_format` system variable must be set to `Barracuda` to use these row formats in those versions.

In MariaDB 10.1 and before, the latter two row formats are also only supported if the table is in a file per-table tablespace. Therefore, the `innodb_file_per_table` system variable must be set to `ON` to use these row formats in those versions.

Default Row Format

The `innodb_default_row_format` system variable can be used to set the default row format for InnoDB tables. The possible values are:

- `redundant`
- `compact`
- `dynamic`

This system variable's default value is `dynamic` , which means that the default row format is `DYNAMIC` .

This system variable cannot be set to `compressed` , which means that the default row format cannot be `COMPRESSED` .

For example, the following statements would create a table with the `DYNAMIC` row format:

```

SET SESSION innodb_strict_mode=ON;

SET GLOBAL innodb_default_row_format='dynamic';

CREATE TABLE tab (
  id int,
  str varchar(50)
) ENGINE=InnoDB;

```

Setting a Table's Row Format

One way to specify an InnoDB table's row format is by setting the `ROW_FORMAT` table option to the relevant row format in a `CREATE TABLE` or `ALTER TABLE` statement. For example:

```

SET SESSION innodb_strict_mode=ON;

SET GLOBAL innodb_file_per_table=ON;

SET GLOBAL innodb_file_format='Barracuda';

CREATE TABLE tab (
  id int,
  str varchar(50)
) ENGINE=InnoDB ROW_FORMAT=DYNAMIC;

```

In MariaDB 10.1 and before, InnoDB can silently ignore and override some row format choices if you do not have the `innodb_file_format` system variable set to `Barracuda` and the `innodb_file_per_table` system variable set to `ON`.

Checking a Table's Row Format

The `SHOW TABLE STATUS` statement can be used to see the row format used by a table. For example:

```

SHOW TABLE STATUS FROM db1 WHERE Name='tab' \G
***** 1. row *****
      Name: tab
      Engine: InnoDB
      Version: 10
      Row_format: Dynamic
      Rows: 0
      Avg_row_length: 0
      Data_length: 16384
      Max_data_length: 0
      Index_length: 0
      Data_free: 0
      Auto_increment: NULL
      Create_time: 2019-04-18 20:24:04
      Update_time: NULL
      Check_time: NULL
      Collation: latin1_swedish_ci
      Checksum: NULL
      Create_options: row_format=DYNAMIC
      Comment:

```

The `information_schema.INNODB_SYS_TABLES` table can also be queried to see the row format used by a table. For example:

```

SELECT * FROM information_schema.INNODB_SYS_TABLES WHERE name='db1/tab'
***** 1. row *****
TABLE_ID: 42
NAME: db1/tab
FLAG: 33
N_COLS: 4
SPACE: 27
FILE_FORMAT: Barracuda
ROW_FORMAT: Dynamic
ZIP_PAGE_SIZE: 0
SPACE_TYPE: Single

```

A table's tablespace is tagged with the lowest InnoDB file format that supports the table's row format. So, even if the Barracuda file format is enabled, tables that use the `COMPACT` or `REDUNDANT` row formats will be tagged with the Antelope file format in the `information_schema.INNODB_SYS_TABLES` table.

Row Formats

REDUNDANT Row Format

The `REDUNDANT` row format is the original non-compacted row format.

The `REDUNDANT` row format was the only available row format before MySQL 5.0.3. In that release, this row format was retroactively named the `REDUNDANT` row format. In the same release, the `COMPACT` row format was introduced as the new default row format.

See [InnoDB REDUNDANT Row Format](#) for more information.

COMPACT Row Format

Default row format in [MariaDB 10.2.1](#) and earlier `COMPACT`.

The `COMPACT` row format is similar to the `REDUNDANT` row format, but it stores data in a more compact manner that requires about 20% less storage.

See [InnoDB COMPACT Row Format](#) for more information.

DYNAMIC Row Format

`DYNAMIC` is the default row format.

The `DYNAMIC` row format is similar to the `COMPACT` row format, but tables using the `DYNAMIC` row format can store even more data on overflow pages than tables using the `COMPACT` row format. This results in more efficient data storage than tables using the `COMPACT` row format, especially for tables containing columns using the `VARBINARY`, `VARCHAR`, `BLOB` and `TEXT` data types. However, InnoDB tables using the `COMPRESSED` row format are more efficient.

See [InnoDB DYNAMIC Row Format](#) for more information.

COMPRESSED Row Format

An alternative way to compress InnoDB tables is by using [InnoDB Page Compression](#).

The `COMPRESSED` row format is similar to the `COMPACT` row format, but tables using the `COMPRESSED` row format can store even more data on overflow pages than tables using the `COMPACT` row format. This results in more efficient data storage than tables using the `COMPACT` row format, especially for tables containing columns using the `VARBINARY`, `VARCHAR`, `BLOB` and `TEXT` data types.

The `COMPRESSED` row format also supports compression of all data and index pages.

See [InnoDB COMPRESSED Row Format](#) for more information.

Maximum Row Size

Several factors help determine the maximum row size of an InnoDB table.

First, MariaDB enforces a 65,535 byte limit on a table's maximum row size. The total size of a table's `BLOB` and `TEXT`

columns do not count towards this limit. Only the pointers for a table's [BLOB](#) and [TEXT](#) columns count towards this limit. MariaDB enforces this limit for all storage engines, so this limit also applies to InnoDB tables. Therefore, this limit is the absolute maximum row size for an InnoDB table.

If you try to create a table that exceeds MariaDB's global limit on a table's maximum row size, then you will see an error like this:

```
ERROR 1118 (42000): Row size too large. The maximum row size for the used table type, not counting BLOBs, is 65535. This includes storage overhead, check the manual. You have to change some columns to TEXT or BLOBs
```

However, InnoDB also has its own limits on the maximum row size, so an InnoDB table's maximum row size could be smaller than MariaDB's global limit.

Second, the maximum amount of data that an InnoDB table can store in a row's main data page depends on the value of the [innodb_page_size](#) system variable. At most, the data that a single row can consume on the row's main data page is half of the value of the [innodb_page_size](#) system variable. With the default value of `16k`, that would mean that a single row can consume at most around 8 KB on the row's main data page. However, the limit on the row's main data page is not the absolute limit on the row's size.

Third, all InnoDB row formats can store certain kinds of data in overflow pages, so the maximum row size of an InnoDB table can be larger than the maximum amount of data that can be stored in the row's main data page.

Some row formats can store more data in overflow pages than others. For example, the [DYNAMIC](#) and [COMPRESSED](#) row formats can store the most data in overflow pages. To see how to determine the how the various InnoDB row formats can use overflow pages, see the following sections:

- [InnoDB REDUNDANT Row Format: Overflow Pages with the REDUNDANT Row Format](#)
- [InnoDB COMPACT Row Format: Overflow Pages with the COMPACT Row Format](#)
- [InnoDB DYNAMIC Row Format: Overflow Pages with the DYNAMIC Row Format](#)
- [InnoDB COMPRESSED Row Format: Overflow Pages with the COMPRESSED Row Format](#)

If a table's definition can allow rows that the table's InnoDB row format can't actually store, then InnoDB will raise errors or warnings in certain scenarios.

If the table were using the [REDUNDANT](#) or [COMPACT](#) row formats, then the error or warning would be the following:

```
ERROR 1118 (42000): Row size too large (> 8126). Changing some columns to TEXT or BLOB or using ROW_FORMAT=DYNAMIC or ROW_FORMAT=COMPRESSED may help. In current row format, BLOB prefix of 768 bytes is stored inline.
```

And if the table were using the [DYNAMIC](#) or [COMPRESSED](#) row formats, then the error or warning would be the following:

```
ERROR 1118 (42000): Row size too large (> 8126). Changing some columns to TEXT or BLOB may help. In current row format, BLOB prefix of 0 bytes is stored inline.
```

These messages are raised in the following cases:

- If [InnoDB strict mode](#) is **enabled** and if a [DDL](#) statement is executed that touches the table, such as [CREATE TABLE](#) or [ALTER TABLE](#), then InnoDB will raise an **error** with this message
- If [InnoDB strict mode](#) is **disabled** and if a [DDL](#) statement is executed that touches the table, such as [CREATE TABLE](#) or [ALTER TABLE](#), then InnoDB will raise a **warning** with this message.
- Regardless of whether [InnoDB strict mode](#) is enabled, if a [DML](#) statement is executed that attempts to write a row that the table's InnoDB row format can't store, then InnoDB will raise an **error** with this message.

For information on how to solve the problem, see [Troubleshooting Row Size Too Large Errors with InnoDB](#).

Known Issues

Upgrading Causes Row Size Too Large Errors

Prior to [MariaDB 10.2.26](#), [MariaDB 10.3.17](#), and [MariaDB 10.4.7](#), MariaDB doesn't properly calculate the row sizes while executing DDL. In these versions, *unsafe* tables can be created, even if [InnoDB strict mode](#) is enabled. The calculations were fixed by [MDEV-19292](#) in [MariaDB 10.2.26](#), [MariaDB 10.3.17](#), and [MariaDB 10.4.7](#).

As a side effect, some tables that could be created or altered in previous versions may get rejected with the following error in these releases and any later releases.

```
ERROR 1118 (42000): Row size too large (> 8126). Changing some columns to TEXT or BLOB may help. In current row format, BLOB prefix of 0 bytes is stored inline.
```

And users could also see the following message as an error or warning in the [error log](#):

```
[Warning] InnoDB: Cannot add field col in table db1.tab because after adding it, the row size is 8478 which is greater than maximum allowed size (8126) for a record on index leaf page.
```

InnoDB used the wrong calculations to determine row sizes for quite a long time, so a lot of users may unknowingly have *unsafe* tables that the InnoDB row format can't actually store.

InnoDB does not currently have an easy way to check which existing tables have this problem. See [MDEV-20400](#) for more information.

For information on how to solve the problem, see [Troubleshooting Row Size Too Large Errors with InnoDB](#).

5.3.2.12.2 InnoDB REDUNDANT Row Format

Contents

- [Using the REDUNDANT Row Format](#)
- [Index Prefixes with the REDUNDANT Row Format](#)
- [Overflow Pages with the REDUNDANT Row Format](#)

The `REDUNDANT` row format is the original non-compacted row format.

The `REDUNDANT` row format was the only available row format before MySQL 5.0.3. In that release, this row format was retroactively named the `REDUNDANT` row format. In the same release, the `COMPACT` row format was introduced as the new default row format.

Using the REDUNDANT Row Format

The easiest way to create an InnoDB table that uses the `REDUNDANT` row format is by setting the `ROW_FORMAT` table option to `REDUNDANT` in a `CREATE TABLE` or `ALTER TABLE` statement.

It is recommended to set the `innodb_strict_mode` system variable to `ON` when using this format.

The `REDUNDANT` row format is supported by both the `Antelope` and the `Barracuda` file formats, so tables with this row format can be created regardless of the value of the `innodb_file_format` system variable.

For example:

```
SET SESSION innodb_strict_mode=ON;

CREATE TABLE tab (
  id int,
  str varchar(50)
) ENGINE=InnoDB ROW_FORMAT=REDUNDANT;
```

Index Prefixes with the REDUNDANT Row Format

The `REDUNDANT` row format supports index prefixes up to 767 bytes.

Overflow Pages with the REDUNDANT Row Format

All InnoDB row formats can store certain kinds of data in overflow pages. This allows for the maximum row size of an InnoDB table to be larger than the maximum amount of data that can be stored in the row's main data page. See [Maximum Row Size](#) for more information about the other factors that can contribute to the maximum row size for InnoDB tables.

In the `REDUNDANT` row format variable-length columns, such as columns using the `VARBINARY`, `VARCHAR`, `BLOB` and `TEXT` data types, can be partially stored in overflow pages.

InnoDB only considers using overflow pages if the table's row size is greater than half of `innodb_page_size`. If the row size is greater than this, then InnoDB chooses variable-length columns to be stored on overflow pages until the row size is less than half of `innodb_page_size`.

For [VARBINARY](#), [VARCHAR](#), [BLOB](#) and [TEXT](#) columns, only values longer than 767 bytes are considered for storage on overflow pages. Bytes that are stored to track a value's length do not count towards this limit. This limit is only based on the length of the actual column's data.

Fixed-length columns greater than 767 bytes are encoded as variable-length columns, so they can also be stored in overflow pages if the table's row size is greater than half of [innodb_page_size](#). Even though a column using the [CHAR](#) data type can hold at most 255 characters, a [CHAR](#) column can still exceed 767 bytes in some cases. For example, a `char(255)` column can exceed 767 bytes if the [character set](#) is `utf8mb4`.

If a column is chosen to be stored on overflow pages, then the first 767 bytes of the column's value and a 20-byte pointer to the column's first overflow page are stored on the main page. Each overflow page is the size of `[innodb-system-variables#innodb_page_size|innodb_page_size]`. If a column is too large to be stored on a single overflow page, then it is stored on multiple overflow pages. Each overflow page contains part of the data and a 20-byte pointer to the next overflow page, if a next page exists.

5.3.2.12.3 InnoDB COMPACT Row Format

MariaDB until [10.2.1](#)

In [MariaDB 10.2.1](#) and before, the default row format is `COMPACT`.

Contents

- [Using the COMPACT Row Format](#)
- [Index Prefixes with the COMPACT Row Format](#)
- [Overflow Pages with the COMPACT Row Format](#)

The `COMPACT` row format is similar to the `REDUNDANT` row format, but it stores data in a more compact manner that requires about 20% less storage.

Using the COMPACT Row Format

MariaDB starting with [10.2.2](#)

In [MariaDB 10.2.2](#) and later, the easiest way to create an InnoDB table that uses the `COMPACT` row format is by setting the `ROW_FORMAT` table option to `COMPACT` in a `CREATE TABLE` or `ALTER TABLE` statement.

It is recommended to set the `innodb_strict_mode` system variable to `ON` when using this row format.

The `COMPACT` row format is supported by both the `Antelope` and the `Barracuda` [file formats](#), so tables with this row format can be created regardless of the value of the `innodb_file_format` system variable.

For example:

```
SET SESSION innodb_strict_mode=ON;

CREATE TABLE tab (
  id int,
  str varchar(50)
) ENGINE=InnoDB ROW_FORMAT=COMPACT;
```

MariaDB until [10.2.1](#)

In [MariaDB 10.2.1](#) and before, the default row format is `COMPACT`. Therefore, in these versions, the easiest way to create an InnoDB table that uses the `COMPACT` row format is by **not** setting the `ROW_FORMAT` table option at all in the `CREATE TABLE` or `ALTER TABLE` statement.

It is recommended to set the `innodb_strict_mode` system variable to `ON` when using this row format.

The `COMPACT` row format is supported by both the `Antelope` and the `Barracuda` [file formats](#), so tables with this row format can be created regardless of the value of the `innodb_file_format` system variable.

For example:

```
SET SESSION innodb_strict_mode=ON;

CREATE TABLE tab (
  id int,
  str varchar(50)
) ENGINE=InnoDB;
```

Index Prefixes with the COMPACT Row Format

The COMPACT row format supports index prefixes up to 767 bytes.

Overflow Pages with the COMPACT Row Format

All InnoDB row formats can store certain kinds of data in overflow pages. This allows for the maximum row size of an InnoDB table to be larger than the maximum amount of data that can be stored in the row's main data page. See [Maximum Row Size](#) for more information about the other factors that can contribute to the maximum row size for InnoDB tables.

In the COMPACT row format variable-length columns, such as columns using the VARBINARY, VARCHAR, BLOB and TEXT data types, can be partially stored in overflow pages.

InnoDB only considers using overflow pages if the table's row size is greater than half of innodb_page_size. If the row size is greater than this, then InnoDB chooses variable-length columns to be stored on overflow pages until the row size is less than half of innodb_page_size.

For VARBINARY, VARCHAR, BLOB and TEXT columns, only values longer than 767 bytes are considered for storage on overflow pages. Bytes that are stored to track a value's length do not count towards this limit. This limit is only based on the length of the actual column's data.

Fixed-length columns greater than 767 bytes are encoded as variable-length columns, so they can also be stored in overflow pages if the table's row size is greater than half of innodb_page_size. Even though a column using the CHAR data type can hold at most 255 characters, a CHAR column can still exceed 767 bytes in some cases. For example, a char(255) column can exceed 767 bytes if the character set is utf8mb4.

If a column is chosen to be stored on overflow pages, then the first 767 bytes of the column's value and a 20-byte pointer to the column's first overflow page are stored on the main page. Each overflow page is the size of innodb_page_size. If a column is too large to be stored on a single overflow page, then it is stored on multiple overflow pages. Each overflow page contains part of the data and a 20-byte pointer to the next overflow page, if a next page exists.

5.3.2.12.4 InnoDB DYNAMIC Row Format

DYNAMIC is the default InnoDB row format.

Contents

1. [Using the DYNAMIC Row Format](#)
2. [Index Prefixes with the DYNAMIC Row Format](#)
3. [Overflow Pages with the DYNAMIC Row Format](#)

The DYNAMIC row format is similar to the COMPACT row format, but tables using the DYNAMIC row format can store even more data on overflow pages than tables using the COMPACT row format. This results in more efficient data storage than tables using the COMPACT row format, especially for tables containing columns using the VARBINARY, VARCHAR, BLOB and TEXT data types. While InnoDB tables using the COMPRESSED row format can result in even greater space-efficiency, COMPRESSED requires substantially more memory and CPU to both read and write, so there is a significant performance and concurrency trade-off for that space-efficiency gain. COMPRESSED tables are not recommended for production use in most situations, while DYNAMIC row format scales well in high-performance environments.

The DYNAMIC row format was originally introduced in [MariaDB 5.5](#).

Using the DYNAMIC Row Format

MariaDB starting with [10.2.2](#)

In [MariaDB 10.2.2](#) and later, the default row format is DYNAMIC, as long as the innodb_default_row_format system variable has not been modified. Therefore, in these versions, the easiest way to create an InnoDB table that uses the DYNAMIC row format is by not setting the ROW_FORMAT table option at all in a CREATE TABLE or ALTER TABLE statement.

It is recommended to set the innodb_strict_mode system variable to ON when using this row format.

For example:

```

SET SESSION innodb_strict_mode=ON;

SET GLOBAL innodb_default_row_format='dynamic';

CREATE TABLE tab (
  id int,
  str varchar(50)
) ENGINE=InnoDB;

```

MariaDB until 10.2.1 [↗](#)

In [MariaDB 10.2.1](#) [↗](#) and before, the easiest way to create an InnoDB table that uses the `DYNAMIC` row format is by setting the `ROW_FORMAT` table option to `DYNAMIC` in a `CREATE TABLE` or `ALTER TABLE` statement.

It is recommended to set the `innodb_strict_mode` system variable to `ON` when using this row format.

The `DYNAMIC` row format is only supported by the `Barracuda` file format. As a side effect, in [MariaDB 10.1](#) and before, the `DYNAMIC` row format is only supported if the `InnoDB file format` is `Barracuda`. Therefore, the `innodb_file_format` system variable must be set to `Barracuda` to use these row formats in those versions.

In [MariaDB 10.1](#) and before, the `DYNAMIC` row format is also only supported if the table is in a `file per-table` tablespace. Therefore, the `innodb_file_per_table` system variable must be set to `ON` to use this row format in those versions.

For example:

```

SET SESSION innodb_strict_mode=ON;

SET GLOBAL innodb_file_per_table=ON;

SET GLOBAL innodb_file_format='Barracuda';

CREATE TABLE tab (
  id int,
  str varchar(50)
) ENGINE=InnoDB ROW_FORMAT=DYNAMIC;

```

Index Prefixes with the DYNAMIC Row Format

The `DYNAMIC` row format supports index prefixes up to 3072 bytes. In [MariaDB 10.2](#) and before, the `innodb_large_prefix` system variable is used to configure the maximum index prefix length. In these versions, if `innodb_large_prefix` is set to `ON`, then the maximum prefix length is 3072 bytes, and if it is set to `OFF`, then the maximum prefix length is 767 bytes.

Overflow Pages with the DYNAMIC Row Format

All InnoDB row formats can store certain kinds of data in overflow pages. This allows for the maximum row size of an InnoDB table to be larger than the maximum amount of data that can be stored in the row's main data page. See [Maximum Row Size](#) for more information about the other factors that can contribute to the maximum row size for InnoDB tables.

In the `DYNAMIC` row format variable-length columns, such as columns using the `VARBINARY`, `VARCHAR`, `BLOB` and `TEXT` data types, can be completely stored in overflow pages.

InnoDB only considers using overflow pages if the table's row size is greater than half of `innodb_page_size`. If the row size is greater than this, then InnoDB chooses variable-length columns to be stored on overflow pages until the row size is less than half of `innodb_page_size`.

For `BLOB` and `TEXT` columns, only values longer than 40 bytes are considered for storage on overflow pages. For `VARBINARY` and `VARCHAR` columns, only values longer than 255 bytes are considered for storage on overflow pages. Bytes that are stored to track a value's length do not count towards these limits. These limits are only based on the length of the actual column's data.

These limits differ from the limits for the `COMPACT` row format, where the limit is 767 bytes for all types.

Fixed-length columns greater than 767 bytes are encoded as variable-length columns, so they can also be stored in overflow pages if the table's row size is greater than half of `innodb_page_size`. Even though a column using the `CHAR` data type can hold at most 255 characters, a `CHAR` column can still exceed 767 bytes in some cases. For example, a `char(255)` column can exceed 767 bytes if the `character set` is `utf8mb4`.

If a column is chosen to be stored on overflow pages, then the entire value of the column is stored on overflow pages, and

only a 20-byte pointer to the column's first overflow page is stored on the main page. Each overflow page is the size of `innodb_page_size`. If a column is too large to be stored on a single overflow page, then it is stored on multiple overflow pages. Each overflow page contains part of the data and a 20-byte pointer to the next overflow page, if a next page exists.

This behavior differs from the behavior of the `COMPACT` row format, which always stores the column prefix on the main page. This allows tables using the `DYNAMIC` row format to contain a high number of columns using the `VARBINARY`, `VARCHAR`, `BLOB` and `TEXT` data types.

5.3.2.12.5 InnoDB COMPRESSED Row Format

Contents

1. [Using the COMPRESSED Row Format](#)
2. [Compression with the COMPRESSED Row Format](#)
3. [Monitoring Performance of the COMPRESSED Row Format](#)
4. [Index Prefixes with the COMPRESSED Row Format](#)
5. [Overflow Pages with the COMPRESSED Row Format](#)
6. [Read-Only](#)

In MariaDB 10.1 and later, an alternative (and usually superior) way to compress InnoDB tables is by using [InnoDB Page Compression](#). See [Comparison with the COMPRESSED Row Format](#).

The `COMPRESSED` row format is similar to the `COMPACT` row format, but tables using the `COMPRESSED` row format can store even more data on overflow pages than tables using the `COMPACT` row format. This results in more efficient data storage than tables using the `COMPACT` row format, especially for tables containing columns using the `VARBINARY`, `VARCHAR`, `BLOB` and `TEXT` data types.

The `COMPRESSED` row format also supports compression of all data and index pages.

Using the COMPRESSED Row Format

An InnoDB table that uses the `COMPRESSED` row format can be created by setting the `ROW_FORMAT` table option to `COMPRESSED` and by setting the `KEY_BLOCK_SIZE` table option to one of the following values in a `CREATE TABLE` or `ALTER TABLE` statement, where the units are in `KB`:

- 1
- 2
- 4
- 8
- 16

`16k` is the default value of the `innodb_page_size` system variable, so using `16` will usually result in minimal compression unless one of the following is true:

- The table has many columns that can be stored in overflow pages, such as columns that use the `VARBINARY`, `VARCHAR`, `BLOB` and `TEXT` data types.
- The server is using a non-default `innodb_page_size` value that is greater than `16k`.

In MariaDB 10.1 and later, the value of the `innodb_page_size` system variable can be set to `32k` and `64k`. This is especially useful because the larger page size permits more columns using the `VARBINARY`, `VARCHAR`, `BLOB` and `TEXT` data types. Regardless, even when the value of the `innodb_page_size` system variable is set to some value higher than `16k`, `16` is still the maximum value for the `KEY_BLOCK_SIZE` table option for InnoDB tables using the `COMPRESSED` row format.

The `COMPRESSED` row format cannot be set as the default row format with the `innodb_default_row_format` system variable.

The `COMPRESSED` row format is only supported by the `Barracuda` file format. As a side effect, in MariaDB 10.1 and before, the `COMPRESSED` row format is only supported if the `InnoDB file format` is `Barracuda`. Therefore, the `innodb_file_format` system variable must be set to `Barracuda` to use these row formats in those versions.

In MariaDB 10.1 and before, the `COMPRESSED` row format is also only supported if the table is in a `file per-table` tablespace. Therefore, the `innodb_file_per_table` system variable must be set to `ON` to use this row format in those versions.

It is also recommended to set the `innodb_strict_mode` system variable to `ON` when using this row format.

InnoDB automatically uses the `COMPRESSED` row format for a table if the `KEY_BLOCK_SIZE` table option is set to some value in a `CREATE TABLE` or `ALTER TABLE` statement. For example:

```

SET SESSION innodb_strict_mode=ON;

SET GLOBAL innodb_file_per_table=ON;

SET GLOBAL innodb_file_format='Barracuda';

CREATE TABLE tab (
  id int,
  str varchar(50)
) ENGINE=InnoDB KEY_BLOCK_SIZE=4;

```

If the `KEY_BLOCK_SIZE` table option is **not** set to some value, but the `ROW_FORMAT` table option is set to `COMPRESSED` in a `CREATE TABLE` or `ALTER TABLE` statement, then InnoDB uses a default value of `8` for the `KEY_BLOCK_SIZE` table option. For example:

```

SET SESSION innodb_strict_mode=ON;

SET GLOBAL innodb_file_per_table=ON;

SET GLOBAL innodb_file_format='Barracuda';

CREATE TABLE tab (
  id int,
  str varchar(50)
) ENGINE=InnoDB ROW_FORMAT=COMPRESSED;

```

Compression with the `COMPRESSED` Row Format

The `COMPRESSED` row format supports compression of all data and index pages.

To avoid compressing and uncompressing pages too many times, InnoDB tries to keep both compressed and uncompressed pages in the `buffer pool` when there is enough room. This results in a bigger cache. When there is not enough room, an adaptive LRU algorithm is used to decide whether compressed or uncompressed pages should be evicted from the buffer: for CPU-bound workloads, the compressed pages are evicted first; for I/O-bound workloads, the uncompressed pages are evicted first. Of course, when necessary, both the compressed and uncompressed version of the same data can be evicted from the buffer.

Each compressed page has an uncompressed *modification log*, stored within the page itself. InnoDB writes small changes into it. When the space in the modification log runs out, the page is uncompressed, changes are applied, and the page is recompressed again. This is done to avoid some unnecessary decompression and compression operations.

Sometimes a *compression failure* might happen, because the data has grown too much to fit the page. When this happens, the page (and the index node) is split into two different pages. This process can be repeated recursively until the data fit the pages. This can be CPU-consuming on some busy servers which perform many write operations.

Before writing a compressed page into a data file, InnoDB writes it into the `redo log`. This ensures that the `redo log` can always be used to recover tables after a crash, even if the compression library is updated and some incompatibilities are introduced. But this also means that the `redo log` will grow faster and might need more space, or the frequency of checkpoints might need to increase.

Monitoring Performance of the `COMPRESSED` Row Format

The following `INFORMATION_SCHEMA` tables can be used to monitor the performances of InnoDB compressed tables:

- `INNODB_CMP` and `INNODB_CMP_RESET`
- `INNODB_CMP_PER_INDEX` and `INNODB_CMP_PER_INDEX_RESET`
- `INNODB_CMPMEM` and `INNODB_CMPMEM_RESET`

Index Prefixes with the `COMPRESSED` Row Format

The `COMPRESSED` row format supports index prefixes up to 3072 bytes. In `MariaDB 10.2` and before, the `innodb_large_prefix` system variable is used to configure the maximum index prefix length. In these versions, if `innodb_large_prefix` is set to `ON`, then the maximum prefix length is 3072 bytes, and if it is set to `OFF`, then the maximum prefix length is 767 bytes.

Overflow Pages with the COMPRESSED Row Format

All InnoDB row formats can store certain kinds of data in overflow pages. This allows for the maximum row size of an InnoDB table to be larger than the maximum amount of data that can be stored in the row's main data page. See [Maximum Row Size](#) for more information about the other factors that can contribute to the maximum row size for InnoDB tables.

In the `COMPRESSED` row format variable-length columns, such as columns using the `VARBINARY`, `VARCHAR`, `BLOB` and `TEXT` data types, can be completely stored in overflow pages.

InnoDB only considers using overflow pages if the table's row size is greater than half of `innodb_page_size`. If the row size is greater than this, then InnoDB chooses variable-length columns to be stored on overflow pages until the row size is less than half of `innodb_page_size`.

For `BLOB` and `TEXT` columns, only values longer than 40 bytes are considered for storage on overflow pages. For `VARBINARY` and `VARCHAR` columns, only values longer than 255 bytes are considered for storage on overflow pages. Bytes that are stored to track a value's length do not count towards these limits. These limits are only based on the length of the actual column's data.

These limits differ from the limits for the `COMPACT` row format, where the limit is 767 bytes for all types.

Fixed-length columns greater than 767 bytes are encoded as variable-length columns, so they can also be stored in overflow pages if the table's row size is greater than half of `innodb_page_size`. Even though a column using the `CHAR` data type can hold at most 255 characters, a `CHAR` column can still exceed 767 bytes in some cases. For example, a `char(255)` column can exceed 767 bytes if the `character set` is `utf8mb4`.

If a column is chosen to be stored on overflow pages, then the entire value of the column is stored on overflow pages, and only a 20-byte pointer to the column's first overflow page is stored on the main page. Each overflow page is the size of `innodb_page_size`. If a column is too large to be stored on a single overflow page, then it is stored on multiple overflow pages. Each overflow page contains part of the data and a 20-byte pointer to the next overflow page, if a next page exists.

This behavior differs from the behavior of the `COMPACT` row format, which always stores the column prefix on the main page. This allows tables using the `COMPRESSED` row format to contain a high number of columns using the `VARBINARY`, `VARCHAR`, `BLOB` and `TEXT` data types.

Read-Only

MariaDB starting with [10.6](#)

From [MariaDB 10.6.0](#) until [MariaDB 10.6.5](#), tables that are of the `COMPRESSED` row format are read-only by default.

This was intended to be the first step towards removing write support and deprecating the feature.

This plan has been scrapped, and from [MariaDB 10.6.6](#), `COMPRESSED` tables are no longer read-only by default.

From [MariaDB 10.6.0](#) to [MariaDB 10.6.5](#), set the `innodb_read_only_compressed` variable to `OFF` to make the tables writable.

5.3.2.3.4 Troubleshooting Row Size Too Large Errors with InnoDB

5.3.2.13 InnoDB Strict Mode

Contents

1. [Configuring InnoDB Strict Mode](#)
2. [InnoDB Strict Mode Errors](#)
 1. [Wrong Create Options](#)
 2. [COMPRESSED Row Format](#)
 3. [Row Size Too Large](#)

`InnoDB` strict mode is similar to [SQL strict mode](#). When it is enabled, certain InnoDB warnings become errors instead.

Configuring InnoDB Strict Mode

InnoDB strict mode is enabled by default.

InnoDB strict mode can be enabled or disabled by configuring the `innodb_strict_mode` server system variable.

Its global value can be changed dynamically with `SET GLOBAL`. For example:

```
SET GLOBAL innodb_strict_mode=ON;
```

Its value for the current session can also be changed dynamically with [SET SESSION](#). For example:

```
SET SESSION innodb_strict_mode=ON;
```

It can also be set in a server [option group](#) in an [option file](#) prior to starting up the server. For example:

```
[mariadb]
...
innodb_strict_mode=ON
```

InnoDB Strict Mode Errors

Wrong Create Options

If InnoDB strict mode is enabled, and if a DDL statement is executed and invalid or conflicting [table options](#) are specified, then an error is raised. The error will only be a generic error that says the following:

```
ERROR 1005 (HY000): Can't create table `db1`.`tab` (errno: 140 "Wrong create options")
```

However, more details about the error can be found by executing [SHOW WARNINGS](#).

For example, the error is raised in the following cases:

- The [KEY_BLOCK_SIZE](#) table option is set to a non-zero value, but the [ROW_FORMAT](#) table option is set to some row format other than the [COMPRESSED](#) row format. For example:

```
SET SESSION innodb_strict_mode=ON;

CREATE OR REPLACE TABLE tab (
  id int PRIMARY KEY,
  str varchar(50)
)
KEY_BLOCK_SIZE=4
ROW_FORMAT=DYNAMIC;
ERROR 1005 (HY000): Can't create table `db1`.`tab` (errno: 140 "Wrong create options")

SHOW WARNINGS;
+-----+-----+-----+
| Level  | Code | Message                                     |
+-----+-----+-----+
| Warning | 1478 | InnoDB: cannot specify ROW_FORMAT = DYNAMIC with KEY_BLOCK_SIZE. |
| Error   | 1005 | Can't create table `db1`.`tab` (errno: 140 "Wrong create options") |
| Warning | 1030 | Got error 140 "Wrong create options" from storage engine InnoDB   |
+-----+-----+-----+
3 rows in set (0.000 sec)
```

- The [KEY_BLOCK_SIZE](#) table option is set to a non-zero value, but the configured value is larger than either 16 or the value of the [innodb_page_size](#) system variable, whichever is smaller.

```

SET SESSION innodb_strict_mode=ON;

CREATE OR REPLACE TABLE tab (
  id int PRIMARY KEY,
  str varchar(50)
)
KEY_BLOCK_SIZE=16;
ERROR 1005 (HY000): Can't create table `db1`.`tab` (errno: 140 "Wrong create options")

SHOW WARNINGS;

 1. [Determining the Checkpoint Age in InnoDB](#)
6. [Determining the Redo Log Occupancy](#)
7. [MariaDB 10.8 Updates](#)

Directly editing or moving the redo logs can cause corruption, and should never normally be attempted.

Overview

The redo log is used by [InnoDB](#) during crash recovery and background flushing of transactions to the tablespaces. The redo log files have names like `ib_logfileN`, where `N` is an integer. From [MariaDB 10.5](#), there is only one redo log, so the file will always be named `ib_logfile0`. If the `innodb_log_group_home_dir` system variable is configured, then the redo log files will be created in that directory. Otherwise, they will be created in the directory defined by the `datadir` system variable.

Flushing Effects on Performance and Consistency

The `innodb_flush_log_at_trx_commit` system variable determines how often the transactions are flushed to the redo log, and it is important to achieve a good balance between speed and reliability.

Binary Log Group Commit and Redo Log Flushing

In [MariaDB 10.0](#) and above, when both `innodb_flush_log_at_trx_commit=1` (the default) is set and the `binary log` is enabled, there is now one less sync to disk inside InnoDB during commit (2 syncs shared between a group of transactions instead of 3). See [Binary Log Group Commit and InnoDB Flushing Performance](#) for more information.

Redo Log Group Capacity

The redo log group capacity is the total combined size of all InnoDB redo logs. The relevant factors are:

- From [MariaDB 10.5](#), there is 1 redo log. For [MariaDB 10.4](#) and before, the number of redo log files is configured by the `innodb_log_files_in_group` system variable.
- The size of each redo log file is configured by the `innodb_log_file_size` system variable. This can safely be set to a much higher value from [MariaDB 10.5](#). Before [MariaDB 10.9](#), resizing required the server to be restarted. From [MariaDB 10.9](#) the variable can be set dynamically.

The redo log group capacity is determined by the following calculation:

```
innodb_log_group_capacity = innodb_log_file_size * innodb_log_files_in_group
```

For example, if `innodb_log_file_size` is set to `2G` and `innodb_log_files_in_group` is set to `2`, then we would have the following:

- `innodb_log_group_capacity = innodb_log_file_size * innodb_log_files_in_group`
- `= 2G * 2`
- `= 4G`

Changing the Redo Log Group Capacity

The number (until [MariaDB 10.4](#) only - from [MariaDB 10.5](#) there is only 1 redo log) or size of redo log files can be changed with the following process:

- Stop the server.
- To change the log file size, configure `innodb_log_file_size`. To increase the number of log files (until [MariaDB 10.4](#) only), configure `innodb_log_files_in_group`.
- Start the server.

Log Sequence Number (LSN)

Records within the InnoDB redo log are identified via a log sequence number (LSN).

Checkpoints

When InnoDB performs a checkpoint, it writes the LSN of the oldest dirty page in the [InnoDB buffer pool](#) to the InnoDB redo log. If a page is the oldest dirty page in the [InnoDB buffer pool](#), then that means that all pages with lower LSNs have been flushed to the physical InnoDB tablespace files. If the server were to crash, then InnoDB would perform crash recovery by only applying log records with LSNs that are greater than or equal to the LSN of the oldest dirty page written in the last checkpoint.

Checkpoints are one of the tasks performed by the InnoDB master background thread. This thread schedules checkpoints 7 seconds apart when the server is very active, but checkpoints can happen more frequently when the server is less active.

Dirty pages are not actually flushed from the buffer pool to the physical InnoDB tablespace files during a checkpoint. That process happens asynchronously on a continuous basis by InnoDB's write I/O background threads configured by the `innodb_write_io_threads` system variable. If you want to make this process more aggressive, then you can decrease the value of the `innodb_max_dirty_pages_pct` system variable. You may also need to better tune InnoDB's I/O capacity on your system by setting the `innodb_io_capacity` system variable.

Determining the Checkpoint Age

The checkpoint age is the amount of data written to the InnoDB redo log since the last checkpoint.

Determining the Checkpoint Age in InnoDB

[[MariaDB starting with [10.5](#)]]

MariaDB 10.5 reintroduced the `InnoDB_checkpoint_age` status variable (available in XtraDB until MariaDB 10.1) for determining the checkpoint age.

The checkpoint age can also be determined by the process shown below.

To determine the InnoDB checkpoint age, do the following:

- Query `SHOW ENGINE INNODB STATUS`.
- Find the `LOG` section. For example:

```
---
LOG
---
```

```
Log sequence number 252794398789379
Log flushed up to 252794398789379
Pages flushed up to 252792767756840
Last checkpoint at 252792767756840
0 pending log flushes, 0 pending chkp writes
23930412 log i/o's done, 2.03 log i/o's/second
```

- Perform the following calculation:

$$\text{innodb_checkpoint_age} = \text{Log sequence number} - \text{Last checkpoint at}$$

In the example above, that would be:

- $\text{innodb_checkpoint_age} = \text{Log sequence number} - \text{Last checkpoint at}$
- $= 252794398789379 - 252792767756840$
- $= 1631032539$ bytes
- $= 1631032539 \text{ bytes} / (1024 * 1024 * 1024)$ (GB/bytes)
- $= 1.5$ GB of redo log written since last checkpoint

Determining the Redo Log Occupancy

The redo log occupancy is the percentage of the InnoDB redo log capacity that is taken up by dirty pages that have not yet been flushed to the physical InnoDB tablespace files in a checkpoint. Therefore, it's determined by the following calculation:

$$\text{innodb_log_occupancy} = \text{innodb_checkpoint_age} / \text{innodb_log_group_capacity}$$

For example, if `innodb_checkpoint_age` is 1.5G and `innodb_log_group_capacity` is 4G, then we would have the following:

- $\text{innodb_log_occupancy} = \text{innodb_checkpoint_age} / \text{innodb_log_group_capacity}$
- $= 1.5\text{G} / 4\text{G}$
- $= 0.375$

If the calculated value for redo log occupancy is too close to 1.0, then the InnoDB redo log capacity may be too small for the current workload.

MariaDB 10.8 Updates

A number of redo log improvements were made in MariaDB 10.8:

- Autosize `innodb_buffer_pool_chunk_size` ([MDEV-25342](#)).
- Improve the redo log for concurrency ([MDEV-14425](#)).
- Remove `FIL_PAGE_FILE_FLUSH_LSN` ([MDEV-27199](#)).

Before [MariaDB 10.8.1](#), `mariadb-backup --prepare` created a zero-length `ib_logfile0` as a dummy placeholder. From [MariaDB 10.8.1](#) ([MDEV-14425](#)), the size of that dummy file was increased to 12304 (0x3010) bytes, and all updates of `FIL_PAGE_FILE_FLUSH_LSN` in the first page of the system tablespace are removed.

From [MariaDB 10.8.1](#), if the server is started up with a zero-sized `ib_logfile0`, it is assumed that an upgrade is being performed after a backup had been prepared. The start LSN will then be read from `FIL_PAGE_FILE_FLUSH_LSN`, and a new log file will be created starting from exactly that LSN.

Manually creating a zero-sized `ib_logfile0` without manually updating the `FIL_PAGE_FILE_FLUSH_LSN` in the system tablespace to a recent enough LSN may result in error messages such as "page LSN is in the future". If a log was discarded while some changes had already been written to data pages, all sort of corruption may occur.

If the database was initialized with a server that never updates the `FIL_PAGE_FILE_FLUSH_LSN` field, then any server startup attempts with a zero-size `ib_logfile0` will be refused because of an invalid LSN. If that field was ever updated with a

valid LSN by an older server, this safety mechanism cannot work, and the server may "rewind" to an earlier LSN.

5.3.2.15 InnoDB Undo Log

Contents

1. [Overview](#)
2. [Implementation Details](#)
3. [Effects of Long-Running Transactions](#)
4. [Configuration](#)

Overview

When a [transaction](#) writes data, it always inserts them in the table indexes or data (in the buffer pool or in physical files). No private copies are created. The old versions of data being modified by active [InnoDB](#) transactions are stored in the undo log. The original data can then be restored, or viewed by a consistent read.

Implementation Details

Before a row is modified, a diff is copied into the undo log. Each normal row contains a pointer to the most recent version of the same row in the undo log. Each row in the undo log contains a pointer to previous version, if any. So, each modified row has a history chain.

Rows are never physically deleted until a transaction ends. If they were deleted, the restore in ROLLBACK would be impossible. Thus, rows are simply marked for deletion.

Each transaction uses a *view* of the records. The [transaction isolation level](#) determines how this view is created. For example, READ UNCOMMITTED usually uses the current version of rows, even if they are not committed (*dirty reads*). Other isolation levels require that the most recent committed version of rows is searched in the undo log. READ COMMITTED uses a different view for each table, while REPEATABLE READ and SERIALIZABLE use the same view for all tables.

There is also a global history list of the data. When a transaction is committed, its history is added to this history list. The order of the list is the chronological order of the commits.

The purge thread deletes the rows in the undo log which are not needed by any existing view. The rows for which a most recent version exists are deleted, as well as the delete-marked rows.

If InnoDB needs to restore an old version, it will simply replace the newer version with the older one. When a transaction inserts a new row, there is no older version. However, in that case, the restore can be done by deleting the inserted rows.

Effects of Long-Running Transactions

Understanding how the undo log works helps with understanding the negative effects long transactions.

- Long transactions generate several old versions of the rows in the undo log. Those rows will probably be needed for a longer time, because other long transactions will need them. Since those transactions will generate more modified rows, a sort of combinatorial explosion can be observed. Thus, the undo log requires more space.
- Transaction may need to read very old versions of the rows in the history list, thus their performance will degrade.

Of course read-only transactions do not write more entries in the undo log; however, they delay the purging of existing entries.

Also, long transactions can more likely result in deadlocks, but this problem is not related to the undo log.

Configuration

System variables affecting undo logs include:

- [innodb_max_undo_log_size](#)
- [innodb_undo_directory](#)
- [innodb_undo_log_truncate](#)
- [innodb_undo_logs](#)
- [innodb_undo_tablespaces](#)
- [innodb_purge_batch_size](#)
- [innodb_purge_rseg_truncate_frequency](#)

The undo log is not a log file that can be viewed on disk in the usual sense, such as the [error log](#) or [slow query log](#), but rather an area of storage.

Before [MariaDB 11.0](#), the undo log is usually part of the physical system tablespace, but from [MariaDB 10.0](#), the `innodb_undo_directory` and `innodb_undo_tablespaces` system variables can be used to split into different tablespaces and store in a different location (perhaps on a different storage device). From [MariaDB 11.0](#), multiple undo tablespaces are enabled by default, and the `innodb_undo_tablespaces` default is changed to 3 so that the space occupied by possible bursts of undo log records can be reclaimed after `innodb_undo_log_truncate` is set.

Each insert or update portion of the undo log is known as a rollback segment. The `innodb_undo_logs` system variable allowed to reduce the number of rollback segments from the usual 128, to limit the number of concurrently active write transactions. `innodb_undo_logs` was deprecated and ignored in [MariaDB 10.5](#) and removed in [MariaDB 10.6](#), as it always makes sense to use the maximum number of rollback segments.

The related `innodb_available_undo_logs` status variable stores the total number of available InnoDB undo logs.

5.3.2.16 InnoDB Page Flushing

Contents

1. [Page Flushing with InnoDB Page Cleaner Threads](#)
 1. [innodb_max_dirty_pages_pct](#)
 2. [innodb_max_dirty_pages_pct_lwm](#)
3. [Page Flushing with Multiple InnoDB Page Cleaner Threads](#)
4. [Page Flushing with a Single InnoDB Page Cleaner Thread](#)
2. [Page Flushing with Multi-threaded Flush Threads](#)
3. [Configuring the InnoDB I/O Capacity](#)

Page Flushing with InnoDB Page Cleaner Threads

InnoDB page cleaner threads flush dirty pages from the [InnoDB buffer pool](#). These dirty pages are flushed using a least-recently used (LRU) algorithm.

`innodb_max_dirty_pages_pct`

The `innodb_max_dirty_pages_pct` variable specifies the maximum percentage of unwritten (dirty) pages in the [buffer pool](#). If this percentage is exceeded, flushing will take place.

`innodb_max_dirty_pages_pct_lwm`

The `innodb_max_dirty_pages_pct_lwm` variable determines the low-water mark percentage of dirty pages that will enable preflushing to lower the dirty page ratio. The value 0 (the default) means that there will be no separate background flushing so long as:

- the share of dirty pages does not exceed `innodb_max_dirty_pages_pct`
- the last checkpoint age (LSN difference since the latest checkpoint) does not exceed `innodb_log_file_size` (minus some safety margin)
- the [buffer pool](#) is not running out of space, which could trigger eviction flushing

Note that in [MariaDB 10.5.7](#) and [MariaDB 10.5.8](#) only, flushing was more aggressive, and the page cleaner thread would always run in the background, as long as dirty pages exist in the buffer pool. To make flushing more eager, set to a higher value, for example `SET GLOBAL innodb_max_dirty_pages_pct_lwm=0.001;` (the default until [MariaDB 10.2.1](#) [↗](#)).

Page Flushing with Multiple InnoDB Page Cleaner Threads

MariaDB [10.2.2](#) [↗](#) - [10.5.1](#)

The `innodb_page_cleaners` system variable was added in [MariaDB 10.2.2](#) [↗](#), and makes it possible to use multiple InnoDB page cleaner threads. It is deprecated and ignored from [MariaDB 10.5.1](#), as the original reasons for for splitting the buffer pool have mostly gone away.

The number of InnoDB page cleaner threads can be configured by setting the `innodb_page_cleaners` system variable. This system variable can be set in a server [option group](#) in an [option file](#) prior to starting up the server. For example:

```
[mariadb]
...
innodb_page_cleaners=8
```

In [MariaDB 10.3.3](#) [↗](#) and later, this system variable can also be changed dynamically with `SET GLOBAL`. For example:

```
SET GLOBAL innodb_page_cleaners=8;
```

This system variable's default value is either `4` or the configured value of the `innodb_buffer_pool_instances` system variable, whichever is lower.

Page Flushing with a Single InnoDB Page Cleaner Thread

In [MariaDB 10.2.1](#) and before, and from [MariaDB 10.5.1](#), when the original reasons for splitting the buffer pool have mostly gone away, only a single InnoDB page cleaner thread is supported.

Page Flushing with Multi-threaded Flush Threads

MariaDB [10.1.0](#) - [10.3.2](#)

InnoDB's multi-thread flush feature was first added in [MariaDB 10.1.0](#). It was deprecated in [MariaDB 10.2.9](#) and removed in [MariaDB 10.3.2](#).

In [MariaDB 10.3.1](#) and before, InnoDB's multi-thread flush feature can be used. This is especially useful in [MariaDB 10.1](#), which only supports a single page cleaner thread.

InnoDB's multi-thread flush feature can be enabled by setting the `innodb_use_mtf flush` system variable. The number of threads can be configured by setting the `innodb_mtf flush_threads` system variable. This system variable can be set in a server [option group](#) in an [option file](#) prior to starting up the server. For example:

```
[mariadb]
...
innodb_use_mtf flush = ON
innodb_mtf flush_threads = 8
```

The `innodb_mtf flush_threads` system variable's default value is `8`. The maximum value is `64`. In multi-core systems, it is recommended to set its value close to the configured value of the `innodb_buffer_pool_instances` system variable. However, it is also recommended to use your own benchmarks to find a suitable value for your particular application.

InnoDB's multi-thread flush feature was deprecated in [MariaDB 10.2.9](#) and removed from [MariaDB 10.3.2](#). In later versions of MariaDB, use multiple InnoDB page cleaner threads instead.

Configuring the InnoDB I/O Capacity

Increasing the amount of I/O capacity available to InnoDB can also help increase the performance of page flushing.

The amount of I/O capacity available to InnoDB can be configured by setting the `innodb_io_capacity` system variable. This system variable can be changed dynamically with `SET GLOBAL`. For example:

```
SET GLOBAL innodb_io_capacity=20000;
```

This system variable can also be set in a server [option group](#) in an [option file](#) prior to starting up the server. For example:

```
[mariadb]
...
innodb_io_capacity=20000
```

The maximum amount of I/O capacity available to InnoDB in an emergency defaults to either `2000` or twice `innodb_io_capacity`, whichever is higher, or can be directly configured by setting the `innodb_io_capacity_max` system variable. This system variable can be changed dynamically with `SET GLOBAL`. For example:

```
SET GLOBAL innodb_io_capacity_max=20000;
```

This system variable can also be set in a server [option group](#) in an [option file](#) prior to starting up the server. For example:

```
[mariadb]
...
innodb_io_capacity_max=20000
```

5.3.2.17 InnoDB Purge

Contents

1. [Optimizing Purge Performance](#)
 1. [Configuring the Purge Threads](#)
 2. [Configuring the Purge Batch Size](#)
 3. [Configuring the Max Purge Lag](#)
 4. [Configuring the Purge Rollback Segment Truncation Frequency](#)
 5. [Configuring the Purge Undo Log Truncation](#)
2. [Purge's Effect on Row Metadata](#)

When a transaction updates a row in an InnoDB table, InnoDB's MVCC implementation keeps old versions of the row in the [InnoDB undo log](#). The old versions are kept at least until all transactions older than the transaction that updated the row are no longer open. At that point, the old versions can be deleted. InnoDB has a purge process that is used to delete these old versions.

Optimizing Purge Performance

Configuring the Purge Threads

The number of purge threads can be set by configuring the [innodb_purge_threads](#) system variable. This system variable can be specified as a command-line argument to [mysqld](#) or it can be specified in a relevant server [option group](#) in an [option file](#). For example:

```
[mariadb]
...
innodb_purge_threads = 6
```

Configuring the Purge Batch Size

The purge batch size is defined as the number of [InnoDB redo log](#) records that must be written before triggering a purge. The purge batch size can be set by configuring the [innodb_purge_batch_size](#) system variable. This system variable can be specified as a command-line argument to [mysqld](#) or it can be specified in a relevant server [option group](#) in an [option file](#). For example:

```
[mariadb]
...
innodb_purge_batch_size = 50
```

Configuring the Max Purge Lag

If purge operations are lagging on a busy server, then this can be a tough situation to recover from. As a solution, InnoDB allows you to set the max purge lag. The max purge lag is defined as the maximum number of [InnoDB undo log](#) that can be waiting to be purged from the history until InnoDB begins delaying DML statements.

The max purge lag can be set by configuring the [innodb_max_purge_lag](#) system variable. This system variable can be changed dynamically with [SET GLOBAL](#). For example:

```
SET GLOBAL innodb_max_purge_lag=1000;
```

This system variable can also be specified as a command-line argument to [mysqld](#) or it can be specified in a relevant server [option group](#) in an [option file](#). For example:

```
[mariadb]
...
innodb_max_purge_lag = 1000
```

The maximum delay can be set by configuring the [innodb_max_purge_lag_delay](#) system variable. This system variable can be changed dynamically with [SET GLOBAL](#). For example:

```
SET GLOBAL innodb_max_purge_lag_delay=100;
```

This system variable can also be specified as a command-line argument to [mysqld](#) or it can be specified in a relevant server

[option group](#) in an [option file](#). For example:

```
[mariadb]
...
innodb_max_purge_lag_delay = 100
```

Configuring the Purge Rollback Segment Truncation Frequency

The purge rollback segment truncation frequency is defined as the number of purge loops that are run before unnecessary rollback segments are truncated. The purge rollback segment truncation frequency can be set by configuring the [innodb_purge_rseg_truncate_frequency](#) system variable. This system variable can be changed dynamically with [SET GLOBAL](#). For example:

```
SET GLOBAL innodb_purge_rseg_truncate_frequency=64;
```

This system variable can also be specified as a command-line argument to [mysqld](#) or it can be specified in a relevant server [option group](#) in an [option file](#). For example:

```
[mariadb]
...
innodb_purge_rseg_truncate_frequency = 64
```

Configuring the Purge Undo Log Truncation

Purge undo log truncation occurs when InnoDB truncates an entire [InnoDB undo log](#) tablespace, rather than deleting individual [InnoDB undo log](#) records.

Purge undo log truncation can be enabled by configuring the [innodb_undo_log_truncate](#) system variable. This system variable can be changed dynamically with [SET GLOBAL](#). For example:

```
SET GLOBAL innodb_undo_log_truncate=ON;
```

This system variable can also be specified as a command-line argument to [mysqld](#) or it can be specified in a relevant server [option group](#) in an [option file](#). For example:

```
[mariadb]
...
innodb_undo_log_truncate = ON
```

An [InnoDB undo log](#) tablespace is truncated when it exceeds the maximum size that is configured for [InnoDB undo log](#) tablespaces. The maximum size can be set by configuring the [innodb_max_undo_log_size](#) system variable. This system variable can be changed dynamically with [SET GLOBAL](#). For example:

```
SET GLOBAL innodb_max_undo_log_size='64M';
```

This system variable can also be specified as a command-line argument to [mysqld](#) or it can be specified in a relevant server [option group](#) in an [option file](#). For example:

```
[mariadb]
...
innodb_max_undo_log_size = 64M
```

Purge's Effect on Row Metadata

An InnoDB table's clustered index has three hidden system columns that are automatically generated. These hidden system columns are:

- `DB_ROW_ID` - If the table has no other `PRIMARY KEY` or no other `UNIQUE KEY` defined as `NOT NULL` that can be promoted to the table's `PRIMARY KEY`, then InnoDB will use a hidden system column called `DB_ROW_ID`. InnoDB will automatically generate the value for the column from a global InnoDB-wide 48-bit sequence (instead of being table-local).
- `DB_TRX_ID` - The transaction ID of either the transaction that last changed the row or the transaction that currently has the row locked.
- `DB_ROLL_PTR` - A pointer to the [InnoDB undo log](#) that contains the row's previous record. The value of

`DB_ROLL_PTR` is only valid if `DB_TRX_ID` belongs to the current read view. The oldest valid read view is the purge view.

If a row's last [InnoDB undo log](#) record is purged, this can obviously effect the value of the row's `DB_ROLL_PTR` column, because there would no longer be any [InnoDB undo log](#) record for the pointer to reference.

In [MariaDB 10.2](#) and before, the purge process wouldn't touch the value of the row's `DB_TRX_ID` column.

However, in [MariaDB 10.3](#) and later, the purge process will set a row's `DB_TRX_ID` column to `0` after all of the row's associated [InnoDB undo log](#) records have been deleted. This change allows InnoDB to perform an optimization: if a query wants to read a row, and if the row's `DB_TRX_ID` column is set to `0`, then it knows that no other transaction has the row locked. Usually, InnoDB needs to lock the transaction system's mutex in order to safely check whether a row is locked, but this optimization allows InnoDB to confirm that the row can be safely read without any heavy internal locking.

This optimization can speed up reads, but it come at a noticeable cost at other times. For example, it can cause the purge process to use more I/O after inserting a lot of rows, since the value of each row's `DB_TRX_ID` column will have to be reset.

 4. [EXCLUSIVE Locking Strategy](#)

InnoDB tables support online DDL, which permits concurrent DML and uses optimizations to avoid unnecessary table copying.

The `ALTER TABLE` statement supports two clauses that are used to implement online DDL:

- `ALGORITHM` - This clause controls how the DDL operation is performed.
- `LOCK` - This clause controls how much concurrency is allowed while the DDL operation is being performed.

Alter Algorithms

InnoDB supports multiple algorithms for performing DDL operations. This offers a significant performance improvement over previous versions. The supported algorithms are:

- `DEFAULT` - This implies the default behavior for the specific operation.
- `COPY`
- `INPLACE`
- `NOCOPY` - This was added in [MariaDB 10.3.7](#).
- `INSTANT` - This was added in [MariaDB 10.3.7](#).

Specifying an Alter Algorithm

The set of alter algorithms can be considered as a hierarchy. The hierarchy is ranked in the following order, with *least efficient* algorithm at the top, and *most efficient* algorithm at the bottom:

- `COPY`
- `INPLACE`
- `NOCOPY`
- `INSTANT`

When a user specifies an alter algorithm for a DDL operation, MariaDB does not necessarily use that specific algorithm for the operation. It interprets the choice in the following way:

- If the user specifies `COPY`, then InnoDB uses the `COPY` algorithm.
- If the user specifies any other algorithm, then InnoDB interprets that choice as the *least efficient* algorithm that the user is willing to accept. This means that if the user specifies `INPLACE`, then InnoDB will use the *most efficient* algorithm supported by the specific operation from the set (`INPLACE`, `NOCOPY`, `INSTANT`). Likewise, if the user specifies `NOCOPY`, then InnoDB will use the *most efficient* algorithm supported by the specific operation from the set (`NOCOPY`, `INSTANT`).

There is also a special value that can be specified:

- If the user specifies `DEFAULT`, then InnoDB uses its default choice for the operation. The default choice is to use the most efficient algorithm supported by the operation. The default choice will also be used if no algorithm is specified. Therefore, if you want InnoDB to use the most efficient algorithm supported by an operation, then you usually do not have to explicitly specify any algorithm at all.

Specifying an Alter Algorithm Using the ALGORITHM Clause

InnoDB supports the `ALGORITHM` clause.

The `ALGORITHM` clause can be used to specify the *least efficient* algorithm that the user is willing to accept. It is supported by the `ALTER TABLE` and `CREATE INDEX` statements.

For example, if a user wanted to add a column to a table, but only if the operation used an algorithm that is at least as efficient as the `INPLACE`, then they could execute the following:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50)  
);  
  
ALTER TABLE tab ADD COLUMN c varchar(50), ALGORITHM=INPLACE;
```

In [MariaDB 10.3](#) and later, the above operation would actually use the `INSTANT` algorithm, because the `ADD COLUMN` operation supports the `INSTANT` algorithm, and the `INSTANT` algorithm is more efficient than the `INPLACE` algorithm.

Specifying an Alter Algorithm Using System Variables

MariaDB starting with 10.3

In [MariaDB 10.3](#) and later, the `alter_algorithm` system variable can be used to pick the *least efficient* algorithm that the user is willing to accept.

For example, if a user wanted to add a column to a table, but only if the operation used an algorithm that is at least as efficient as the `INPLACE`, then they could execute the following:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50)  
);  
  
SET SESSION alter_algorithm='INPLACE';  
ALTER TABLE tab ADD COLUMN c varchar(50);
```

In [MariaDB 10.3](#) and later, the above operation would actually use the `INSTANT` algorithm, because the `ADD COLUMN` operation supports the `INSTANT` algorithm, and the `INSTANT` algorithm is more efficient than the `INPLACE` algorithm.

MariaDB until 10.2

In [MariaDB 10.2](#) and before, the `old_alter_table` system variable can be used to specify whether the `COPY` algorithm should be used.

For example, if a user wanted to add a column to a table, but they wanted to use the `COPY` algorithm instead of the default algorithm for the operation, then they could execute the following:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50)  
);  
  
SET SESSION old_alter_table=1;  
ALTER TABLE tab ADD COLUMN c varchar(50);
```

Supported Alter Algorithms

The supported algorithms are described in more details below.

DEFAULT Algorithm

The default behavior, which occurs if `ALGORITHM=DEFAULT` is specified, or if `ALGORITHM` is not specified at all, usually only makes a copy if the operation doesn't support being done in-place at all. In this case, the *most efficient* available algorithm will usually be used.

This means that, if an operation supports the `INSTANT` algorithm, then it will use that algorithm by default. If an operation does not support the `INSTANT` algorithm, but it does support the `NOCOPY` algorithm, then it will use that algorithm by default. If an operation does not support the `NOCOPY` algorithm, but it does support the `INPLACE` algorithm, then it will use that algorithm by default.

COPY Algorithm

The `COPY` algorithm refers to the original `ALTER TABLE` algorithm.

When the `COPY` algorithm is used, MariaDB essentially does the following operations:

```

-- Create a temporary table with the new definition
CREATE TEMPORARY TABLE tmp_tab (
...
);

-- Copy the data from the original table
INSERT INTO tmp_tab
  SELECT * FROM original_tab;

-- Drop the original table
DROP TABLE original_tab;

-- Rename the temporary table, so that it replaces the original one
RENAME TABLE tmp_tab TO original_tab;

```

This algorithm is very inefficient, but it is generic, so it works for all storage engines.

If the `COPY` algorithm is specified with the `ALGORITHM` clause or with the `alter_algorithm` system variable, then the `COPY` algorithm will be used even if it is not necessary. This can result in a lengthy table copy. If multiple `ALTER TABLE` operations are required that each require the table to be rebuilt, then it is best to specify all operations in a single `ALTER TABLE` statement, so that the table is only rebuilt once.

Using the COPY Algorithm with InnoDB

If the `COPY` algorithm is used with an `InnoDB` table, then the following statements apply:

- The table will be rebuilt using the current values of the `innodb_file_per_table`, `innodb_file_format`, and `innodb_default_row_format` system variables.
- The operation will have to create a temporary table to perform the table copy. This temporary table will be in the same directory as the original table, and its file name will be in the format `#sql${PID}_${THREAD_ID}_${TMP_TABLE_COUNT}`, where `${PID}` is the process ID of `mysqld`, `${THREAD_ID}` is the connection ID, and `${TMP_TABLE_COUNT}` is the number of temporary tables that the connection has open. Therefore, the `datadir` may contain files with file names like `#sql1234_12_1.ibd`.
- The operation inserts one record at a time into each index, which is very inefficient.
- InnoDB does not use a sort buffer.
- In [MariaDB 10.2.13](#), [MariaDB 10.3.5](#) and later, the table copy operation creates a lot fewer `InnoDB undo log` writes. See [MDEV-11415](#) for more information.
- The table copy operation creates a lot of `InnoDB redo log` writes.

INPLACE Algorithm

The `COPY` algorithm can be incredibly slow, because the whole table has to be copied and rebuilt. The `INPLACE` algorithm was introduced as a way to avoid this by performing operations in-place and avoiding the table copy and rebuild, when possible.

When the `INPLACE` algorithm is used, the underlying storage engine uses optimizations to perform the operation while avoiding the table copy and rebuild. However, `INPLACE` is a bit of a misnomer, since some operations may still require the table to be rebuilt for some storage engines. Regardless, several operations can be performed without a full copy of the table for some storage engines.

A more accurate name for the algorithm would have been the `ENGINE` algorithm, since the `storage engine` decides how to implement the algorithm.

If an `ALTER TABLE` operation supports the `INPLACE` algorithm, then it can be performed using optimizations by the underlying storage engine, but it may rebuild.

If the `INPLACE` algorithm is specified with the `ALGORITHM` clause or with the `alter_algorithm` system variable and if the `ALTER TABLE` operation does not support the `INPLACE` algorithm, then an error will be raised. For example:

```

SET SESSION alter_algorithm='INPLACE';

ALTER TABLE tab MODIFY COLUMN c int;
ERROR 1846 (0A000): ALGORITHM=INPLACE is not supported. Reason: Cannot change column type
INPLACE. Try ALGORITHM=COPY

```

In this case, raising an error is preferable, if the alternative is for the operation to make a copy of the table, and perform

unexpectedly slowly.

Using the INPLACE Algorithm with InnoDB

If the `INPLACE` algorithm is used with an `InnoDB` table, then the following statements apply:

- The operation might have to write sort files in the directory defined by the `innodb_tmpdir` system variable.
- The operation might also have to write a temporary log file to track data changes by `DML queries` executed during the operation. The maximum size for this log file is configured by the `innodb_online_alter_log_max_size` system variable.
- Some operations require the table to be rebuilt, even though the algorithm is inaccurately called "in-place". This includes operations such as adding or dropping columns, adding a primary key, changing a column to `NULL`, etc.
- If the operation requires the table to be rebuilt, then the operation might have to create temporary tables.
 - It may have to create a temporary intermediate table for the actual table rebuild operation.
 - In [MariaDB 10.2.19](#) and later, this temporary table will be in the same directory as the original table, and its file name will be in the format `#sql${PID}_${THREAD_ID}_${TMP_TABLE_COUNT}`, where `${PID}` is the process ID of `mysqld`, `${THREAD_ID}` is the connection ID, and `${TMP_TABLE_COUNT}` is the number of temporary tables that the connection has open. Therefore, the `datadir` may contain files with file names like `#sql1234_12_1.ibd`.
 - In [MariaDB 10.2.18](#) and before, this temporary table will be in the same directory as the original table, and its file name will be in the format `#sql-ib${TABLESPACE_ID}-${RAND}`, where `${TABLESPACE_ID}` is the table's tablespace ID within InnoDB and `${RAND}` is a randomly initialized number. Therefore, the `datadir` may contain files with file names like `#sql-ib230291-1363966925.ibd`.
 - When it replaces the original table with the rebuilt table, it may also have to rename the original table using a temporary table name.
 - If the server is [MariaDB 10.3](#) or later or if it is running [MariaDB 10.2](#) and the `innodb_safe_truncate` system variable is set to `OFF`, then the format will actually be `#sql-ib${TABLESPACE_ID}-${RAND}`, where `${TABLESPACE_ID}` is the table's tablespace ID within InnoDB and `${RAND}` is a randomly initialized number. Therefore, the `datadir` may contain files with file names like `#sql-ib230291-1363966925.ibd`.
 - If the server is running [MariaDB 10.1](#) or before or if it is running [MariaDB 10.2](#) and the `innodb_safe_truncate` system variable is set to `ON`, then the renamed table will have a temporary table name in the format `#sql-ib${TABLESPACE_ID}`, where `${TABLESPACE_ID}` is the table's tablespace ID within InnoDB. Therefore, the `datadir` may contain files with file names like `#sql-ib230291.ibd`.
- The storage needed for the above items can add up to the size of the original table, or more in some cases.
- Some operations are instantaneous, if they only require the table's metadata to be changed. This includes operations such as renaming a column, changing a column's `DEFAULT` value, etc.

Operations Supported by InnoDB with the INPLACE Algorithm

With respect to the allowed operations, the `INPLACE` algorithm supports a subset of the operations supported by the `COPY` algorithm, and it supports a superset of the operations supported by the `NOCOPY` algorithm.

See [InnoDB Online DDL Operations with ALGORITHM=INPLACE](#) for more information.

NOCOPY Algorithm

MariaDB starting with [10.3](#)
In [MariaDB 10.3](#) and later, the `NOCOPY` algorithm is supported.

The `INPLACE` algorithm can sometimes be surprisingly slow in instances where it has to rebuild the clustered index, because when the clustered index has to be rebuilt, the whole table has to be rebuilt. The `NOCOPY` algorithm was introduced as a way to avoid this.

If an `ALTER TABLE` operation supports the `NOCOPY` algorithm, then it can be performed without rebuilding the clustered index.

If the `NOCOPY` algorithm is specified with the `ALGORITHM` clause or with the `alter_algorithm` system variable and if the `ALTER TABLE` operation does not support the `NOCOPY` algorithm, then an error will be raised. For example:

```
SET SESSION alter_algorithm='NOCOPY';

ALTER TABLE tab MODIFY COLUMN c int;
ERROR 1846 (0A000): ALGORITHM=NOCOPY is not supported. Reason: Cannot change column type INPLACE.
```

In this case, raising an error is preferable, if the alternative is for the operation to rebuild the clustered index, and perform unexpectedly slowly.

Operations Supported by InnoDB with the `NOCOPY` Algorithm

With respect to the allowed operations, the `NOCOPY` algorithm supports a subset of the operations supported by the `INPLACE` algorithm, and it supports a superset of the operations supported by the `INSTANT` algorithm.

See [InnoDB Online DDL Operations with ALGORITHM=NOCOPY](#) for more information.

INSTANT Algorithm

MariaDB starting with [10.3](#)
In [MariaDB 10.3](#) and later, the `INSTANT` algorithm is supported.

The `INPLACE` algorithm can sometimes be surprisingly slow in instances where it has to modify data files. The `INSTANT` algorithm was introduced as a way to avoid this.

If an `ALTER TABLE` operation supports the `INSTANT` algorithm, then it can be performed without modifying any data files.

If the `INSTANT` algorithm is specified with the `ALGORITHM` clause or with the `alter_algorithm` system variable and if the `ALTER TABLE` operation does not support the `INSTANT` algorithm, then an error will be raised. For example:

```
SET SESSION alter_algorithm='INSTANT';

ALTER TABLE tab MODIFY COLUMN c int;
ERROR 1846 (0A000): ALGORITHM=INSTANT is not supported. Reason: Cannot change column type
INPLACE. Try ALGORITHM=COPY
```

In this case, raising an error is preferable, if the alternative is for the operation to modify data files, and perform unexpectedly slowly.

Operations Supported by InnoDB with the `INSTANT` Algorithm

With respect to the allowed operations, the `INSTANT` algorithm supports a subset of the operations supported by the `NOCOPY` algorithm.

See [InnoDB Online DDL Operations with ALGORITHM=INSTANT](#) for more information.

Alter Locking Strategies

InnoDB supports multiple locking strategies for performing DDL operations. This offers a significant performance improvement over previous versions. The supported locking strategies are:

- `DEFAULT` - This implies the default behavior for the specific operation.
- `NONE`
- `SHARED`
- `EXCLUSIVE`

Regardless of which locking strategy is used to perform a DDL operation, InnoDB will have to exclusively lock the table for a short time at the start and end of the operation's execution. This means that any active transactions that may have accessed the table must be committed or aborted for the operation to continue. This applies to most DDL statements, such as `ALTER TABLE`, `CREATE INDEX`, `DROP INDEX`, `OPTIMIZE TABLE`, `RENAME TABLE`, etc.

Specifying an Alter Locking Strategy

Specifying an Alter Locking Strategy Using the `LOCK` Clause

The `ALTER TABLE` statement supports the `LOCK` clause.

The `LOCK` clause can be used to specify the locking strategy that the user is willing to accept. It is supported by the `ALTER TABLE` and `CREATE INDEX` statements.

For example, if a user wanted to add a column to a table, but only if the operation is non-locking, then they could execute the following:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50)  
);  
  
ALTER TABLE tab ADD COLUMN c varchar(50), ALGORITHM=INPLACE, LOCK=NONE;
```

If the `LOCK` clause is not explicitly set, then the operation uses `LOCK=DEFAULT`.

Specifying an Alter Locking Strategy Using `ALTER ONLINE TABLE`

`ALTER ONLINE TABLE` is equivalent to `LOCK=NONE`. Therefore, the `ALTER ONLINE TABLE` statement can be used to ensure that your `ALTER TABLE` operation allows all concurrent DML.

Supported Alter Locking Strategies

The supported algorithms are described in more details below.

To see which locking strategies InnoDB supports for each operation, see the pages that describe which operations are supported for each algorithm:

- [InnoDB Online DDL Operations with ALGORITHM=INPLACE](#)
- [InnoDB Online DDL Operations with ALGORITHM=NOCOPY](#)
- [InnoDB Online DDL Operations with ALGORITHM=INSTANT](#)

DEFAULT Locking Strategy

The default behavior, which occurs if `LOCK=DEFAULT` is specified, or if `LOCK` is not specified at all, acquire the least restrictive lock on the table that is supported for the specific operation. This permits the maximum amount of concurrency that is supported for the specific operation.

NONE Locking Strategy

The `NONE` locking strategy performs the operation without acquiring any lock on the table. This permits **all** concurrent DML.

If this locking strategy is not permitted for an operation, then an error is raised.

SHARED Locking Strategy

The `SHARED` locking strategy performs the operation after acquiring a read lock on the table. This permit **read-only** concurrent DML.

If this locking strategy is not permitted for an operation, then an error is raised.

EXCLUSIVE Locking Strategy

The `EXCLUSIVE` locking strategy performs the operation after acquiring a write lock on the table. This does **not** permit concurrent DML.

 9. OPTIMIZE TABLE ...
 10. ALTER TABLE ... RENAME TO and RENAME TABLE ...
5. Limitations
 1. Limitations Related to Fulltext Indexes
 2. Limitations Related to Spatial Indexes
 3. Limitations Related to Generated (Virtual and Persistent/Stored) Columns

Supported Operations by Inheritance

When the `ALGORITHM` clause is set to `INPLACE`, the supported operations are a superset of the operations that are supported when the `ALGORITHM` clause is set to `NOCOPY`. Similarly, when the `ALGORITHM` clause is set to `NOCOPY`, the supported operations are a superset of the operations that are supported when the `ALGORITHM` clause is set to `INSTANT`.

Therefore, when the `ALGORITHM` clause is set to `INPLACE`, some operations are supported by inheritance. See the following additional pages for more information about these supported operations:

- [InnoDB Online DDL Operations with ALGORITHM=NOCOPY](#)
- [InnoDB Online DDL Operations with ALGORITHM=INSTANT](#)

Column Operations

```
ALTER TABLE ... ADD COLUMN
```

InnoDB supports adding columns to a table with `ALGORITHM` set to `INPLACE`.

The table is rebuilt, which means that all of the data is reorganized substantially, and the indexes are rebuilt. As a result, the operation is quite expensive.

With the exception of adding an `auto-increment` column, this operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the `LOCK` clause to `NONE`. When this strategy is used, all concurrent DML is permitted.

For example:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50)  
);  
  
SET SESSION alter_algorithm='INPLACE';  
ALTER TABLE tab ADD COLUMN c varchar(50);  
Query OK, 0 rows affected (0.006 sec)
```

This applies to [ALTER TABLE ... ADD COLUMN](#) for InnoDB tables.

ALTER TABLE ... DROP COLUMN

InnoDB supports dropping columns from a table with [ALGORITHM](#) set to `INPLACE`.

The table is rebuilt, which means that all of the data is reorganized substantially, and the indexes are rebuilt. As a result, the operation is quite expensive.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the [LOCK](#) clause to `NONE`. When this strategy is used, all concurrent DML is permitted.

For example:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50)  
);  
  
SET SESSION alter_algorithm='INPLACE';  
ALTER TABLE tab DROP COLUMN c;  
Query OK, 0 rows affected (0.021 sec)
```

This applies to [ALTER TABLE ... DROP COLUMN](#) for InnoDB tables.

ALTER TABLE ... MODIFY COLUMN

This applies to [ALTER TABLE ... MODIFY COLUMN](#) for InnoDB tables.

Reordering Columns

InnoDB supports reordering columns within a table with [ALGORITHM](#) set to `INPLACE`.

The table is rebuilt, which means that all of the data is reorganized substantially, and the indexes are rebuilt. As a result, the operation is quite expensive.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the [LOCK](#) clause to `NONE`. When this strategy is used, all concurrent DML is permitted.

For example:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50)  
);  
  
SET SESSION alter_algorithm='INPLACE';  
ALTER TABLE tab MODIFY COLUMN c varchar(50) AFTER a;  
Query OK, 0 rows affected (0.022 sec)
```

Changing the Data Type of a Column

InnoDB does **not** support modifying a column's data type with [ALGORITHM](#) set to `INPLACE` in most cases. There are some exceptions:

- In [MariaDB 10.2.2](#) and later, InnoDB supports increasing the length of `VARCHAR` columns with [ALGORITHM](#) set to `INPLACE`, unless it would require changing the number of bytes required to represent the column's length. A

VARCHAR column that is between 0 and 255 bytes in size requires 1 byte to represent its length, while a VARCHAR column that is 256 bytes or longer requires 2 bytes to represent its length. This means that the length of a column cannot be increased with `ALGORITHM` set to `INPLACE` if the original length was less than 256 bytes, and the new length is 256 bytes or more.

- In [MariaDB 10.4.3](#) and later, InnoDB supports increasing the length of VARCHAR columns with `ALGORITHM` set to `INPLACE` in the cases where the operation supports having the `ALGORITHM` clause set to `INSTANT`.

See [InnoDB Online DDL Operations with ALGORITHM=INSTANT: Changing the Data Type of a Column](#) for more information.

For example, this fails:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50)  
);  
  
SET SESSION alter_algorithm='INPLACE';  
ALTER TABLE tab MODIFY COLUMN c int;  
ERROR 1846 (0A000): ALGORITHM=INPLACE is not supported. Reason: Cannot change column type  
INPLACE. Try ALGORITHM=COPY
```

But this succeeds in [MariaDB 10.2.2](#) and later, because the original length of the column is less than 256 bytes, and the new length is still less than 256 bytes:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50)  
) CHARACTER SET=latin1;  
  
SET SESSION alter_algorithm='INPLACE';  
ALTER TABLE tab MODIFY COLUMN c varchar(100);  
Query OK, 0 rows affected (0.005 sec)
```

But this fails in [MariaDB 10.2.2](#) and later, because the original length of the column is less than 256 bytes, and the new length is greater than 256 bytes:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(255)  
) CHARACTER SET=latin1;  
  
SET SESSION alter_algorithm='INPLACE';  
ALTER TABLE tab MODIFY COLUMN c varchar(256);  
ERROR 1846 (0A000): ALGORITHM=INPLACE is not supported. Reason: Cannot change column type  
INPLACE. Try ALGORITHM=COPY
```

Changing a Column to NULL

InnoDB supports modifying a column to allow NULL values with `ALGORITHM` set to `INPLACE`.

The table is rebuilt, which means that all of the data is reorganized substantially, and the indexes are rebuilt. As a result, the operation is quite expensive.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the `LOCK` clause to `NONE`. When this strategy is used, all concurrent DML is permitted.

For example:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50) NOT NULL
);

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab MODIFY COLUMN c varchar(50) NULL;
Query OK, 0 rows affected (0.021 sec)

```

Changing a Column to NOT NULL

InnoDB supports modifying a column to **not** allow **NULL** values with **ALGORITHM** set to `INPLACE`. It is required for **strict mode** to be enabled in **SQL_MODE**. The operation will fail if the column contains any **NULL** values. Changes that would interfere with referential integrity are also not permitted.

The table is rebuilt, which means that all of the data is reorganized substantially, and the indexes are rebuilt. As a result, the operation is quite expensive.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the **LOCK** clause to `NONE`. When this strategy is used, all concurrent DML is permitted.

For example:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
);

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab MODIFY COLUMN c varchar(50) NOT NULL;
Query OK, 0 rows affected (0.021 sec)

```

Adding a New ENUM Option

InnoDB supports adding a new **ENUM** option to a column with **ALGORITHM** set to `INPLACE`. In order to add a new **ENUM** option with **ALGORITHM** set to `INPLACE`, the following requirements must be met:

- It must be added to the end of the list.
- The storage requirements must not change.

This operation only changes the table's metadata, so the table does not have to be rebuilt..

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the **LOCK** clause to `NONE`. When this strategy is used, all concurrent DML is permitted.

For example, this succeeds:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c ENUM('red', 'green')
);

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab MODIFY COLUMN c ENUM('red', 'green', 'blue');
Query OK, 0 rows affected (0.004 sec)

```

But this fails:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c ENUM('red', 'green')
);

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab MODIFY COLUMN c ENUM('red', 'blue', 'green');
ERROR 1846 (0A000): ALGORITHM=INPLACE is not supported. Reason: Cannot change column type
INPLACE. Try ALGORITHM=COPY

```

Adding a New SET Option

InnoDB supports adding a new **SET** option to a column with **ALGORITHM** set to **INPLACE**. In order to add a new **SET** option with **ALGORITHM** set to **INPLACE**, the following requirements must be met:

- It must be added to the end of the list.
- The storage requirements must not change.

This operation only changes the table's metadata, so the table does not have to be rebuilt.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the **LOCK** clause to **NONE**. When this strategy is used, all concurrent DML is permitted.

For example, this succeeds:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c SET('red', 'green')  
);  
  
SET SESSION alter_algorithm='INPLACE';  
ALTER TABLE tab MODIFY COLUMN c SET('red', 'green', 'blue');  
Query OK, 0 rows affected (0.004 sec)
```

But this fails:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c SET('red', 'green')  
);  
  
SET SESSION alter_algorithm='INPLACE';  
ALTER TABLE tab MODIFY COLUMN c SET('red', 'blue', 'green');  
ERROR 1846 (0A000): ALGORITHM=INPLACE is not supported. Reason: Cannot change column type  
INPLACE. Try ALGORITHM=COPY
```

Removing System Versioning from a Column

In [MariaDB 10.3.8](#) and later, InnoDB supports removing **system versioning** from a column with **ALGORITHM** set to **INPLACE**. In order for this to work, the **system_versioning_alter_history** system variable must be set to **KEEP**. See [MDEV-16330](#) for more information.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the **LOCK** clause to **NONE**. When this strategy is used, all concurrent DML is permitted.

For example:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50) WITH SYSTEM VERSIONING  
);  
  
SET SESSION system_versioning_alter_history='KEEP';  
SET SESSION alter_algorithm='INPLACE';  
ALTER TABLE tab MODIFY COLUMN c varchar(50) WITHOUT SYSTEM VERSIONING;  
Query OK, 0 rows affected (0.005 sec)
```

ALTER TABLE ... ALTER COLUMN

This applies to **ALTER TABLE ... ALTER COLUMN** for InnoDB tables.

Setting a Column's Default Value

InnoDB supports modifying a column's **DEFAULT** value with **ALGORITHM** set to **INPLACE**.

This operation only changes the table's metadata, so the table does not have to be rebuilt.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the **LOCK** clause to

NONE . When this strategy is used, all concurrent DML is permitted. For example:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50)  
);  
  
SET SESSION alter_algorithm='INPLACE';  
ALTER TABLE tab ALTER COLUMN c SET DEFAULT 'No value explicitly provided.';  
Query OK, 0 rows affected (0.005 sec)
```

Removing a Column's Default Value

InnoDB supports removing a column's **DEFAULT** value with **ALGORITHM** set to **INPLACE** .

This operation only changes the table's metadata, so the table does not have to be rebuilt.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the **LOCK** clause to **NONE** . When this strategy is used, all concurrent DML is permitted.

For example:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50) DEFAULT 'No value explicitly provided.'  
);  
  
SET SESSION alter_algorithm='INPLACE';  
ALTER TABLE tab ALTER COLUMN c DROP DEFAULT;  
Query OK, 0 rows affected (0.005 sec)
```

ALTER TABLE ... CHANGE COLUMN

InnoDB supports renaming a column with **ALGORITHM** set to **INPLACE** , unless the column's data type or attributes changed in addition to the name.

This operation only changes the table's metadata, so the table does not have to be rebuilt.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the **LOCK** clause to **NONE** . When this strategy is used, all concurrent DML is permitted.

For example, this succeeds:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50)  
);  
  
SET SESSION alter_algorithm='INPLACE';  
ALTER TABLE tab CHANGE COLUMN c str varchar(50);  
Query OK, 0 rows affected (0.006 sec)
```

But this fails:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50)  
);  
  
SET SESSION alter_algorithm='INPLACE';  
ALTER TABLE tab CHANGE COLUMN c num int;  
ERROR 1846 (0A000): ALGORITHM=INPLACE is not supported. Reason: Cannot change column type  
INPLACE. Try ALGORITHM=COPY
```

This applies to **ALTER TABLE ... CHANGE COLUMN** for InnoDB tables.

Index Operations

ALTER TABLE ... ADD PRIMARY KEY

InnoDB supports adding a primary key to a table with `ALGORITHM` set to `INPLACE`.

If the new primary key column is not defined as `NOT NULL`, then it is highly recommended for `strict mode` to be enabled in `SQL_MODE`. Otherwise, `NULL` values will be silently converted to the default value for the given data type, which is probably not the desired behavior in this scenario.

The table is rebuilt, which means that all of the data is reorganized substantially, and the indexes are rebuilt. As a result, the operation is quite expensive.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the `LOCK` clause to `NONE`. When this strategy is used, all concurrent DML is permitted.

For example, this succeeds:

```
CREATE OR REPLACE TABLE tab (  
  a int,  
  b varchar(50),  
  c varchar(50)  
);  
  
SET SESSION sql_mode='STRICT_TRANS_TABLES';  
SET SESSION alter_algorithm='INPLACE';  
ALTER TABLE tab ADD PRIMARY KEY (a);  
Query OK, 0 rows affected (0.021 sec)
```

But this fails:

```
CREATE OR REPLACE TABLE tab (  
  a int,  
  b varchar(50),  
  c varchar(50)  
);  
  
INSERT INTO tab VALUES (NULL, NULL, NULL);  
  
SET SESSION sql_mode='STRICT_TRANS_TABLES';  
SET SESSION alter_algorithm='INPLACE';  
ALTER TABLE tab ADD PRIMARY KEY (a);  
ERROR 1265 (01000): Data truncated for column 'a' at row 1
```

And this fails:

```
CREATE OR REPLACE TABLE tab (  
  a int,  
  b varchar(50),  
  c varchar(50)  
);  
  
INSERT INTO tab VALUES (1, NULL, NULL);  
INSERT INTO tab VALUES (1, NULL, NULL);  
  
SET SESSION sql_mode='STRICT_TRANS_TABLES';  
SET SESSION alter_algorithm='INPLACE';  
ALTER TABLE tab ADD PRIMARY KEY (a);  
ERROR 1062 (23000): Duplicate entry '1' for key 'PRIMARY'
```

This applies to `ALTER TABLE ... ADD PRIMARY KEY` for InnoDB tables.

ALTER TABLE ... DROP PRIMARY KEY

InnoDB does **not** support dropping a primary key with `ALGORITHM` set to `INPLACE` in most cases.

If you try to do so, then you will see an error. InnoDB only supports this operation with `ALGORITHM` set to `COPY`. Concurrent DML is *not* permitted.

However, there is an exception. If you are dropping a primary key, and adding a new one at the same time, then that

operation can be performed with `ALGORITHM` set to `INPLACE`. This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the `LOCK` clause to `NONE`. When this strategy is used, all concurrent DML is permitted.

For example, this fails:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50)  
);  
  
SET SESSION alter_algorithm='INPLACE';  
ALTER TABLE tab DROP PRIMARY KEY;  
ERROR 1846 (0A000): ALGORITHM=INPLACE is not supported. Reason: Dropping a primary key is not  
allowed without also adding a new primary key. Try ALGORITHM=COPY
```

But this succeeds:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50)  
);  
  
SET SESSION sql_mode='STRICT_TRANS_TABLES';  
SET SESSION alter_algorithm='INPLACE';  
ALTER TABLE tab DROP PRIMARY KEY, ADD PRIMARY KEY (b);  
Query OK, 0 rows affected (0.020 sec)
```

This applies to `ALTER TABLE ... DROP PRIMARY KEY` for InnoDB tables.

ALTER TABLE ... ADD INDEX and CREATE INDEX

This applies to `ALTER TABLE ... ADD INDEX` and `CREATE INDEX` for InnoDB tables.

Adding a Plain Index

InnoDB supports adding a plain index to a table with `ALGORITHM` set to `INPLACE`. The table is not rebuilt.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the `LOCK` clause to `NONE`. When this strategy is used, all concurrent DML is permitted.

For example, this succeeds:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50)  
);  
  
SET SESSION alter_algorithm='INPLACE';  
ALTER TABLE tab ADD INDEX b_index (b);  
Query OK, 0 rows affected (0.010 sec)
```

And this succeeds:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50)  
);  
  
SET SESSION alter_algorithm='INPLACE';  
CREATE INDEX b_index ON tab (b);  
Query OK, 0 rows affected (0.011 sec)
```

Adding a Fulltext Index

InnoDB supports adding a **FULLTEXT** index to a table with **ALGORITHM** set to **INPLACE** . The table is not rebuilt in some cases.

However, there are some limitations, such as:

- Adding a **FULLTEXT** index to a table that does not have a user-defined **FTS_DOC_ID** column will require the table to be rebuilt once. When the table is rebuilt, the system adds a hidden **FTS_DOC_ID** column. From that point forward, adding additional **FULLTEXT** indexes to the same table will not require the table to be rebuilt when **ALGORITHM** is set to **INPLACE** .
- Only one **FULLTEXT** index may be added at a time when **ALGORITHM** is set to **INPLACE** .
- If a table has more than one **FULLTEXT** index, then it cannot be rebuilt by any **ALTER TABLE** operations when **ALGORITHM** is set to **INPLACE** .
- If a table has a **FULLTEXT** index, then it cannot be rebuilt by any **ALTER TABLE** operations when the **LOCK** clause is set to **NONE** .

This operation supports a read-only locking strategy. This strategy can be explicitly chosen by setting the **LOCK** clause to **SHARED** . When this strategy is used, read-only concurrent DML is permitted.

For example, this succeeds, but requires the table to be rebuilt, so that the hidden **FTS_DOC_ID** column can be added:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50)  
);  
  
SET SESSION alter_algorithm='INPLACE';  
ALTER TABLE tab ADD FULLTEXT INDEX b_index (b);  
Query OK, 0 rows affected (0.055 sec)
```

And this succeeds in the same way as above:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50)  
);  
  
SET SESSION alter_algorithm='INPLACE';  
CREATE FULLTEXT INDEX b_index ON tab (b);  
Query OK, 0 rows affected (0.041 sec)
```

And this succeeds, and the second command does not require the table to be rebuilt:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50)  
);  
  
SET SESSION alter_algorithm='INPLACE';  
ALTER TABLE tab ADD FULLTEXT INDEX b_index (b);  
Query OK, 0 rows affected (0.043 sec)  
  
ALTER TABLE tab ADD FULLTEXT INDEX c_index (c);  
Query OK, 0 rows affected (0.017 sec)
```

But this second command fails, because only one **FULLTEXT** index can be added at a time:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50),
  d varchar(50)
);

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab ADD FULLTEXT INDEX b_index (b);
Query OK, 0 rows affected (0.041 sec)

ALTER TABLE tab ADD FULLTEXT INDEX c_index (c), ADD FULLTEXT INDEX d_index (d);
ERROR 1846 (0A000): ALGORITHM=INPLACE is not supported. Reason: InnoDB presently supports one
FULLTEXT index creation at a time. Try ALGORITHM=COPY

```

And this third command fails, because a table cannot be rebuilt when it has more than one **FULLTEXT** index:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
);

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab ADD FULLTEXT INDEX b_index (b);
Query OK, 0 rows affected (0.040 sec)

ALTER TABLE tab ADD FULLTEXT INDEX c_index (c);
Query OK, 0 rows affected (0.015 sec)

ALTER TABLE tab FORCE;
ERROR 1846 (0A000): ALGORITHM=INPLACE is not supported. Reason: InnoDB presently supports one
FULLTEXT index creation at a time. Try ALGORITHM=COPY

```

Adding a Spatial Index

InnoDB supports adding a **SPATIAL** index to a table with **ALGORITHM** set to `INPLACE`.

However, there are some limitations, such as:

- If a table has a **SPATIAL** index, then it cannot be rebuilt by any **ALTER TABLE** operations when the **LOCK** clause is set to `NONE`.

This operation supports a read-only locking strategy. This strategy can be explicitly chosen by setting the **LOCK** clause to `SHARED`. When this strategy is used, read-only concurrent DML is permitted.

For example, this succeeds:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c GEOMETRY NOT NULL
);

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab ADD SPATIAL INDEX c_index (c);
Query OK, 0 rows affected (0.006 sec)

```

And this succeeds in the same way as above:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c GEOMETRY NOT NULL
);

SET SESSION alter_algorithm='INPLACE';
CREATE SPATIAL INDEX c_index ON tab (c);
Query OK, 0 rows affected (0.006 sec)

```

ALTER TABLE ... DROP INDEX and DROP INDEX

InnoDB supports dropping indexes from a table with `ALGORITHM` set to `INPLACE`.

This operation only changes the table's metadata, so the table does not have to be rebuilt.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the `LOCK` clause to `NONE`. When this strategy is used, all concurrent DML is permitted.

For example, this succeeds:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50),  
  INDEX b_index (b)  
);  
  
SET SESSION alter_algorithm='INPLACE';  
ALTER TABLE tab DROP INDEX b_index;
```

And this succeeds:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50),  
  INDEX b_index (b)  
);  
  
SET SESSION alter_algorithm='INPLACE';  
DROP INDEX b_index ON tab;
```

This applies to `ALTER TABLE ... DROP INDEX` and `DROP INDEX` for InnoDB tables.

ALTER TABLE ... ADD FOREIGN KEY

InnoDB supports adding foreign key constraints to a table with `ALGORITHM` set to `INPLACE`. In order to add a new foreign key constraint to a table with `ALGORITHM` set to `INPLACE`, the `foreign_key_checks` system variable needs to be set to `OFF`. If it is set to `ON`, then `ALGORITHM=COPY` is required.

This operation only changes the table's metadata, so the table does not have to be rebuilt.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the `LOCK` clause to `NONE`. When this strategy is used, all concurrent DML is permitted.

For example, this fails:

```
CREATE OR REPLACE TABLE tab1 (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50),  
  d int  
);  
  
CREATE OR REPLACE TABLE tab2 (  
  a int PRIMARY KEY,  
  b varchar(50)  
);  
  
SET SESSION alter_algorithm='INPLACE';  
ALTER TABLE tab1 ADD FOREIGN KEY tab2_fk (d) REFERENCES tab2 (a);  
ERROR 1846 (0A000): ALGORITHM=INPLACE is not supported. Reason: Adding foreign keys needs  
foreign_key_checks=OFF. Try ALGORITHM=COPY
```

But this succeeds:

```

CREATE OR REPLACE TABLE tab1 (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50),
  d int
);

CREATE OR REPLACE TABLE tab2 (
  a int PRIMARY KEY,
  b varchar(50)
);

SET SESSION foreign_key_checks=OFF;
SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab1 ADD FOREIGN KEY tab2_fk (d) REFERENCES tab2 (a);
Query OK, 0 rows affected (0.011 sec)

```

This applies to [ALTER TABLE ... ADD FOREIGN KEY](#) for InnoDB tables.

ALTER TABLE ... DROP FOREIGN KEY

InnoDB supports dropping foreign key constraints from a table with [ALGORITHM](#) set to `INPLACE`.

This operation only changes the table's metadata, so the table does not have to be rebuilt.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the [LOCK](#) clause to `NONE`. When this strategy is used, all concurrent DML is permitted.

For example:

```

CREATE OR REPLACE TABLE tab2 (
  a int PRIMARY KEY,
  b varchar(50)
);

CREATE OR REPLACE TABLE tab1 (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50),
  d int,
  FOREIGN KEY tab2_fk (d) REFERENCES tab2 (a)
);

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab1 DROP FOREIGN KEY tab2_fk;
Query OK, 0 rows affected (0.005 sec)

```

This applies to [ALTER TABLE ... DROP FOREIGN KEY](#) for InnoDB tables.

Table Operations

ALTER TABLE ... AUTO_INCREMENT=...

InnoDB supports changing a table's [AUTO_INCREMENT](#) value with [ALGORITHM](#) set to `INPLACE`. This operation should finish instantly. The table is not rebuilt.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the [LOCK](#) clause to `NONE`. When this strategy is used, all concurrent DML is permitted.

For example:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
);

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab AUTO_INCREMENT=100;
Query OK, 0 rows affected (0.004 sec)

```

This applies to [ALTER TABLE ... AUTO_INCREMENT=...](#) for InnoDB tables.

ALTER TABLE ... ROW_FORMAT=...

InnoDB supports changing a table's [row format](#) with [ALGORITHM](#) set to `INPLACE`.

The table is rebuilt, which means that all of the data is reorganized substantially, and the indexes are rebuilt. As a result, the operation is quite expensive.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the [LOCK](#) clause to `NONE`. When this strategy is used, all concurrent DML is permitted.

For example:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
) ROW_FORMAT=DYNAMIC;

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab ROW_FORMAT=COMPRESSED;
Query OK, 0 rows affected (0.025 sec)

```

This applies to [ALTER TABLE ... ROW_FORMAT=...](#) for InnoDB tables.

ALTER TABLE ... KEY_BLOCK_SIZE=...

InnoDB supports changing a table's [KEY_BLOCK_SIZE](#) with [ALGORITHM](#) set to `INPLACE`.

The table is rebuilt, which means that all of the data is reorganized substantially, and the indexes are rebuilt. As a result, the operation is quite expensive.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the [LOCK](#) clause to `NONE`. When this strategy is used, all concurrent DML is permitted.

For example:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
) ROW_FORMAT=COMPRESSED
KEY_BLOCK_SIZE=4;

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab KEY_BLOCK_SIZE=2;
Query OK, 0 rows affected (0.021 sec)

```

This applies to [KEY_BLOCK_SIZE=...](#) for InnoDB tables.

ALTER TABLE ... PAGE_COMPRESSED=... and ALTER TABLE ... PAGE_COMPRESSION_LEVEL=...

In [MariaDB 10.3.10](#) and later, InnoDB supports setting a table's [PAGE_COMPRESSED](#) value to `1` with [ALGORITHM](#) set to `INPLACE`. InnoDB also supports changing a table's [PAGE_COMPRESSED](#) value from `1` to `0` with [ALGORITHM](#) set to `INPLACE`.

In these versions, InnoDB also supports changing a table's [PAGE_COMPRESSION_LEVEL](#) value with [ALGORITHM](#) set to

INPLACE .

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the `LOCK` clause to `NONE` . When this strategy is used, all concurrent DML is permitted.

See [MDEV-16328](#) for more information.

For example, this succeeds:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50)  
);  
  
SET SESSION alter_algorithm='INPLACE';  
ALTER TABLE tab PAGE_COMPRESSED=1;  
Query OK, 0 rows affected (0.006 sec)
```

And this succeeds:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50)  
) PAGE_COMPRESSED=1;  
  
SET SESSION alter_algorithm='INPLACE';  
ALTER TABLE tab PAGE_COMPRESSED=0;  
Query OK, 0 rows affected (0.020 sec)
```

And this succeeds:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50)  
) PAGE_COMPRESSED=1  
  PAGE_COMPRESSION_LEVEL=5;  
  
SET SESSION alter_algorithm='INPLACE';  
ALTER TABLE tab PAGE_COMPRESSION_LEVEL=4;  
Query OK, 0 rows affected (0.006 sec)
```

This applies to `PAGE_COMPRESSED=...` and `PAGE_COMPRESSION_LEVEL=...` for InnoDB tables.

ALTER TABLE ... DROP SYSTEM VERSIONING

InnoDB supports dropping `system versioning` from a table with `ALGORITHM` set to `INPLACE` .

This operation supports the read-only locking strategy. This strategy can be explicitly chosen by setting the `LOCK` clause to `SHARED` . When this strategy is used, read-only concurrent DML is permitted.

For example:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50)  
) WITH SYSTEM VERSIONING;  
  
SET SESSION alter_algorithm='INPLACE';  
ALTER TABLE tab DROP SYSTEM VERSIONING;
```

This applies to `ALTER TABLE ... DROP SYSTEM VERSIONING` for InnoDB tables.

ALTER TABLE ... DROP CONSTRAINT

In [MariaDB 10.3.6](#) and later, InnoDB supports dropping a `CHECK` constraint from a table with `ALGORITHM` set to `INPLACE` . See [MDEV-16331](#) for more information.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the [LOCK](#) clause to `NONE` . When this strategy is used, all concurrent DML is permitted.

For example:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50),  
  CONSTRAINT b_not_empty CHECK (b != '')  
);  
  
SET SESSION alter_algorithm='INPLACE';  
ALTER TABLE tab DROP CONSTRAINT b_not_empty;  
Query OK, 0 rows affected (0.004 sec)
```

This applies to [ALTER TABLE ... DROP CONSTRAINT](#) for `InnoDB` tables.

ALTER TABLE ... FORCE

`InnoDB` supports forcing a table rebuild with [ALGORITHM](#) set to `INPLACE` .

The table is rebuilt, which means that all of the data is reorganized substantially, and the indexes are rebuilt. As a result, the operation is quite expensive.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the [LOCK](#) clause to `NONE` . When this strategy is used, all concurrent DML is permitted.

For example:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50)  
);  
  
SET SESSION alter_algorithm='INPLACE';  
ALTER TABLE tab FORCE;  
Query OK, 0 rows affected (0.022 sec)
```

This applies to [ALTER TABLE ... FORCE](#) for `InnoDB` tables.

ALTER TABLE ... ENGINE=InnoDB

`InnoDB` supports forcing a table rebuild with [ALGORITHM](#) set to `INPLACE` .

The table is rebuilt, which means that all of the data is reorganized substantially, and the indexes are rebuilt. As a result, the operation is quite expensive.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the [LOCK](#) clause to `NONE` . When this strategy is used, all concurrent DML is permitted.

For example:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50)  
);  
  
SET SESSION alter_algorithm='INPLACE';  
ALTER TABLE tab ENGINE=InnoDB;  
Query OK, 0 rows affected (0.022 sec)
```

This applies to [ALTER TABLE ... ENGINE=InnoDB](#) for `InnoDB` tables.

OPTIMIZE TABLE ...

`InnoDB` supports optimizing a table with [ALGORITHM](#) set to `INPLACE` .

If the `innodb_defragment` system variable is set to `OFF`, and if the `innodb_optimize_fulltext_only` system variable is also set to `OFF`, then `OPTIMIZE TABLE` will be equivalent to `ALTER TABLE ... FORCE`.

The table is rebuilt, which means that all of the data is reorganized substantially, and the indexes are rebuilt. As a result, the operation is quite expensive.

If either of the previously mentioned system variables is set to `ON`, then `OPTIMIZE TABLE` will optimize some data without rebuilding the table. However, the file size will not be reduced.

For example, this succeeds:

```
CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
);

SHOW GLOBAL VARIABLES WHERE Variable_name IN('innodb_defragment', 'innodb_optimize_fulltext_only')
+-----+-----+
| Variable_name | Value |
+-----+-----+
| innodb_defragment | OFF |
| innodb_optimize_fulltext_only | OFF |
+-----+-----+

SET SESSION alter_algorithm='INPLACE';
OPTIMIZE TABLE tab;
+-----+-----+
| Table | Op | Msg_type | Msg_text |
+-----+-----+
| db1.tab | optimize | note | Table does not support optimize, doing recreate + analyze instead |
| db1.tab | optimize | status | OK |
+-----+-----+
2 rows in set (0.026 sec)
```

And this succeeds, but the table is not rebuilt:

```
CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
);

SET GLOBAL innodb_defragment=ON;
SHOW GLOBAL VARIABLES WHERE Variable_name IN('innodb_defragment', 'innodb_optimize_fulltext_only')
+-----+-----+
| Variable_name | Value |
+-----+-----+
| innodb_defragment | ON |
| innodb_optimize_fulltext_only | OFF |
+-----+-----+

SET SESSION alter_algorithm='INPLACE';
OPTIMIZE TABLE tab;
+-----+-----+
| Table | Op | Msg_type | Msg_text |
+-----+-----+
| db1.tab | optimize | status | OK |
+-----+-----+
1 row in set (0.004 sec)
```

This applies to `OPTIMIZE TABLE` for `InnoDB` tables.

ALTER TABLE ... RENAME TO and RENAME TABLE ...

`InnoDB` supports renaming a table with `ALGORITHM` set to `INPLACE`.

This operation only changes the table's metadata, so the table does not have to be rebuilt.

This operation supports the exclusive locking strategy. This strategy can be explicitly chosen by setting the `LOCK` clause to

EXCLUSIVE . When this strategy is used, concurrent DML is **not** permitted.

For example, this succeeds:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50)  
);  
  
SET SESSION alter_algorithm='INPLACE';  
ALTER TABLE tab RENAME TO old_tab;  
Query OK, 0 rows affected (0.011 sec)
```

And this succeeds:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50)  
);  
  
SET SESSION alter_algorithm='INPLACE';  
RENAME TABLE tab TO old_tab;
```

This applies to [ALTER TABLE ... RENAME TO](#) and [RENAME TABLE](#) for InnoDB tables.

Limitations

Limitations Related to Fulltext Indexes

- If a table has more than one [FULLTEXT](#) index, then it cannot be rebuilt by any [ALTER TABLE](#) operations when [ALGORITHM](#) is set to `INPLACE` .
- If a table has a [FULLTEXT](#) index, then it cannot be rebuilt by any [ALTER TABLE](#) operations when the [LOCK](#) clause is set to `NONE` .

Limitations Related to Spatial Indexes

- If a table has a [SPATIAL](#) index, then it cannot be rebuilt by any [ALTER TABLE](#) operations when the [LOCK](#) clause is set to `NONE` .

Limitations Related to Generated (Virtual and Persistent/Stored) Columns

[Generated columns](#) do not currently support online DDL for all of the same operations that are supported for "real" columns.

See [Generated \(Virtual and Persistent/Stored\) Columns: Statement Support](#) for more information on the limitations.

Supported Operations by Inheritance

When the `ALGORITHM` clause is set to `NOCOPY`, the supported operations are a superset of the operations that are supported when the `ALGORITHM` clause is set to `INSTANT`.

Therefore, when the `ALGORITHM` clause is set to `NOCOPY`, some operations are supported by inheritance. See the following additional pages for more information about these supported operations:

- [InnoDB Online DDL Operations with ALGORITHM=INSTANT](#)

Column Operations

`ALTER TABLE ... ADD COLUMN`

In [MariaDB 10.3.2](#) and later, InnoDB supports adding columns to a table with `ALGORITHM` set to `NOCOPY` in the cases where the operation supports having the `ALGORITHM` clause set to `INSTANT`.

See [InnoDB Online DDL Operations with ALGORITHM=INSTANT: ALTER TABLE ... ADD COLUMN](#) for more information.

This applies to `ALTER TABLE ... ADD COLUMN` for InnoDB tables.

`ALTER TABLE ... DROP COLUMN`

In [MariaDB 10.4](#) and later, InnoDB supports dropping columns from a table with `ALGORITHM` set to `NOCOPY` in the cases where the operation supports having the `ALGORITHM` clause set to `INSTANT`.

See [InnoDB Online DDL Operations with ALGORITHM=INSTANT: ALTER TABLE ... DROP COLUMN](#) for more information.

This applies to [ALTER TABLE ... DROP COLUMN](#) for InnoDB tables.

ALTER TABLE ... MODIFY COLUMN

This applies to [ALTER TABLE ... MODIFY COLUMN](#) for InnoDB tables.

Reordering Columns

In [MariaDB 10.4](#) and later, InnoDB supports reordering columns within a table with `ALGORITHM` set to `NOCOPY` in the cases where the operation supports having the `ALGORITHM` clause set to `INSTANT`.

See [InnoDB Online DDL Operations with ALGORITHM=INSTANT: Reordering Columns](#) for more information.

Changing the Data Type of a Column

InnoDB does **not** support modifying a column's data type with `ALGORITHM` set to `NOCOPY` in most cases. There are a few exceptions in the cases where the operation supports having the `ALGORITHM` clause set to `INSTANT`.

See [InnoDB Online DDL Operations with ALGORITHM=INSTANT: Changing the Data Type of a Column](#) for more information.

Changing a Column to NULL

In [MariaDB 10.4.3](#) and later, InnoDB supports modifying a column to allow `NULL` values with `ALGORITHM` set to `NOCOPY` in the cases where the operation supports having the `ALGORITHM` clause set to `INSTANT`.

See [InnoDB Online DDL Operations with ALGORITHM=INSTANT: Changing a Column to NULL](#) for more information.

Changing a Column to NOT NULL

InnoDB does **not** support modifying a column to **not** allow `NULL` values with `ALGORITHM` set to `NOCOPY`.

For example:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50)  
) ROW_FORMAT=REDUNDANT;  
  
SET SESSION alter_algorithm='NOCOPY';  
ALTER TABLE tab MODIFY COLUMN c varchar(50) NOT NULL;  
ERROR 1845 (0A000): ALGORITHM=NOCOPY is not supported for this operation. Try ALGORITHM=INPLACE
```

Adding a New ENUM Option

InnoDB supports adding a new `ENUM` option to a column with `ALGORITHM` set to `NOCOPY` in the cases where the operation supports having the `ALGORITHM` clause set to `INSTANT`.

See [InnoDB Online DDL Operations with ALGORITHM=INSTANT: Adding a New ENUM Option](#) for more information.

Adding a New SET Option

InnoDB supports adding a new `SET` option to a column with `ALGORITHM` set to `NOCOPY` in the cases where the operation supports having the `ALGORITHM` clause set to `INSTANT`.

See [InnoDB Online DDL Operations with ALGORITHM=INSTANT: Adding a New SET Option](#) for more information.

Removing System Versioning from a Column

In [MariaDB 10.3.8](#) and later, InnoDB supports removing `system versioning` from a column with `ALGORITHM` set to `NOCOPY` in the cases where the operation supports having the `ALGORITHM` clause set to `INSTANT`.

See [InnoDB Online DDL Operations with ALGORITHM=INSTANT: Removing System Versioning from a Column](#) for more information.

ALTER TABLE ... ALTER COLUMN

This applies to [ALTER TABLE ... ALTER COLUMN](#) for InnoDB tables.

Setting a Column's Default Value

InnoDB supports modifying a column's `DEFAULT` value with `ALGORITHM` set to `NOCOPY` in the cases where the operation supports having the `ALGORITHM` clause set to `INSTANT`.

See [InnoDB Online DDL Operations with ALGORITHM=INSTANT: Setting a Column's Default Value](#) for more information.

Removing a Column's Default Value

InnoDB supports removing a column's `DEFAULT` value with `ALGORITHM` set to `NOCOPY` in the cases where the operation supports having the `ALGORITHM` clause set to `INSTANT`.

See [InnoDB Online DDL Operations with ALGORITHM=INSTANT: Removing a Column's Default Value](#) for more information.

ALTER TABLE ... CHANGE COLUMN

InnoDB supports renaming a column with `ALGORITHM` set to `NOCOPY` in the cases where the operation supports having the `ALGORITHM` clause set to `INSTANT`.

See [InnoDB Online DDL Operations with ALGORITHM=INSTANT: ALTER TABLE ... CHANGE COLUMN](#) for more information.

This applies to [ALTER TABLE ... CHANGE COLUMN](#) for InnoDB tables.

Index Operations

ALTER TABLE ... ADD PRIMARY KEY

InnoDB does **not** support adding a primary key to a table with `ALGORITHM` set to `NOCOPY`.

For example:

```
CREATE OR REPLACE TABLE tab (  
  a int,  
  b varchar(50),  
  c varchar(50)  
);  
  
SET SESSION sql_mode='STRICT_TRANS_TABLES';  
SET SESSION alter_algorithm='NOCOPY';  
ALTER TABLE tab ADD PRIMARY KEY (a);  
ERROR 1845 (0A000): ALGORITHM=NOCOPY is not supported for this operation. Try ALGORITHM=INPLACE
```

This applies to [ALTER TABLE ... ADD PRIMARY KEY](#) for InnoDB tables.

ALTER TABLE ... DROP PRIMARY KEY

InnoDB does **not** support dropping a primary key with `ALGORITHM` set to `NOCOPY`.

For example:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50)  
);  
  
SET SESSION alter_algorithm='NOCOPY';  
ALTER TABLE tab DROP PRIMARY KEY;  
ERROR 1846 (0A000): ALGORITHM=NOCOPY is not supported. Reason: Dropping a primary key is not allowed without also adding a new primary key. Try ALGORITHM=COPY
```

This applies to [ALTER TABLE ... DROP PRIMARY KEY](#) for InnoDB tables.

ALTER TABLE ... ADD INDEX and CREATE INDEX

This applies to [ALTER TABLE ... ADD INDEX](#) and [CREATE INDEX](#) for InnoDB tables.

Adding a Plain Index

InnoDB supports adding a plain index to a table with [ALGORITHM](#) set to `NOCOPY`.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the [LOCK](#) clause to `NONE`. When this strategy is used, all concurrent DML is permitted.

For example, this succeeds:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50)  
);  
  
SET SESSION alter_algorithm='NOCOPY';  
ALTER TABLE tab ADD INDEX b_index (b);  
Query OK, 0 rows affected (0.009 sec)
```

And this succeeds:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50)  
);  
  
SET SESSION alter_algorithm='NOCOPY';  
CREATE INDEX b_index ON tab (b);  
Query OK, 0 rows affected (0.009 sec)
```

Adding a Fulltext Index

InnoDB supports adding a [FULLTEXT](#) index to a table with [ALGORITHM](#) set to `NOCOPY`.

However, there are some limitations, such as:

- Adding a [FULLTEXT](#) index to a table that does not have a user-defined `FTS_DOC_ID` column will require the table to be rebuilt once. When the table is rebuilt, the system adds a hidden `FTS_DOC_ID` column. This initial operation will have to be performed with [ALGORITHM](#) set to `INPLACE`. From that point forward, adding additional [FULLTEXT](#) indexes to the same table will not require the table to be rebuilt, and [ALGORITHM](#) can be set to `NOCOPY`.
- Only one [FULLTEXT](#) index may be added at a time when [ALGORITHM](#) is set to `NOCOPY`.

This operation supports a read-only locking strategy. This strategy can be explicitly chosen by setting the [LOCK](#) clause to `SHARED`. When this strategy is used, read-only concurrent DML is permitted.

For example, this succeeds, but the first operation requires the table to be rebuilt [ALGORITHM](#) set to `INPLACE`, so that the hidden `FTS_DOC_ID` column can be added:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50)  
);  
  
SET SESSION alter_algorithm='INPLACE';  
ALTER TABLE tab ADD FULLTEXT INDEX b_index (b);  
Query OK, 0 rows affected (0.043 sec)  
  
SET SESSION alter_algorithm='NOCOPY';  
ALTER TABLE tab ADD FULLTEXT INDEX c_index (c);  
Query OK, 0 rows affected (0.017 sec)
```

And this succeeds in the same way as above:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
);

SET SESSION alter_algorithm='INPLACE';
CREATE FULLTEXT INDEX b_index ON tab (b);
Query OK, 0 rows affected (0.048 sec)

SET SESSION alter_algorithm='NOCOPY';
CREATE FULLTEXT INDEX c_index ON tab (c);
Query OK, 0 rows affected (0.016 sec)

```

But this second command fails, because only one **FULLTEXT** index can be added at a time:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50),
  d varchar(50)
);

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab ADD FULLTEXT INDEX b_index (b);
Query OK, 0 rows affected (0.041 sec)

SET SESSION alter_algorithm='NOCOPY';
ALTER TABLE tab ADD FULLTEXT INDEX c_index (c), ADD FULLTEXT INDEX d_index (d);
ERROR 1846 (0A000): ALGORITHM=NOCOPY is not supported. Reason: InnoDB presently supports one
FULLTEXT index creation at a time. Try ALGORITHM=COPY

```

Adding a Spatial Index

InnoDB supports adding a **SPATIAL** index to a table with **ALGORITHM** set to **NOCOPY**.

This operation supports a read-only locking strategy. This strategy can be explicitly chosen by setting the **LOCK** clause to **SHARED**. When this strategy is used, read-only concurrent DML is permitted.

For example, this succeeds:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c GEOMETRY NOT NULL
);

SET SESSION alter_algorithm='NOCOPY';
ALTER TABLE tab ADD SPATIAL INDEX c_index (c);
Query OK, 0 rows affected (0.005 sec)

```

And this succeeds in the same way as above:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c GEOMETRY NOT NULL
);

SET SESSION alter_algorithm='NOCOPY';
CREATE SPATIAL INDEX c_index ON tab (c);
Query OK, 0 rows affected (0.005 sec)

```

ALTER TABLE ... DROP INDEX and DROP INDEX

InnoDB supports dropping indexes from a table with **ALGORITHM** set to **NOCOPY** in the cases where the operation supports having the **ALGORITHM** clause set to **INSTANT**.

See [InnoDB Online DDL Operations with ALGORITHM=INSTANT: ALTER TABLE ... DROP INDEX and DROP INDEX](#) for more information.

This applies to [ALTER TABLE ... DROP INDEX](#) and [DROP INDEX](#) for InnoDB tables.

ALTER TABLE ... ADD FOREIGN KEY

InnoDB does supports adding foreign key constraints to a table with [ALGORITHM](#) set to `NOCOPY`. In order to add a new foreign key constraint to a table with [ALGORITHM](#) set to `NOCOPY`, the [foreign_key_checks](#) system variable needs to be set to `OFF`. If it is set to `ON`, then `ALGORITHM=COPY` is required.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the [LOCK](#) clause to `NONE`. When this strategy is used, all concurrent DML is permitted.

For example, this fails:

```
CREATE OR REPLACE TABLE tab1 (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50),  
  d int  
);  
  
CREATE OR REPLACE TABLE tab2 (  
  a int PRIMARY KEY,  
  b varchar(50)  
);  
  
SET SESSION alter_algorithm='NOCOPY';  
ALTER TABLE tab1 ADD FOREIGN KEY tab2_fk (d) REFERENCES tab2 (a);  
ERROR 1846 (0A000): ALGORITHM=NOCOPY is not supported. Reason: Adding foreign keys needs  
foreign_key_checks=OFF. Try ALGORITHM=COPY
```

But this succeeds:

```
CREATE OR REPLACE TABLE tab1 (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50),  
  d int  
);  
  
CREATE OR REPLACE TABLE tab2 (  
  a int PRIMARY KEY,  
  b varchar(50)  
);  
  
SET SESSION foreign_key_checks=OFF;  
SET SESSION alter_algorithm='NOCOPY';  
ALTER TABLE tab1 ADD FOREIGN KEY tab2_fk (d) REFERENCES tab2 (a);  
Query OK, 0 rows affected (0.011 sec)
```

This applies to [ALTER TABLE ... ADD FOREIGN KEY](#) for InnoDB tables.

ALTER TABLE ... DROP FOREIGN KEY

InnoDB supports dropping foreign key constraints from a table with [ALGORITHM](#) set to `NOCOPY` in the cases where the operation supports having the [ALGORITHM](#) clause set to `INSTANT`.

See [InnoDB Online DDL Operations with ALGORITHM=INSTANT: ALTER TABLE ... DROP FOREIGN KEY](#) for more information.

This applies to [ALTER TABLE ... DROP FOREIGN KEY](#) for InnoDB tables.

Table Operations

ALTER TABLE ... AUTO_INCREMENT=...

InnoDB supports changing a table's [AUTO_INCREMENT](#) value with [ALGORITHM](#) set to `NOCOPY` in the cases where the operation supports having the [ALGORITHM](#) clause set to `INSTANT`.

See [InnoDB Online DDL Operations with ALGORITHM=INSTANT: ALTER TABLE ... AUTO_INCREMENT=...](#) for more

information.

This applies to `ALTER TABLE ... AUTO_INCREMENT=...` for InnoDB tables.

```
ALTER TABLE ... ROW_FORMAT=...
```

InnoDB does **not** support changing a table's `row format` with `ALGORITHM` set to `NOCOPY`.

For example:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50)  
) ROW_FORMAT=DYNAMIC;  
  
SET SESSION alter_algorithm='NOCOPY';  
ALTER TABLE tab ROW_FORMAT=COMPRESSED;  
ERROR 1846 (0A000): ALGORITHM=NOCOPY is not supported. Reason: Changing table options requires  
the table to be rebuilt. Try ALGORITHM=INPLACE
```

This applies to `ALTER TABLE ... ROW_FORMAT=...` for InnoDB tables.

```
ALTER TABLE ... KEY_BLOCK_SIZE=...
```

InnoDB does **not** support changing a table's `KEY_BLOCK_SIZE` with `ALGORITHM` set to `NOCOPY`.

For example:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50)  
) ROW_FORMAT=COMPRESSED  
  KEY_BLOCK_SIZE=4;  
  
SET SESSION alter_algorithm='NOCOPY';  
ALTER TABLE tab KEY_BLOCK_SIZE=2;  
ERROR 1846 (0A000): ALGORITHM=NOCOPY is not supported. Reason: Changing table options requires  
the table to be rebuilt. Try ALGORITHM=INPLACE
```

This applies to `KEY_BLOCK_SIZE=...` for InnoDB tables.

```
ALTER TABLE ... PAGE_COMPRESSED=1 and ALTER TABLE ...  
PAGE_COMPRESSION_LEVEL=...
```

In [MariaDB 10.3.10](#) and later, InnoDB supports setting a table's `PAGE_COMPRESSED` value to `1` with `ALGORITHM` set to `NOCOPY` in the cases where the operation supports having the `ALGORITHM` clause set to `INSTANT`.

InnoDB does **not** support changing a table's `PAGE_COMPRESSED` value from `1` to `0` with `ALGORITHM` set to `NOCOPY`.

In these versions, InnoDB also supports changing a table's `PAGE_COMPRESSION_LEVEL` value with `ALGORITHM` set to `NOCOPY` in the cases where the operation supports having the `ALGORITHM` clause is set to `INSTANT`.

See [InnoDB Online DDL Operations with ALGORITHM=INSTANT: ALTER TABLE ... PAGE_COMPRESSED=1 and ALTER TABLE ... PAGE_COMPRESSION_LEVEL=...](#) for more information.

This applies to `ALTER TABLE ... PAGE_COMPRESSED=...` and `ALTER TABLE ... PAGE_COMPRESSION_LEVEL=...` for InnoDB tables.

```
ALTER TABLE ... DROP SYSTEM VERSIONING
```

InnoDB does **not** support dropping `system versioning` from a table with `ALGORITHM` set to `NOCOPY`.

For example:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
) WITH SYSTEM VERSIONING;

SET SESSION alter_algorithm='NOCOPY';
ALTER TABLE tab DROP SYSTEM VERSIONING;
ERROR 1845 (0A000): ALGORITHM=NOCOPY is not supported for this operation. Try ALGORITHM=INPLACE

```

This applies to [ALTER TABLE ... DROP SYSTEM VERSIONING](#) for InnoDB tables.

ALTER TABLE ... DROP CONSTRAINT

In [MariaDB 10.3.6](#) and later, InnoDB supports dropping a [CHECK](#) constraint from a table with [ALGORITHM](#) set to [NOCOPY](#) in the cases where the operation supports having the [ALGORITHM](#) clause set to [INSTANT](#).

See [InnoDB Online DDL Operations with ALGORITHM=INSTANT: ALTER TABLE ... DROP CONSTRAINT](#) for more information.

This applies to [ALTER TABLE ... DROP CONSTRAINT](#) for InnoDB tables.

ALTER TABLE ... FORCE

InnoDB does **not** support forcing a table rebuild with [ALGORITHM](#) set to [NOCOPY](#).

For example:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
);

SET SESSION alter_algorithm='NOCOPY';
ALTER TABLE tab FORCE;
ERROR 1845 (0A000): ALGORITHM=NOCOPY is not supported for this operation. Try ALGORITHM=INPLACE

```

This applies to [ALTER TABLE ... FORCE](#) for InnoDB tables.

ALTER TABLE ... ENGINE=InnoDB

InnoDB does **not** support forcing a table rebuild with [ALGORITHM](#) set to [NOCOPY](#).

For example:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
);

SET SESSION alter_algorithm='NOCOPY';
ALTER TABLE tab ENGINE=InnoDB;
ERROR 1845 (0A000): ALGORITHM=NOCOPY is not supported for this operation. Try ALGORITHM=INPLACE

```

This applies to [ALTER TABLE ... ENGINE=InnoDB](#) for InnoDB tables.

OPTIMIZE TABLE ...

InnoDB does **not** support optimizing a table with with [ALGORITHM](#) set to [NOCOPY](#).

For example:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
);

SHOW GLOBAL VARIABLES WHERE Variable_name IN('innodb_defragment',
'innodb_optimize_fulltext_only');
+-----+-----+
| Variable_name          | Value |
+-----+-----+
| innodb_defragment      | OFF   |
| innodb_optimize_fulltext_only | OFF   |
+-----+-----+
2 rows in set (0.001 sec)

SET SESSION alter_algorithm='NOCOPY';
OPTIMIZE TABLE tab;
+-----+-----+-----+-----+
| Table | Op      | Msg_type | Msg_text
+-----+-----+-----+-----+
| db1.tab | optimize | note     | Table does not support optimize, doing recreate + analyze
instead
| db1.tab | optimize | error    | ALGORITHM=NOCOPY is not supported for this operation. Try
ALGORITHM=INPLACE
| db1.tab | optimize | status   | Operation failed
+-----+-----+-----+-----+
3 rows in set, 1 warning (0.002 sec)

```

This applies to [OPTIMIZE TABLE](#) for [InnoDB](#) tables.

ALTER TABLE ... RENAME TO and RENAME TABLE ...

InnoDB supports renaming a table with [ALGORITHM](#) set to `NOCOPY` in the cases where the operation supports having the [ALGORITHM](#) clause set to `INSTANT`.

See [InnoDB Online DDL Operations with ALGORITHM=INSTANT: ALTER TABLE ... RENAME TO and RENAME TABLE ...](#) for more information.

This applies to [ALTER TABLE ... RENAME TO](#) and [RENAME TABLE](#) for [InnoDB](#) tables.

Limitations

Limitations Related to Generated (Virtual and Persistent/Stored) Columns

[Generated columns](#) do not currently support online DDL for all of the same operations that are supported for "real" columns.

See [Generated \(Virtual and Persistent/Stored\) Columns: Statement Support](#) for more information on the limitations.

4. Limitations
 1. Limitations Related to Generated (Virtual and Persistent/Stored) Columns
 2. Non-canonical Storage Format Caused by Some Operations
 3. Known Bugs
 1. Closed Bugs

Column Operations

ALTER TABLE ... ADD COLUMN

In [MariaDB 10.3.2](#) and later, InnoDB supports adding columns to a table with `ALGORITHM` set to `INSTANT` if the new column is the last column in the table. See [MDEV-11369](#) for more information. If the table has a hidden `FTS_DOC_ID` column is present, then this is not supported.

In [MariaDB 10.4](#) and later, InnoDB supports adding columns to a table with `ALGORITHM` set to `INSTANT`, regardless of where in the column list the new column is added.

When this operation is performed with `ALGORITHM` set to `INSTANT`, the tablespace file will have a non-canonical storage format. See [Non-canonical Storage Format Caused by Some Operations](#) for more information.

With the exception of adding an [auto-increment](#) column, this operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the `LOCK` clause to `NONE`. When this strategy is used, all concurrent DML is permitted.

For example, this succeeds:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50)  
);  
  
SET SESSION alter_algorithm='INSTANT';  
ALTER TABLE tab ADD COLUMN c varchar(50);  
Query OK, 0 rows affected (0.004 sec)
```

And this succeeds in [MariaDB 10.4](#) and later:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50)  
);  
  
SET SESSION alter_algorithm='INSTANT';  
ALTER TABLE tab ADD COLUMN c varchar(50) AFTER a;  
Query OK, 0 rows affected (0.004 sec)
```

This applies to [ALTER TABLE ... ADD COLUMN](#) for [InnoDB](#) tables.

See [Instant ADD COLUMN for InnoDB](#) for more information.

ALTER TABLE ... DROP COLUMN

In [MariaDB 10.4](#) and later, [InnoDB](#) supports dropping columns from a table with [ALGORITHM](#) set to `INSTANT`. See [MDEV-15562](#) for more information.

When this operation is performed with [ALGORITHM](#) set to `INSTANT`, the tablespace file will have a non-canonical storage format. See [Non-canonical Storage Format Caused by Some Operations](#) for more information.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the [LOCK](#) clause to `NONE`. When this strategy is used, all concurrent DML is permitted.

For example:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50)  
);  
  
SET SESSION alter_algorithm='INSTANT';  
ALTER TABLE tab DROP COLUMN c;  
Query OK, 0 rows affected (0.004 sec)
```

This applies to [ALTER TABLE ... DROP COLUMN](#) for [InnoDB](#) tables.

ALTER TABLE ... MODIFY COLUMN

This applies to [ALTER TABLE ... MODIFY COLUMN](#) for [InnoDB](#) tables.

Reordering Columns

In [MariaDB 10.4](#) and later, [InnoDB](#) supports reordering columns within a table with [ALGORITHM](#) set to `INSTANT`. See [MDEV-15562](#) for more information.

When this operation is performed with [ALGORITHM](#) set to `INSTANT`, the tablespace file will have a non-canonical storage format. See [Non-canonical Storage Format Caused by Some Operations](#) for more information.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the [LOCK](#) clause to `NONE`. When this strategy is used, all concurrent DML is permitted.

For example:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
);

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab MODIFY COLUMN c varchar(50) AFTER a;
Query OK, 0 rows affected (0.004 sec)

```

Changing the Data Type of a Column

InnoDB does **not** support modifying a column's data type with `ALGORITHM` set to `INSTANT` in most cases. There are some exceptions:

- InnoDB supports increasing the length of `VARCHAR` columns with `ALGORITHM` set to `INSTANT`, unless it would require changing the number of bytes required to represent the column's length. A `VARCHAR` column that is between 0 and 255 bytes in size requires 1 byte to represent its length, while a `VARCHAR` column that is 256 bytes or longer requires 2 bytes to represent its length. This means that the length of a column cannot be increased with `ALGORITHM` set to `INSTANT` if the original length was less than 256 bytes, and the new length is 256 bytes or more.
- In [MariaDB 10.4.3](#) and later, InnoDB supports increasing the length of `VARCHAR` columns with `ALGORITHM` set to `INSTANT` with no restrictions if the `ROW_FORMAT` table option is set to `REDUNDANT`. See [MDEV-15563](#) for more information.
- In [MariaDB 10.4.3](#) and later, InnoDB also supports increasing the length of `VARCHAR` columns with `ALGORITHM` set to `INSTANT` in a more limited manner if the `ROW_FORMAT` table option is set to `COMPACT`, `DYNAMIC`, or `COMPRESSED`. In this scenario, the following limitations apply:
 - The length can be increased with `ALGORITHM` set to `INSTANT` if the original length of the column is 127 bytes or less, and the new length of the column is 256 bytes or more.
 - The length can be increased with `ALGORITHM` set to `INSTANT` if the original length of the column is 255 bytes or less, and the new length of the column is still 255 bytes or less.
 - The length can be increased with `ALGORITHM` set to `INSTANT` if the original length of the column is 256 bytes or more, and the new length of the column is still 256 bytes or more.
 - The length can **not** be increased with `ALGORITHM` set to `INSTANT` if the original length was between 128 bytes and 255 bytes, and the new length is 256 bytes or more.
 - See [MDEV-15563](#) for more information.

The supported operations in this category support the non-locking strategy. This strategy can be explicitly chosen by setting the `LOCK` clause to `NONE`. When this strategy is used, all concurrent DML is permitted.

For example, this fails:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
);

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab MODIFY COLUMN c int;
ERROR 1846 (0A000): ALGORITHM=INSTANT is not supported. Reason: Cannot change column type
INPLACE. Try ALGORITHM=COPY

```

But this succeeds because the original length of the column is less than 256 bytes, and the new length is still less than 256 bytes:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
) CHARACTER SET=latin1;

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab MODIFY COLUMN c varchar(100);
Query OK, 0 rows affected (0.005 sec)

```

But this fails because the original length of the column is between 128 bytes and 255 bytes, and the new length is greater than 256 bytes:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(255)
) CHARACTER SET=latin1;

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab MODIFY COLUMN c varchar(256);
ERROR 1846 (0A000): ALGORITHM=INSTANT is not supported. Reason: Cannot change column type
INPLACE. Try ALGORITHM=COPY

```

But this succeeds in [MariaDB 10.4.3](#) and later because the table has `ROW_FORMAT=REDUNDANT` :

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(200)
) ROW_FORMAT=REDUNDANT;

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab MODIFY COLUMN c varchar(300);
Query OK, 0 rows affected (0.004 sec)

```

And this succeeds in [MariaDB 10.4.3](#) and later because the table has `ROW_FORMAT=DYNAMIC` and the column's original length is 127 bytes or less:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(127)
) ROW_FORMAT=DYNAMIC
CHARACTER SET=latin1;

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab MODIFY COLUMN c varchar(300);
Query OK, 0 rows affected (0.003 sec)

```

And this succeeds in [MariaDB 10.4.3](#) and later because the table has `ROW_FORMAT=COMPRESSED` and the column's original length is 127 bytes or less:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(127)
) ROW_FORMAT=COMPRESSED
CHARACTER SET=latin1;

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab MODIFY COLUMN c varchar(300);
Query OK, 0 rows affected (0.003 sec)

```

But this fails even in [MariaDB 10.4.3](#) and later because the table has `ROW_FORMAT=DYNAMIC` and the column's original length is between 128 bytes and 255 bytes:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(128)
) ROW_FORMAT=DYNAMIC
CHARACTER SET=latin1;

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab MODIFY COLUMN c varchar(300);
ERROR 1846 (0A000): ALGORITHM=INSTANT is not supported. Reason: Cannot change column type
INPLACE. Try ALGORITHM=COPY

```

Changing a Column to NULL

In [MariaDB 10.4.3](#) and later, InnoDB supports modifying a column to allow `NULL` values with `ALGORITHM` set to

INSTANT if the `ROW_FORMAT` table option is set to `REDUNDANT`. See [MDEV-15563](#) for more information.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the `LOCK` clause to `NONE`. When this strategy is used, all concurrent DML is permitted.

For example:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50) NOT NULL  
) ROW_FORMAT=REDUNDANT;  
  
SET SESSION alter_algorithm='INSTANT';  
ALTER TABLE tab MODIFY COLUMN c varchar(50) NULL;  
Query OK, 0 rows affected (0.004 sec)
```

Changing a Column to NOT NULL

InnoDB does **not** support modifying a column to **not** allow `NULL` values with `ALGORITHM` set to `INSTANT`.

For example:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50)  
) ROW_FORMAT=REDUNDANT;  
  
SET SESSION alter_algorithm='INSTANT';  
ALTER TABLE tab MODIFY COLUMN c varchar(50) NOT NULL;  
ERROR 1845 (0A000): ALGORITHM=INSTANT is not supported for this operation. Try  
ALGORITHM=INPLACE
```

Adding a New ENUM Option

InnoDB supports adding a new `ENUM` option to a column with `ALGORITHM` set to `INSTANT`. In order to add a new `ENUM` option with `ALGORITHM` set to `INSTANT`, the following requirements must be met:

- It must be added to the end of the list.
- The storage requirements must not change.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the `LOCK` clause to `NONE`. When this strategy is used, all concurrent DML is permitted.

For example, this succeeds:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c ENUM('red', 'green')  
);  
  
SET SESSION alter_algorithm='INSTANT';  
ALTER TABLE tab MODIFY COLUMN c ENUM('red', 'green', 'blue');  
Query OK, 0 rows affected (0.002 sec)
```

But this fails:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c ENUM('red', 'green')  
);  
  
SET SESSION alter_algorithm='INSTANT';  
ALTER TABLE tab MODIFY COLUMN c ENUM('red', 'blue', 'green');  
ERROR 1846 (0A000): ALGORITHM=INSTANT is not supported. Reason: Cannot change column type  
INPLACE. Try ALGORITHM=COPY
```

Adding a New SET Option

InnoDB supports adding a new **SET** option to a column with **ALGORITHM** set to **INSTANT**. In order to add a new **SET** option with **ALGORITHM** set to **INSTANT**, the following requirements must be met:

- It must be added to the end of the list.
- The storage requirements must not change.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the **LOCK** clause to **NONE**. When this strategy is used, all concurrent DML is permitted.

For example, this succeeds:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c SET('red', 'green')  
);  
  
SET SESSION alter_algorithm='INSTANT';  
ALTER TABLE tab MODIFY COLUMN c SET('red', 'green', 'blue');  
Query OK, 0 rows affected (0.002 sec)
```

But this fails:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c SET('red', 'green')  
);  
  
SET SESSION alter_algorithm='INSTANT';  
ALTER TABLE tab MODIFY COLUMN c SET('red', 'blue', 'green');  
ERROR 1846 (0A000): ALGORITHM=INSTANT is not supported. Reason: Cannot change column type  
INPLACE. Try ALGORITHM=COPY
```

Removing System Versioning from a Column

In [MariaDB 10.3.8](#) and later, InnoDB supports removing **system versioning** from a column with **ALGORITHM** set to **INSTANT**. In order for this to work, the **system_versioning_alter_history** system variable must be set to **KEEP**. See [MDEV-16330](#) for more information.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the **LOCK** clause to **NONE**. When this strategy is used, all concurrent DML is permitted.

For example:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50) WITH SYSTEM VERSIONING  
);  
  
SET SESSION system_versioning_alter_history='KEEP';  
SET SESSION alter_algorithm='INSTANT';  
ALTER TABLE tab MODIFY COLUMN c varchar(50) WITHOUT SYSTEM VERSIONING;  
Query OK, 0 rows affected (0.004 sec)
```

ALTER TABLE ... ALTER COLUMN

This applies to **ALTER TABLE ... ALTER COLUMN** for InnoDB tables.

Setting a Column's Default Value

InnoDB supports modifying a column's **DEFAULT** value with **ALGORITHM** set to **INSTANT**.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the **LOCK** clause to **NONE**. When this strategy is used, all concurrent DML is permitted.

For example:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
);

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab ALTER COLUMN c SET DEFAULT 'No value explicitly provided.';
Query OK, 0 rows affected (0.003 sec)

```

Removing a Column's Default Value

InnoDB supports removing a column's **DEFAULT** value with **ALGORITHM** set to `INSTANT`.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the **LOCK** clause to `NONE`. When this strategy is used, all concurrent DML is permitted.

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50) DEFAULT 'No value explicitly provided.'
);

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab ALTER COLUMN c DROP DEFAULT;
Query OK, 0 rows affected (0.002 sec)

```

ALTER TABLE ... CHANGE COLUMN

InnoDB supports renaming a column with **ALGORITHM** set to `INSTANT`, unless the column's data type or attributes changed in addition to the name.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the **LOCK** clause to `NONE`. When this strategy is used, all concurrent DML is permitted.

For example, this succeeds:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
);

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab CHANGE COLUMN c str varchar(50);
Query OK, 0 rows affected (0.004 sec)

```

But this fails:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
);

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab CHANGE COLUMN c num int;
ERROR 1846 (0A000): ALGORITHM=INSTANT is not supported. Reason: Cannot change column type
INPLACE. Try ALGORITHM=COPY

```

This applies to **ALTER TABLE ... CHANGE COLUMN** for InnoDB tables.

Index Operations

ALTER TABLE ... ADD PRIMARY KEY

InnoDB does **not** support adding a primary key to a table with **ALGORITHM** set to `INSTANT`.

For example:

```
CREATE OR REPLACE TABLE tab (  
  a int,  
  b varchar(50),  
  c varchar(50)  
);  
  
SET SESSION sql_mode='STRICT_TRANS_TABLES';  
SET SESSION alter_algorithm='INSTANT';  
ALTER TABLE tab ADD PRIMARY KEY (a);  
ERROR 1845 (0A000): ALGORITHM=INSTANT is not supported for this operation. Try  
ALGORITHM=INPLACE
```

This applies to [ALTER TABLE ... ADD PRIMARY KEY](#) for InnoDB tables.

ALTER TABLE ... DROP PRIMARY KEY

InnoDB does **not** support dropping a primary key with [ALGORITHM](#) set to `INSTANT`.

For example:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50)  
);  
  
SET SESSION alter_algorithm='INSTANT';  
ALTER TABLE tab DROP PRIMARY KEY;  
ERROR 1846 (0A000): ALGORITHM=INSTANT is not supported. Reason: Dropping a primary key is not  
allowed without also adding a new primary key. Try ALGORITHM=COPY
```

This applies to [ALTER TABLE ... DROP PRIMARY KEY](#) for InnoDB tables.

ALTER TABLE ... ADD INDEX and CREATE INDEX

This applies to [ALTER TABLE ... ADD INDEX](#) and [CREATE INDEX](#) for InnoDB tables.

Adding a Plain Index

InnoDB does **not** support adding a plain index to a table with [ALGORITHM](#) set to `INSTANT`.

For example, this fails:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50)  
);  
  
SET SESSION alter_algorithm='INSTANT';  
ALTER TABLE tab ADD INDEX b_index (b);  
ERROR 1846 (0A000): ALGORITHM=INSTANT is not supported. Reason: ADD INDEX. Try ALGORITHM=NOCOPY
```

And this fails:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50)  
);  
  
SET SESSION alter_algorithm='INSTANT';  
CREATE INDEX b_index ON tab (b);  
ERROR 1846 (0A000): ALGORITHM=INSTANT is not supported. Reason: ADD INDEX. Try ALGORITHM=NOCOPY
```

Adding a Fulltext Index

InnoDB does **not** support adding a **FULLTEXT** index to a table with **ALGORITHM** set to `INSTANT`.

For example, this fails:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50)  
);  
  
SET SESSION alter_algorithm='INPLACE';  
ALTER TABLE tab ADD FULLTEXT INDEX b_index (b);  
Query OK, 0 rows affected (0.042 sec)  
  
SET SESSION alter_algorithm='INSTANT';  
ALTER TABLE tab ADD FULLTEXT INDEX c_index (c);  
ERROR 1846 (0A000): ALGORITHM=INSTANT is not supported. Reason: ADD INDEX. Try ALGORITHM=NOCOPY
```

And this fails:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50)  
);  
  
SET SESSION alter_algorithm='INPLACE';  
CREATE FULLTEXT INDEX b_index ON tab (b);  
Query OK, 0 rows affected (0.040 sec)  
  
SET SESSION alter_algorithm='INSTANT';  
CREATE FULLTEXT INDEX c_index ON tab (c);  
ERROR 1846 (0A000): ALGORITHM=INSTANT is not supported. Reason: ADD INDEX. Try ALGORITHM=NOCOPY
```

Adding a Spatial Index

InnoDB does **not** support adding a **SPATIAL** index to a table with **ALGORITHM** set to `INSTANT`.

For example, this fails:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c GEOMETRY NOT NULL  
);  
  
SET SESSION alter_algorithm='INSTANT';  
ALTER TABLE tab ADD SPATIAL INDEX c_index (c);  
ERROR 1846 (0A000): ALGORITHM=INSTANT is not supported. Reason: ADD INDEX. Try ALGORITHM=NOCOPY
```

And this fails:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c GEOMETRY NOT NULL  
);  
  
SET SESSION alter_algorithm='INSTANT';  
CREATE SPATIAL INDEX c_index ON tab (c);  
ERROR 1846 (0A000): ALGORITHM=INSTANT is not supported. Reason: ADD INDEX. Try ALGORITHM=NOCOPY
```

ALTER TABLE ... ADD FOREIGN KEY

InnoDB does **not** support adding foreign key constraints to a table with **ALGORITHM** set to `INSTANT`.

For example:

```

CREATE OR REPLACE TABLE tab1 (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50),
  d int
);

CREATE OR REPLACE TABLE tab2 (
  a int PRIMARY KEY,
  b varchar(50)
);

SET SESSION foreign_key_checks=OFF;
SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab1 ADD FOREIGN KEY tab2_fk (d) REFERENCES tab2 (a);
ERROR 1846 (0A000): ALGORITHM=INSTANT is not supported. Reason: ADD INDEX. Try ALGORITHM=NOCOPY

```

This applies to [ALTER TABLE ... ADD FOREIGN KEY](#) for InnoDB tables.

ALTER TABLE ... DROP FOREIGN KEY

InnoDB supports dropping foreign key constraints from a table with [ALGORITHM](#) set to `INSTANT`.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the [LOCK](#) clause to `NONE`. When this strategy is used, all concurrent DML is permitted.

For example:

```

CREATE OR REPLACE TABLE tab2 (
  a int PRIMARY KEY,
  b varchar(50)
);

CREATE OR REPLACE TABLE tab1 (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50),
  d int,
  FOREIGN KEY tab2_fk (d) REFERENCES tab2 (a)
);

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab1 DROP FOREIGN KEY tab2_fk;
Query OK, 0 rows affected (0.004 sec)

```

This applies to [ALTER TABLE ... DROP FOREIGN KEY](#) for InnoDB tables.

Table Operations

ALTER TABLE ... AUTO_INCREMENT=...

InnoDB supports changing a table's [AUTO_INCREMENT](#) value with [ALGORITHM](#) set to `INSTANT`.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the [LOCK](#) clause to `NONE`. When this strategy is used, all concurrent DML is permitted.

For example:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
);

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab AUTO_INCREMENT=100;
Query OK, 0 rows affected (0.002 sec)

```

This applies to [ALTER TABLE ... AUTO_INCREMENT=...](#) for InnoDB tables.

```
ALTER TABLE ... ROW_FORMAT=...
```

InnoDB does **not** support changing a table's `row format` with `ALGORITHM` set to `INSTANT`.

For example:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50)  
) ROW_FORMAT=DYNAMIC;  
  
SET SESSION alter_algorithm='INSTANT';  
ALTER TABLE tab ROW_FORMAT=COMPRESSED;  
ERROR 1846 (0A000): ALGORITHM=INSTANT is not supported. Reason: Changing table options requires  
the table to be rebuilt. Try ALGORITHM=INPLACE
```

This applies to `ALTER TABLE ... ROW_FORMAT=...` for InnoDB tables.

```
ALTER TABLE ... KEY_BLOCK_SIZE=...
```

InnoDB does **not** support changing a table's `KEY_BLOCK_SIZE` with `ALGORITHM` set to `INSTANT`.

For example:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50)  
) ROW_FORMAT=COMPRESSED  
KEY_BLOCK_SIZE=4;  
  
SET SESSION alter_algorithm='INSTANT';  
ALTER TABLE tab KEY_BLOCK_SIZE=2;  
ERROR 1846 (0A000): ALGORITHM=INSTANT is not supported. Reason: Changing table options requires  
the table to be rebuilt. Try ALGORITHM=INPLACE
```

This applies to `KEY_BLOCK_SIZE=...` for InnoDB tables.

```
ALTER TABLE ... PAGE_COMPRESSED=1 and ALTER TABLE ...  
PAGE_COMPRESSION_LEVEL=...
```

In [MariaDB 10.3.10](#) and later, InnoDB supports setting a table's `PAGE_COMPRESSED` value to `1` with `ALGORITHM` set to `INSTANT`. InnoDB does **not** support changing a table's `PAGE_COMPRESSED` value from `1` to `0` with `ALGORITHM` set to `INSTANT`.

In these versions, InnoDB also supports changing a table's `PAGE_COMPRESSION_LEVEL` value with `ALGORITHM` set to `INSTANT`.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the `LOCK` clause to `NONE`. When this strategy is used, all concurrent DML is permitted.

See [MDEV-16328](#) for more information.

For example, this succeeds:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50)  
);  
  
SET SESSION alter_algorithm='INSTANT';  
ALTER TABLE tab PAGE_COMPRESSED=1;  
Query OK, 0 rows affected (0.004 sec)
```

And this succeeds:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
) PAGE_COMPRESSED=1
  PAGE_COMPRESSION_LEVEL=5;

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab PAGE_COMPRESSION_LEVEL=4;
Query OK, 0 rows affected (0.004 sec)

```

But this fails:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
) PAGE_COMPRESSED=1;

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab PAGE_COMPRESSED=0;
ERROR 1846 (0A000): ALGORITHM=INSTANT is not supported. Reason: Changing table options requires
the table to be rebuilt. Try ALGORITHM=INPLACE

```

This applies to [ALTER TABLE ... PAGE_COMPRESSED=...](#) and [ALTER TABLE ... PAGE_COMPRESSION_LEVEL=...](#) for [InnoDB](#) tables.

ALTER TABLE ... DROP SYSTEM VERSIONING

InnoDB does **not** support dropping [system versioning](#) from a table with [ALGORITHM](#) set to `INSTANT`.

For example:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
) WITH SYSTEM VERSIONING;

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab DROP SYSTEM VERSIONING;
ERROR 1845 (0A000): ALGORITHM=INSTANT is not supported for this operation. Try
ALGORITHM=INPLACE

```

This applies to [ALTER TABLE ... DROP SYSTEM VERSIONING](#) for [InnoDB](#) tables.

ALTER TABLE ... DROP CONSTRAINT

In [MariaDB 10.3.6](#) and later, InnoDB supports dropping a [CHECK](#) constraint from a table with [ALGORITHM](#) set to `INSTANT`. See [MDEV-16331](#) for more information.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the [LOCK](#) clause to `NONE`. When this strategy is used, all concurrent DML is permitted.

For example:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50),
  CONSTRAINT b_not_empty CHECK (b != '')
);

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab DROP CONSTRAINT b_not_empty;
Query OK, 0 rows affected (0.002 sec)

```

This applies to [ALTER TABLE ... DROP CONSTRAINT](#) for [InnoDB](#) tables.

ALTER TABLE ... FORCE

InnoDB does **not** support forcing a table rebuild with [ALGORITHM](#) set to `INSTANT` .

For example:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50)  
);  
  
SET SESSION alter_algorithm='INSTANT';  
ALTER TABLE tab FORCE;  
ERROR 1845 (0A000): ALGORITHM=INSTANT is not supported for this operation. Try  
ALGORITHM=INPLACE
```

This applies to [ALTER TABLE ... FORCE](#) for InnoDB tables.

ALTER TABLE ... ENGINE=InnoDB

InnoDB does **not** support forcing a table rebuild with [ALGORITHM](#) set to `INSTANT` .

For example:

```
CREATE OR REPLACE TABLE tab (  
  a int PRIMARY KEY,  
  b varchar(50),  
  c varchar(50)  
);  
  
SET SESSION alter_algorithm='INSTANT';  
ALTER TABLE tab ENGINE=InnoDB;  
ERROR 1845 (0A000): ALGORITHM=INSTANT is not supported for this operation. Try  
ALGORITHM=INPLACE
```

This applies to [ALTER TABLE ... ENGINE=InnoDB](#) for InnoDB tables.

OPTIMIZE TABLE ...

InnoDB does **not** support optimizing a table with with [ALGORITHM](#) set to `INSTANT` .

For example:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
);

SHOW GLOBAL VARIABLES WHERE Variable_name IN('innodb_defragment',
'innodb_optimize_fulltext_only');
+-----+-----+
| Variable_name          | Value |
+-----+-----+
| innodb_defragment      | OFF   |
| innodb_optimize_fulltext_only | OFF   |
+-----+-----+
2 rows in set (0.001 sec)

SET SESSION alter_algorithm='INSTANT';
OPTIMIZE TABLE tab;
+-----+-----+-----+-----+
| Table | Op      | Msg_type | Msg_text
|
+-----+-----+-----+-----+
| db1.tab | optimize | note     | Table does not support optimize, doing recreate + analyze
instead
|
| db1.tab | optimize | error    | ALGORITHM=INSTANT is not supported for this operation. Try
ALGORITHM=INPLACE |
| db1.tab | optimize | status   | Operation failed
|
+-----+-----+-----+-----+
3 rows in set, 1 warning (0.002 sec)

```

This applies to [OPTIMIZE TABLE](#) for [InnoDB](#) tables.

ALTER TABLE ... RENAME TO and RENAME TABLE ...

InnoDB supports renaming a table with [ALGORITHM](#) set to `INSTANT`.

This operation supports the exclusive locking strategy. This strategy can be explicitly chosen by setting the [LOCK](#) clause to `EXCLUSIVE`. When this strategy is used, concurrent DML is **not** permitted.

For example, this succeeds:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
);

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab RENAME TO old_tab;
Query OK, 0 rows affected (0.008 sec)

```

And this succeeds:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
);

SET SESSION alter_algorithm='INSTANT';
RENAME TABLE tab TO old_tab;
Query OK, 0 rows affected (0.008 sec)

```

This applies to [ALTER TABLE ... RENAME TO](#) and [RENAME TABLE](#) for [InnoDB](#) tables.

Limitations

Limitations Related to Generated (Virtual and Persistent/Stored) Columns

[Generated columns](#) do not currently support online DDL for all of the same operations that are supported for "real" columns.

See [Generated \(Virtual and Persistent/Stored\) Columns: Statement Support](#) for more information on the limitations.

Non-canonical Storage Format Caused by Some Operations

Some operations cause a table's tablespace file to use a non-canonical storage format when the `INSTANT` algorithm is used. The affected operations include:

- [Adding a column.](#)
- [Dropping a column.](#)
- [Reordering columns.](#)

These operations require the following non-canonical changes to the storage format:

- A hidden metadata record at the start of the clustered index is used to store each column's `DEFAULT` value. This makes it possible to add new columns that have default values without rebuilding the table.
- A `BLOB` in the hidden metadata record is used to store column mappings. This makes it possible to drop or reorder columns without rebuilding the table. This also makes it possible to add columns to any position or drop columns from any position in the table without rebuilding the table.
- If a column is dropped, old records will contain garbage in that column's former position, and new records will be written with `NULL` values, empty strings, or dummy values.

This non-canonical storage format has the potential to incur some performance or storage overhead for all subsequent DML operations. If you notice some issues like this and you want to normalize a table's storage format to avoid this problem, then you can do so by forcing a table rebuild by executing `ALTER TABLE ... FORCE` with `ALGORITHM` set to `INPLACE`. For example:

```
SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab FORCE;
Query OK, 0 rows affected (0.008 sec)
```

However, keep in mind that there are certain scenarios where you may not be able to rebuild the table with `ALGORITHM` set to `INPLACE`. See [InnoDB Online DDL Operations with ALGORITHM=INPLACE: Limitations](#) for more information on those cases. If you hit one of those scenarios, but you still want to rebuild the table, then you would have to do so with `ALGORITHM` set to `COPY`.

Known Bugs

There are some known bugs that could lead to issues when an InnoDB DDL operation is performed using the `INSTANT` algorithm. This algorithm will usually be chosen by default if the operation supports the algorithm.

The effect of many of these bugs is that the table seems to *forget* that its tablespace file is in the [non-canonical storage format](#).

If you are concerned that a table may be affected by one of these bugs, then your best option would be to normalize the table structure. This can be done by rebuilding the table. For example:

```
SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab FORCE;
Query OK, 0 rows affected (0.008 sec)
```

If you are concerned about these bugs, and you want to perform an operation that supports the `INSTANT` algorithm, but you want to avoid using that algorithm, then you can set the algorithm to `INPLACE` and add the `FORCE` keyword to the `ALTER TABLE` statement:

```
SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab ADD COLUMN c varchar(50), FORCE;
```

Closed Bugs

- [MDEV-20066](#): This bug could cause a table to become corrupt if a column was added instantly. It is fixed in

[MariaDB 10.3.18](#) and [MariaDB 10.4.8](#).

- [MDEV-20117](#): This bug could cause a table to become corrupt if a column was dropped instantly. It is fixed in [MariaDB 10.4.9](#).
- [MDEV-19743](#): This bug could cause a table to become corrupt during page reorganization if a column was added instantly. It is fixed in [MariaDB 10.3.17](#) and [MariaDB 10.4.7](#).
- [MDEV-19783](#): This bug could cause a table to become corrupt if a column was added instantly. It is fixed in [MariaDB 10.3.17](#) and [MariaDB 10.4.7](#).
- [MDEV-20090](#): This bug could cause a table to become corrupt if columns were added, dropped, or reordered instantly. It is fixed in [MariaDB 10.4.9](#).
- [MDEV-18519](#): This bug could cause a table to become corrupt if a column was added instantly. It is fixed in [MariaDB 10.6.9](#), [MariaDB 10.7.5](#), [MariaDB 10.8.4](#) and [MariaDB 10.9.2](#).
- [MDEV-18519](#): This bug could cause a table to become corrupt if a column was added instantly. This isn't and won't be fixed in versions less than [MariaDB 10.6](#).

5.3.2.19.5 Instant ADD COLUMN for InnoDB

Contents

1. [Limitations](#)
2. [Example](#)

Normally, adding a column to a table requires the full table to be rebuilt. The complexity of the operation is proportional to the size of the table, or $O(n \cdot m)$ where n is the number of rows in the table and m is the number of indexes.

In [MariaDB 10.0](#) and later, the `ALTER TABLE` statement supports [online DDL](#) for storage engines that have implemented the relevant online DDL [algorithms](#) and [locking strategies](#).

The [InnoDB](#) storage engine has implemented online DDL for many operations. These online DDL optimizations allow concurrent DML to the table in many cases, even if the table needs to be rebuilt.

See [InnoDB Online DDL Overview](#) for more information about online DDL with InnoDB.

Allowing concurrent DML during the operation does not solve all problems. When a column was added to a table with the older in-place optimization, the resulting table rebuild could still significantly increase the I/O and memory consumption and cause replication lag.

In contrast, with the new instant `ALTER TABLE ... ADD COLUMN`, all that is needed is an $O(1)$ operation to insert a special hidden record into the table, and an update of the data dictionary. For a large table, instead of taking several hours, the operation would be completed in the blink of an eye. The `ALTER TABLE ... ADD COLUMN` operation is only slightly more expensive than a regular `INSERT`, due to locking constraints.

In the past, some developers may have implemented a kind of "instant add column" in the application by encoding multiple columns in a single `TEXT` or `BLOB` column. MariaDB [Dynamic Columns](#) was an early example of that. A more recent example is `JSON` and related string manipulation functions.

Adding real columns has the following advantages over encoding columns into a single "expandable" column:

- Efficient storage in a native binary format
- Data type safety
- Indexes can be built natively
- Constraints are available: `UNIQUE`, `CHECK`, `FOREIGN KEY`
- `DEFAULT` values can be specified
- Triggers can be written more easily

With instant `ALTER TABLE ... ADD COLUMN`, you can enjoy all the benefits of structured storage without the drawback of having to rebuild the table.

Instant `ALTER TABLE ... ADD COLUMN` is available for both old and new InnoDB tables. Basically you can just upgrade from MySQL 5.x or MariaDB and start adding columns instantly.

Columns instantly added to a table exist in a separate data structure from the main table definition, similar to how InnoDB separates `BLOB` columns. If the table ever becomes empty, (such as from `TRUNCATE` or `DELETE` statements), InnoDB incorporates the instantly added columns into the main table definition. See [InnoDB Online DDL Operations with ALGORITHM=INSTANT: Non-canonical Storage Format Caused by Some Operations](#) for more information.

The operation is also crash safe. If the server is killed while executing an instant `ALTER TABLE ... ADD COLUMN`, when the table is restored InnoDB integrates the new column, flattening the table definition.

Limitations

- In [MariaDB 10.3](#), instant `ALTER TABLE ... ADD COLUMN` only applies when the added columns appear last in the table. The place specifier `LAST` is the default. If `AFTER col` is specified, then `col` must be the last column, or the

operation will require the table to be rebuilt. In [MariaDB 10.4](#), this restriction was lifted.

- If the table contains a hidden `FTS_DOC_ID` column due to a [FULLTEXT INDEX](#), then instant [ALTER TABLE ... ADD COLUMN](#) will not be possible.
- InnoDB data files after instant [ALTER TABLE ... ADD COLUMN](#) cannot be imported to older versions of MariaDB or MySQL without first being rebuilt.
- After using Instant [ALTER TABLE ... ADD COLUMN](#), any table-rebuilding operation such as [ALTER TABLE ... FORCE](#) will incorporate instantaneously added columns into the main table body.
- Instant [ALTER TABLE ... ADD COLUMN](#) is not available for [ROW_FORMAT=COMPRESSED](#).
- In [MariaDB 10.3](#), [ALTER TABLE ... DROP COLUMN](#) requires the table to be rebuilt. In [MariaDB 10.4](#), this restriction was lifted.

Example

```
CREATE TABLE t(id INT PRIMARY KEY, u INT UNSIGNED NOT NULL UNIQUE)
ENGINE=InnoDB;

INSERT INTO t(id,u) VALUES (1,1), (2,2), (3,3);

ALTER TABLE t ADD COLUMN
(d DATETIME DEFAULT current_timestamp(),
 p POINT NOT NULL DEFAULT ST_GeomFromText('POINT(0 0)'),
 t TEXT CHARSET utf8 DEFAULT 'The quick brown fox jumps over the lazy dog');

UPDATE t SET t=NULL WHERE id=3;

SELECT id,u,d,ST_AsText(p),t FROM t;

SELECT variable_value FROM information_schema.global_status
WHERE variable_name = 'innodb_instant_alter_column';
```

The above example illustrates that when the added columns are declared NOT NULL, a DEFAULT value must be available, either implied by the data type or set explicitly by the user. The expression need not be constant, but it must not refer to the columns of the table, such as `DEFAULT u+1` (a MariaDB extension). The `DEFAULT current_timestamp()` would be evaluated at the time of the `ALTER TABLE` and apply to each row, like it does for non-instant `ALTER TABLE`. If a subsequent `ALTER TABLE` changes the DEFAULT value for subsequent `INSERT`, the values of the columns in existing records will naturally be unaffected.

The design was brainstormed in April by engineers from MariaDB Corporation, Alibaba and Tencent. A prototype was developed by Vin Chen (陈福荣) from the Tencent Game DBA Team.

5.3.2.20 Binary Log Group Commit and InnoDB Flushing Performance

Contents

1. [Overview](#)
2. [Switching to Old Flushing Behavior](#)
 1. [Non-durable Binary Log Settings](#)
 2. [Recent Transactions Missing from Backups](#)

[MariaDB 10.0](#) introduced a performance improvement related to [group commit](#) that affects the performance of flushing InnoDB transactions when the [binary log](#) is enabled.

Overview

In [MariaDB 10.0](#) and above, when both `innodb_flush_log_at_trx_commit=1` (the default) is set and the [binary log](#) is enabled, there is now one less sync to disk inside InnoDB during commit (2 syncs shared between a group of transactions instead of 3).

Durability of commits is not decreased — this is because even if the server crashes before the commit is written to disk by InnoDB, it will be recovered from the binary log at next server startup (and it is guaranteed that sufficient information is synced to disk so that such a recovery is always possible).

Switching to Old Flushing Behavior

The old behavior, with 3 syncs to disk per (group) commit (and consequently lower performance), can be selected with the new `innodb_flush_log_at_trx_commit=3` option. There is normally no benefit to doing this, however there are a couple of edge cases to be aware of.

Non-durable Binary Log Settings

If `innodb_flush_log_at_trx_commit=1` is set and the `binary log` is enabled, but `sync_binlog=0` is set, then commits are not guaranteed durable inside InnoDB after commit. This is because if `sync_binlog=0` is set and if the server crashes, then transactions that were not flushed to the binary log prior to the crash will be missing from the binary log.

In this specific scenario, `innodb_flush_log_at_trx_commit=3` can be set to ensure that transactions will be durable in InnoDB, even if they are not necessarily durable from the perspective of the binary log.

One should be aware that if `sync_binlog=0` is set, then a crash is nevertheless likely to cause transactions to be missing from the binary log. This will cause the binary log and InnoDB to be inconsistent with each other. This is also likely to cause any `replication slaves` to become inconsistent, since transactions are replicated through the `binary log`. Thus it is recommended to set `sync_binlog=1`. With the `group commit` improvements introduced in `MariaDB 5.3`, this setting has much less penalty in recent versions compared to older versions of MariaDB and MySQL.

Recent Transactions Missing from Backups

`Mariabackup` and `Percona XtraBackup` only see transactions that have been flushed to the `redo log`. With the `group commit` improvements, there may be a small delay (defined by the `binlog_commit_wait_usec` system variable) between when a commit happens and when the commit will be included in a backup.

Note that the backup will still be fully consistent with itself and the `binary log`. This problem is normally not an issue in practice. A backup usually takes a long time to complete (relative to the 1 second or so that `binlog_commit_wait_usec` is normally set to), and a backup usually includes a lot of transactions that were committed during the backup. With this in mind, it is not generally noticeable if the backup does not include transactions that were committed during the last 1 second or so of the backup process. It is just mentioned here for completeness.

Overview

InnoDB page compression provides a way to compress InnoDB tables.

Use Cases

- InnoDB page compression can be used on any storage device and any file system.
- InnoDB page compression is most efficient on file systems that support sparse files. See [Saving Storage Space with Sparse Files](#) for more information.
- InnoDB page compression is most beneficial on solid state drives (SSDs) and other flash storage. See [Optimized for Flash Storage](#) for more information.
- InnoDB page compression performs best when your storage device and file system support atomic writes, since that allows the [InnoDB doublewrite buffer](#) to be disabled. See [Atomic Write Support](#) for more information.

Comparison with the COMPRESSED Row Format

InnoDB page compression is a modern way to compress your InnoDB tables. It is similar to InnoDB's [COMPRESSED](#) row format, but it has many advantages. Some of the differences are:

- With InnoDB page compression, compressed pages are immediately decompressed after being read from the tablespace file, and only uncompressed pages are stored in the buffer pool. In contrast, with InnoDB's [COMPRESSED](#) row format, compressed pages are decompressed immediately after they are read from the tablespace file, and both the uncompressed and compressed pages are stored in the buffer pool. This means that the [COMPRESSED](#) row format uses more space in the buffer pool than InnoDB page compression does.
- With InnoDB page compression, pages are compressed just before being written to the tablespace file. In contrast, with InnoDB's [COMPRESSED](#) row format, pages are re-compressed immediately after any changes, and the compressed pages are stored in the buffer pool alongside the uncompressed pages. These changes are then occasionally flushed to disk. This means that the [COMPRESSED](#) row format re-compresses data more frequently than InnoDB page compression does.
- With InnoDB page compression, multiple compression algorithms are supported. In contrast, with InnoDB's [COMPRESSED](#) row format, [zlib](#) is the only supported compression algorithm. This means that the [COMPRESSED](#) row format has less compression options than InnoDB page compression does.

In general, InnoDB page compression is superior to the [COMPRESSED](#) row format.

Comparison with Storage Engine-Independent Column Compression

- See [Storage Engine-Independent Column Compression - Comparison with InnoDB Page Compression](#).

Configuring the InnoDB Page Compression Algorithm

There is not currently a table option to set different InnoDB page compression algorithms for individual tables.

However, the server-wide InnoDB page compression algorithm can be configured by setting the [innodb_compression_algorithm](#) system variable.

When this system variable is changed, the InnoDB page compression algorithm does not change for existing pages that were already compressed with a different InnoDB page compression algorithm. InnoDB is able to handle this situation without issues, because every page in an InnoDB tablespace contains metadata about the InnoDB page compression algorithm in the page header. This means that InnoDB supports having uncompressed pages and pages compressed with different InnoDB page compression algorithms in the same InnoDB tablespace at the same time.

This system variable can be set to one of the following values:

System Variable Value	Description
none	Pages are not compressed. This is the default value in MariaDB 10.2.3 and before, and MariaDB 10.1.21 and before.
zlib	Pages are compressed using the bundled zlib compression algorithm. This is the default value in MariaDB 10.2.4 and later, and MariaDB 10.1.22 and later.
lz4	Pages are compressed using the lz4 compression algorithm.
lzo	Pages are compressed using the lzo compression algorithm.
lzma	Pages are compressed using the lzma compression algorithm.

bzip2	Pages are compressed using the bzip2 compression algorithm.
snappy	Pages are compressed using the snappy algorithm.

However, on many distributions, the standard MariaDB builds do not support all InnoDB page compression algorithms by default. From [MariaDB 10.7](#), algorithms can be [installed as a plugin](#).

This system variable can be changed dynamically with [SET GLOBAL](#). For example:

```
SET GLOBAL innodb_compression_algorithm='lzma';
```

This system variable can also be set in a server [option group](#) in an [option file](#) prior to starting up the server. For example:

```
[mariadb]
...
innodb_compression_algorithm=lzma
```

Checking Supported InnoDB Page Compression Algorithms

On many distributions, the standard MariaDB builds do not support all InnoDB page compression algorithms by default. Therefore, if you want to use a specific InnoDB page compression algorithm, then you should check whether your MariaDB build supports it.

The [zlib](#) compression algorithm is always supported. From [MariaDB 10.7](#), algorithms can be [installed as a plugin](#).

A MariaDB build's support for other InnoDB page compression algorithms can be checked by querying the following status variables with [SHOW GLOBAL STATUS](#):

Status Variable	Description
Innodb_have_lz4	Whether InnoDB supports the lz4 compression algorithm.
Innodb_have_lzo	Whether InnoDB supports the lzo compression algorithm.
Innodb_have_lzma	Whether InnoDB supports the lzma compression algorithm.
Innodb_have_bzip2	Whether InnoDB supports the bzip2 compression algorithm.
Innodb_have_snappy	Whether InnoDB supports the snappy compression algorithm.

For example:

```
SHOW GLOBAL STATUS WHERE Variable_name IN (
  'Innodb_have_lz4',
  'Innodb_have_lzo',
  'Innodb_have_lzma',
  'Innodb_have_bzip2',
  'Innodb_have_snappy'
);
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Innodb_have_lz4 | OFF |
| Innodb_have_lzo | OFF |
| Innodb_have_lzma | ON |
| Innodb_have_bzip2 | OFF |
| Innodb_have_snappy | OFF |
+-----+-----+
```

Adding Support for an InnoDB Page Compression Algorithm

On many distributions, the standard MariaDB builds do not support all InnoDB page compression algorithms by default. From [MariaDB 10.7](#), algorithms can be [installed as a plugin](#), but in earlier versions, if you want to use certain InnoDB page compression algorithms, then you may need to do the following:

- Download the package for the desired compression library from the above links.
- Install the package for the desired compression library.
- Compile MariaDB from the source distribution.

The general steps for compiling MariaDB are:

- Download and unpack the source code distribution:

```
wget https://downloads.mariadb.com/MariaDB/mariadb-10.4.8/source/mariadb-10.4.8.tar.gz
tar -xvzf mariadb-10.4.8.tar.gz
cd mariadb-10.4.8/
```

- Configure the build using [cmake](#):

```
cmake .
```

- Check [CMakeCache.txt](#) to confirm that it has found the desired compression library on your system.
- Compile the build:

```
make
```

- Either install the build:

```
make install
```

Or make a package to install:

```
make package
```

See [Compiling MariaDB From Source](#) for more information.

Enabling InnoDB Page Compression

InnoDB page compression is not enabled by default. However, InnoDB page compression can be enabled for just individual InnoDB tables or it can be enabled for all new InnoDB tables by default.

InnoDB page compression is also only supported if the InnoDB table is in a [file per-table](#) tablespace. Therefore, the [innodb_file_per_table](#) system variable must be set to `ON` to use InnoDB page compression.

InnoDB page compression is only supported if the InnoDB table uses the `Barracuda` [file format](#). Therefore, in [MariaDB 10.1](#) and before, the [innodb_file_format](#) system variable must be set to `Barracuda` to use InnoDB page compression.

InnoDB page compression is also only supported if the InnoDB table's [row format](#) is `COMPACT` or `DYNAMIC`.

Enabling InnoDB Page Compression by Default

In [MariaDB 10.2.3](#) and later, InnoDB page compression can be enabled for all new InnoDB tables by default by setting the [innodb_compression_default](#) system variable to `ON`.

This system variable can be set to one of the following values:

System Variable Value	Description
OFF	New InnoDB tables do not use InnoDB page compression. This is the default value.
ON	New InnoDB tables use InnoDB page compression.

This system variable can be changed dynamically with [SET GLOBAL](#). For example:

```
SET GLOBAL innodb_compression_default=ON;
```

This system variable's session value can be changed dynamically with [SET SESSION](#). For example:

```

SET GLOBAL innodb_file_per_table=ON;

SET GLOBAL innodb_file_format='Barracuda';

SET GLOBAL innodb_default_row_format='dynamic';

SET GLOBAL innodb_compression_algorithm='lzma';

SET SESSION innodb_compression_default=ON;

CREATE TABLE users (
  user_id int not null,
  b varchar(200),
  primary key(user_id)
)
ENGINE=InnoDB;

```

This system variable can also be set in a server [option group](#) in an [option file](#) prior to starting up the server. For example:

```

[mariadb]
...
innodb_compression_default=ON

```

Enabling InnoDB Page Compression for Individual Tables

InnoDB page compression can be enabled for individual tables by setting the [PAGE_COMPRESSED](#) table option to `1`. For example:

```

SET GLOBAL innodb_file_per_table=ON;

SET GLOBAL innodb_file_format='Barracuda';

SET GLOBAL innodb_default_row_format='dynamic';

SET GLOBAL innodb_compression_algorithm='lzma';

CREATE TABLE users (
  user_id int not null,
  b varchar(200),
  primary key(user_id)
)
ENGINE=InnoDB
PAGE_COMPRESSED=1;

```

Configuring the Compression Level

Some InnoDB page compression algorithms support a compression level option, which configures how the InnoDB page compression algorithm will balance speed and compression.

The compression level's supported values range from `1` to `9`. The range goes from the fastest to the most compact, which means that `1` is the fastest and `9` is the most compact.

Only the following InnoDB page compression algorithms currently support compression levels:

- [zlib](#)
- [lzma](#)

If an InnoDB page compression algorithm does not support compression levels, then it ignores any provided compression level value.

Configuring the Default Compression Level

The default compression level can be configured by setting the [innodb_compression_level](#) system variable.

This system variable's default value is `6`.

This system variable can be changed dynamically with [SET GLOBAL](#). For example:

```

SET GLOBAL innodb_compression_level=9;

```

This system variable can also be set in a server [option group](#) in an [option file](#) prior to starting up the server. For example:

```
[mariadb]
...
innodb_compression_level=9
```

Configuring the Compression Level for Individual Tables

The compression level for individual tables can also be configured by setting the [PAGE_COMPRESSION_LEVEL](#) table option for the table. For example:

```
SET GLOBAL innodb_file_per_table=ON;

SET GLOBAL innodb_file_format='Barracuda';

SET GLOBAL innodb_default_row_format='dynamic';

SET GLOBAL innodb_compression_algorithm='lzma';

CREATE TABLE users (
  user_id int not null,
  b varchar(200),
  primary key(user_id)
)
ENGINE=InnoDB
PAGE_COMPRESSED=1
PAGE_COMPRESSION_LEVEL=9;
```

Configuring the Failure Threshold and Maximum Padding

InnoDB page compression can encounter compression failures.

InnoDB page compression's failure threshold can be configured. If InnoDB encounters more compression failures than the failure threshold, then it pads pages with zeroed out bytes before attempting to compress them as a way to reduce failures. If the failure rate stays above the failure threshold, then InnoDB pads pages with more zeroed out bytes in 128 byte increments.

InnoDB page compression's maximum padding can also be configured.

Configuring the Failure Threshold

The failure threshold can be configured by setting the [innodb_compression_failure_threshold_pct](#) system variable.

This system variable's supported values range from 0 to 100 .

This system variable's default value is 5 .

This system variable can be changed dynamically with [SET GLOBAL](#). For example:

```
SET GLOBAL innodb_compression_failure_threshold_pct=10;
```

This system variable can also be set in a server [option group](#) in an [option file](#) prior to starting up the server. For example:

```
[mariadb]
...
innodb_compression_failure_threshold_pct=10
```

Configuring the Maximum Padding

The maximum padding can be configured by setting the [innodb_compression_pad_pct_max](#) system variable.

This system variable's supported values range from 0 to 75 .

This system variable's default value is 50 .

This system variable can be changed dynamically with [SET GLOBAL](#). For example:

```
SET GLOBAL innodb_compression_pad_pct_max=75;
```

This system variable can also be set in a server [option group](#) in an [option file](#) prior to starting up the server. For example:

```
[mariadb]
...
innodb_compression_pad_pct_max=75
```

Saving Storage Space with Sparse Files

When InnoDB page compression is used, InnoDB may still write the compressed page to the tablespace file with the original size of the uncompressed page, which would be equivalent to the value of the [innodb_page_size](#) system variable. This is done by design, because when InnoDB's I/O code needs to read the page from disk, it can only read the full page size. However, this is obviously not optimal.

On file systems that support sparse files, this problem is solved by writing the tablespace file as a sparse file using the *punch hole* technique. With the *punch hole* technique, InnoDB will only write the actual compressed page size to the tablespace file, aligned to sector size. The rest of the page is trimmed.

This *punch hole* technique allows InnoDB to read the compressed page from disk as the full page size, even though the compressed page really takes up less space on the file system.

There are some potential disadvantages to using sparse files:

- Some utilities may require special options in order to handle sparse files in an efficient manner.
- Most existing file systems are slow to [unlink\(\)](#) sparse files. As a consequence, if a tablespace file is a sparse file, then dropping the table can be very slow.

Sparse File Support on Linux

On Linux, the following file systems support sparse files:

- ext3
- ext4
- xfs
- btrfs
- nvme

On Linux, file systems need to support the [fallocate\(\)](#) system call with the `FALLOC_FL_PUNCH_HOLE` and `FALLOC_FL_KEEP_SIZE` flags. For example:

```
fallocate(file_handle, FALLOC_FL_PUNCH_HOLE | FALLOC_FL_KEEP_SIZE, file_offset, remainder_len);
```

Some Linux utilities may require special options in order to work with sparse files efficiently. For example:

- The `ls` utility will report the non-sparse size of the tablespace file when executed with default behavior, but `ls -s` will report the actual amount of storage allocated for the tablespace file.
- The `cp` utility is pretty good at auto-detecting sparse files, but it also provides the `cp --sparse=always` and `cp --sparse=never` options, if the auto-detection is not desired.
- The `tar` utility will archive sparse files with their non-sparse size when executed with default behavior, but `tar --sparse` will auto-detect sparse files, and archive them with their sparse size.

Sparse File Support on Windows

On Windows, the following file systems support sparse files:

- NTFS

On Windows, file systems need to support the [DeviceIoControl\(\)](#) function with the `FSCTL_SET_SPARSE` and `FSCTL_SET_ZERO_DATA` control codes. For example:

```
DeviceIoControl(file_handle, FSCTL_SET_SPARSE, inbuf, inbuf_size,
    outbuf, outbuf_size, NULL, &overlapped)
...
DeviceIoControl(file_handle, FSCTL_SET_ZERO_DATA, inbuf, inbuf_size,
    outbuf, outbuf_size, NULL, &overlapped)
```

Configuring InnoDB to use Sparse Files

In [MariaDB 10.3](#) and later, InnoDB uses the *punch hole* technique to create sparse files used automatically when the

underlying file system supports sparse files.

In [MariaDB 10.2](#) and before, InnoDB can be configured to use the *punch hole* technique to create sparse files by configuring the `innodb_use_trim` and `innodb_use_fallocate` system variables. These system variables can be set in a server [option group](#) in an [option file](#) prior to starting up the server. For example:

```
[mariadb]
...
innodb_use_trim=ON
innodb_use_fallocate=ON
```

Optimized for Flash Storage

InnoDB page compression was designed to be optimized on solid state drives (SSDs) and other flash storage.

InnoDB page compression was originally developed by collaborating with [Fusion-io](#). As a consequence, it was originally designed to work best on [FusionIO devices](#) using [NVMFS](#). [Fusion-io](#) has since been acquired by [Western Digital](#), and they have decided not to continue supporting [NVMFS](#).

However, InnoDB page compression is still likely to be most optimized on solid state drives (SSDs) and other flash storage.

InnoDB page compression works without any issues on hard disk drives (HDDs). However, since its compression relies on the use of sparse files, the data may be somewhat fragmented on disk. This fragmentation may hurt performance on HDDs, since they handle random reads and writes much more slowly than flash storage.

Configuring InnoDB Page Flushing

With InnoDB page compression, pages are compressed when they are flushed to disk. Therefore, it can be helpful to optimize the configuration of InnoDB's page flushing. See [InnoDB Page Flushing](#) for more information.

Monitoring InnoDB Page Compression

InnoDB page compression can be monitored by querying the following status variables with [SHOW GLOBAL STATUS](#):

Status Variable	Description
Innodb_page_compression_saved	Bytes saved by compression
Innodb_page_compression_trim_sect512	Number of 512 sectors trimmed
Innodb_page_compression_trim_sect1024	Number of 1024 sectors trimmed
Innodb_page_compression_trim_sect2048	Number of 2048 sectors trimmed
Innodb_page_compression_trim_sect4096	Number of 4096 sectors trimmed
Innodb_page_compression_trim_sect8192	Number of 8192 sectors trimmed
Innodb_page_compression_trim_sect16384	Number of 16384 sectors trimmed
Innodb_page_compression_trim_sect32768	Number of 32768 sectors trimmed
Innodb_num_pages_page_compressed	Number of pages compressed
Innodb_num_page_compressed_trim_op	Number of trim operations
Innodb_num_page_compressed_trim_op_saved	Number of trim operations saved
Innodb_num_pages_page_decompressed	Number of pages decompressed
Innodb_num_pages_page_compression_error	Number of compression errors

With InnoDB page compression, a page is only compressed when it is flushed to disk. This means that if you are monitoring InnoDB page compression via these status variables, then the status variables values will only get incremented when the dirty pages are flushed to disk, which does not necessarily happen immediately. For example:

```

CREATE TABLE `tab` (
  `id` int(11) NOT NULL,
  `str` varchar(50) DEFAULT NULL,
  PRIMARY KEY (`id`)
) ENGINE=InnoDB;

INSERT INTO tab VALUES (1, 'str1');

SHOW GLOBAL STATUS LIKE 'Innodb_num_pages_page_compressed';
+-----+
| Variable_name          | Value |
+-----+
| Innodb_num_pages_page_compressed | 0     |
+-----+

SET GLOBAL innodb_file_per_table=ON;

SET GLOBAL innodb_file_format='Barracuda';

SET GLOBAL innodb_default_row_format='dynamic';

SET GLOBAL innodb_compression_algorithm='lzma';

ALTER TABLE tab PAGE_COMPRESSED=1;

SHOW GLOBAL STATUS LIKE 'Innodb_num_pages_page_compressed';
+-----+
| Variable_name          | Value |
+-----+
| Innodb_num_pages_page_compressed | 0     |
+-----+

SELECT SLEEP(10);
+-----+
| SLEEP(10) |
+-----+
|          0 |
+-----+

SHOW GLOBAL STATUS LIKE 'Innodb_num_pages_page_compressed';
+-----+
| Variable_name          | Value |
+-----+
| Innodb_num_pages_page_compressed | 3     |
+-----+

```

Compatibility with Backup Tools

[Mariabackup](#) supports InnoDB page compression.

[Percona XtraBackup](#) [↗](#) does not support InnoDB page compression.

Acknowledgements

- InnoDB page compression was developed by collaborating with [Fusion-io](#) [↗](#). Special thanks especially to Dhananjay Das and Torben Mathiasen.

5.3.2.22 InnoDB Data Scrubbing

Note that most of the background and redo log scrubbing code has been removed in [MariaDB 10.5.2](#). See [MDEV-15528](#) [↗](#) and [MDEV-21870](#) [↗](#).

Sometimes there is a requirement that when some data is deleted, it is really gone. This might be the case when one stores user's personal information or some other sensitive data. Normally though, when a row is deleted, the space is only marked as free on the page. It may eventually be overwritten, but there is no guarantee when that will happen. A copy of the deleted rows may also be present in the log files.

MariaDB 10.1.3 [↗](#) introduced support for InnoDB data scrubbing. Background threads periodically scan tablespaces and logs and remove all data that should be deleted. The number of background threads for tablespace scans is set by `innodb-encryption-threads`. Log scrubbing happens in a separate thread.

To configure scrubbing one can use the following variables:

<code>innodb-background-scrub-data-check-interval</code>	Seconds	Check at this interval if tablespaces needs scrubbing. Deprecated and ignored from MariaDB 10.5.2 .
<code>innodb-background-scrub-data-compressed</code>	Boolean	Enable scrubbing of compressed data by background threads. Deprecated and ignored from MariaDB 10.5.2 .
<code>innodb-background-scrub-data-interval</code>	Seconds	Scrub spaces that were last scrubbed longer than this many seconds ago. Deprecated and ignored from MariaDB 10.5.2 .
<code>innodb-background-scrub-data-uncompressed</code>	Boolean	Enable scrubbing of uncompressed data by background threads. Deprecated and ignored from MariaDB 10.5.2 .
<code>innodb-immediate-scrub-data-uncompressed</code>	Boolean	Enable scrubbing of uncompressed data
<code>innodb-scrub-log</code>	Boolean	Enable redo log scrubbing. Deprecated and ignored from MariaDB 10.5.2 .
<code>innodb-scrub-log-speed</code>	Bytes/sec	Redo log scrubbing speed in bytes/sec. Deprecated and ignored from MariaDB 10.5.2 .

Redo log scrubbing did not fully work as intended, and was deprecated and ignored in [MariaDB 10.5.2 \(MDEV-21870 ↗\)](#). If old log contents should be kept secret, then enabling `innodb_encrypt_log` or setting a smaller `innodb_log_file_size` could help.

The [Information Schema INNODB_TABLESPACES_SCRUBBING](#) table contains scrubbing information.

Thanks

- Scrubbing was donated to the MariaDB project by Google.

5.3.2.23 InnoDB Lock Modes

Contents

1. [Shared and Exclusive Locks](#)
2. [Intention Locks](#)
3. [AUTO_INCREMENT Locks](#)
4. [Gap Locks](#)

Locks are acquired by a transaction to prevent concurrent transactions from modifying, or even reading, some rows or ranges of rows. This is done to make sure that concurrent write operations never collide.

InnoDB supports a number of lock modes.

Shared and Exclusive Locks

The two standard row-level locks are *share locks*(S) and *exclusive locks*(X).

A shared lock is obtained to read a row, and allows other transactions to read the locked row, but not to write to the locked row. Other transactions may also acquire their own shared locks.

An exclusive lock is obtained to write to a row, and stops other transactions from locking the same row. It's specific behavior depends on the [isolation level](#); the default (REPEATABLE READ), allows other transactions to read from the exclusively locked row.

Intention Locks

InnoDB also permits table locking, and to allow locking at both table and row level to co-exist gracefully, a series of locks called *intention locks* exist.

An *intention shared lock*(IS) indicates that a transaction intends to set a shared lock.

An *intention exclusive lock*(IX) indicates that a transaction intends to set an exclusive lock.

Whether a lock is granted or not can be summarised as follows:

- An X lock is not granted if any other lock (X, S, IX, IS) is held.
- An S lock is not granted if an X or IX lock is held. It is granted if an S or IS lock is held.
- An IX lock is not granted if in X or S lock is held. It is granted if an IX or IS lock is held.
- An IS lock is not granted if an X lock is held. It is granted if an S, IX or IS lock is held.

AUTO_INCREMENT Locks

Locks are also required for auto-increments - see [AUTO_INCREMENT handling in InnoDB](#).

Gap Locks

With the default [isolation level](#), `REPEATABLE READ`, and, until [MariaDB 10.4](#), the default setting of the [innodb_locks_unsafe_for_binlog](#) variable, a method called gap locking is used. When InnoDB sets a shared or exclusive lock on a record, it's actually on the index record. Records will have an internal InnoDB index even if they don't have a unique index defined. At the same time, a lock is held on the gap before the index record, so that another transaction cannot insert a new index record in the gap between the record and the preceding record.

The gap can be a single index value, multiple index values, or not exist at all depending on the contents of the index.

If a statement uses all the columns of a unique index to search for unique row, gap locking is not used.

Similar to the shared and exclusive intention locks described above, there can be a number of types of gap locks. These include the shared gap lock, exclusive gap lock, intention shared gap lock and intention exclusive gap lock.

Gap locks are disabled if the [innodb_locks_unsafe_for_binlog](#) system variable is set (until [MariaDB 10.4](#)), or the [isolation level](#) is set to `READ COMMITTED`.

5.3.2.24 InnoDB Monitors

Contents

1. [Standard InnoDB Monitor](#)
2. [InnoDB Lock Monitor](#)
3. [InnoDB Tablespace Monitor](#)
4. [InnoDB Table Monitor](#)
5. [SHOW ENGINE INNODB STATUS](#)

The [InnoDB Monitor](#) refers to particular kinds of monitors included in MariaDB and since the early versions of MySQL.

There are four types: the standard InnoDB monitor, the InnoDB Lock Monitor, InnoDB Tablespace Monitor and the InnoDB Table Monitor.

Standard InnoDB Monitor

The standard InnoDB Monitor returns extensive InnoDB information, particularly lock, semaphore, I/O and buffer activity:

To enable the standard InnoDB Monitor, from [MariaDB 10.0.14](#), set the [innodb_status_output](#) system variable to 1. Before [MariaDB 10.0.14](#), running the following statement was the method used:

```
CREATE TABLE innodb_monitor (a INT) ENGINE=INNODB;
```

To disable the standard InnoDB monitor, either set the system variable to zero, or, before [MariaDB 10.0.14](#), drop the table

```
DROP TABLE innodb_monitor;
```

The CREATE TABLE and DROP TABLE method of enabling and disabling the InnoDB Monitor has been deprecated, and may be removed in a future version of MariaDB.

For a description of the output, see [SHOW ENGINE INNODB STATUS](#).

InnoDB Lock Monitor

The InnoDB Lock Monitor displays additional lock information.

To enable the InnoDB Lock Monitor, the standard InnoDB monitor must be enabled. Then, from [MariaDB 10.0.14](#), set the

`innodb_status_output_locks` system variable to 1. Before [MariaDB 10.0.14](#), running the following statement was the method used:

```
CREATE TABLE innodb_lock_monitor (a INT) ENGINE=INNODB;
```

To disable the standard InnoDB monitor, either set the system variable to zero, or, before [MariaDB 10.0.14](#), drop the table

```
DROP TABLE innodb_lock_monitor;
```

The CREATE TABLE and DROP TABLE method of enabling and disabling the InnoDB Lock Monitor has been deprecated, and may be removed in a future version of MariaDB.

InnoDB Tablespace Monitor

The InnoDB Tablespace Monitor is deprecated, and may be removed in a future version of MariaDB.

Enabling the Tablespace Monitor outputs a list of file segments in the shared tablespace to the error log, and validates the tablespace allocation data structures.

To enable the Tablespace Monitor, run the following statement:

```
CREATE TABLE innodb_tablespace_monitor (a INT) ENGINE=INNODB;
```

To disable it, drop the table:

```
DROP TABLE innodb_tablespace_monitor;
```

InnoDB Table Monitor

The InnoDB Table Monitor is deprecated, and may be removed in a future version of MariaDB.

Enabling the Table Monitor outputs the contents of the InnoDB internal data dictionary to the error log every fifteen seconds.

To enable the Table Monitor, run the following statement:

```
CREATE TABLE innodb_table_monitor (a INT) ENGINE=INNODB;
```

To disable it, drop the table:

```
DROP TABLE innodb_table_monitor;
```

SHOW ENGINE INNODB STATUS

The `SHOW ENGINE INNODB STATUS` statement can be used to obtain the standard InnoDB Monitor output when required, rather than sending it to the error log. It will also display the InnoDB Lock Monitor information if the `innodb_status_output_locks` system variable is set to 1.

5.3.2.25 InnoDB Encryption Overview

Contents

1. [Basic Configuration](#)
2. [Creating Encrypted Tables](#)
3. [Finding Encrypted Tables](#)
4. [Redo Logs](#)

MariaDB supports data-at-rest encryption for tables using the InnoDB storage engines. When enabled, the server encrypts data when it writes it to and decrypts data when it reads it from the file system. You can [configure InnoDB encryption](#) to

automatically have all new InnoDB tables automatically encrypted, or specify encrypt per table.

For encrypting data with the Aria storage engine, see [Encrypting Data for Aria](#).

Basic Configuration

Using data-at-rest encryption requires that you first configure an [Encryption Key Management](#) plugin, such as the [file_key_management](#) or [aws_key_management](#) plugins. MariaDB uses this plugin to store, retrieve and manage the various keys it uses when encrypting data to and decrypting data from the file system.

Once you have the plugin configured, you need to set a few additional system variables to enable encryption on InnoDB tables, including [innodb_encrypt_tables](#), [innodb_encrypt_log](#), [innodb_encryption_threads](#), [innodb_encrypt_temporary_tables](#) and [innodb_encryption_rotate_key_age](#).

```
[mariadb]
...

# File Key Management
plugin_load_add = file_key_management
file_key_management_filename = /etc/mysql/encryption/keyfile.enc
file_key_management_filekey = FILE:/etc/mysql/encryption/keyfile.key
file_key_management_encryption_algorithm = AES_CTR

# InnoDB Encryption
innodb_encrypt_tables = ON
innodb_encrypt_temporary_tables = ON
innodb_encrypt_log = ON
innodb_encryption_threads = 4
innodb_encryption_rotate_key_age = 1
```

For more information on system variables for encryption and other features, see the InnoDB [system variables](#) page.

Creating Encrypted Tables

To create encrypted tables, specify the table options `ENCRYPTED=YES` and `ENCRYPTION_KEY_ID=` with a corresponding key id;

```
CREATE TABLE t (i int primary key) ENGINE=InnoDB ENCRYPTED=YES ENCRYPTION_KEY_ID=2;
```

Finding Encrypted Tables

When using data-at-rest encryption with the InnoDB storage engine, it is not necessary that you encrypt every table in your database. You can check which tables are encrypted and which are not by querying the [INNODB_TABLESPACES_ENCRYPTION](#) table in the [Information Schema](#). This table provides information on which tablespaces are encrypted, which encryption key each tablespace is encrypted with, and whether the background encryption threads are currently working on the tablespace. Since the [system tablespace](#) can also contain tables, it can be helpful to join the [INNODB_TABLESPACES_ENCRYPTION](#) table with the [INNODB_SYS_TABLES](#) table to find out the encryption status of each specific table, rather than each tablespace. For example:

```
SELECT st.SPACE, st.NAME, te.ENCRYPTION_SCHEME, te.ROTATING_OR_FLUSHING
FROM information_schema.INNODB_TABLESPACES_ENCRYPTION te
JOIN information_schema.INNODB_SYS_TABLES st
  ON te.SPACE = st.SPACE \G
***** 1. row *****
      SPACE: 0
      NAME: SYS_DATAFILES
      ENCRYPTION_SCHEME: 1
      ROTATING_OR_FLUSHING: 0
***** 2. row *****
      SPACE: 0
      NAME: SYS_FOREIGN
      ENCRYPTION_SCHEME: 1
      ROTATING_OR_FLUSHING: 0
***** 3. row *****
      SPACE: 0
      NAME: SYS_FOREIGN_COLS
      ENCRYPTION_SCHEME: 1
      ROTATING_OR_FLUSHING: 0
```

```

***** 4. row *****
      SPACE: 0
      NAME: SYS_TABLESPACES
      ENCRYPTION_SCHEME: 1

Redo Logs

Using data-at-rest encryption with InnoDB, the [innodb_encrypt_tables](#) system variable only encrypts the InnoDB tablespaces. In order to also encrypt the InnoDB Redo Logs, you also need to set the [innodb_encrypt_log](#) system variable.

Beginning in [MariaDB 10.4](#), where the encryption key management plugin supports key rotation the InnoDB Redo Log can also rotate encryption keys. In previous releases, the Redo Log can only use the first encryption key.

5.3.3 MariaDB ColumnStore

MariaDB ColumnStore is a columnar storage engine that utilizes a massively parallel distributed data architecture. It's a columnar storage system built by porting InfiniDB 4.6.7 to MariaDB, and released under the GPL license.

From [MariaDB 10.5.4](#), it is available as a storage engine for MariaDB Server. Before then, it is only available as a separate download.

MariaDB ColumnStore is designed for big data scaling to process petabytes of data, linear scalability and exceptional performance with real-time response to analytical queries. It leverages the I/O benefits of columnar storage, compression, just-in-time projection, and horizontal and vertical partitioning to deliver tremendous performance when analyzing large data sets.

Release notes and other documentation for ColumnStore is also available in the Enterprise docs section of the MariaDB website. For example:

5.3.4.1 Aria Storage Engine

Contents

1. [Startup Options for Aria](#)
2. [Aria Log Files](#)
 1. [Missing valid id](#)

The [Aria](#) storage engine is compiled in by default from [MariaDB 5.1](#) and it is required to be 'in use' when MariaDB is started.

From [MariaDB 10.4](#), all [system tables](#) are Aria.

Additionally, internal on-disk tables are in the Aria table format instead of the [MyISAM](#) table format. This should speed up some [GROUP BY](#) and [DISTINCT](#) queries because Aria has better caching than MyISAM.

Note: The [Aria](#) storage engine was previously called [Maria](#) (see [The Aria Name](#) for details on the rename) and in previous versions of [MariaDB](#) [↗](#) the engine was still called Maria.

The following table options to Aria tables in [CREATE TABLE](#) and [ALTER TABLE](#):

- **TRANSACTIONAL= 0 | 1** : If the `TRANSACTIONAL` table option is set for an Aria table, then the table will be crash-safe. This is implemented by logging any changes to the table to Aria's transaction log, and syncing those writes at the end of the statement. This will marginally slow down writes and updates. However, the benefit is that if the server dies before the statement ends, all non-durable changes will roll back to the state at the beginning of the statement. This also needs up to 6 bytes more for each row and key to store the transaction id (to allow concurrent insert's and selects).
 - `TRANSACTIONAL=1` is not supported for partitioned tables.
 - An Aria table's default value for the `TRANSACTIONAL` table option depends on the table's value for the `ROW_FORMAT` table option. See below for more details.
 - If the `TRANSACTIONAL` table option is set for an Aria table, the table does not actually support transactions. See [MDEV-21364](#) for more information. In this context, *transactional* just means *crash-safe*.
- **PAGE_CHECKSUM= 0 | 1** : If index and data should use page checksums for extra safety.
- **TABLE_CHECKSUM= 0 | 1** : Same as `CHECKSUM` in MySQL 5.1
- **ROW_FORMAT=PAGE | FIXED | DYNAMIC** : The table's [row format](#).
 - The default value is `PAGE`.
 - To emulate MyISAM, set `ROW_FORMAT=FIXED` or `ROW_FORMAT=DYNAMIC`

The `TRANSACTIONAL` and `ROW_FORMAT` table options interact as follows:

- If `TRANSACTIONAL=1` is set, then the only supported row format is `PAGE`. If `ROW_FORMAT` is set to some other value, then Aria issues a warning, but still forces the row format to be `PAGE`.
- If `TRANSACTIONAL=0` is set, then the table will be not be crash-safe, and any row format is supported.
- If `TRANSACTIONAL` is not set to any value, then any row format is supported. If `ROW_FORMAT` is set, then the table will use that row format. Otherwise, the table will use the default `PAGE` row format. In this case, if the table uses the `PAGE` row format, then it will be crash-safe. If it uses some other row format, then it will not be crash-safe.

Some other improvements are:

- **CHECKSUM TABLE** now ignores values in NULL fields. This makes `CHECKSUM TABLE` faster and fixes some cases where same table definition could give different checksum values depending on [row format](#). The disadvantage is that the value is now different compared to other MySQL installations. The new checksum calculation is fixed for all table engines that uses the default way to calculate and MyISAM which does the calculation internally. Note: Old MyISAM tables with internal checksum will return the same checksum as before. To fix them to calculate according to new rules you have to do an [ALTER TABLE](#). You can use the old ways to calculate checksums by using the option `--old` to `mariadbmysqld` or set the system variable `'@@old'` to 1 when you do `CHECKSUM TABLE ... EXTENDED;`
- At startup Aria will check the Aria logs and automatically recover the tables from the last checkpoint if the server was not taken down correctly. See [Aria Log Files](#)

Startup Options for Aria

For a full list, see [Aria System Variables](#).

In normal operations, the only variables you have to consider are:

- [aria-pagecache-buffer-size](#)
 - This is where all index and data pages are cached. The bigger this is, the faster Aria will work.
- [aria-block-size](#)
 - The default value 8192, should be ok for most cases. The only problem with a higher value is that it takes longer to find a packed key in the block as one has to search roughly 8192/2 to find each key. We plan to fix this by adding a dictionary at the end of the page to be able to do a binary search within the block before starting a scan. Until this is done and key lookups takes too long time even if you are not hitting disk, then you should consider making this smaller.
 - Possible values to try are 2048, 4096 or 8192
 - Note that you can't change this without dumping, deleting old tables and deleting all log files and then restoring your Aria tables. (This is the only option that requires a dump and load)
- [aria-log-purge-type](#)
 - Set this to `"at_flush"` if you want to keep a copy of the transaction logs (good as an extra backup). The logs will stay around until you execute [FLUSH ENGINE LOGS](#).

Aria Log Files

`aria_log_control` file is a very short log file (52 bytes) that contains the current state of all Aria tables related to logging and checkpoints. In particular, it contains the following information:

```
Aria file version: 1
Block size: 8192
maria_uuid: ee948482-6cb7-11ed-accb-3c7c3ff16468
last_checkpoint_lsn: (1,0x235a)
last_log_number: 1
trid: 28
recovery_failures: 0
```

- The `uuid` is a unique identifier per system. All Aria files created will have a copy of this in their `.MAI` headers. This is mainly used to check if someone has copied an Aria file between MariaDB servers.
- `last_checkpoint_lsn` and `last_log_number` are information about the current `aria_log` files.
- `trid` is the highest transaction number seen so far. Used by recovery.

`aria_log.*` files contain the log of all operations that change Aria files (including create table, drop table, insert etc..) This is a 'normal' WAL (Write Ahead Log), similar to the InnoDB log file, except that `aria_logs` contain both redo and undo. Old `aria_log` files are automatically deleted when they are not needed anymore (Neither the last checkpoint or any running transaction need to refer to the old data anymore).

Missing valid id

The error `Missing valid id at start of file. File is not a valid aria control file` means that something overwrote at least the first 4 bytes in the file. This can happen due to a problem with the file system (hardware or software), or a bug in which a thread inside MariaDB wrote on the wrong file descriptor (in which case you should [report the bug](#), attaching a copy of the control file to assist).

In the case of a corrupted log file, with the server shut down, one should be able to fix that by deleting all `aria_log` files. If the `control_file` is corrupted, then one has to delete the `aria_control_file` and all `aria_log.*` files. The effect of this is that on table open of an Aria table, the server will think that it has been moved from another system and do an automatic check and repair of it. If there was no issues, the table will be opened and can be used as normal. See also [When is it safe to remove old log files](#).

What is Aria?

Aria is a storage engine for MySQL® and MariaDB. It was originally developed with the goal of becoming the default transactional **and** non-transactional storage engine for MariaDB and MySQL.

It has been in development since 2007 and was first announced on Monty's [blog](#). The same core MySQL engineers who developed the MySQL server and the [MyISAM](#), [MERGE](#), and [MEMORY](#) storage engines are also working on Aria.

Why is the engine called Aria?

Originally, the storage engine was called **Maria**, after Monty's younger daughter. Monty named MySQL after his first child, **My** and his second child **Max** gave his name to MaxDB and the MySQL-Max distributions.

In practice, having both *MariaDB* the database server and *Maria* the storage engine with such similar names proved confusing. To mitigate this, the decision was made to change the name. A Rename Maria contest was held during the first half of 2010 and names were submitted from around the world. Monty picked the name **Aria** from a short list of finalist. Chris Tooley, who suggested it, received the prize of a Linux-powered [System 76 Meerkat NetTop](#) from Monty Program.

For more information, see the [Aria Name](#).

What's the goal for the current version?

The current version of Aria is 1.5. The goal of this release is to develop a crash-safe alternative to MyISAM. That is, when MariaDB restarts after a crash, Aria recovers all tables to the state as of the start of a statement or at the start of the last `LOCK TABLES` statement.

The current goal is to keep the code stable and fix all bugs.

What's the goal for the next version?

The next version of Aria is 2.0. The goal for this release is to develop a fully transactional storage engine with at least all the major features of InnoDB.

Currently, Aria 2.0 is on hold as its developers are focusing on improving MariaDB. However, they are interested in working with interested customers and partners to add more features to Aria and eventually release 2.0.

These are some of the goals for Aria 2.0:

- ACID compliant
- Commit/Rollback
- Concurrent updates/deletes
- Row locking

- Group commit (Already in [MariaDB 5.2](#))
- Faster lookup in index pages (Page directory)

Beginning in Aria 2.5, the plan is to focus on improving performance.

What is the ultimate goal of Aria?

Long term, we have the following goals for Aria:

- To create a new, ACID and Multi-Version Concurrency Control (MVCC), transactional storage engine that can function as both the default non-transactional and transactional storage engine for MariaDB and MySQL®.
- To be a MyISAM replacement. This is possible because Aria can also be run in non-transactional mode, supports the same row formats as MyISAM, and supports or will support all major features of MyISAM.
- To be the default non-transactional engine in MariaDB (instead of MyISAM).

What are the design goals in Aria?

- Multi-Version Concurrency Control (MVCC) and ACID storage engine.
- Optionally non-transactional tables that should be 'as fast and as compact' as MyISAM tables.
- Be able to use Aria for internal temporary tables in MariaDB (instead of MyISAM).
- All indexes should have equal speed (clustered index is not on our current road map for Aria. If you need clustered index, you should use XtraDB).
- Allow 'any' length transactions to work (Having long running transactions will cause more log space to be used).
- Allow log shipping; that is, you can do incremental backups of Aria tables just by copying the Aria logs.
- Allow copying of Aria tables between different Aria servers (under some well-defined constraints).
- Better blob handling (than is currently offered in MyISAM, at a minimum).
- No memory copying or extra memory used for blobs on insert/update.
- Blobs allocated in big sequential blocks - Less fragmentation over time.
- Blobs are stored so that Aria can easily be extended to have access to any part of a blob with a single fetch in the future.
- Efficient storage on disk (that is, low row data overhead, low page data overhead and little lost space on pages).
Note: There is still some more work to succeed with this goal. The disk layout is fine, but we need more in-memory caches to ensure that we get a higher fill factor on the pages.
- Small footprint, to make MariaDB + Aria suitable for desktop and embedded applications.
- Flexible memory allocation and scalable algorithms to utilize large amounts of memory efficiently, when it is available.

Where can I find documentation and help about Aria?

Documentation is available at [Aria](#) and related topics. The project is maintained on [GitHub](#).

If you want to know what happens or be part of developing Aria, you can subscribe to the [developers](#), [docs](#), or [discuss](#) mailing lists.

To report and check bugs in Aria, see [Reporting Bugs](#).

You can usually find some of the Maria developers on our Zulip instance at <https://mariadb.zulipchat.com> or on the IRC channel #maria at <https://libera.chat/>.

Who develops Aria?

The Core Team who develop Aria are:

Technical lead

- Michael "Monty" Widenius - Creator of MySQL and MyISAM

Core Developers (in alphabetical order)

- Guilhem Bichot - Replication expert, on line backup for MyISAM, etc.
- Kristian Nielsen - MySQL build tools, NDB, MySQL server
- Oleksandr Byelkin - Query cache, sub-queries, views.
- Sergei Golubchik - Server Architect, Full text search, keys for MyISAM-Merge, Plugin architecture, etc.

All except Guilhem Bichot are working for [MariaDB Corporation Ab](#).

What is the release policy/schedule of Aria?

Aria follows the same [release criteria](#) as for [MariaDB](#). Some clarifications, unique for the Aria storage engine:

- Aria index and data file formats should be backwards and forwards compatible to ensure easy upgrades and downgrades.
- The [log file](#) format should also be compatible, but we don't make any guarantees yet. In some cases when upgrading, you must remove the old `aria_log.%` and `maria_log.%` files before restarting MariaDB. (So far, this has only occurred in the upgrade from [MariaDB 5.1](#) and [MariaDB 5.2](#)).

Extended commitment for Beta 1.5

- Aria is now feature complete according to specification.

How does Aria 1.5 Compare to MyISAM?

Aria 1.0 was basically a crash-safe non-transactional version of MyISAM. Aria 1.5 added more concurrency (multiple inserters) and some optimizations.

Aria supports all aspects of MyISAM, except as noted below. This includes external and internal check/repair/compressing of rows, different row formats, different index compress formats, `aria_chk` etc. After a normal shutdown you can copy Aria files between servers.

Advantages of Aria compared to MyISAM

- Data and indexes are crash safe.
- On a crash, changes will be rolled back to state of the start of a statement or a last `LOCK TABLES` statement.
- Aria can replay almost everything from the log. (Including `CREATE`, `DROP`, `RENAME`, `TRUNCATE` tables). Therefore, you make a backup of Aria by just copying the log. The things that can't be replayed (yet) are:
 - Batch `INSERT` into an empty table (This includes `LOAD DATA INFILE`, `SELECT... INSERT` and `INSERT` (many rows)).
 - `ALTER TABLE`. Note that `.frm` tables are NOT recreated!
- `LOAD INDEX` can skip index blocks for unwanted indexes.
- Supports all MyISAM `ROW` formats and new `PAGE` format where data is stored in pages. (default size is 8K).
- Multiple concurrent inserters into the same table.
- When using `PAGE` format (default) row data is cached by page cache.
- Aria has unit tests of most parts.
- Supports both crash-safe (soon to be transactional) and not transactional tables. (Non-transactional tables are not logged and rows uses less space): `CREATE TABLE foo (...) TRANSACTIONAL=0|1 ENGINE=Aria`.
- `PAGE` is the only crash-safe/transactional row format.
- `PAGE` format should give a notable speed improvement on systems which have bad data caching. (For example Windows).
- From [MariaDB 10.5](#), max key length is 2000 bytes, compared to 1000 bytes in MyISAM.

Differences between Aria and MyISAM

- Aria uses BIG (1G by default) [log files](#).
- Aria has a log control file (`aria_log_control`) and log files (`aria_log.%`). The log files can be automatically purged when not needed or purged on demand (after backup).
- Aria uses 8K pages by default (MyISAM uses 1K). This makes Aria a bit faster when using keys of fixed size, but slower when using variable-length packed keys (until we add a directory to index pages).

Disadvantages of Aria compared to MyISAM

- Aria doesn't support `INSERT DELAYED`.
- Aria does not support multiple key caches.
- Storage of very small rows (< 25 bytes) are not efficient for `PAGE` format.
- `MERGE` tables don't support Aria (should be very easy to add later).
- Aria data pages in block format have an overhead of 10 bytes/page and 5 bytes/row. Transaction and multiple concurrent-writer support will use an extra overhead of 7 bytes for new rows, 14 bytes for deleted rows and 0 bytes for old compacted rows.
- No external locking (MyISAM has external locking, but this is a rarely used feature).
- Aria has one page size for both index and data (defined when Aria is used the first time). MyISAM supports different page sizes per index.
- Small overhead (15 bytes) per index page.
- Aria doesn't support MySQL internal RAID (disabled in MyISAM too, it's a deprecated feature).
- Minimum data file size for `PAGE` format is 16K (with 8K pages).

- Aria doesn't support indexes on virtual fields.

Differences between [MariaDB 5.1](#) release and the normal MySQL-5.1 release?

See:

- [Aria storage engine](#)
- [MariaDB versus MySQL](#)

Why do you use the `TRANSACTIONAL` keyword now when Aria is not yet transactional?

In the current development phase Aria tables created with `TRANSACTIONAL=1` are crash safe and atomic but not transactional because changes in Aria tables can't be rolled back with the `ROLLBACK` command. As we planned to make Aria tables fully transactional, we decided it was better to use the `TRANSACTIONAL` keyword from the start so that applications don't need to be changed later.

What are the known problems with the MySQL-5.1-Maria release?

- See `KNOWN_BUGS.txt` for open/design bugs.
- See jira.mariadb.org for newly reported bugs. Please report anything you can't find here!
- If there is a bug in the Aria recovery code or in the code that generates the logs, or if the logs become corrupted, then `mysqld` may fail to start because Aria can't execute the logs at start up.
- Query cache and concurrent insert using page row format have a bug, please disable query cache while using page row format and [MDEV-6817](#) isn't complete

If Aria doesn't start or you have an unrecoverable table (shouldn't happen):

- Remove the `aria_log.%` files from the data directory.
- Restart `mysqld` and run [CHECK TABLE](#), [REPAIR TABLE](#) or [mariadb-check](#) on your Aria tables.

Alternatively,

- Remove logs and run [aria_chk](#) on your `*.MAI` files.

What is going to change in later Aria main releases?

The `LOCK TABLES` statement will not start a crash-safe segment. You should use [BEGIN](#) and [COMMIT](#) instead.

To make things future safe, you could do this:

```
BEGIN;
LOCK TABLES ....
UNLOCK TABLES;
COMMIT;
```

And later you can just remove the `LOCK TABLES` and `UNLOCK TABLES` statements.

How can I create a MyISAM-like (non-transactional) table in Aria?

Example:

```
CREATE TABLE t1 (a int) ROW_FORMAT=FIXED TRANSACTIONAL=0 PAGE_CHECKSUM=0;
CREATE TABLE t2 (a int) ROW_FORMAT=DYNAMIC TRANSACTIONAL=0 PAGE_CHECKSUM=0;
SHOW CREATE TABLE t1;
SHOW CREATE TABLE t2;
```

Note that the rows are not cached in the page cache for `FIXED` or `DYNAMIC` format. If you want to have the data cached (something MyISAM doesn't support) you should use `ROW_FORMAT=PAGE` :

```
CREATE TABLE t3 (a int) ROW_FORMAT=PAGE TRANSACTIONAL=0 PAGE_CHECKSUM=0;
SHOW CREATE TABLE t3;
```

You can use `PAGE_CHECKSUM=1` also for non-transactional tables; This puts a page checksums on all index pages. It also puts a checksum on data pages if you use `ROW_FORMAT=PAGE`.

You may still have a speed difference (may be slightly positive or negative) between MyISAM and Aria because of different page sizes. You can change the page size for MariaDB with `--aria-block-size=\ #`, where `\ #` is 1024, 2048, 4096, 8192, 16384 or 32768.

Note that if you change the page size you have to dump all your old tables into text (with [mariadb-dump](#)) and remove the old Aria log and files:

```
# rm datadir/aria_log*
```

What are the advantages/disadvantages of the new `PAGE` format compared to the old MyISAM-like row formats (`DYNAMIC` and `FIXED`)

The MyISAM-like `DYNAMIC` and `FIXED` format are extremely simple and have very little space overhead, so it's hard to beat them for when it comes to simple scanning of unmodified data. The `DYNAMIC` format does however get notably worse over time if you update the row a lot in a manner that increases the size of the row.

The advantages of the `PAGE` format (compared to `DYNAMIC` or `FIXED`) for non-transactional tables are:

- It's cached by the Page Cache, which gives better random performance (as it uses less system calls).
- Does not fragment as easily as the `DYNAMIC` format during `UPDATE` statements. The maximum number of fragments are very low.
- Code can easily be extended to only read the accessed columns (for example to skip reading blobs).
- Faster updates (compared to `DYNAMIC`).

The disadvantages are:

- Slight storage overhead (should only be notable for very small row sizes)
- Slower full table scan time.
- When using `row_format=PAGE`, (the default), Aria first writes the row, then the keys, at which point the check for duplicate keys happens. This makes `PAGE` format slower than `DYNAMIC` (or MyISAM) if there is a lot of duplicated keys because of the overhead of writing and removing the row. If this is a problem, you can use `row_format=DYNAMIC` to get same behavior as MyISAM.

What's the proper way to copy a Aria table from one place to another?

An Aria table consists of 3 files:

```
XXX.frm : The definition for the table, used by MySQL.
XXX.MYI : Aria internal information about the structure of the data and index and data for all in
XXX.MAD : The data.
```

It's safe to copy all the Aria files to another directory or MariaDB instance if any of the following holds:

- If you shutdown the MariaDB Server properly with [mariadb-admin shutdown](#), so that there is nothing for Aria to recover when it starts.

or

- If you have run a [FLUSH TABLES](#) statement and not accessed the table using SQL from that time until the tables have been copied.

In addition, you must adhere the following rule for transactional tables:

You can't copy the table to a location within the same MariaDB server if the new table has existed before and the new table is still active in the Aria recovery log (that is, Aria may need to access the old data during recovery). If you are unsure whether the old name existed, run [aria_chk --zerofill](#) on the table before you use it.

After copying a transactional table and before you use the table, we recommend that you run the command:

```
$ aria_chk --zerofill table_name
```

This will overwrite all references to the logs (LSN), all transactional references (TRN) and all unused space with 0. It also marks the table as 'movable'. An additional benefit of zerofill is that the Aria files will compress better. No real data is ever removed as part of zerofill.

Aria will automatically notice if you have copied a table from another system and do 'zerofill' for the first access of the table if it was not marked as 'movable'. The reason for using [aria_chk --zerofill](#) is that you avoid a delay in the MariaDB server for the first access of the table.

Note that this automatic detection doesn't work if you copy tables within the same MariaDB server!

When is it safe to remove old log files?

If you want to remove the [Aria log files](#) (`aria_log.*`) with `rm` or `delete`, then you must first shut down MariaDB cleanly (for example, with [mariadb-admin shutdown](#)) before deleting the old files.

The same rules apply when upgrading MariaDB; When upgrading, first take down MariaDB in a clean way and then upgrade. This will allow you to remove the old log files if there are incompatible problems between releases.

Don't remove the `aria_log_control` file! This is not a log file, but a file that contains information about the Aria setup (current transaction id, unique id, next log file number etc.).

If you do, Aria will generate a new `aria_log_control` file at startup and will regard all old Aria files as files moved from another system. This means that they have to be 'zerofilled' before they can be used. This will happen automatically at next access of the Aria files, which can take some time if the files are big.

If this happens, you will see things like this in your `mysqld.err` file:

```
[Note] Zerofilling moved table: './database\xxxx'
```

As part of zerofilling no vital data is removed.

How does one solve the Missing valid id error?

See [Aria Log Files](#) for details.

5.3.4.4 Aria Storage Formats

Contents

1. [Fixed-length](#)
2. [Dynamic](#)
3. [Page](#)
4. [Transactional](#)

The [Aria](#) storage engine supports three different table storage formats.

These are FIXED, DYNAMIC and PAGE, and they can be set with the ROW FORMAT option in the [CREATE TABLE](#) statement. PAGE is the default format, while FIXED and DYNAMIC are essentially the same as the [MyISAM formats](#).

The [SHOW TABLE STATUS](#) statement can be used to see the storage format used by a table.

Fixed-length

Fixed-length (or static) tables contain records of a fixed-length. Each column is the same length for all records, regardless of the actual contents. It is the default format if a table has no BLOB, TEXT, VARCHAR or VARBINARY fields, and no ROW FORMAT is provided. You can also specify a fixed table with ROW_FORMAT=FIXED in the table definition.

Tables containing BLOB or TEXT fields cannot be FIXED, as by design these are both dynamic fields.

Fixed-length tables have a number of characteristics

- fast, since MariaDB will always know where a record begins
- easy to cache
- take up more space than dynamic tables, as the maximum amount of storage space will be allocated to each record.

- reconstructing after a crash is uncomplicated due to the fixed positions
- no fragmentation or need to re-organize, unless records have been deleted and you want to free the space up.

Dynamic

Dynamic tables contain records of a variable length. It is the default format if a table has any BLOB, TEXT, VARCHAR or VARBINARY fields, and no ROW FORMAT is provided. You can also specify a DYNAMIC table with ROW_FORMAT=DYNAMIC in the table definition.

Dynamic tables have a number of characteristics

- Each row contains a header indicating the length of the row.
- Rows tend to become fragmented easily. UPDATING a record to be longer will likely ensure it is stored in different places on the disk.
- All string columns with a length of four or more are dynamic.
- They require much less space than fixed-length tables.
- Restoring after a crash is more complicated than with FIXED tables.

Page

Page format is the default format for Aria tables, and is the only format that can be used if TRANSACTIONAL=1.

Page tables have a number of characteristics:

- It's cached by the page cache, which gives better random performance as it uses fewer system calls.
- Does not fragment as easily as the DYNAMIC format during UPDATES. The maximum number of fragments are very low.
- Updates more quickly than dynamic tables.
- Has a slight storage overhead, mainly notable on very small rows
- Slower to perform a full table scan
- Slower if there are multiple duplicated keys, as Aria will first write a row, then keys, and only then check for duplicates

Transactional

See [Aria Storage Engine](#) for the impact of the TRANSACTIONAL option on the row format.

5.3.4.5 Aria Status Variables

Contents

1. [Aria_pagecache_blocks_not_flushed](#)
2. [Aria_pagecache_blocks_unused](#)
3. [Aria_pagecache_blocks_used](#)
4. [Aria_pagecache_read_requests](#)
5. [Aria_pagecache_reads](#)
6. [Aria_pagecache_write_requests](#)
7. [Aria_pagecache_writes](#)
8. [Aria_transaction_log_syncs](#)

This page documents status variables related to the [Aria storage engine](#). See [Server Status Variables](#) for a complete list of status variables that can be viewed with [SHOW STATUS](#).

See also the [Full list of MariaDB options, system and status variables](#).

`Aria_pagecache_blocks_not_flushed`

- **Description:** The number of dirty blocks in the Aria page cache. The global value can be flushed by [FLUSH STATUS](#).
- **Scope:** Global
- **Data Type:** `numeric`

`Aria_pagecache_blocks_unused`

- **Description:** Free blocks in the Aria page cache. The global value can be flushed by [FLUSH STATUS](#).
- **Scope:** Global
- **Data Type:** `numeric`

Aria_pagecache_blocks_used

- **Description:** Blocks used in the Aria page cache. The global value can be flushed by `FLUSH STATUS` .
 - **Scope:** Global
 - **Data Type:** `numeric`
-

Aria_pagecache_read_requests

- **Description:** The number of requests to read something from the Aria page cache.
 - **Scope:** Global
 - **Data Type:** `numeric`
-

Aria_pagecache_reads

- **Description:** The number of Aria page cache read requests that caused a block to be read from the disk.
 - **Scope:** Global
 - **Data Type:** `numeric`
-

Aria_pagecache_write_requests

- **Description:** The number of requests to write a block to the Aria page cache.
 - **Scope:** Global
 - **Data Type:** `numeric`
-

Aria_pagecache_writes

- **Description:** The number of blocks written to disk from the Aria page cache.
 - **Scope:** Global
 - **Data Type:** `numeric`
-

Aria_transaction_log_syncs

- **Description:** The number of Aria log fsyncs.
 - **Scope:** Global
 - **Data Type:** `numeric`
-

5.3.4.6 Aria System Variables

Contents

1. [aria_block_size](#)
2. [aria_checkpoint_interval](#)
3. [aria_checkpoint_log_activity](#)
4. [aria_encrypt_tables](#)
5. [aria_force_start_after_recovery_failures](#)
6. [aria_group_commit](#)
7. [aria_group_commit_interval](#)
8. [aria_log_dir_path](#)
9. [aria_log_file_size](#)
10. [aria_log_purge_type](#)
11. [aria_max_sort_file_size](#)
12. [aria_page_checksum](#)
13. [aria_pagecache_age_threshold](#)
14. [aria_pagecache_buffer_size](#)
15. [aria_pagecache_division_limit](#)
16. [aria_pagecache_file_hash_size](#)
17. [aria_recover](#)
18. [aria_recover_options](#)
19. [aria_repair_threads](#)
20. [aria_sort_buffer_size](#)
21. [aria_stats_method](#)
22. [aria_sync_log_dir](#)
23. [aria_used_for_temp_tables](#)
24. [deadlock_search_depth_long](#)
25. [deadlock_search_depth_short](#)
26. [deadlock_timeout_long](#)
27. [deadlock_timeout_short](#)

This page documents system variables related to the [Aria storage engine](#). For options that are not system variables, see [Aria Options](#).

See [Server System Variables](#) for a complete list of system variables and instructions on setting system variables.

Also see the [Full list of MariaDB options, system and status variables](#).

`aria_block_size`

- **Description:** Block size to be used for Aria index pages. Changing this requires dumping, deleting old tables and deleting all log files, and then restoring your Aria tables. If key lookups take too long (and one has to search roughly 8192/2 by default to find each key), can be made smaller, e.g. 4096 .
- **Commandline:** `--aria-block-size=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** 8192
- **Range:**
 - `>= MariaDB 10.4.7`: 4096 to 32768 in increments of 1024
 - `<= MariaDB 10.4.6`: 1024 to 32768 in increments of 1024

`aria_checkpoint_interval`

- **Description:** Interval in seconds between automatic checkpoints. 0 means 'no automatic checkpoints' which makes sense only for testing.
- **Commandline:** `--aria-checkpoint-interval=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** 30
- **Range:** 0 to 4294967295

`aria_checkpoint_log_activity`

- **Description:** Number of bytes that the transaction log has to grow between checkpoints before a new checkpoint is written to the log.

- **Commandline:** `aria-checkpoint-log-activity=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `1048576`
 - **Range** `0` to `4294967295`
-

`aria_encrypt_tables`

- **Description:** Enables automatic encryption of all user-created Aria tables that have the `ROW_FORMAT` table option set to `PAGE`. See [Data at Rest Encryption](#) and [Enabling Encryption for User-created Tables](#).
 - **Commandline:** `aria-encrypt-tables={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
-

`aria_force_start_after_recovery_failures`

- **Description:** Number of consecutive log recovery failures after which logs will be automatically deleted to cure the problem; 0 (the default) disables the feature.
 - **Commandline:** `--aria-force-start-after-recovery-failures=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:** `0`
-

`aria_group_commit`

- **Description:** Specifies Aria [group commit mode](#).
 - **Commandline:** `--aria_group_commit="value"`
 - **Alias:** `maria_group_commit`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `string`
 - **Valid values:**
 - `none` - *Group commit is disabled.*
 - `hard` - *Wait the number of microseconds specified by `aria_group_commit_interval` before actually doing the commit. If the interval is 0 then just check if any other threads have requested a commit during the time this commit was preparing (just before `sync()` file) and send their data to disk also before `sync()`.*
 - `soft` - *The service thread will wait the specified time and then `sync()` to the log. If the interval is 0 then it won't wait for any commits (this is dangerous and should generally not be used in production)*
 - **Default Value:** `none`
-

`aria_group_commit_interval`

- **Description:** Interval between [Aria group commits](#) in microseconds (1/1000000 second) for other threads to come and do a commit in "hard" mode and `sync()/commit` at all in "soft" mode. Option only has effect if [aria_group_commit](#) is used.
 - **Commandline:** `--aria_group_commit_interval=#`
 - **Alias:** `maria_group_commit_interval`
 - **Scope:** Global
 - **Dynamic:** No
 - **Type:** `numeric`
 - **Valid Values:**
 - **Default Value:** `0` (*no waiting*)
 - **Range:** `0-4294967295`
-

`aria_log_dir_path`

- **Description:** Path to the directory where transactional log should be stored
 - **Commandline:** `--aria-log-dir-path=value`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `string`
 - **Default Value:** Same as DATADIR
 - **Introduced:** [MariaDB 10.5.20](#), [MariaDB 10.6.13](#), [MariaDB 10.11.3](#) (as a system variable, existed as an option only before that)
-

`aria_log_file_size`

- **Description:** Limit for Aria transaction log size
 - **Commandline:** `--aria-log-file-size=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `1073741824`
-

`aria_log_purge_type`

- **Description:** Specifies how the Aria transactional log will be purged. Set to `at_flush` to keep a copy of the transaction logs (good as an extra backup). The logs will stay until the next [FLUSH LOGS](#);
 - **Commandline:** `--aria-log-purge-type=name`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `enumeration`
 - **Default Value:** `immediate`
 - **Valid Values:** `immediate, external, at_flush`
-

`aria_max_sort_file_size`

- **Description:** Don't use the fast sort index method to created index if the temporary file would get bigger than this.
 - **Commandline:** `--aria-max-sort-file-size=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `9223372036853727232`
 - **Range:** `0 to 9223372036854775807`
-

`aria_page_checksum`

- **Description:** Determines whether index and data should use page checksums for extra safety. Can be overridden per table with `PAGE_CHECKSUM` clause in [CREATE TABLE](#).
 - **Commandline:** `--aria-page-checksum=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `ON`
-

`aria_pagecache_age_threshold`

- **Description:** This characterizes the number of hits a hot block has to be untouched until it is considered aged enough to be downgraded to a warm block. This specifies the percentage ratio of that number of hits to the total number of blocks in the page cache.
 - **Commandline:** `--aria-pagecache-age-threshold=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `300`
 - **Range:** `100 to 9999900`
-

aria_pagecache_buffer_size

- **Description:** The size of the buffer used for index and data blocks for Aria tables. This can include explicit Aria tables, system tables, and temporary tables. Increase this to get better handling and measure by looking at [aria-status-variables/#aria_pagecache_reads](#) (should be small) vs [aria-status-variables/#aria_pagecache_read_requests](#).
 - **Commandline:** `--aria-pagecache-buffer-size=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:** `134217720` (128MB)
 - **Range:** `131072` (128KB) upwards
-

aria_pagecache_division_limit

- **Description:** The minimum percentage of warm blocks in the key cache.
 - **Commandline:** `--aria-pagecache-division-limit=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `100`
 - **Range:** `1` to `100`
-

aria_pagecache_file_hash_size

- **Description:** Number of hash buckets for open and changed files. If you have many Aria files open you should increase this for faster flushing of changes. A good value is probably 1/10th of the number of possible open Aria files.
 - **Commandline:** `--aria-pagecache-file-hash-size=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:** `512`
 - **Range:** `128` to `16384`
-

aria_recover

- **Description:** `aria_recover` has been renamed to `aria_recover_options` in [MariaDB 10.2.0](#). See [aria_recover_options](#) for the description.
-

aria_recover_options

- **Description:** Specifies how corrupted tables should be automatically repaired. More than one option can be specified, for example `FORCE, BACKUP`.
 - `NORMAL`: Normal automatic repair, the default until [MariaDB 10.2.3](#)
 - `OFF`: Autorecovery is disabled, the equivalent of not using the option
 - `QUICK`: Does not check rows in the table if there are no delete blocks.
 - `FORCE`: Runs the recovery even if it determines that more than one row from the data file will be lost.
 - `BACKUP`: Keeps a backup of the data files.
 - **Commandline:** `--aria-recover-options[=#]`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `enumeration`
 - **Default Value:**
 - `BACKUP, QUICK` (\geq [MariaDB 10.2.4](#))
 - `NORMAL` (\leq [MariaDB 10.2.3](#))
 - **Valid Values:** `NORMAL`, `BACKUP`, `FORCE`, `QUICK`, `OFF`
 - **Introduced:** [MariaDB 10.2.0](#)
-

aria_repair_threads

- **Description:** Number of threads to use when repairing Aria tables. The value of 1 disables parallel repair. Increasing from the default will usually result in faster repair, but will use more CPU and memory.
 - **Commandline:** `--aria-repair-threads=#`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** 1
-

`aria_sort_buffer_size`

- **Description:** The buffer that is allocated when sorting the index when doing a [REPAIR](#) or when creating indexes with [CREATE INDEX](#) or [ALTER TABLE](#).
 - **Commandline:** `--aria-sort-buffer-size=#`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** 268434432
-

`aria_stats_method`

- **Description:** Determines how NULLs are treated for Aria index statistics purposes. If set to `nulls_equal`, all NULL index values are treated as a single group. This is usually fine, but if you have large numbers of NULLs the average group size is slanted higher, and the optimizer may miss using the index for ref accesses when it would be useful. If set to `nulls_unequal`, the default, the opposite approach is taken, with each NULL forming its own group of one. Conversely, the average group size is slanted lower, and the optimizer may use the index for ref accesses when not suitable. Setting to `nulls_ignored` ignores NULLs altogether from index group calculations. Statistics need to be recalculated after this method is changed. See also [Index Statistics](#), [myisam_stats_method](#) and [innodb_stats_method](#).
 - **Commandline:** `--aria-stats-method=#`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `nulls_unequal`
 - **Valid Values:** `nulls_equal`, `nulls_unequal`, `nulls_ignored`
-

`aria_sync_log_dir`

- **Description:** Controls syncing directory after log file growth and new file creation.
 - **Commandline:** `--aria-sync-log-dir=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `enumeration`
 - **Default Value:** `NEWFILE`
 - **Valid Values:** `NEWFILE`, `NEVER`, `ALWAYS`
-

`aria_used_for_temp_tables`

- **Description:** Readonly variable indicating whether the [Aria](#) storage engine is used for temporary tables. If set to `ON`, the default, the Aria storage engine is used. If set to `OFF`, MariaDB reverts to using [MyISAM](#) for on-disk temporary tables. The [MEMORY](#) storage engine is used for temporary tables regardless of this variable's setting where appropriate. The default can be changed by not using the `--with-aria-tmp-tables` option when building MariaDB.
 - **Commandline:** No
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `ON`
-

`deadlock_search_depth_long`

- **Description:** Long search depth for the [two-step deadlock detection](#). Only used by the [Aria](#) storage engine.
 - **Commandline:** `--deadlock-search-depth-long=#`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** 15
 - **Range:** 0 to 33
-

`deadlock_search_depth_short`

- **Description:** Short search depth for the [two-step deadlock detection](#). Only used by the [Aria](#) storage engine.
 - **Commandline:** `--deadlock-search-depth-short=#`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** 4
 - **Range:** 0 to 32
-

`deadlock_timeout_long`

- **Description:** Long timeout in microseconds for the [two-step deadlock detection](#). Only used by the [Aria](#) storage engine.
 - **Commandline:** `--deadlock-timeout-long=#`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** 50000000
 - **Range:** 0 to 4294967295
-

`deadlock_timeout_short`

- **Description:** Short timeout in microseconds for the [two-step deadlock detection](#). Only used by the [Aria](#) storage engine.
 - **Commandline:** `--deadlock-timeout-short=#`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** 10000
 - **Range:** 0 to 4294967295
-

5.3.4.7 Aria Group Commit

Since [MariaDB 5.2](#), the [Aria storage engine](#) has included a feature to group commits to speed up concurrent threads doing many inserts into the same or different Aria tables.

By default, group commit for Aria is turned off. It is controlled by the [aria_group_commit](#) and [aria_group_commit_interval](#) system variables.

Information on setting server variables can be found on the [Server System Variables](#) page.

Terminology

- A `commit` is `flush of logs` followed by a `sync`.
- `sent to disk` means written to disk but not `sync()`ed,
- `flushed` mean sent to disk and `synced()`.
- `LSN` means log serial number. It's refers to the position in the transaction log.

Non Group commit logic (`aria_group_commit="none"`)

The thread which first started the `commit` is performing the actual flush of logs. Other threads set the new goal (LSN) of the next pass (if it is maximum) and wait for the pass end or just wait for the pass end.

The effect of this is that a flush (write of logs + sync) will save all data for all threads/transactions that have been waiting since the last flush.

If hard group commit is enabled (`aria_group_commit="hard"`)

If hard commit and `aria_group_commit_interval=0`

The first thread sends all changed buffers to disk. This is repeated as long as there are new LSNs added. The process can not loop forever because we have a limited number of threads and they will wait for the data to be synced.

Pseudo code:

```
do
    send changed buffers to disk
while new_goal
sync
```

If hard commit and `aria_group_commit_interval > 0`

If less than rate microseconds has passed since the last sync, then after buffers have been sent to disk, wait until rate microseconds has passed since last sync, do sync and return. This ensures that if we call sync infrequently we don't do any waits.

If soft group commit is enabled (`aria_group_commit="soft"`)

Note that soft group commit should only be used if you can afford to lose a few rows if your machine shuts down hard (as in the case of a power failure).

Works like in `non_group_commit'` but the thread doesn't do any real `sync()`. If `aria_group_commit_interval` is not zero, the `sync()` will be performed by a service thread with the given rate when needed (new LSN appears). If `aria_group_commit_interval` is zero, there will be no `sync()` calls.

Code

The code for this can be found in `storage/maria/ma_loghandler.c::translog_flush()`

5.3.4.8 Benchmarking Aria

We have not yet had time to benchmark [Aria](#) properly. Here follows some things that have been discussed on the [maria-discuss](#) email list.

Aria used for internal temporary tables

By default Aria (instead of MyISAM) is used for the internal temporary tables when MEMORY tables overflows to disk or MEMORY tables can't be used (for example when you are using temporary results with BLOB's). In most cases Aria should give you better performance than using MyISAM, but this is not always the case.

```
CREATE TABLE `t1` (`id` int(11) DEFAULT NULL, `tea` text)
ENGINE=MyISAM DEFAULT CHARSET=latin1;
insert t1 select rand()*2e8, repeat(rand(), rand()*64) from t1;
```

Repeat the last row until you get 2097152 rows.

The queries tested

```

Q1: SELECT id, tea from t1 group by left(id,1) order by null;
Q2: SELECT id, count(*), tea from t1 group by left(id,1) order by null;
Q3: SELECT id, tea from t1 group by left(id,2) order by null;
Q4: SELECT id, count(*), tea from t1 group by left(id,2) order by null;
Q5: SELECT id, tea from t1 group by id % 100 order by null;
Q6: SELECT id, count(*), tea from t1 group by id % 100 order by null;

```

Results (times in seconds, lower is better):

Test	Aria 8K page size	Aria 2K page size	MyISAM
Q1	3.08	2.41	2.17
Q2	6.24	5.21	12.89
Q3	4.87	4.05	4.04
Q4	8.20	7.04	15.14
Q5	7.10	6.37	6.28
Q6	10.38	9.09	17.00

The good news is that for common group by queries that is using summary functions there is a close to 50 % speedup of using Aria for internal temporary tables.

Note that queries Q1,Q3 and Q5 are not typical queries as there is no sum functions involved. In this case rows are just written to the tmp tables and there is no updates. As soon as there are summary functions and updates the new row format in Aria gives a close to 50 % speedup.

The above table also shows how the page size (determined by the [aria_block_size](#) system variable) affects the performance. The reason for the difference is that there is more data to move back/from the page cache for inserting of keys. (When reading data we are normally not copying pages). The bigger page size however allows longer keys and fewer index levels so for bigger data sets the difference should be smaller. It's possible to in the future optimize Aria to not copy pages from the page cache also for index writes and then this difference should disappear.

The default page size for Aria is 8K.

If you want to run MariaDB with MyISAM for temporary tables, don't use the configure option '--with-aria-tmp-tables' when building MariaDB.

5.3.4.9 Aria Two-step Deadlock Detection

Description

The [Aria](#) storage engine can automatically detect and deal with deadlocks (see the [Wikipedia deadlocks article](#) [↗](#)).

This feature is controlled by four configuration variables, two that control the search depth and two that control the timeout.

- [deadlock_search_depth_long](#)
- [deadlock_search_depth_short](#)
- [deadlock_timeout_long](#)
- [deadlock_timeout_short](#)

How it Works

If Aria is ever unable to obtain a lock, we might have a deadlock. There are two primary ways for detecting if a deadlock has actually occurred. First is to search a wait-for graph (see the [wait-for graph on Wikipedia](#) [↗](#)) and the second is to just wait and let the deadlock exhibit itself. Aria Two-step Deadlock Detection does a combination of both.

First, if the lock request cannot be granted immediately, we do a short search of the wait-for graph with a small search depth as configured by the `deadlock_search_depth_short` variable. We have a depth limit because the graph can (theoretically) be arbitrarily big and we don't want to recursively search the graph arbitrarily deep. This initial, short search is very fast and most deadlocks will be detected right away. If no deadlock cycles are found with the short search the system waits for the amount of time configured in `deadlock_timeout_short` to see if the lock conflicts will be removed and the lock can be granted. Assuming this did not happen and the lock request still waits, the system then moves on to step two, which is a repeat of the process but this time searching deeper using the `deadlock_search_depth_long`. If no deadlock has been detected, it waits `deadlock_timeout_long` and times out.

When a deadlock is detected the system uses a weighting algorithm to determine which thread in the deadlock should be

killed and then kills it.

5.3.4.10 Aria Encryption Overview

Contents

1. [Basic Configuration](#)
2. [Determining Whether a Table is Encrypted](#)
3. [Encryption and the Aria Log](#)

MariaDB can encrypt data in tables that use the [Aria storage engine](#). This includes both user-created tables and internal on-disk temporary tables that use the Aria storage engine. This ensures that your Aria data is only accessible through MariaDB.

For encryption with the InnoDB and XtraDB storage engines, see [Encrypting Data for InnoDB/XtraDB](#).

Basic Configuration

In order to enable encryption for tables using the [Aria storage engine](#), there are a couple server system variables that you need to set and configure. Most users will want to set `aria_encrypt_tables` and `encrypt_tmp_disk_tables`.

Users of data-at-rest encryption will also need to have a [key management and encryption plugin](#) configured. Some examples are [File Key Management Plugin](#) and [AWS Key Management Plugin](#).

```
[mariadb]
...

# File Key Management
plugin_load_add = file_key_management
file_key_management_filename = /etc/mysql/encryption/keyfile.enc
file_key_management_filekey = FILE:/etc/mysql/encryption/keyfile.key
file_key_management_encryption_algorithm = AES_CTR

# Aria Encryption
aria_encrypt_tables=ON
encrypt_tmp_disk_tables=ON
```

Determining Whether a Table is Encrypted

The [InnoDB storage engine](#) has the `information_schema.INNODB_TABLESPACES_ENCRYPTION` table that can be used to get information about which tables are encrypted. Aria does not currently have anything like that (see [MDEV-17324](#) about that).

To determine whether an Aria table is encrypted, you currently have to search the data file for some plain text that you know is in the data.

For example, let's say that we have the following table:

```
SELECT * FROM db1.aria_tab LIMIT 1;
+----+-----+
| id | str |
+----+-----+
| 1 | str1 |
+----+-----+
1 row in set (0.00 sec)
```

Then, we could search the data file that belongs to `db1.aria_tab` for `str1` using a command-line tool, such as [strings](#):

```
$ sudo strings /var/lib/mysql/db1/aria_tab.MAD | grep "str1"
str1
```

If you can find the plain text of the string, then you know that the table is not encrypted.

Encryption and the Aria Log

Only Aria tables are currently encrypted. The [Aria log](#) is not yet encrypted. See [MDEV-8587](#) about that.

5.3.4.11 The Aria Name

Contents

1. [Backstory](#)
2. [Renaming Maria \(the engine\)](#)

The [Aria](#) storage engine used to be called Maria. This page gives the history and background of how and why this name was changed to Aria.

Backstory

When starting what became the MariaDB project, Monty and the initial developers only planned to work on a next generation [MyISAM](#) storage engine replacement. This storage engine would be crash safe and eventually support transactions. Monty named the storage engine, and the project, after his daughter, Maria.

Work began in earnest on the Maria storage engine but the plans quickly expanded and morphed and soon the developers were not just working on a storage engine, but on a complete branch of the MySQL database. Since the project was already called Maria, it made sense to call the whole database server MariaDB.

Renaming Maria (the engine)

So now there was the database, MariaDB, and the storage engine, Maria. To end the confusion this caused, the decision was made to rename the storage engine.

Monty's first suggestion was to name it *Lucy*, after his dog, but few who heard it liked that idea. So the decision was made that the next best thing was for the community to suggest and vote on names.

This was done by running a contest in 2009 through the end of May 2010. After that the best names were voted on by the community and Monty picked and [announced the winner](#) (Aria) at OSCon 2010 in Portland.

The winning entry was submitted by Chris Tooley. He received a Linux-powered [System 76](#) Meerkat NetTop as his prize for suggesting the winning name from Monty Program.

5.3.5 Archive

The [ARCHIVE](#) storage engine is a storage engine that uses gzip to compress rows. It is mainly used for storing large amounts of data, without indexes, with only a very small footprint.

A table using the [ARCHIVE](#) storage engine is stored in two files on disk. There's a table definition file with an extension of `.frm`, and a data file with the extension `.ARZ`. At times during optimization, a `.ARN` file will appear.

New rows are inserted into a compression buffer and are flushed to disk when needed. `SELECT`s cause a flush. Sometimes, rows created by multi-row inserts are not visible until the statement is complete.

[ARCHIVE](#) allows a maximum of one key. The key must be on an [AUTO_INCREMENT](#) column, and can be a [PRIMARY KEY](#) or a non-unique key. However, it has a limitation: it is not possible to insert a value which is lower than the next [AUTO_INCREMENT](#) value.

Contents

1. [Installing the Plugin](#)
2. [Uninstalling the Plugin](#)
3. [Characteristics](#)

Installing the Plugin

Although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing `INSTALL SONAME` or `INSTALL PLUGIN`. For example:

```
INSTALL SONAME 'ha_archive';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the `--plugin-load` or the `--plugin-load-add` options. This can be specified as a command-line argument to `mysqld` or it can be specified in a relevant server [option group](#) in an [option file](#). For example:

```
[mariadb]
...
plugin_load_add = ha_archive
```

Uninstalling the Plugin

You can uninstall the plugin dynamically by executing `UNINSTALL SONAME` or `UNINSTALL PLUGIN`. For example:

```
UNINSTALL SONAME 'ha_archive';
```

If you installed the plugin by providing the `--plugin-load` or the `--plugin-load-add` options in a relevant server [option group](#) in an [option file](#), then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

Characteristics

- Supports [INSERT](#) and [SELECT](#), but not [DELETE](#), [UPDATE](#) or [REPLACE](#).
- Data is compressed with zlib as it is inserted, making it very small.
- Data is slow the select, as it needs to be uncompressed, and, besides the [query cache](#), there is no cache.
- Supports `AUTO_INCREMENT` (since MariaDB/MySQL 5.1.6), which can be a unique or a non-unique index.
- Since MariaDB/MySQL 5.1.6, selects scan past BLOB columns unless they are specifically requested, making these queries much more efficient.
- Does not support [spatial](#) [data types](#).
- Does not support [transactions](#).
- Does not support foreign keys.
- Does not support [virtual columns](#).
- No storage limit.
- Supports row locking.
- Supports [table discovery](#), and the server can access ARCHIVE tables even if the corresponding `.frm` file is missing.
- [OPTIMIZE TABLE](#) and [REPAIR TABLE](#) can be used to compress the table in its entirety, resulting in slightly better compression.
- With MariaDB, it is possible to upgrade from the MySQL 5.0 format without having to dump the tables.
- [INSERT DELAYED](#) is supported.
- Running many SELECTs during the insertions can deteriorate the compression, unless only multi-rows INSERTs and INSERT DELAYED are used.

No items found.

There are [3 related questions](#).

5.3.6 BLACKHOLE

The `BLACKHOLE` storage engine accepts data but does not store it and always returns an empty result.

A table using the `BLACKHOLE` storage engine consists of a single `.frm` table format file, but no associated data or index files.

This storage engine can be useful, for example, if you want to run complex filtering rules on a slave without incurring any overhead on a master. The master can run a `BLACKHOLE` storage engine, with the data replicated to the slave for processing.

Contents

1. [Installing the Plugin](#)
2. [Uninstalling the Plugin](#)
3. [Using the BLACKHOLE Storage Engine](#)
 1. [Using with DML](#)
 2. [Using with Replication](#)
 3. [Using with Triggers](#)
 4. [Using with Foreign Keys](#)
 5. [Using with Virtual Columns](#)
 6. [Using with AUTO_INCREMENT](#)
4. [Limits](#)
5. [Examples](#)

Installing the Plugin

Although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing [INSTALL SONAME](#) or [INSTALL PLUGIN](#). For example:

```
INSTALL SONAME 'ha_blackhole';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the `--plugin-load` or the `--plugin-load-add` options. This can be specified as a command-line argument to [mysqld](#) or it can be specified in a relevant server [option group](#) in an [option file](#). For example:

```
[mariadb]
...
plugin_load_add = ha_blackhole
```

Uninstalling the Plugin

You can uninstall the plugin dynamically by executing [UNINSTALL SONAME](#) or [UNINSTALL PLUGIN](#). For example:

```
UNINSTALL SONAME 'ha_blackhole';
```

If you installed the plugin by providing the `--plugin-load` or the `--plugin-load-add` options in a relevant server [option group](#) in an [option file](#), then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

Using the BLACKHOLE Storage Engine

Using with DML

[INSERT](#), [UPDATE](#), and [DELETE](#) statements all work with the `BLACKHOLE` storage engine. However, no data changes are actually applied.

Using with Replication

If the binary log is enabled, all SQL statements will be logged as usual, and replicated to any slave servers. However, since rows are not stored, it is important to use statement-based rather than the row or mixed format, as [UPDATE](#) and [DELETE](#) statements are neither logged nor replicated. See [Binary Log Formats](#).

Using with Triggers

Some [triggers](#) work with the `BLACKHOLE` storage engine.

`BEFORE` [triggers](#) for [INSERT](#) statements are still activated.

[Triggers](#) for [UPDATE](#) and [DELETE](#) statements are **not** activated.

[Triggers](#) with the `FOR EACH ROW` clause do not apply, since the tables have no rows.

Using with Foreign Keys

Foreign keys are not supported. If you convert an [InnoDB](#) table to `BLACKHOLE`, then the foreign keys will disappear. If you convert the same table back to InnoDB, then you will have to recreate them.

Using with Virtual Columns

If you convert an [InnoDB](#) table which contains [virtual columns](#) to `BLACKHOLE`, then it produces an error.

Using with AUTO_INCREMENT

Because a `BLACKHOLE` table does not store data, it will not maintain the [AUTO_INCREMENT](#) value. If you are replicating to a table that can handle `AUTO_INCREMENT` columns, and are not explicitly setting the primary key auto-increment value in the [INSERT](#) query, or using the [SET INSERT_ID](#) statement, inserts will fail on the slave due to duplicate keys.

Limits

The maximum key size is:

- 3500 bytes (>= [MariaDB 10.1.48](#), [MariaDB 10.2.35](#), [MariaDB 10.3.26](#), [MariaDB 10.4.16](#) and [MariaDB 10.5.7](#))
- 1000 bytes (<= [MariaDB 10.1.47](#), [MariaDB 10.2.34](#), [MariaDB 10.3.25](#), [MariaDB 10.4.15](#) and [MariaDB 10.5.6](#)).

Examples

```
CREATE TABLE table_name (  
  id int unsigned primary key not null,  
  v varchar(30)  
) ENGINE=BLACKHOLE;  
  
INSERT INTO table_name VALUES (1, 'bob'), (2, 'jane');  
  
SELECT * FROM table_name;  
Empty set (0.001 sec)
```

5.3.7 CONNECT

Note: You can download a [PDF version of the CONNECT documentation](#) (1.7.0003).

Connect Version	Introduced	Maturity
Connect 1.07.0002	MariaDB 10.5.9 , MariaDB 10.4.18 , MariaDB 10.3.28 , MariaDB 10.2.36	Stable

Connect 1.04.0003	MariaDB 10.1.9	Beta

The CONNECT storage engine enables MariaDB to access external local or remote data (MED). This is done by defining tables based on different data types, in particular files in various formats, data extracted from other DBMS or products (such as Excel or MongoDB) via ODBC or JDBC, or data retrieved from the environment (for example DIR, WMI, and MAC tables)

This storage engine supports table partitioning, MariaDB virtual columns and permits defining *special* columns such as ROWID, FILEID, and SERVID.

No precise definition of maturity exists. Because CONNECT handles many table types, each type has a different maturity depending on whether it is old and well-tested, less well-tested or newly implemented. This will be indicated for all data types.

CONNECT Data Types

Data types supported by CONNECT.

Current Status of the CONNECT Handler

The current CONNECT handler is a stable release.

CONNECT Table Types

CONNECT Table Types Overview

CONNECT can handle many table formats.

Inward and Outward Tables

The two broad categories of CONNECT tables.

CONNECT Table Types - Data Files

CONNECT plain DOS or UNIX data files.

CONNECT Zipped File Tables

When the table file or files are compressed in one or several zip files.

CONNECT DOS and FIX Table Types

CONNECT tables based on text files

CONNECT DBF Table Type

CONNECT dBASE III or IV tables.

CONNECT BIN Table Type

CONNECT binary files in which each row is a logical record of fixed length

CONNECT VEC Table Type

CONNECT binary files organized in vectors

CONNECT CSV and FMT Table Types

Variable length CONNECT data files.

CONNECT - NoSQL Table Types

Based on files that do not match the relational format but often represent hierarchical data.

CONNECT - Files Retrieved Using Rest Queries

JSON, XML and CSV data files can be retrieved as results from REST queries.

CONNECT JSON Table Type

JSON (JavaScript Object Notation) is a widely-used lightweight data-interchange format.

CONNECT XML Table Type

CONNECT XML files

CONNECT INI Table Type

CONNECT INI Windows configuration or initialization files.

CONNECT - External Table Types

Access tables belonging to the current or another server.

CONNECT ODBC Table Type: Accessing Tables From Another DBMS

CONNECT Table Types - ODBC Table Type: Accessing Tables from other DBMS

CONNECT JDBC Table Type: Accessing Tables from Another DBMS

Using JDBC to access other tables.

CONNECT MONGO Table Type: Accessing Collections from MongoDB

Used to directly access MongoDB collections as tables.

CONNECT MYSQL Table Type: Accessing MySQL/MariaDB Tables

Accessing a MySQL or MariaDB table or view

CONNECT PROXY Table Type

Tables that access and read the data of another table or view

CONNECT XCOL Table Type

Based on another table/view, used when object tables have a column that contains a list of values

CONNECT OCCUR Table Type

Extension to the PROXY type when referring to a table/view having several c...

CONNECT PIVOT Table Type

Transform the result of another table into another table along "pivot" and "fact" columns.

CONNECT TBL Table Type: Table List

Define a table as a list of tables of any engine and type.

CONNECT - Using the TBL and MYSQL Table Types Together

Used together, the TBL and MYSQL types lift all the limitations of the FEDERATED and MERGE engines

CONNECT Table Types - Special "Virtual" Tables

VIR, WMI and MAC special table types

CONNECT Table Types - VIR

VIR virtual type for CONNECT

CONNECT Table Types - OEM: Implemented in an External LIB

CONNECT OEM table types are implemented in an external library.

CONNECT Table Types - Catalog Tables

Catalog tables return information about another table or data source

There are [20 related questions](#)

5.3.7.1 Introduction to the CONNECT Engine

CONNECT is not just a new “YASE” (Yet another Storage Engine) that provides another way to store data with additional features. It brings a new dimension to MariaDB, already one of the best products to deal with traditional database transactional applications, further into the world of business intelligence and data analysis, including NoSQL facilities. Indeed, BI is the set of techniques and tools for the transformation of raw data into meaningful and useful information. And where is this data?

"It's amazing in an age where relational databases reign supreme when it comes to managing data that so much information still exists outside RDBMS engines in the form of flat files and other such constructs. In most enterprises, data is passed back and forth between disparate systems in a fashion and speed that would rival the busiest expressways in the world, with much of this data existing in common, delimited files. Target systems intercept these source files and then typically proceed to load them via ETL (extract, transform, load) processes into databases that then utilize the information for business intelligence, transactional functions, or other standard operations. ETL tasks and data movement jobs can consume quite a bit of time and resources, especially if large volumes of data are present that require loading into a database. This being the case, many DBAs welcome alternative means of accessing and managing data that exists in file format."

- Robin Schumacher^[1]

What he describes is known as MED (Management of External Data) enabling the handling of data not stored in a DBMS database as if it were stored in tables. An ISO standard exists that describes one way to implement and use MED in SQL by defining foreign tables for which an external FDW (Foreign Data Wrapper) has been developed in C.

However, since this was written, a new source of data was developed as the “cloud”. Data are existing worldwide and, in particular, can be obtained in JSON or XML format in answer to REST queries. From [Connect 1.06.0010](#), it is possible to create JSON, XML or CSV tables based on data retrieved from such REST queries.

MED as described above is a rather complex way to achieve this goal and MariaDB does not support the ISO SQL/MED standard. But, to cover the need, possibly in transactional but mostly in decision support applications, the CONNECT storage engine supports MED in a much simpler way.

The main features of CONNECT are:

1. No need for additional SQL language extensions.
2. Embedded wrappers for many external data types (files, data sources, virtual).
3. NoSQL query facilities for [JSON](#), [XML](#), HTML files and using JSON UDFs.
4. NoSQL data obtained from REST queries (requires cpprestsdk).
5. NoSQL new data type [MONGO](#) accessing MongoDB collections as relational tables.
6. Read/Write access to external files of most commonly used formats.
7. Direct access to most external data sources via ODBC, JDBC and MySQL or MongoDB API.
8. Only used columns are retrieved from external scan.
9. Push-down WHERE clauses when appropriate.
10. Support of special and virtual columns.
11. Parallel execution of multi-table tables (currently unavailable).
12. Supports partitioning by sub-files or by sub-tables (enabling table sharding).
13. Support of MRR for SELECT, UPDATE and DELETE.
14. Provides remote, block, dynamic and virtual indexing.
15. Can execute complex queries on remote servers.
16. Provides an API that allows writing additional FDW in C++.

With CONNECT, MariaDB has one of the most advanced implementations of MED and NoSQL, without the need for complex additions to the SQL syntax (foreign tables are "normal" tables using the CONNECT engine).

Giving MariaDB easy and natural access to external data enables the use of all of its powerful functions and SQL-handling abilities for developing business intelligence applications.

With version 1.07 of CONNECT, retrieving data from REST queries is available in all binary distributed version of MariaDB, and, from 1.07.002, CONNECT allows workspaces greater than 4GB.

1. [↑](#) Robin Schumacher is Vice President Products at DataStax and former Director of Product Management at MySQL. He has over 13 years of database experience in DB2, MySQL, Oracle, SQL Server and other database engines.

5.3.7.2 Installing the CONNECT Storage Engine

The `CONNECT` storage engine enables MariaDB to access external local or remote data (MED). This is done by defining tables based on different data types, in particular files in various formats, data extracted from other DBMS or products (such as Excel or MongoDB) via ODBC or JDBC, or data retrieved from the environment (for example DIR, WMI, and MAC tables)

This storage engine supports table partitioning, MariaDB virtual columns and permits defining special columns such as ROWID, FILEID, and SERVID.

The storage engine must be installed before it can be used.

Contents

1. [Installing the Plugin's Package](#)
 1. [Installing on Linux](#)
 1. [Installing with a Package Manager](#)
 1. [Installing with yum/dnf](#)
 2. [Installing with apt-get](#)
 3. [Installing with zypper](#)
 2. [Installing the Plugin](#)
 3. [Uninstalling the Plugin](#)
 4. [Installing Dependencies](#)
 1. [Installing unixODBC](#)

Installing the Plugin's Package

The `CONNECT` storage engine's shared library is included in MariaDB packages as the `ha_connect.so` or `ha_connect.so` shared library on systems where it can be built.

Installing on Linux

The `CONNECT` storage engine is included in [binary tarballs](#) on Linux.

Installing with a Package Manager

The `CONNECT` storage engine can also be installed via a package manager on Linux. In order to do so, your system needs to be configured to install from one of the MariaDB repositories.

You can configure your package manager to install it from MariaDB Corporation's MariaDB Package Repository by using the [MariaDB Package Repository setup script](#).

You can also configure your package manager to install it from MariaDB Foundation's MariaDB Repository by using the [MariaDB Repository Configuration Tool](#).

Installing with yum/dnf

On RHEL, CentOS, Fedora, and other similar Linux distributions, it is highly recommended to install the relevant [RPM package](#) from MariaDB's repository using `yum` or `dnf`. Starting with RHEL 8 and Fedora 22, `yum` has been replaced by `dnf`, which is the next major version of `yum`. However, `yum` commands still work on many systems that use `dnf`. For example:

```
sudo yum install MariaDB-connect-engine
```

Installing with apt-get

On Debian, Ubuntu, and other similar Linux distributions, it is highly recommended to install the relevant [DEB package](#) from MariaDB's repository using `apt-get`. For example:

```
sudo apt-get install mariadb-plugin-connect
```

Installing with zypper

On SLES, OpenSUSE, and other similar Linux distributions, it is highly recommended to install the relevant [RPM package](#) from MariaDB's repository using `zypper`. For example:

```
sudo zypper install MariaDB-connect-engine
```

Installing the Plugin

Once the shared library is in place, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing `INSTALL SONAME` or `INSTALL PLUGIN`. For example:

```
INSTALL SONAME 'ha_connect';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the `--plugin-load` or the `--plugin-load-add` options. This can be specified as a command-line argument to `mysqld` or it can be specified in a relevant server [option group](#) in an [option file](#). For example:

```
[mariadb]
...
plugin_load_add = ha_connect
```

Uninstalling the Plugin

You can uninstall the plugin dynamically by executing `UNINSTALL SONAME` or `UNINSTALL PLUGIN`. For example:

```
UNINSTALL SONAME 'ha_connect';
```

If you installed the plugin by providing the `--plugin-load` or the `--plugin-load-add` options in a relevant server [option group](#) in an [option file](#), then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

Installing Dependencies

The `CONNECT` storage engine has some external dependencies.

Installing unixODBC

The `CONNECT` storage engine requires an ODBC library. On Unix-like systems, that usually means installing [unixODBC](#). On some systems, this is installed as the `unixODBC` package. For example:

```
sudo yum install unixODBC
```

On other systems, this is installed as the `libodbc1` package. For example:

```
sudo apt-get install libodbc1
```

If you do not have the ODBC library installed, then you may get an error about a missing library when you attempt to install the plugin. For example:

```
INSTALL SONAME 'ha_connect';
ERROR 1126 (HY000): Can't open shared library
'/home/ian/MariaDB_Downloads/10.1.17/lib/plugin/ha_connect.so'
(errno: 2, libodbc.so.1: cannot open shared object file: No such file or directory)
```

5.3.7.3 CONNECT Create Table Options

Contents

- 1. [Table Options](#)
- 2. [Column Options](#)
- 3. [Index Options](#)

Create Table statements for “CONNECT” tables are standard MariaDB create statements specifying `engine=CONNECT`. There are a few additional table and column options specific to `CONNECT`.

Table Options

Table Option	Type	Description
<code>AVG_ROW_LENGTH</code>	Integer	Can be specified to help <code>CONNECT</code> estimate the size of a variable record table length.
<code>BLOCK_SIZE</code>	Integer	The number of rows each block of a <code>FIX</code> , <code>BIN</code> , <code>DBF</code> , or <code>VEC</code> table contains. For an <code>ODBC</code> table this is the <code>RowSet</code> size option. For a <code>JDBC</code> table this is the <code>fetch size</code> .
<code>CATFUNC</code>	String	The catalog function used by a catalog table .
<code>COLIST</code>	String	The column list of <code>OCCUR</code> tables or <code>\$project</code> of <code>MONGO</code> tables.
<code>COMPRESS</code>	Number	1 or 2 if the data file is g-zip compressed. Defaults to 0. Before <code>CONNECT 1.05.0001</code> , this was boolean, and true if the data file is compressed.
<code>CONNECTION</code>	String	Specifies the connection of an <code>ODBC</code> , <code>JDBC</code> or <code>MYSQL</code> table.
<code>DATA_CHARSET</code>	String	The character set used in the external file or data source.
<code>DBNAME</code>	String	The target database for <code>ODBC</code> , <code>JDBC</code> , <code>MYSQL</code> , <code>catalog</code> , and <code>PROXY</code> based tables. The database concept is sometimes known as a <i>schema</i> .
<code>ENGINE</code>	String	Must be specified as <code>CONNECT</code> .
<code>ENDING</code>	Integer	End of line length. Defaults to 1 for Unix/Linux and 2 for Windows.
<code>FILE_NAME</code>	String	The file (path) name for all table types based on files. Can be absolute or relative to the current data directory. If not specified, this is an <code>Inward table</code> and a default value is used.
<code>FILTER</code>	String	To filter an external table. Currently <code>MONGO</code> tables only.
<code>HEADER</code>	Integer	Applies to <code>CSV</code> , <code>VEC</code> , and HTML files. Its meaning depends on the table type.
<code>HTTP</code>	String	The HTTP of the client of REST queries. From Connect 1.06.0010 .
<code>HUGE</code>	Boolean	To specify that a table file can be larger than 2GB. For a <code>MYSQL</code> table, prevents the result set from being stored in memory.

LRECL	Integer	The file record size (often calculated by default).
MAPPED	Boolean	Specifies whether <i>file mapping</i> is used to handle the table file.
MODULE	String	The (path) name of the DLL or shared lib implementing the access of a non-standard (OEM) table type.
MULTIPLE	Integer	Used to specify multiple file tables.
OPTION_LIST	String	Used to specify all other options not yet directly defined.
QCHAR	String	Specifies the character used for quoting some fields of a CSV table or the identifiers of an ODBC/JDBC tables.
QUOTED	Integer	The level of quoting used in CSV table files.
READONLY	Boolean	True if the data file must not be modified or erased.
SEP_CHAR	String	Specifies the field separator character of a CSV or XCOL table. Also, used to specify the Jpath separator for JSON tables.
SEPINDEX	Boolean	When true, indexes are saved in separate files.
SPLIT	Boolean	True for a VEC table when all columns are in separate files.
SRCDEF	String	The source definition of a table retrieved via ODBC, JDBC or the MySQL API or used by a PIVOT table.
SUBTYPE	String	The subtype of an OEM table type.
TABLE_LIST	String	The comma separated list of TBL table sub-tables.
TABLE_TYPE	String	The external table type: DOS, FIX, BIN, CSV, FMT, XML, JSON, INI, DBF, VEC, ODBC, JDBC, MYSQL, TBL, PROXY, XCOL, OCCUR, PIVOT, ZIP, VIR, DIR, WMI, MAC, and OEM. Defaults to DOS, MYSQL, or PROXY depending on what options are used.
TABNAME	String	The target table or node for ODBC, JDBC, MYSQL, PROXY, or catalog tables; or the top node name for XML tables.
URI	String	The URI of a REST request.. From Connect 1.06.0010.
XFILE_NAME	String	The file (path) base name for table index files. Can be absolute or relative to the data directory. Defaults to the file name.
ZIPPED	Boolean	True if the table file(s) is/are zipped in one or several zip files.

All integers in the above table are unsigned big integers.

Because CONNECT handles many table types; many table type specific options are not in the above list and must be entered using the `OPTION_LIST` option. The syntax to use is:

```
... option_list='opname1=opvalue1,opname2=opvalue2...'
```

Be aware that until Connect 1.5.5, no blanks should be inserted before or after the '=' and ',' characters. The option name is all that is between the start of the string or the last ',' character and the next '=' character, and the option value is all that is between this '=' character and the next ',' or end of string. For instance:

```
option_list='name=TABLE,coltype=HTML,attribute=border=1;cellpadding=5,headattr=bgcolor=yellow';
```

This defines four options, 'name', 'coltype', 'attribute', and 'headattr'; with values 'TABLE', 'HTML', 'border=1;cellpadding=5', and 'bgcolor=yellow', respectively. The only restriction is that values cannot contain commas, but they can contain equal signs.

Column Options

Column Option	Type	Description
DATE_FORMAT	String	The format indicating how a date is stored in the file.
DISTRIB	Enum	"scattered", "clustered", "sorted" (ascending).
FIELD_FORMAT	String	The column format for some table types.

FIELD_LENGTH	Integer	Set the internal field length for DATE columns.
FLAG	Integer	An integer value whose meaning depends on the table type.
JPATH	String	The Json path of JSON table columns.
MAX_DIST	Integer	Maximum number of distinct values in this column.
SPECIAL	String	The name of the SPECIAL column that set this column value.
XPATH	String	The XML path of XML table columns.

- The `MAX_DIST` and `DISTRIB` column options are used for block indexing.
- All integers in the above table are unsigned big integers.
- `JPATH` and `XPATH` were added to make `CREATE TABLE` statements more readable, but they do the same thing as `FIELD_FORMAT` and any of them can be used with the same result.

Index Options

Index Option	Type	Description
DYNAM	Boolean	Set the index as “dynamic”.
MAPPED	Boolean	Use index file mapping.

Note 1: Creating a `CONNECT` table based on file does not erase or create the file if the file name is specified in the `CREATE TABLE` statement (“outward” table). If the file does not exist, it will be populated by subsequent `INSERT` or `LOAD` commands or by the “AS select statement” of the `CREATE TABLE` command. Unlike the CSV engine, `CONNECT` easily permits the creation of tables based on already existing files, for instance files made by other applications. However, if the file name is not specified, a file with a name defaulting to `tablename.tabletype` will be created in the data directory (“inward” table).

Note 2: Dropping a `CONNECT` table is done with a standard `DROP` statement. For `outward tables`, this drops only the `CONNECT` table definition but does not erase the corresponding data file and index files. Use `DELETE` or `TRUNCATE` to do so. This is contrary to data and index files of `inward tables` are erased on `DROP` like for other MariaDB engines.

5.3.7.4 CONNECT Data Types

Contents

1. [TYPE_STRING](#)
2. [TYPE_INT](#)
3. [TYPE_SHORT](#)
4. [TYPE_TINY](#)
5. [TYPE_BIGINT](#)
6. [TYPE_DOUBLE](#)
7. [TYPE_DECIM](#)
8. [DATE Data type](#)
 1. [Date Format in Text Tables](#)
 2. [Usage Notes](#)
 3. [Handling dates that are out of the range of supported CONNECT dates](#)
9. [NULL handling](#)
10. [Unsigned numeric types](#)
11. [Data type conversion](#)

Many data types make no or little sense when applied to plain files. This why `CONNECT` supports only a restricted set of data types. However, ODBC, JDBC or MYSQL source tables may contain data types not supported by `CONNECT`. In this case, `CONNECT` makes an automatic conversion to a similar supported type when it is possible.

The data types currently supported by `CONNECT` are:

Type name	Description	Used for
TYPE_STRING	Zero ended string	<code>char</code> , <code>varchar</code> , <code>text</code>
TYPE_INT	4 bytes integer	<code>int</code> , <code>mediumint</code> , <code>integer</code>
TYPE_SHORT	2 bytes integer	<code>smallint</code>
TYPE_TINY	1 byte integer	<code>tinyint</code>

TYPE_BIGINT	8 bytes integer	bigint , longlong
TYPE_DOUBLE	8 bytes floating point	double , float , real
TYPE_DECIM	Numeric value	decimal , numeric , number
TYPE_DATE	4 bytes integer	date , datetime , time , timestamp , year

TYPE_STRING

This type corresponds to what is generally known as [CHAR](#) or [VARCHAR](#) by database users, or as strings by programmers. Columns containing characters have a maximum length but the character string is of fixed or variable length depending on the file format.

The DATA_CHARSET option must be used to specify the character set used in the data source or file. Note that, unlike usually with MariaDB, when a multi-byte character set is used, the column size represents the number of bytes the column value can contain, not the number of characters.

TYPE_INT

The [INTEGER](#) type contains signed integer numeric 4-byte values (the *int/* of the C language) ranging from $-2,147,483,648$ to $2,147,483,647$ for signed type and 0 to $4,294,967,295$ for unsigned type.

TYPE_SHORT

The SHORT data type contains signed [integer numeric 2-byte](#) values (the *short integer* of the C language) ranging from $-32,768$ to $32,767$ for signed type and 0 to $65,535$ for unsigned type.

TYPE_TINY

The TINY data type contains [integer numeric 1-byte](#) values (the *char* of the C language) ranging from -128 to 127 for signed type and 0 to 255 for unsigned type. For some table types, TYPE_TINY is used to represent Boolean values (0 is false, anything else is true).

TYPE_BIGINT

The [BIGINT](#) data type contains signed integer 8-byte values (the *long long* of the C language) ranging from $-9,223,372,036,854,775,808$ to $9,223,372,036,854,775,807$ for signed type and from 0 to $18,446,744,073,709,551,615$ for unsigned type.

Inside tables, the coding of all integer values depends on the table type. In tables represented by text files, the number is written in characters, while in tables represented by binary files ([BIN](#) or [VEC](#)) the number is directly stored in the binary representation corresponding to the platform.

The *length* (or *precision*) specification corresponds to the length of the table field in which the value is stored for text files only. It is used to set the output field length for all table types.

TYPE_DOUBLE

The DOUBLE data type corresponds to the C language [double](#) type, a floating-point double precision value coded with 8 bytes. Like for integers, the internal coding in tables depends on the table type, characters for text files, and platform binary representation for binary files.

The *length* specification corresponds to the length of the table field in which the value is stored for text files only. The *scale* (was *precision*) is the number of decimal digits written into text files. For binary table types (BIN and VEC) this does not apply. The *length* and *scale* specifications are used to set the output field length and number of decimals for all types of tables.

TYPE_DECIM

The DECIMAL data type corresponds to what MariaDB or ODBC data sources call NUMBER, NUMERIC, or [DECIMAL](#): a numeric value with a maximum number of digits (the precision) some of them eventually being decimal digits (the scale). The internal coding in CONNECT is a character representation of the number. For instance:

```
colname decimal(14,6)
```

This defines a column *colname* as a number having a *precision* of 14 and a *scale* of 6. Supposing it is populated by:

```
insert into xxx values (-2658.74);
```

The internal representation of it will be the character string `-2658.740000`. The way it is stored in a file table depends on the table type. The *length* field specification corresponds to the length of the table field in which the value is stored and is calculated by CONNECT from the *precision* and the *scale* values. This length is *precision* plus 1 if *scale* is not 0 (for the decimal point) plus 1 if this column is not unsigned (for the eventual minus sign). In fix formatted tables the number is right justified in the field of width *length*, for variable formatted tables, such as CSV, the field is the representing character string.

Because this type is mainly used by CONNECT to handle numeric or decimal fields of ODBC, JDBC and MySQL table types, CONNECT does not provide decimal calculations or comparison by itself. This is why decimal columns of CONNECT tables cannot be indexed.

DATE Data type

Internally, date/time values are stored by CONNECT as a signed 4-byte integer. The value 0 corresponds to 01 January 1970 12:00:00 am coordinated universal time (UTC [↗](#)). All other date/time values are represented by the number of seconds elapsed since or before midnight (00:00:00), 1 January 1970, to that date/time value. Date/time values before midnight 1 January 1970 are represented by a negative number of seconds.

CONNECT handles dates from **13 December 1901, 20:45:52** to **18 January 2038, 19:14:07**.

Although date and time information can be represented in both CHAR and INTEGER data types, the DATE data type has special associated properties. For each DATE value, CONNECT can store all or only some of the following information: century, year, month, day, hour, minute, and second.

Date Format in Text Tables

Internally, date/time values are handled as a signed 4-byte integer. But in text tables (type DOS, FIX, CSV, FMT, and DBF) dates are most of the time stored as a formatted character string (although they also can be stored as a numeric string representing their internal value). Because there are infinite ways to format a date, the format to use for decoding dates, as well as the field length in the file, must be associated to date columns (except when they are stored as the internal numeric value).

Note that this associated format is used only to describe the way the temporal value is stored internally. This format is used both for output to decode the date in a SELECT statement as well as for input to encode the date in INSERT or UPDATE statements. However, what is kept in this value depends on the data type used in the column definition (all the MariaDB temporal values can be specified). When creating a table, the format is associated to a date column using the DATE_FORMAT option in the column definition, for instance:

```
create table birthday (
  Name varchar(17),
  Bday date field_length=10 date_format='MM/DD/YYYY',
  Btime time field_length=8 date_format='hh:mm tt')
engine=CONNECT table_type=CSV;

insert into birthday values ('Charlie','2012-11-12','15:30:00');

select * from birthday;
```

The SELECT query returns:

Name	Bday	Btime
Charlie	2012-11-12	15:30:00

The values of the INSERT statement must be specified using the standard MariaDB syntax and these values are displayed as MariaDB temporal values. Sure enough, the column formats apply only to the way these values are represented inside the CSV files. Here, the inserted record will be:

```
Charlie,11/12/2012,03:30 PM
```

Note: The *field_length* option exists because the MariaDB syntax does not allow specifying the field length between parentheses for temporal column types. If not specified, the field length is calculated from the date format (sometimes as a

max value) or made equal to the default length value if there is no date format. In the above example it could have been removed as the calculated values are the ones specified. However, if the table type would have been DOS or FIX, these values could be adjusted to fit the actual field length within the file.

A CONNECT format string consists of a series of elements that represent a particular piece of information and define its format. The elements will be recognized in the order they appear in the format string. Date and time format elements will be replaced by the actual date and time as they appear in the source string. They are defined by the following groups of characters:

Element	Description
YY	The last two digits of the year (that is, 1996 would be coded as "96").
YYYY	The full year (that is, 1996 could be entered as "96" but displayed as "1996").
MM	The one or two-digit month number.
MMM	The three-character month abbreviation.
MMMM	The full month name.
DD	The one or two-digit month day.
DDD	The three-character weekday abbreviation.
DDDD	The full weekday name.
hh	The one or two-digit hour in 12-hour or 24-hour format.
mm	The one or two-digit minute.
ss	The one or two-digit second.
t	The one-letter AM/PM abbreviation (that is, AM is entered as "A").
tt	The two-letter AM/PM abbreviation (that is, AM is entered as "AM").

Usage Notes

- To match the source string, you can add body text to the format string, enclosing it in single quotes or double quotes if it would be ambiguous. Punctuation marks do not need to be quoted.
- The hour information is regarded as 12-hour format if a "t" or "tt" element follows the "hh" element in the format or as 24-hour format otherwise.
- The "MM", "DD", "hh", "mm", "ss" elements can be specified with one or two letters (e.g. "MM" or "M") making no difference on input, but placing a leading zero to one-digit values on output^[1] for two-letter elements.
- If the format contains elements DDD or DDDD, the day of week name is skipped on input and ignored to calculate the internal date value. On output, the correct day of week name is generated and displayed.
- Temporal values are always stored as numeric in [BIN](#) and [VEC](#) tables.

Handling dates that are out of the range of supported CONNECT dates

If you want to make a table containing, for instance, historical dates not being convertible into CONNECT dates, make your column CHAR or VARCHAR and store the dates in the MariaDB format. All date functions applied to these strings will convert them to MariaDB dates and will work as if they were real dates. Of course they must be inserted and will be displayed using the MariaDB format.

NULL handling

CONNECT handles [null values](#) for data sources able to produce nulls. Currently this concerns mainly the [ODBC](#), [JDBC](#), [MONGO](#), [MYSQL](#), [XML](#), [JSON](#) and [INI](#) table types. For INI, JSON, MONGO or XML types, null values are returned when the key is missing in the section (INI) or when the corresponding node does not exist in a row (XML, JSON, MONGO).

For other file tables, the issue is to define what a null value is. In a numeric column, 0 can sometimes be a valid value but, in some other cases, it can make no sense. The same for character columns; is a blank field a valid value or not?

A special case is DATE columns with a DATE_FORMAT specified. Any value not matching the format can be regarded as NULL.

CONNECT leaves the decision to you. When declaring a column in the [CREATE TABLE](#) statement, if it is declared NOT NULL, blank or zero values will be considered as valid values. Otherwise they will be considered as NULL values. In all cases, nulls are replaced on insert or update by pseudo null values, a zero-length character string for text types or a zero value for numeric types. Once converted to pseudo null values, they will be recognized as NULL only for columns declared as nullable.

For instance:

```
create table t1 (a int, b char(10)) engine=connect;
insert into t1 values (0, 'zero'), (1, 'one'), (2, 'two'), (null, '???');
select * from t1 where a is null;
```

The select query replies:

a	b
NULL	zero
NULL	???

Sure enough, the value 0 entered on the first row is regarded as NULL for a nullable column. However, if we execute the query:

```
select * from t1 where a = 0;
```

This will return no line because a NULL is not equal to 0 in an SQL where clause.

Now let us see what happens with not null columns:

```
create table t1 (a int not null, b char(10) not null) engine=connect;
insert into t1 values (0, 'zero'), (1, 'one'), (2, 'two'), (null, '???');
```

The insert statement will produce a warning saying:

Level	Code	Message
Warning	1048	Column 'a' cannot be null

It is replaced by a pseudo null 0 on the fourth row. Let us see the result:

```
select * from t1 where a is null;
select * from t1 where a = 0;
```

The first query returns no rows, 0 are valid values and not NULL. The second query replies:

a	b
0	zero
0	???

It shows that the NULL inserted value was replaced by a valid 0 value.

Unsigned numeric types

They are supported by CONNECT since version 1.01.0010 for fixed numeric types (TINY, SHORT, INTEGER, and BITINT).

Data type conversion

CONNECT is able to convert data from one type to another in most cases. These conversions are done without warning even when this leads to truncation or loss of precision. This is true, in particular, for tables of type ODBC, JDBC, MYSQL and PROXY (via MySQL) because the source table may contain some data types not supported by CONNECT. They are converted when possible to CONNECT types.

When converted, MariaDB types are converted as:

MariaDB Types	CONNECT Type	Remark
integer , medium integer	TYPE_INT	4 byte integer
small integer	TYPE_SHORT	2 byte integer
tiny integer	TYPE_TINY	1 byte integer
char , varchar	TYPE_STRING	Same length

double, float, real	TYPE_DOUBLE	8 byte floating point
decimal, numeric	TYPE_DECIM	Length depends on precision and scale
all date related types	TYPE_DATE	Date format can be set accordingly
bigint, longlong	TYPE_BIGINT	8 byte integer
enum, set	TYPE_STRING	Numeric value not accessible
All text types	TYPE_STRING TYPE_ERROR	Depending on the value of the connect_type_conv system variable value.
Other types	TYPE_ERROR	Not supported, no conversion provided.

For [ENUM](#), the length of the column is the length of the longest value of the enumeration. For [SET](#) the length is enough to contain all the set values concatenated with comma separator.

In the case of [TEXT](#) columns, the handling depends on the values given to the [connect_type_conv](#) and [connect_conv_size](#) system variables.

Note: [BLOB](#) is currently not converted by default until a TYPE_BIN type is added to CONNECT. However, the FORCE option (from Connect 1.06.006) can be specified for blob columns containing text and the SKIP option also applies to ODBC BLOB columns.

ODBC SQL types are converted as:

SQL Types	Connect Type	Remark
SQL_CHAR, SQL_VARCHAR	TYPE_STRING	
SQL_LONGVARCHAR	TYPE_STRING	$len = \min(\text{abs}(len), \text{connect_conv_size})$ If the column is generated by discovery (columns not specified) its length is connect_conv_size .
SQL_NUMERIC, SQL_DECIMAL	TYPE_DECIM	
SQL_INTEGER	TYPE_INT	
SQL_SMALLINT	TYPE_SHORT	
SQL_TINYINT, SQL_BIT	TYPE_TINY	
SQL_FLOAT, SQL_REAL, SQL_DOUBLE	TYPE_DOUBLE	
SQL_DATETIME	TYPE_DATE	$len = 10$
SQL_INTERVAL	TYPE_STRING	$len = 8 + ((scale) ? (scale+1) : 0)$
SQL_TIMESTAMP	TYPE_DATE	$len = 19 + ((scale) ? (scale + 1) : 0)$
SQL_BIGINT	TYPE_BIGINT	
SQL_GUID	TYPE_STRING	$len=36$
SQL_BINARY, SQL_VARBINARY, SQL_LONG-VARBINARY	TYPE_STRING	$len = \min(\text{abs}(len), \text{connect_conv_size})$ Only if the value of connect_type_conv is <i>force</i> . The column should use the binary charset.
Other types	TYPE_ERROR	<i>Not supported.</i>

JDBC SQL types are converted as:

JDBC Types	Connect Type	Remark
(N)CHAR, (N)VARCHAR	TYPE_STRING	
LONG(N)VARCHAR	TYPE_STRING	$len = \min(\text{abs}(len), \text{connect_conv_size})$ If the column is generated by discovery (columns not specified), its length is connect_conv_size
NUMERIC, DECIMAL, VARBINARY	TYPE_DECIM	
INTEGER	TYPE_INT	

SMALLINT	TYPE_SHORT	
TINYINT, BIT	TYPE_TINY	
FLOAT, REAL, DOUBLE	TYPE_DOUBLE	
DATE	TYPE_DATE	len = 10
TIME	TYPE_DATE	len = 8 + ((scale) ? (scale+1) : 0)
TIMESTAMP	TYPE_DATE	len = 19 + ((scale) ? (scale +1) : 0)
BIGINT	TYPE_BIGINT	
UUID (specific to PostgreSQL)	TYPE_STRING TYPE_ERROR	len=36 If <code>connect_type_conv=NO</code>
Other types	TYPE_ERROR	Not supported.

Note: The `connect_type_conv SKIP` option also applies to ODBC and JDBC tables.

- ↑ Here input and output are used to specify respectively decoding the date to get its numeric value from the data file and encoding a date to write it in the table file. Input is performed within `SELECT` queries; output is performed in `UPDATE` or `INSERT` queries.

5.3.7.5 Current Status of the CONNECT Handler

The current CONNECT handler is a GA (stable) release. It was written starting both from an aborted project written for MySQL in 2004 and from the “DBCONNECT” program. It was tested on all the examples described in this document, and is distributed with a set of 53 test cases. Here is a not limited list of future developments:

- Adding more table types.
- Make more tests files (53 are already made)
- Adding more data types, in particular unsigned ones (done for unsigned).
- Supporting indexing on nullable and decimal columns.
- Adding more optimize tools (block indexing, dynamic indexing, etc.) (done)
- Supporting MRR (done)
- Supporting partitioning (done)
- Getting NOSQL data from the Net as answers from REST queries (done)

No programs are bug free, especially new ones. Please [report all bugs](#) or documentation errors using the means provided by MariaDB.

5.3.7.6 CONNECT Table Types

The main feature of `CONNECT` is to give MariaDB the ability to handle tables from many sources, native files, other DBMS’s tables, or special “virtual” tables. Moreover, for all tables physically represented by data files, `CONNECT` recognizes many different file formats, described below but not limited in the future to this list, because more can be easily added to it on demand ([OEM tables](#)).

Note: You can download a [PDF version of the CONNECT documentation](#) (1.7.0003).

CONNECT Table Types Overview

CONNECT can handle many table formats.

Inward and Outward Tables

The two broad categories of CONNECT tables.

CONNECT Table Types - Data Files

CONNECT plain DOS or UNIX data files.

CONNECT Zipped File Tables

When the table file or files are compressed in one or several zip files.

CONNECT DOS and FIX Table Types

CONNECT tables based on text files

CONNECT DBF Table Type

CONNECT dBASE III or IV tables.

CONNECT BIN Table Type

CONNECT binary files in which each row is a logical record of fixed length

CONNECT VEC Table Type

CONNECT binary files organized in vectors

CONNECT CSV and FMT Table Types

Variable length CONNECT data files.

CONNECT - NoSQL Table Types

Based on files that do not match the relational format but often represent hierarchical data.

CONNECT - Files Retrieved Using Rest Queries

JSON, XML and CSV data files can be retrieved as results from REST queries.

CONNECT JSON Table Type

JSON (JavaScript Object Notation) is a widely-used lightweight data-interchange format.

CONNECT XML Table Type

CONNECT XML files

CONNECT INI Table Type

CONNECT INI Windows configuration or initialization files.

CONNECT - External Table Types

Access tables belonging to the current or another server.

CONNECT ODBC Table Type: Accessing Tables From Another DBMS

CONNECT Table Types - ODBC Table Type: Accessing Tables from other DBMS

CONNECT JDBC Table Type: Accessing Tables from Another DBMS

Using JDBC to access other tables.

CONNECT MONGO Table Type: Accessing Collections from MongoDB

Used to directly access MongoDB collections as tables.

CONNECT MYSQL Table Type: Accessing MySQL/MariaDB Tables

Accessing a MySQL or MariaDB table or view

CONNECT PROXY Table Type

Tables that access and read the data of another table or view

CONNECT XCOL Table Type

Based on another table/view, used when object tables have a column that contains a list of values

CONNECT OCCUR Table Type

Extension to the PROXY type when referring to a table/view having several c...

CONNECT PIVOT Table Type

Transform the result of another table into another table along "pivot" and "fact" columns.

CONNECT TBL Table Type: Table List

Define a table as a list of tables of any engine and type.

CONNECT - Using the TBL and MYSQL Table Types Together

Used together, the TBL and MYSQL types lift all the limitations of the FEDERATED and MERGE engines

CONNECT Table Types - Special "Virtual" Tables

VIR, WMI and MAC special table types

CONNECT Table Types - VIR

VIR virtual type for CONNECT

CONNECT Table Types - OEM: Implemented in an External LIB

CONNECT OEM table types are implemented in an external library.

CONNECT Table Types - Catalog Tables

Catalog tables return information about another table or data source

There are [4 related questions](#).

5.3.7.6.1 CONNECT Table Types Overview

CONNECT can handle very many table formats; it is indeed one of its main features. The Type option specifies the type and format of the table. The Type options available values and their descriptions are listed in the following table:

Type	Description
BIN	Binary file with numeric values in platform representation, also with columns at fixed offset within records and fixed record length.
BSON	(Temporary) JSON table handled by the new JSON handling.
CSV*\$	"Comma Separated Values" file in which each variable length record contains column values separated by a specific character (defaulting to the comma)
DBF*	File having the dBASE format.
DOS	The table is contained in one or several files. The file format can be refined by some other options of the command or more often using a specific type as many of those described below. Otherwise, it is a flat text file where columns are placed at a fixed offset within each record, the last column being of variable length.
DIR	Virtual table that returns a file list like the Unix <code>ls</code> or DOS <code>dir</code> command.
FIX	Text file arranged like DOS but with fixed length records.
FMT	File in which each record contains the column values in a non-standard format (the same for each record) This format is specified in the column definition.
INI	File having the format of the initialization or configuration files used by many applications.
JDBC*	Table accessed via a JDBC driver.
JSON*\$	File having the JSON format.
MAC	Virtual table returning information about the machine and network cards (Windows only).
MONGO*	Table accessed via the MongoDB C Driver API.
MYSQL  *	Table accessed using the MySQL API like the FEDERATED engine.
OCCUR*	A table based on another table existing on the current server, several columns of the object table containing values that can be grouped in only one column.
ODBC*	Table extracted from an application accessible via ODBC or unixODBC. For example from another DBMS or from an Excel spreadsheet.
OEM*	Table of any other formats not directly handled by CONNECT but whose access is implemented by an external FDW (foreign data wrapper) written in C++ (as a DLL or Shared Library).
PIVOT*	Used to "pivot" the display of an existing table or view.
PROXY*	A table based on another table existing on the current server.
TBL*	Accessing a collection of tables as one table (like the MERGE engine does for MyIsam tables)

VEC	Binary file organized in vectors, in which column values are grouped consecutively, either split in separate files or in a unique file.
VIR*	Virtual table containing only special and virtual columns.
WMI*	Windows Management Instrumentation table displaying information coming from a WMI provider. This type enables to get in tabular format all sorts of information about the machine hardware and operating system (Windows only).
XCOL*	A table based on another table existing on the current server with one of its columns containing comma separated values.
XML*\$	File having the XML or HTML format.
ZIP	Table giving information about the contents of a zip file.

Catalog Tables

For all table types marked with a '*' in the table above, CONNECT is able to analyze the data source to retrieve the column definition. This can be used to define a "catalog" table that display the column description of the source, or to create a table without specifying the column definition that will be automatically constructed by CONNECT when creating the table.

When marked with a '\$' the file can be the result returned by a REST query.

5.3.7.6.2 Inward and Outward Tables

Contents

1. [Outward Tables](#)
 1. [Altering Outward Tables](#)
2. [Inward Tables](#)
 1. [Altering Inward Tables](#)

There are two broad categories of file-based CONNECT tables. Inward and Outward. They are described below.

Outward Tables

Tables are "outward" when their file name is specified in the CREATE TABLE statement using the *file_name* option.

Firstly, remember that CONNECT implements MED (Management of External Data). This means that the "true" CONNECT tables – "outward tables" – are based on data that belongs to files that can be produced by other applications or data imported from another DBMS.

Therefore, their data is "precious" and should not be modified except by specific commands such as [INSERT](#), [UPDATE](#), or [DELETE](#). For other commands such as [CREATE](#), [DROP](#), or [ALTER](#) their data is never modified or erased.

Outward tables can be created on existing files or external tables. When they are dropped, only the local description is dropped, the file or external table is not dropped or erased. Also, [DROP TABLE](#) does not erase the indexes.

[ALTER TABLE](#) produces the following warning, as a reminder:

```
Warning (Code 1105): This is an outward table, table data were not modified.
```

If the specified file does not exist, it is created when data is inserted into the table. If a [SELECT](#) is issued before the file is created, the following error is produced:

```
Warning (Code 1105): Open(rb) error 2 on <file_path>: No such file or directory
```

Altering Outward Tables

When an [ALTER TABLE](#) is issued, it just modifies the table definition accordingly without changing the data. [ALTER](#) can be used safely to, for instance, modify options such as MAPPED, HUGE or READONLY but with extreme care when modifying column definitions or order options because some column options such as FLAG should also be modified or may become wrong.

Changing the table type with [ALTER](#) often makes no sense. But many suspicious alterations can be acceptable if they are just meant to correct an existing wrong definition.

Translating a CONNECT table to another engine is fine but the opposite is forbidden when the target CONNECT table is not

table based or when its data file exists (because when the target table data cannot be changed and if the source table is dropped, the table data would be lost). However, it can be done to create a new file-based tables when its file does not exist or is void.

Creating or dropping indexes is accepted because it does not modify the table data. However, it is often unsafe to do it with an [ALTER TABLE](#) statement that does other modifications.

Of course, all changes are acceptable for empty tables.

Note: Using outward tables requires the [FILE](#) privilege.

Inward Tables

A special type of file-based CONNECT tables are "inward" tables. They are file-based tables whose file name is not specified in the [CREATE TABLE](#) statement (no `file_name` option).

Their file will be located in the current database directory and their name will default to `tablename.type` where `tablename` is the table name and `type` is the table type folded to lower case. When they are created without using a `CREATE TABLE ... SELECT ...` statement, an empty file is made at create time and they can be populated by further inserts.

They behave like tables of other storage engines and, unlike outward CONNECT tables, they are erased when the table is dropped. Of course they should not be read-only to be usable. Even though their utility is limited, they can be used for testing purposes or when the user does not have the [FILE](#) privilege.

Altering Inward Tables

One thing to know, because CONNECT builds indexes in a specific way, is that all index modifications are done using an "in-place" algorithm – meaning not using a temporary table. This is why, when indexing is specified in an [ALTER TABLE](#) statement containing other changes that cannot be done "in-place", the statement cannot be executed and raises an error.

Converting an inward table to an outward table, using an [ALTER TABLE](#) statement specifying a new file name and/or a new table type, is restricted the same way it is when converting a table from another engine to an outward table. However there are no restrictions to convert another engine table to a CONNECT inward table.

5.3.7.6.3 CONNECT Table Types - Data Files

Contents

1. [Multiple File Tables](#)
2. [Record Format](#)
3. [File Mapping](#)
4. [Big File Tables](#)
5. [Compressed File Tables](#)
6. [Relational Formatted Tables](#)
7. [NoSQL Table Types](#)

Most of the tables processed by CONNECT are just plain DOS or UNIX data files, logically regarded as tables thanks to the description given when creating the table. This description comes from the [CREATE TABLE](#) statement. Depending on the application, these tables can already exist as data files, used as is by CONNECT, or can have been physically made by CONNECT as the result of a `CREATE TABLE ... SELECT ...` and/or `INSERT` statement(s).

The file `path/name` is given by the `FILE_NAME` option. If it is a relative path/name, it will be relative to the database directory, the one containing the table `.FRM` file.

Unless specified, the maturity of file table types is stable.

Multiple File Tables

A **multiple** file table is one that is physically contained in several files of the same type instead of just one. These files are processed sequentially during the process of a query and the result is the same as if all the table files were merged into one. This is great to process files coming from different sources (such as cash register log files) or made at different time periods (such as bank monthly reports) regarded as one table. Note that the operations on such files are restricted to sequential Select and Update; and that VEC multiple tables are not supported by CONNECT. The file list depends on the setting of the **multiple** option of the [CREATE TABLE](#) statement for that table.

Multiple tables are specified by the option `MULTIPLE=n`, which can take four values:

0	Not a multiple table (the default). This can be used in an ALTER TABLE statement.
---	---

1	The table is made from files located in the same directory. The FILE_NAME option is a pattern such as 'cash*.log' that all the table file path/names verify.
2	The FILE_NAME gives the name of a file that contains the path/names of all the table files. This file can be made using a DIR table.
3	Like multiple=1 but also including eligible files from the directory sub-folders.

The FILEID special column, described [here](#), allows query pruning by filtering the file list or doing some grouping on the files that make a multiple table.

Note: Multiple was not initially implemented for XML tables. This restriction was removed in version 1.02.

Record Format

This characteristic applies to table files handled by the operating system input/output functions. It is **fixed** for table types [FIX](#), [BIN](#), [DBF](#) and [VEC](#), and it is variable for [DOS](#), [VCT](#), [FMT](#) and some [JSON](#) tables.

For fixed tables, most I/O operations are done by block of BLOCK_SIZE rows. This diminishes the number of I/O's and enables block indexing.

Starting with CONNECT version 1.6.6, the BLOCK_SIZE option can also be specified for variable tables. Then, a file similar to the block indexing file is created by CONNECT that gives the size in bytes of each block of BLOCK_SIZE rows. This enables the use of block I/Os and block indexing to variable tables. It also enables CONNECT to return the exact row number for info commands

File Mapping

For file-based tables of reasonable size, processing time can be greatly enhanced under Windows(TM) and some flavors of UNIX or Linux by using the technique of "file mapping", in which a file is processed as if it were entirely in memory. Mapping is specified when creating the table by the use of the MAPPED=YES option. This does not apply to tables not handled by system I/O functions ([XML](#) and [INI](#)).

Big File Tables

Because all files are handled by the standard input/output functions of the operating system, their size is limited to 2GB, the maximum size handled by standard functions. For some table types, CONNECT can deal with files that are larger than 2GB, or prone to become larger than this limit. These are the [FIX](#), [BIN](#) and [VEC](#) types. To tell connect to use input/output functions dealing with big files, specify the option huge=1 or huge=YES for that table. Note however that CONNECT cannot randomly access tables having more than 2G records.

Compressed File Tables

CONNECT can make and process some tables whose data file is compressed. The only supported compression format is the gzlib format. Zip and zlib formats are supported differently. The table types that can be compressed are [DOS](#), [FIX](#), [BIN](#), [CSV](#) and [FMT](#). This can save some disk space at the cost of a somewhat longer processing time.

Some restrictions apply to compressed tables:

- Compressed tables are not indexable.
- Update and partial delete are not supported.

Use the numeric compress option to specify a compressed table:

1. Not compressed
2. Compressed in gzlib format.
3. Made of compressed blocks of block_size records (enabling block indexing)

Relational Formatted Tables

These are based on files whose records represent one table row. Only the column representation within each record can differ. The following relational formatted tables are supported:

- [DOS and FIX Table Types](#)
- [DBF Table Type](#)
- [BIN Table Type](#)
- [VEC Table Type](#)
- [CSV and FMT Table Types](#)

NoSQL Table Types

These are based on files that do not match the relational format but often represent hierarchical data. CONNECT can handle JSON, INI-CFG, XML and some HTML files..

The way it is done is different from what PostgreSQL does. In addition to including in a table some column values of a specific data format (JSON, XML) to be handled by specific functions, CONNECT can directly use JSON, XML or INI files that can be produced by other applications and this is the table definition that describes where and how the contained information must be retrieved.

This is also different from what MariaDB does with [dynamic columns](#), which is close to what MySQL and PostgreSQL do with the JSON column type.

The following NoSQL types are supported:

- [XML Table Type](#)
- [JSON Table Type](#)
- [INI Table Type](#)

5.3.7.6.4 CONNECT Zipped File Tables

MariaDB starting with [10.2.4](#)

Connect can work on table files that are compressed in one or several zip files.

The specific options used when creating tables based on zip files are:

Table Option	Type	Description
ZIPPED	Boolean	Required to be set as true.
ENTRY*	String	The optional name or pattern of the zip entry or entries to be used with the table. If not specified, all entries or only the first one will be used depending on the <i>muletries</i> option setting.
MULETRIES*	Boolean	True if several entries are part of the table. If not specified, it defaults to false if the <i>entry</i> option is not specified. If the entry option is specified, it defaults to true if the entry name contains wildcard characters or false if it does not.
APPEND*	Boolean	Used when creating new zipped tables (see below)
LOAD*	String	Used when creating new zipped tables (see below)

Options marked with a '*' must be specified in the option list.

Examples of use:

Example 1: Single CSV File Included in a Single ZIP File

Let's suppose you have a CSV file from which you would create a table by:

```
create table emp
... optional column definition
engine=connect table_type=CSV file_name='E:/Data/employee.csv'
sep_char=';' header=1;
```

If the CSV file is included in a ZIP file, the CREATE TABLE becomes:

```
create table empzip
... optional column definition
engine=connect table_type=CSV file_name='E:/Data/employee.zip'
sep_char=';' header=1 zipped=1 option_list='Entry=emp.csv';
```

The *file_name* option is the name of the zip file. The *entry* option is the name of the entry inside the zip file. If there is only one entry file inside the zip file, this option can be omitted.

Example 2: Several CSV Files Included in a Single ZIP File

If the table is made from several files such as emp01.csv, emp02.csv, etc., the standard create table would be:

```
create table empmul (
... required column definition
) engine=connect table_type=CSV file_name='E:/Data/emp*.csv'
sep_char=';' header=1 multiple=1;
```

But if these files are all zipped inside a unique zip file, it becomes:

```
create table empzmul
... required column definition
engine=connect table_type=CSV file_name='E:/Data/emp.zip'
sep_char=';' header=1 zipped=1 option_list='Entry=emp*.csv';
```

Here the *entry* option is the pattern that the files inside the zip file must match. If all entry files are ok, the *entry* option can be omitted but the Boolean option *mulentries* must be specified as true.

Example 3: Single CSV File included in Multiple ZIP Files (Without considering subfolders)

If the table is created on several zip files, it is specified as for all other multiple tables:

```
create table zempmul (
... required column definition
) engine=connect table_type=CSV file_name='E:/Data/emp*.zip'
sep_char=';' header=1 multiple=1 zipped=yes
option_list='Entry=employee.csv';
```

Here again the *entry* option is used to restrict the entry file(s) to be used inside the zip files and can be omitted if all are ok.

The column descriptions can be retrieved by the discovery process for table types allowing it. It cannot be done for multiple tables or multiple entries.

A catalog table can be created by adding *catfunc=columns*. This can be used to show the column definitions of multiple tables. *Multiple* must be set to false and the column definitions will be the ones of the first table or entry.

This first implementation has some restrictions:

1. Zipped tables are read-only. **UPDATE** and **DELETE** are not supported. However, **INSERT** is supported in a specific way when making tables.
2. The inside files are decompressed into memory. Memory problems may arise with huge files.
3. Only file types that can be handled from memory are eligible for this. This includes **DOS**, **FIX**, **BIN**, **CSV**, **FMT**, **DBF**, **JSON**, and **XML** table types, as well as types based on these such as **XCOL**, **OCCUR** and **PIVOT**.

Optimization by indexing or block indexing is possible for table types supporting it. However, it applies to the uncompressed table. This means that the whole table is always uncompressed.

Partitioning is also supported. See how to do it in the section about partitioning.

Creating New Zipped Tables

Tables can be created to access already existing zip files. However, is it also possible to make the zip file from an existing file or table. Two ways are available to make the zip file:

Insert Method

insert can be used to make the table file for table types based on records (this excludes DBF, XML and JSON when pretty is not 0). However, the current implementation of the used package (minizip) does not support adding to an already existing zip entry. This means that when executing an insert statement the inserted records are not added but replace the existing ones. CONNECT protects existing data by not allowing such inserts, Therefore, only three ways are available to do so:

1. Using only one insert statement to make the whole table. This is possible only for small tables and is principally useful when making tests.
2. Making the table from the data of another table. This can be done by executing an "insert into table select * from another_table" or by specifying "as select * from another_table" in the create table statement.
3. Making the table from a file whose format enables to use the "load data infile" statement.

To add a new entry in an existing zip file, specify "append=YES" in the option list. When inserting several entries, use ALTER to specify the required options, for instance:

```

create table znumul (
Chiffre int(3) not null,
Lettre char(16) not null)
engine=CONNECT table_type=CSV
file_name='C:/Data/FMT/mnum.zip' header=1 lrecl=20 zipped=1
option_list='Entry=Num1';
insert into znumul select * from num1;
alter table znumul option_list='Entry=Num2,Append=YES';
insert into znumul select * from num2;
alter table znumul option_list='Entry=Num3,Append=YES';
insert into znumul select * from num3;
alter table znumul option_list='Entry=Num*,Append=YES';
select * from znumul;

```

The last ALTER is needed to display all the entries.

File Zipping Method

This method enables to make the zip file from another file when creating the table. It applies to all table types including DBF, XML and JSON. It is specified in the create table statement with the load option. For example:

```

create table XSERVZIP (
NUMERO varchar(4) not null,
LIEU varchar(15) not null,
CHEF varchar(5) not null,
FONCTION varchar(12) not null,
NOM varchar(21) not null)
engine=CONNECT table_type=XML file_name='E:/Xml/perso.zip' zipped=1
option_list='entry=services,load=E:/Xml/serv2.xml';

```

When executing this statement, the *serv2.xml* file will be zipped as */perso.zip*. *The entry name can be specified or defaults to the source file name.*

If the column descriptions are specified, the table can be used later to read from the zipped table, but they are not used when creating the zip file. Thus, a fake column (there must be one) can be specified and another table created to read the zip file. This one can take advantage of the discovery process to avoid providing the columns description for table types allowing it. For instance:

```

create table mkzq (whatever int)
engine=connect table_type=DBF zipped=1
file_name='C:/Data/EAUX/dbf/CQUART.ZIP'
option_list='Load=C:/Data/EAUX/dbf/CQUART.DBF';

create table zquart
engine=connect table_type=DBF zipped=1
file_name='C:/Data/EAUX/dbf/CQUART.ZIP';

```

It is also possible to create a multi-entries table from several files:

```

CREATE TABLE znewcities (
_id char(5) NOT NULL,
city char(16) NOT NULL,
lat double(18,6) NOT NULL `FIELD_FORMAT`='loc:[0]',
lng double(18,6) NOT NULL `FIELD_FORMAT`='loc:[1]',
pop int(6) NOT NULL,
state char(2) NOT NULL
) ENGINE=CONNECT TABLE_TYPE=JSON FILE_NAME='E:/Json/newcities.zip' ZIPPED=1 LRECL=1000
OPTION_LIST='Load=E:/Json/city_*.json,mulentries=YES,pretty=0';

```

Here the files to load are specified with wildcard characters and the *mulentries* options must be specified. However, the *entry* option must not be specified, entry names will be made from the file names. Provide a fake column description if the files have different column layout, but specific tables will have to be created to read each of them.

ZIP Table Type

A ZIP table type is also available. It is not meant to read the inside files but to display information about the zip file contents. For instance:

```
create table xzipinfo2 (
entry varchar(256) not null,
cmpsize bigint not null flag=1,
unysize bigint not null flag=2,
method int not null flag=3,
date datetime not null flag=4)
engine=connect table_type=ZIP file_name='E:/Data/Json/cities.zip';
```

This will display the name, compressed size, uncompressed size, and compress method of all entries inside the zip file. Column names are irrelevant; these are flag values that mean what information to retrieve.

It is possible to retrieve this information from several zip files by specifying the multiple option:

```
create table TestZip1 (
entry varchar(260) not null,
cmpsize bigint not null flag=1,
unysize bigint not null flag=2,
method int not null flag=3,
date datetime not null flag=4,
zipname varchar(256) special='FILEID')
engine=connect table_type=ZIP multiple=1
file_name='C:/Data/Ziptest/CCAM06300_DBF_PART*.zip';
```

Here we added the special column zipname to get the name of the zip file for each entry.

5.3.7.6.5 CONNECT DOS and FIX Table Types

Contents

1. [Overview](#)
2. [Specifying the Field Format](#)
3. [Example](#)

Overview

Tables of type DOS and FIX are based on text files (see [CONNECT Table Types - Data Files](#)). Within a record, column fields are positioned at a fixed offset from the beginning of the record. Except sometimes for the last field, column fields are also of fixed length. If the last field has varying length, the type of the table is DOS. For instance, having the file *dept.dat* formatted like:

```
0318 KINGSTON      70012 SALES      Bank/Insurance
0021 ARMONK        87777 CHQ        Corporate headquarter
0319 HARRISON      40567 SALES      Federal Administration
2452 POUGHKEEPSIE 31416 DEVELOPMENT Research & development
```

You can define a table based on it with:

```
create table department (
number char(4) not null,
location char(15) not null flag=5,
director char(5) not null flag=20,
function char(12) not null flag=26,
name char(22) not null flag=38)
engine=CONNECT table_type=DOS file_name='dept.dat';
```

Here the flag column option represents the offset of this column inside the records. If the offset of a column is not specified, it defaults to the end of the previous column and defaults to 0 for the first one. The *lrecl* parameter that represents the maximum size of a record is calculated by default as the end of the rightmost column and can be unspecified except when some trailing information exists after the rightmost column.

Note: A special case is files having an encoding such as UTF-8 (for instance specifying `charset=UTF8`) in which some characters may be represented with several bytes. Unlike the type size that MariaDB interprets as a number of characters, the *lrecl* value is the record size in bytes and the flag value represents the offset of the field in the record in bytes. If the flag and/or the *lrecl* value are not specified, they will be calculated by the number of characters in the fields multiplied by a value that is the maximum size in bytes of a character for the corresponding charset. For UTF-8 this value is 3 which is often far too much as there are very few characters requiring 3 bytes to be

represented. When creating a new file, you are on the safe side by only doubling the maximum number of characters of a field to calculate the offset of the next field. Of course, for already existing files, the offset must be specified according to what it is in it.

Although the field representation is always text in the table file, you can freely choose the corresponding column type, characters, date, integer or floating point according to its contents.

Sometimes, as in the *number* column of the above *department* table, you have the choice of the type, numeric or characters. This will modify how the column is internally handled — in characters `0021` is different from `21` but not in numeric — as well as how it is displayed.

If the last field has fixed length, the table should be referred as having the type `FIX`. For instance, to create a table on the file *boys.txt*:

```
John      Boston      25/01/1986  02/06/2010
Henry     Boston      07/06/1987  01/04/2008
George    San Jose    10/08/1981  02/06/2010
Sam       Chicago     22/11/1979  10/10/2007
James     Dallas      13/05/1992  14/12/2009
Bill      Boston      11/09/1986  10/02/2008
```

You can for instance use the command:

```
create table boys (
  name char(12) not null,
  city char(12) not null,
  birth date not null date_format='DD/MM/YYYY',
  hired date not null date_format='DD/MM/YYYY' flag=36)
engine=CONNECT table_type=FIX file_name='boys.txt' lrecl=48;
```

Here some *flag* options were not specified because the fields have no intermediate space between them except for the last column. The offsets are calculated by default adding the field length to the *offset* of the preceding field. However, for formatted date columns, the offset in the file depends on the format and cannot be calculated by default. For fixed files, the *lrecl* option is the physical length of the record including the line ending character(s). It is calculated by adding to the end of the last field 2 bytes under Windows (CRLF) or 1 byte under UNIX. If the file is imported from another operating system, the `ENDING` option will have to be specified with the proper value.

For this table, the last offset and the record length must be specified anyway because the date columns have field length coming from their format that is not known by `CONNECT`. Do not forget to add the line ending length to the total length of the fields.

This table is displayed as:

name	city	birth	hired
John	Boston	1986-01-25	2010-06-02
Henry	Boston	1987-06-07	2008-04-01
George	San Jose	1981-08-10	2010-06-02
Sam	Chicago	1979-11-22	2007-10-10
James	Dallas	1992-05-13	2009-12-14
Bill	Boston	1986-09-11	2008-02-10

Whenever possible, the fixed format should be preferred to the varying one because it is much faster to deal with fixed tables than with variable tables. Sure enough, instead of being read or written record by record, `FIX` tables are processed by blocks of `BLOCK_SIZE` records, resulting in far less input/output operations to execute. The block size defaults to 100 if not specified in the Create Table statement.

Note 1: It is not mandatory to declare in the table all the fields existing in the source file. However, if some fields are ignored, the *flag* option of the following field and/or the *lrecl* option will have to be specified.

Note 2: Some files have an EOF marker (CTRL+Z 1A) that can prevent the table to be recognized as fixed because the file length is not a multiple of the fixed record size. To indicate this, use in the option list the create option `EOF`. For instance, if after creating the `FIX` table *xtab* on the file *foo.dat* that you know have fixed record size, you get, when you try to use it, a message such as:

```
File foo.dat is not fixed length, len=302587 lrecl=141
```

After checking that the LRECL default or specified specification is correct, you can indicate to ignore that extra EOF character by:

```
alter table xtab option_list='eof=1';
```

Of course, you can specify this option directly in the Create statement. All this applies to some other table types, in particular to BIN tables.

Note 3: The width of the fields is the length specified in the column declaration. For instance for a column declared as:

```
number int(3) not null,
```

The field width in the file is 3 characters. This is the value used to calculate the offset of the next field if it is not specified. If this length is not specified, it defaults to the MySQL default type length.

Specifying the Field Format

Some files have specific format for their numeric fields. For instance, the decimal point is absent and/or the field should be filled with leading zeros. To deal with such files, as well in reading as in writing, the format can be specified in the `CREATE TABLE` column definition. The syntax of the field format specification is:

```
Field_format='[Z][N][d]'
```

The optional parts of the format are:

- Z** The field has leading zeros
- N** No decimal point exist in the file
- d** The number of decimals, defaults to the column precision

Example

Let us see how it works in the following example. We define a table based on the file `xfmt.txt` having eight fields of 12 characters:

```
create table xfmt (  
  col1 double(12,3) not null,  
  col2 double(12,3) not null field_format='4',  
  col3 double(12,2) not null field_format='N3',  
  col4 double(12,3) not null field_format='Z',  
  col5 double(12,3) not null field_format='Z3',  
  col6 double(12,5) not null field_format='ZN5',  
  col7 int(12) not null field_format='N3',  
  col8 smallint(12) not null field_format='N3')  
engine=CONNECT table_type=FIX file_name='xfmt.txt';  
  
insert into xfmt values(4567.056,4567.056,4567.056,4567.056,-23456.8,  
  3.14159,4567,4567);  
select * from xfmt;
```

The first row is displayed as:

COL1	COL2	COL3	COL4	COL5	COL6	COL7	COL8
4567.056	4567.056	4567.06	4567.056	-23456.800	3.14159	4567	4567

The number of decimals displayed for all float columns is the column precision, the second argument of the column type option. Of course, integer columns have no decimals, although their formats specify some.

More interesting is the file layout. To see it let us define another table based on the same file but whose columns are all characters:

```

create table cfmt (
  col1 char(12) not null,
  col2 char(12) not null,
  col3 char(12) not null,
  col4 char(12) not null,
  col5 char(12) not null,
  col6 char(12) not null,
  col7 char(12) not null,
  col8 char(12) not null)
engine=CONNECT table_type=FIX file_name='xfmt.txt';
select * from cfmt;

```

The (transposed) display of the select command shows the file text layout for each field. Below a third column was added in this document to comment this result.

Column	Row 1	Comment (all numeric fields are written right justified)
COL1	4567.056	No format, the value was entered as is.
COL2	4567.0560	The format '4' forces to write 4 decimals.
COL3	4567060	N3 → No decimal point. The last 3 digits are decimals. However, the second decimal was rounded because of the column precision.
COL4	00004567.056	Z → Leading zeros, 3 decimals (the column precision)
COL5	-0023456.800	Z3 → (Minus sign) leading zeros, 3 decimals.
COL6	000000314159	ZN5 → Leading zeros, no decimal point, 5 decimals.
COL7	4567000	N3 → No decimal point. The last 3 digits are decimals.
COL8	4567000	Same. Any decimals would be ignored.

Note: For columns internally using double precision floating-point numbers, MariaDB limits the decimal precision of any calculation to the column precision. The declared column precision should be at least the number of decimals of the format to avoid a loss of decimals as it happened for `col3` of the above example.

5.3.7.6.6 CONNECT DBF Table Type

Contents

- [1. Overview](#)
- [2. Conversion of dBASE Data Types](#)
- [3. Reading soft deleted lines of a DBF table](#)

Overview

A table of type `DBF` is physically a dBASE III or IV formatted file (used by many products like dBASE, Xbase, FoxPro etc.). This format is similar to the `FIX` type format with in addition a prefix giving the characteristics of the file, describing in particular all the fields (columns) of the table.

Because `DBF` files have a header that contains Meta data about the file, in particular the column description, it is possible to create a table based on an existing `DBF` file without giving the column description, for instance:

```

create table cust engine=CONNECT table_type=DBF file_name='cust.dbf';

```

To see what `CONNECT` has done, you can use the `DESCRIBE` or `SHOW CREATE TABLE` commands, and eventually modify some options with the `ALTER TABLE` command.

The case of deleted lines is handled in a specific way for `DBF` tables. Deleted lines are not removed from the file but are "soft deleted" meaning they are marked as deleted. In particular, the number of lines contained in the file header does not take care of soft deleted lines. This is why if you execute these two commands applied to a `DBF` table named `tabdbf`:

```

select count(*) from tabdbf;
select count(*) from tabdbf where 1;

```

They can give a different result, the (fast) first one giving the number of physical lines in the file and the second one giving the number of line that are not (soft) deleted.

The commands UPDATE, INSERT, and DELETE can be used with DBF tables. The DELETE command marks the deleted lines as suppressed but keeps them in the file. The INSERT command, if it is used to populate a newly created table, constructs the file header before inserting new lines.

Note: For DBF tables, column name length is limited to 11 characters and field length to 256 bytes.

Conversion of dBASE Data Types

CONNECT handles only types that are stored as characters.

Symbol	DBF Type	CONNECT Type	Description
B	Binary (string)	TYPE_STRING	10 digits representing a .DBT block number.
C	Character	TYPE_STRING	All OEM code page characters - padded with blanks to the width of the field.
D	Date	TYPE_DATE	8 bytes - date stored as a string in the format YYYYMMDD.
N	Numeric	TYPE_INT TYPE_BIGINT TYPE_DOUBLE	Number stored as a string, right justified, and padded with blanks to the width of the field.
L	Logical	TYPE_STRING	1 byte - initialized to 0x20 otherwise T or F.
M	Memo (string)	TYPE_STRING	10 digits representing a .DBT block number.
@	Timestamp	Not supported	8 bytes - two longs, first for date, second for time. It is the number of days since 01/01/4713 BC.
I	Long	Not supported	4 bytes. Leftmost bit used to indicate sign, 0 negative.
+	Autoincrement	Not supported	Same as a Long
F	Float	TYPE_DOUBLE	Number stored as a string, right justified, and padded with blanks to the width of the field.
O	Double	Not supported	8 bytes - no conversions, stored as a double.
G	OLE	TYPE_STRING	10 digits representing a .DBT block number.

For the N numeric type, CONNECT converts it to TYPE_DOUBLE if the decimals value is not 0, to TYPE_BIGINT if the length value is greater than 10, else to TYPE_INT.

For M, B, and G types, CONNECT just returns the DBT number.

Reading soft deleted lines of a DBF table

It is possible to read these lines by changing the read mode of the table. This is specified by an option `READMODE` that can take the values:

- 0 Standard mode. This is the default option.
- 1 Read all lines including soft deleted ones.
- 2 Read only the soft deleted lines.

For example, to read all lines of the `tabdbf` table, you can do:

```
alter table tabdbf option_list='Readmode=1';
```

To come back to normal mode, specify `READMODE=0`.

5.3.7.6.7 CONNECT BIN Table Type

Contents

1. [Overview](#)
2. [Type Conversion in BIN Tables](#)
3. [Example](#)
4. [Numeric fields alignment](#)

Overview

A table of type BIN is physically a binary file in which each row is a logical record of fixed length ^[1]. Within a record, column fields are of a fixed offset and length as with [FIX tables](#). Specific to BIN tables is that numerical values are internally encoded using native platform representation, so no conversion is needed to handle numerical values in expressions.

It is not required that the lines of a BIN file be separated by characters such as CR and/or LF but this is possible. In such an event, the *irecl* option must be specified accordingly.

Note: Unlike for the [DOS and FIX types](#), the width of the fields is the length of their internal representation in the file. For instance for a column declared as:

```
number int(5) not null,
```

The field width in the file is 4 characters, the size of a binary integer. This is the value used to calculate the offset of the next field if it is not specified. Therefore, if the next field is placed 5 characters after this one, this declaration is not enough, and the flag option will have to be used on the next field.

Type Conversion in BIN Tables

Here are the correspondences between the column type and field format provided by default:

Column type	File default format
Char(<i>n</i>)	Text of <i>n</i> characters.
Date	Integer (4 bytes)
Int(<i>n</i>)	Integer (4 bytes)
Smallint(<i>n</i>)	Short integer (2 bytes)
TinyInt(<i>n</i>)	Char (1 Byte)
Bigint(<i>n</i>)	Large integer (8 bytes)
Double(<i>n</i> , <i>d</i>)	Double floating point (8 bytes)

However, the column type need not necessarily match the field format within the table file. In particular, this occurs for field formats that correspond to numeric types that are not handled by [CONNECT](#)^[2]. Indeed, BIN table files may internally contain float numbers or binary numbers of any byte length in big-endian or little-endian representation^[3]. Also, as in [DOS or FIX types](#) tables, you may want to handle some character fields as numeric or vice versa.

This is why it is possible to specify the field format when it does not correspond to the column type default using the *field_format* column option in the [CREATE TABLE](#) statement. Here are the available field formats for BIN tables:

Field_format	Internal representation
[<i>n</i>]{ L or B or H }[<i>n</i>]	<i>n</i> bytes binary number in little endian, big endian or host endian representation.
C	Characters string (<i>n</i> bytes)
I	integer (4 bytes)
D	Double float (8 bytes)
S	Short integer (2 bytes)
T	Tiny integer (1 byte)
G	Big integer (8 bytes)
F or R	Real or float (Floating point number on 4 bytes)
X	Use the default format field for the column type

All field formats (except the first one) are a one-character specification ^[4]. 'X' is equivalent to not specifying the field format. For the 'C' character specification, *n* is the column width as specified with the column type. For one-column formats, the number of bytes of the numeric fields corresponds to what it is on most platforms. However, it could vary for some. The G, I, S and T formats are deprecated because they correspond to supported data types and may not be supported in future versions.

Example

Here is an example of a BIN table. The file record layout is supposed to be:

```
NNNNCCCCCCCCCIIIISSFFFFSS
```

Here N represents numeric characters, C any characters, I integer bytes, S short integer bytes, and F float number bytes. The `IIII` field contains a date in numeric format.

The table could be created by:

```
create table testbal (  
  fig int(4) not null field_format='C',  
  name char(10) not null,  
  birth date not null field_format='L',  
  id char(5) not null field_format='L2',  
  salary double(9,2) not null default 0.00 field_format='F',  
  dept int(4) not null field_format='L2')  
engine=CONNECT table_type=BIN block_size=5 file_name='Testbal.dat';
```

Specifying the little-endian representation for binary values is not useful on most machines, but makes the create table statement portable on a machine using big endian, as well as the table file.

The field offsets and the file record length are calculated according the column internal format and eventually modified by the field format. It is not necessary to specify them for a packed binary file without line endings. If a line ending is desired, specify the ending option or specify the `lrecl` option adding the ending width. The table can be filled by:

```
insert into testbal values  
  (5500, 'ARCHIBALD', '1980-01-25', '3789', 4380.50, 318),  
  (123, 'OLIVER', '1953-08-10', '23456', 3400.68, 2158),  
  (3123, 'FOO', '2002-07-23', '888', default, 318);
```

Note that the types of the inserted values must match the column type, not the field format type.

The query:

```
select * from testbal;
```

returns:

fig	name	birth	id	salary	dept
5500	ARCHIBALD	1980-01-25	3789	4380.50	318
123	OLIVER	1953-08-10	23456	3400.68	2158
3123	FOO	2002-07-23	888	0.00	318

Numeric fields alignment

In binary files, numeric fields and record length can be aligned on 4-or-8-byte boundaries to optimize performance on certain processors. This can be modified in the `OPTION_LIST` with an "align" option ("packed" meaning `align=1` is the default).

- ↑ Sometimes it can be a physical record if LF or CRLF have been written in the file.
- ↑ Most of these are obsolete because CONNECT supports all column types except float
- ↑ The default endian representation used in the table file can be specified by setting the `ENDIAN` option as 'L' or 'B' in the option list.
- ↑ It can be specified with more than one character, but only the first one is significant.

5.3.7.6.8 CONNECT VEC Table Type

Contents

- [Integral vector formats](#)
- [Differences between vector formats](#)
- [Header option](#)

Warning: Avoid using this table type in production applications. This file format is specific to CONNECT and may not be supported in future versions.

Tables of type `VEC` are binary files that in some cases can provide good performance on read-intensive query workloads. CONNECT organizes their data on disk as columns of values from the same attribute, as opposed to storing it as rows of tabular records. This organization means that when a query needs to access only a few columns of a particular table, only those columns need to be read from disk. Conversely, in a row-oriented table, all values in a table are typically read from disk, wasting I/O bandwidth.

CONNECT provides two integral VEC formats, in which each column's data is adjacent.

Integral vector formats

In these true vertical formats, the VEC files are made of all the data of the first column, followed by all the data of the second column etc. All this can be in one physical file or each column data can be in a separate file. In the first case, the option `max_rows=m`, where `m` is the estimate of the maximum size (number of rows) of the table, must be specified to be able to insert some new records. This leaves an empty space after each column area in which new data can be inserted. In the second case, the "Split" option can be specified^[2] at table creation and each column will be stored in a file named sequentially from the table file name followed by the rank of the column. Inserting new lines can freely augment such a table.

Differences between vector formats

These formats correspond to different needs. The integral vector format provides the best performance gain. It will be chosen when the speed of decisional queries must be optimized.

In the case of a unique file, inserting new data will be limited but there will be only one open and close to do. However, the size of the table cannot be calculated from the file size because of the eventual unused space in the file. It must be kept in a header containing the maximum number of rows and the current number of valid rows in the table. To achieve this, specify the option `Header=n` when creating the table. If `n=1` the header will be placed at the beginning of the file, if `n=2` it will be a separate file with the type `'blk'`, and if `n=3` the header will be placed at the end of the file. This last value is provided because batch inserting is sometimes slower when the header is at the beginning of the file. If not specified, the header option will default to 2 for this table type.

On the other hand, the "Split" format with separate files have none of these issues, and is a much safer solution when the table must frequently be inserted or shared among several users.

For instance:

```
create table vtab (  
  a int not null,  
  b char(10) not null)  
engine=CONNECT table_type=VEC file_name='vt.vec';
```

This table, split by default, will have the column values in files `vt1.vec` and `vt2.vec`.

For vector tables, the option `block_size=n` is used for block reading and writing; however, to have a file made of blocks of equal size, the internal value of the `max_rows=m` option is eventually increased to become a multiple of `n`.

Like for BIN tables, numeric values are stored using platform internal layout, the correspondence between column types and internal format being the same than the default ones given above for BIN. However, field formats are not available for VEC tables.

Header option

This applies to VEC tables that are not split. Because the file size depends on the `MAX_ROWS` value, CONNECT cannot know how many valid records exist in the file. Depending on the value of the `HEADER` option, this information is stored in a header that can be placed at the beginning of the file, at the end of the file or in a separate file called `fn.blk`. The valid values for the `HEADER` option are:

- 0 Defaults to 2 for standard tables and to 3 for inward tables.
- 1 The header is at the beginning of the file.
- 2 The header is in a separate file.
- 3 The header is at the end of the file.

The value 2 can be used when dealing with files created by another application with no header. The value 3 makes sometimes inserting in the file faster than when the header is at the beginning of the file.

Note: VEC being a file format specific to CONNECT, no big endian / little endian conversion is provided. These files are not portable between machines using a different byte order setting.

5.3.7.6.9 CONNECT CSV and FMT Table Types

Contents

- 1. [CSV Type](#)
 - 1. [Restrictions on CSV Tables](#)
- 2. [FMT Type](#)
- 3. [Column Format Specification of FMT tables](#)
- 4. [Optional Fields](#)
- 5. [Bad Record Error Processing](#)
- 6. [Fields Containing a Formatted Date](#)

CSV Type

Many source data files are formatted with variable length fields and records. The simplest format, known as `CSV` (Comma Separated Variables), has column fields separated by a separator character. By default, the separator is a comma but can be specified by the `SEP_CHAR` option as any character, for instance a semi-colon.

If the CSV file first record is the list of column names, specifying the `HEADER=1` option will skip the first record on reading. On writing, if the file is empty, the column names record is automatically written.

For instance, given the following `people.csv` file:

```
Name;birth;children
"Archibald";17/05/01;3
"Nabucho";12/08/03;2
```

You can create the corresponding table by:

```
create table people (
  name char(12) not null,
  birth date not null date_format='DD/MM/YY',
  children smallint(2) not null)
engine=CONNECT table_type=CSV file_name='people.csv'
header=1 sep_char=';' quoted=1;
```

Alternatively the engine can attempt to automatically detect the column names, data types and widths using:

```
create table people
engine=CONNECT table_type=CSV file_name='people.csv'
header=1 sep_char=';' quoted=1;
```

For CSV tables, the `flag` column option is the rank of the column into the file starting from 1 for the leftmost column. This is to enable having column displayed in a different order than in the file and/or to define the table specifying only some columns of the CSV file. For instance:

```
create table people (
  name char(12) not null,
  children smallint(2) not null flag=3,
  birth date not null flag=2 date_format='DD/MM/YY')
engine=CONNECT table_type=CSV file_name='people.csv'
header=1 sep_char=';' quoted=1;
```

In this case the command:

```
select * from people;
```

will display the table as:

name	children	birth
Archibald	3	2001-05-17
Nabucho	2	2003-08-12

Many applications produce CSV files having some fields quoted, in particular because the field text contains the separator character. For such files, specify the `'QUOTED=n'` option to indicate the level of quoting and/or the `'QCHAR=c'` to specify what is this eventual quoting character, which is `"` by default. Quoting with single quotes must be specified as

`QCHAR='''` . On writing, fields will be quoted depending on the value of the quoting level, which is `-1` by default meaning no quoting:

- 0 The fields between quotes are read and the quotes discarded. On writing, fields will be quoted only if they contain the separator character or begin with the quoting character. If they contain the quoting character, it will be doubled.
- 1 Only text fields will be written between quotes, except null fields. This includes also the column names of an eventual header.
- 2 All fields will be written between quotes, except null fields.
- 3 All fields will be written between quotes, including null fields.

Files written this way are successfully read by most applications including spreadsheets.

Note 1: If only the `QCHAR` option is specified, the `QUOTED` option will default to 1.

Note 2: For CSV tables whose separator is the tab character, specify `sep_char='\t'` .

Note 3: When creating a table on an existing CSV file, you can let `CONNECT` analyze the file and make the column description. However, this is not an elaborate analysis of the file and, for instance, `DATE` fields will not be recognized as such but will be regarded as string fields.

Note 4: The CSV parser only reads and buffers up to 4KB per row by default, rows longer than this will be truncated when read from the file. If the rows are expected to be longer than this use `lrecl` to increase this. For example to set an 8KB maximum row read you would use `lrecl=8192`

Restrictions on CSV Tables

- If `secure_file_priv` is set to the path of some directory, then CSV tables can only be created with files in that directory.

FMT Type

FMT tables handle files of various formats that are an extension of the concept of CSV files. `CONNECT` supports these files providing all lines have the same format and that all fields present in all records are recognizable (optional fields must have recognizable delimiters). These files are made by specific application and `CONNECT` handles them in read only mode.

FMT tables must be created as CSV tables, specifying their type as `FMT`. In addition, each column description must be added to its format specification.

Column Format Specification of FMT tables

The input format for each column is specified as a `FIELD_FORMAT` option. A simple example is:

```
IP Char(15) not null field_format=' %n%s%n',
```

In the above example, the format for this (1st) field is `' %n%s%n'` . Note that the blank character at the beginning of this format is significant. No trailing blank should be specified in the column formats.

The syntax and meaning of the column input format is the one of the `C scanf` function.

However, `CONNECT` uses the input format in a specific way. Instead of using it to directly store the input value in the column buffer; it uses it to delimit the sub string of the input record that contains the corresponding column value. Retrieving this value is done later by the column functions as for standard CSV files.

This is why all column formats are made of five components:

1. An eventual description of what is met and ignored before the column value.
2. A marker of the beginning of the column value written as `%n` .
3. The format specification of the column value itself.
4. A marker of the end of the column value written as `%n` (or `%m` for optional fields).
5. An eventual description of what is met after the column value (not valid is `%m` was used).

For example, taking the file `funny.txt`:

```
12345, 'BERTRAND', #200; 5009.13
56, 'POIROT-DELMOTTE' , #4256 ; 18009
345 , 'TRUCMUCHE' , #67; 19000.25
```

You can make a table `fmtsampl` with 4 columns `ID`, `NAME`, `DEPNO` and `SALARY`, using the `Create Table` statement and

column formats:

```
create table FMTSAMPLE (  
  ID Integer(5) not null field_format=' %n%d%n',  
  NAME Char(16) not null field_format=' , ''%n%[^']*%n'',  
  DEPNO Integer(4) not null field_format=' , #%n%d%n',  
  SALARY Double(12,2) not null field_format=' ; %n%f%n')  
Engine=CONNECT table_type=FMT file_name='funny.txt';
```

Field 1 is an integer (%d) with eventual leading blanks.

Field 2 is separated from field 1 by optional blanks, a comma, and other optional blanks and is between single quotes. The leading quote is included in component 1 of the column format, followed by the %n marker. The column value is specified as %['^'] meaning to keep any characters read until a quote is met. The ending marker (%n) is followed by the 5th component of the column format, the single quote that follows the column value.

Field 3, also separated by a comma, is a number preceded by a pound sign.

Field 4, separated by a semicolon eventually surrounded by blanks, is a number with an optional decimal point (%f).

This table will be displayed as:

ID	NAME	DEPNO	SALARY
12345	BERTRAND	200	5009.13
56	POIROT-DELMOTTE	4256	18009.00
345	TRUCMUCHE	67	19000.25

Optional Fields

To be recognized, a field normally must be at least one character long. For instance, a numeric field must have at least one digit, or a character field cannot be void. However many existing files do not follow this format.

Let us suppose for instance that the preceding example file could be:

```
12345, 'BERTRAND', #200; 5009.13  
56, 'POIROT-DELMOTTE' , # ; 18009  
345 , ' ' , #67; 19000.25
```

This will display an error message such as "Bad format line x field y of FMTSAMPLE". To avoid this and accept these records, the corresponding fields must be specified as "optional". In the above example, fields 2 and 3 can have null values (in lines 3 and 2 respectively). To specify them as optional, their format must be terminated by %m (instead of the second %n). A statement such as this can do the table creation:

```
create table FMTAMPLE (  
  ID Integer(5) not null field_format=' %n%d%n',  
  NAME Char(16) not null field_format=' , ''%n%[^']*%m',  
  DEPNO Integer(4) field_format=' ' , #%n%d%m',  
  SALARY Double(12,2) field_format=' ; %n%f%n')  
Engine=CONNECT table_type=FMT file_name='funny.txt';
```

Note that, because the statement must be terminated by %m with no additional characters, skipping the ending quote of field 2 was moved from the end of the second column format to the beginning of the third column format.

The table result is:

ID	NAME	DEPNO	SALARY
12345	BERTRAND	200	5,009.13
56	POIROT-DELMOTTE	NULL	18,009.00
345	NULL	67	19,000.25

Missing fields are replaced by null values if the column is nullable, blanks for character strings and 0 for numeric fields if it is not.

Note 1: Because the formats are specified between quotes, quotes belonging to the formats must be doubled or escaped to avoid a CREATE TABLE statement syntax error.

Note 2: Characters separating columns can be included as well in component 5 of the preceding column format or in

component 1 of the succeeding column format but for blanks, which should be always included in component 1 of the succeeding column format because line trailing blanks can be sometimes lost. This is also mandatory for optional fields.

Note 3: Because the format is mainly used to find the sub-string corresponding to a column value, the field specification does not necessarily match the column type. For instance supposing a table contains two integer columns, NBONE and NBTWO, the two lines describing these columns could be:

```
NBONE integer(5) not null field_format=' %n%d%n',
NBTWO integer(5) field_format=' %n%s%n',
```

The first one specifies a required integer field (%d), the second line describes a field that can be an integer, but can be replaced by a "-" (or any other) character. Specifying the format specification for this column as a character field (%s) enables to recognize it with no error in all cases. Later on, this field will be converted to integer by the column read function, and a null 0 value will be generated for field specified in their format as non-numeric.

Bad Record Error Processing

When no match is found for a column field the process aborts with a message such as:

```
Bad format line 3 field 4 of funny.txt
```

This can mean as well that one line of the input line is ill formed or that the column format for this field has been wrongly specified. When you know that your file contains records that are ill formatted and should be eliminated from normal processing, set the "maxerr" option of the CREATE TABLE statement, for instance:

```
Option_list='maxerr=100'
```

This will indicate that no error message be raised for the 100 first wrong lines. You can set Maxerr to a number greater than the number of wrong lines in your files to ignore them and get no errors.

Additionally, the "accept" option permit to keep those ill formatted lines with the bad field, and all succeeding fields of the record, nullified. If "accept" is specified without "maxerr", all ill formatted lines will be accepted.

Note: This error processing also applies to CSV tables.

Fields Containing a Formatted Date

A special case is one of columns containing a formatted date. In this case, two formats must be specified:

1. The field recognition format used to delimit the date in the input record.
2. The date format used to interpret the date.
3. The field length option if the date representation is different than the standard type size.

For example, let us suppose we have a web log source file containing records such as:

```
165.91.215.31 - - [17/Jul/2001:00:01:13 -0400] - "GET /usnews/home.htm HTTP/1.1" 302
```

The create table statement shall be like this:

```
create table WEBSAMP (
  IP char(15) not null field_format='%n%s%n',
  DATE datetime not null field_format=' - - [%n%s%n -0400]'
  date_format='DD/MMM/YYYY:hh:mm:ss' field_length=20,
  FILE char(128) not null field_format=' - "GET %n%s%n',
  HTTP double(4,2) not null field_format=' HTTP/%n%f%n"',
  NBONE int(5) not null field_format=' %n%d%n')
Engine=CONNECT table_type=FMT lrecl=400
file_name='e:\\data\\token\\Websamp.dat';
```

Note 1: Here, field_length=20 was necessary because the default size for datetime columns is only 19. The lrecl=400 was also specified because the actual file contains more information in each records making the record size calculated by default too small.

Note 2: The file name could have been specified as 'e:/data/token/Websamp.dat' .

Note 3: FMT tables are currently read only.

5.3.7.6.10 CONNECT - NoSQL Table Types

They are based on files that do not match the relational format but often represent hierarchical data. CONNECT can handle [JSON](#), [INI-CFG](#), [XML](#), and some HTML files.

The way it is done is different from what MySQL or PostgreSQL does. In addition to including in a table some column values of a specific data format (JSON, XML) to be handled by specific functions, CONNECT can directly use JSON, XML or INI files that are produced by other applications, and this is the table definition that describes where and how the contained information must be retrieved.

This is also different from what MariaDB does with dynamic columns, which is close to what MySQL and PostgreSQL do with the JSON column type.

Note: The LEVEL option used with these tables should, from Connect 1.07.0002, be specified as DEPTH. Also, what was specified with the FIELD_FORMAT column option should now also be specified using JPATH or XPATH.

5.3.7.6.11 CONNECT - Files Retrieved Using Rest Queries

Starting with [CONNECT version 1.07.0001](#), JSON, XML and possibly CSV data files can be retrieved as results from REST queries when creating or querying such tables. This is done internally by CONNECT using the CURL program generally available on all systems (if not just install it).

This can also be done using the Microsoft Casablanca (cpprestsdk) package. To enable it, first, install the package as explained in <https://github.com/microsoft/cpprestsdk>. Then make the GetRest library (dll or so) as explained in [Making the GetRest Library](#).

Note: If both are available, cpprestsdk is used preferably because it is faster. This can be changed by specifying 'curl=1' in the option list.

Note: If you want to use this feature with an older distributed version of MariaDB not featuring REST, it is possible to add it as an OEM module as explained in [Adding the REST Feature as a Library Called by an OEM Table](#).

Creating Tables using REST

To do so, specify the HTTP of the web client and eventually the URI of the request in the [CREATE TABLE](#) statement. For example, for a query returning JSON data:

```
CREATE TABLE webusers (  
  id bigint(2) NOT NULL,  
  name char(24) NOT NULL,  
  username char(16) NOT NULL,  
  email char(25) NOT NULL,  
  address varchar(256) DEFAULT NULL,  
  phone char(21) NOT NULL,  
  website char(13) NOT NULL,  
  company varchar(256) DEFAULT NULL  
) ENGINE=CONNECT DEFAULT CHARSET=utf8  
TABLE_TYPE=JSON FILE_NAME='users.json' HTTP='http://jsonplaceholder.typicode.com' URI='/users';
```

As with standard JSON tables, discovery is possible, meaning that you can leave CONNECT to define the columns by analyzing the JSON file. Here you could just do:

```
CREATE TABLE webusers  
ENGINE=CONNECT DEFAULT CHARSET=utf8  
TABLE_TYPE=JSON FILE_NAME='users.json'  
HTTP='http://jsonplaceholder.typicode.com' URI='/users';
```

For example, executing:

```
SELECT name, address FROM webusers2 LIMIT 1;
```

returns:

name	address
Leanne Graham	Kulas Light Apt. 556 Gwenborough 92998-3874 -37.3159 81.1496

Here we see that for some complex elements such as *address*, which is a Json object containing values and objects, CONNECT by default has just listed their texts separated by blanks. But it is possible to ask it to analyze in more depth the json result by adding the DEPTH option. For instance:

```
CREATE OR REPLACE TABLE webusers
ENGINE=CONNECT DEFAULT CHARSET=utf8
TABLE_TYPE=JSON FILE_NAME='users.json'
HTTP='http://jsonplaceholder.typicode.com' URI='/users'
OPTION_LIST='Depth=2';
```

Then the table will be created as:

```
CREATE TABLE `webusers3` (
  `id` bigint(2) NOT NULL,
  `name` char(24) NOT NULL,
  `username` char(16) NOT NULL,
  `email` char(25) NOT NULL,
  `address_street` char(17) NOT NULL `JPATH`='$.address.street',
  `address_suite` char(9) NOT NULL `JPATH`='$.address.suite',
  `address_city` char(14) NOT NULL `JPATH`='$.address.city',
  `address_zipcode` char(10) NOT NULL `JPATH`='$.address.zipcode',
  `address_geo_lat` char(8) NOT NULL `JPATH`='$.address.geo.lat',
  `address_geo_lng` char(9) NOT NULL `JPATH`='$.address.geo.lng',
  `phone` char(21) NOT NULL,
  `website` char(13) NOT NULL,
  `company_name` char(18) NOT NULL `JPATH`='$.company.name',
  `company_catchPhrase` char(40) NOT NULL `JPATH`='$.company.catchPhrase',
  `company_bs` varchar(36) NOT NULL `JPATH`='$.company.bs'
) ENGINE=CONNECT DEFAULT CHARSET=utf8 `TABLE_TYPE`='JSON' `FILE_NAME`='users.json'
`OPTION_LIST`='Depth=2' `HTTP`='http://jsonplaceholder.typicode.com' `URI`='/users';
```

Allowing one to get all the values of the Json result, for example:

```
SELECT name, address_city city, company_name company FROM webusers3;
```

That results in:

name	city	company
Leanne Graham	Gwenborough	Romaguera-Crona
Ervin Howell	Wisokyburgh	Deckow-Crist
Clementine Bauch McKenziehaven	Romaguera-Jacobson	
Patricia Lebsack	South Elvis	Robel-Corkery
Chelsey Dietrich	Roscoeview	Keebler LLC
Mrs. Dennis Schulist	South Christy	Considine-Lockman
Kurtis Weissnat	Howemouth	Johns Group
Nicholas Runolfsson	Aliyaview	Abernathy Group
Glenna Reichert	Bartholomebury	Yost and Sons
Clementina DuBuque	Lebsackbury	Hoeger LLC

Of course, the complete create table (obtained by SHOW CREATE TABLE) can later be edited to make your table return exactly what you want to get. See the [JSON table type](#) for details about what and how to specify these.

Note that such tables are read only. In addition, the data will be retrieved from the web each time you query the table with a **SELECT** statement. This is fine if the result varies each time, such as when you query a weather forecasting site. But if you want to use the retrieved file many times without reloading it, just create another table on the same file without specifying the HTTP option.

Note: For JSON tables, specifying the file name is optional and defaults to tablename.type. However, you should specify it if you want to use the file later for other tables.

See the [JSON table type](#) for changes that will occur in the new CONNECT versions (distributed in early 2021).

Overview

JSON (JavaScript Object Notation) is a lightweight data-interchange format widely used on the Internet. Many applications, generally written in JavaScript or PHP use and produce JSON data, which are exchanged as files of different physical formats. JSON data is often returned from REST queries.

It is also possible to query, create or update such information in a database-like manner. MongoDB does it using a JavaScript-like language. PostgreSQL includes these facilities by using a specific data type and related functions like dynamic columns.

The CONNECT engine adds this facility to MariaDB by supporting tables based on JSON data files. This is done like for XML tables by creating tables describing what should be retrieved from the file and how it should be processed.

Starting with 1.07.0002, the internal way JSON was parsed and handled was changed. The main advantage of the new way

is to reduce the memory required to parse JSON. It was from 6 to 10 times the size of the JSON source and is now only 2 to 4 times. However, this is in Beta mode and JSON tables are still handled using the old mode. To use the new mode, tables should be created with `TABLE_TYPE=BSON`. Another way is to set the `connect_force_bson` session variable to 1 or ON. Then all JSON tables will be handled as BSON. Of course, this is temporary and when successfully tested, the new way will replace the old way and all tables be created as JSON.

Let us start from the file "biblio3.json" that is the JSON equivalent of the XML Xsample file described in the XML table chapter:

```
[
  {
    "ISBN": "9782212090819",
    "LANG": "fr",
    "SUBJECT": "applications",
    "AUTHOR": [
      {
        "FIRSTNAME": "Jean-Christophe",
        "LASTNAME": "Bernadac"
      },
      {
        "FIRSTNAME": "François",
        "LASTNAME": "Knab"
      }
    ],
    "TITLE": "Construire une application XML",
    "PUBLISHER": {
      "NAME": "Eyrolles",
      "PLACE": "Paris"
    },
    "DATEPUB": 1999
  },
  {
    "ISBN": "9782840825685",
    "LANG": "fr",
    "SUBJECT": "applications",
    "AUTHOR": [
      {
        "FIRSTNAME": "William J.",
        "LASTNAME": "Pardi"
      }
    ],
    "TITLE": "XML en Action",
    "TRANSLATED": {
      "PREFIX": "adapté de l'anglais par",
      "TRANSLATOR": {
        "FIRSTNAME": "James",
        "LASTNAME": "Guerin"
      }
    },
    "PUBLISHER": {
      "NAME": "Microsoft Press",
      "PLACE": "Paris"
    },
    "DATEPUB": 1999
  }
]
```

This file contains the different items existing in JSON.

- **Arrays** : They are enclosed in square brackets and contain a list of comma separated values.
- **Objects** : They are enclosed in curly brackets. They contain a comma separated list of pairs, each pair composed of a key name between double quotes, followed by a ':' character and followed by a value.
- **Values** : Values can be an array or an object. They also can be a string between double quotes, an integer or float number, a Boolean value or a null value. The simplest way for CONNECT to locate a table in such a file is by an array containing a list of objects (this is what MongoDB calls a collection of documents). Each array value will be a table row and each pair of the row objects will represent a column, the key being the column name and the value the column value.

A first try to create a table on this file will be to take the outer array as the table:

```

create table jsample (
  ISBN char(15),
  LANG char(2),
  SUBJECT char(32),
  AUTHOR char(128),
  TITLE char(32),
  TRANSLATED char(80),
  PUBLISHER char(20),
  DATEPUB int(4)
engine=CONNECT table_type=JSON
File_name='biblio3.json';

```

If we execute the query:

```

select isbn, author, title, publisher from jsample;

```

We get the result:

isbn	author	title	publisher
9782212090819	Jean-Christophe Bernadac	Construire une application XML	Eyrolles Paris
9782840825685	William J. Pardi	XML en Action	Microsoft Press Pari

Note that by default, column values that are objects have been set to the concatenation of all the string values of the object separated by a blank. When a column value is an array, only the first item of the array is retrieved (This will change in later versions of Connect).

However, things are generally more complicated. If JSON files do not contain attributes (although object pairs are similar to attributes) they contain a new item, arrays. We have seen that they can be used like XML multiple nodes, here to specify several authors, but they are more general because they can contain objects of different types, even it may not be advisable to do so.

This is why CONNECT enables the specification of a column field_format option "JPATH" (FIELD_FORMAT until Connect 1.6) that is used to describe exactly where the items to display are and how to handles arrays.

Here is an example of a new table that can be created on the same file, allowing choosing the column names, to get some sub-objects and to specify how to handle the author array.

Until Connect 1.5:

```

create table jsampall (
  ISBN char(15),
  Language char(2) field_format='LANG',
  Subject char(32) field_format='SUBJECT',
  Author char(128) field_format='AUTHOR:[" and "]',
  Title char(32) field_format='TITLE',
  Translation char(32) field_format='TRANSLATOR:PREFIX',
  Translator char(80) field_format='TRANSLATOR',
  Publisher char(20) field_format='PUBLISHER:NAME',
  Location char(16) field_format='PUBLISHER:PLACE',
  Year int(4) field_format='DATEPUB')
engine=CONNECT table_type=JSON File_name='biblio3.json';

```

From Connect 1.6:

```

create table jsampall (
  ISBN char(15),
  Language char(2) field_format='LANG',
  Subject char(32) field_format='SUBJECT',
  Author char(128) field_format='AUTHOR.[" and "]',
  Title char(32) field_format='TITLE',
  Translation char(32) field_format='TRANSLATOR.PREFIX',
  Translator char(80) field_format='TRANSLATOR',
  Publisher char(20) field_format='PUBLISHER.NAME',
  Location char(16) field_format='PUBLISHER.PLACE',
  Year int(4) field_format='DATEPUB')
engine=CONNECT table_type=JSON File_name='biblio3.json';

```

From Connect 1.07.0002

```

create table jsampall (
  ISBN char(15),
  Language char(2) jpath='$.LANG',
  Subject char(32) jpath='$.SUBJECT',
  Author char(128) jpath='$.AUTHOR[" and "]',
  Title char(32) jpath='$.TITLE',
  Translation char(32) jpath='$.TRANSLATOR.PREFIX',
  Translator char(80) jpath='$.TRANSLATOR',
  Publisher char(20) jpath='$.PUBLISHER.NAME',
  Location char(16) jpath='$.PUBLISHER.PLACE',
  Year int(4) jpath='$.DATEPUB')
engine=CONNECT table_type=JSON File_name='biblio3.json';

```

Given the query:

```

select title, author, publisher, location from jsampall;

```

The result is:

title	author	publisher	location
Construire une application XML	Jean-Christophe Bernadac and François Knab	Eyrolles	Paris
XML en Action	William J. Pardi	Microsoft Press	Paris

Note: The JPATH was not specified for column ISBN because it defaults to the column name.

Here is another example showing that one can choose what to extract from the file and how to “expand” an array, meaning to generate one row for each array value:

Until Connect 1.5:

```

create table jsampex (
  ISBN char(15),
  Title char(32) field_format='TITLE',
  AuthorFN char(128) field_format='AUTHOR:[X]:FIRSTNAME',
  AuthorLN char(128) field_format='AUTHOR:[X]:LASTNAME',
  Year int(4) field_format='DATEPUB')
engine=CONNECT table_type=JSON File_name='biblio3.json';

```

From Connect 1.6:

```

create table jsampex (
  ISBN char(15),
  Title char(32) field_format='TITLE',
  AuthorFN char(128) field_format='AUTHOR.[X].FIRSTNAME',
  AuthorLN char(128) field_format='AUTHOR.[X].LASTNAME',
  Year int(4) field_format='DATEPUB')
engine=CONNECT table_type=JSON File_name='biblio3.json';

```

From Connect 1.06.006:

```

create table jsampex (
  ISBN char(15),
  Title char(32) field_format='TITLE',
  AuthorFN char(128) field_format='AUTHOR[*].FIRSTNAME',
  AuthorLN char(128) field_format='AUTHOR[*].LASTNAME',
  Year int(4) field_format='DATEPUB')
engine=CONNECT table_type=JSON File_name='biblio3.json';

```

From Connect 1.07.0002

```

create table jsampex (
  ISBN char(15),
  Title char(32) jpath='TITLE',
  AuthorFN char(128) jpath='AUTHOR[*].FIRSTNAME',
  AuthorLN char(128) jpath='AUTHOR[*].LASTNAME',
  Year int(4) jpath='DATEPUB')
engine=CONNECT table_type=JSON File_name='biblio3.json';

```

It is displayed as:

ISBN	Title	AuthorFN	AuthorLN	Year
9782212090819	Construire une application XML	Jean-Christophe	Bernadac	1999
9782212090819	Construire une application XML	François	Knab	1999
9782840825685	XML en Action	William J.	Pardi	1999

Note: The example above shows that the '\$.', that means the beginning of the path, can be omitted.

The Jpath Specification

From Connect 1.6, the Jpath specification has changed to be the one of the native JSON functions and more compatible with what is generally used. It is close to the standard definition and compatible to what MongoDB and other products do. The ':' separator is replaced by '.'. Position in array is accepted MongoDB style with no square brackets. Array specification specific to CONNECT are still accepted but [*] is used for expanding and [x] for multiply. However, tables created with the previous syntax can still be used by adding SEP_CHAR=':' (can be done with alter table). Also, it can be now specified as JPATH (was FIELD_FORMAT) but FIELD_FORMAT is still accepted.

Until Connect 1.5, it is the description of the path to follow to reach the required item. Each step is the key name (case sensitive) of the pair when crossing an object, and the number of the value between square brackets when crossing an array. Each specification is separated by a ':' character.

From Connect 1.6, It is the description of the path to follow to reach the required item. Each step is the key name (case sensitive) of the pair when crossing an object, and the position number of the value when crossing an array. Key specifications are separated by a '.' character.

For instance, in the above file, the last name of the second author of a book is reached by:

`$.AUTHOR[1].LASTNAME` *standard style* `$AUTHOR.1.LASTNAME` *MongoDB style* `AUTHOR:[1]:LASTNAME` *old style when SEP_CHAR=':' or until Connect 1.5*

The '\$' or "\$." prefix specifies the root of the path and can be omitted with CONNECT.

The array specification can also indicate how it must be processed:

For instance, in the above file, the last name of the second author of a book is reached by:

`AUTHOR:[1]:LASTNAME`

The array specification can also indicate how it must be processed:

Specification	Array Type	Limit	Description
<code>n</code> (Connect >= 1.6) or <code>[n]</code> ^[1]	All	N.A	Take the nth value of the array.
<code>[*]</code> (Connect >= 1.6), <code>[X]</code> or <code>[x]</code> (Connect <= 1.5)	All		Expand. Generate one row for each array value.
<code>["string"]</code>	String		Concatenate all values separated by the specified string.
<code>[+]</code>	Numeric		Make the sum of all the non-null array values.
<code>[x]</code> (Connect >= 1.6), <code>[*]</code> (Connect <= 1.5)	Numeric		Make the product of all non-null array values.
<code>[!]</code>	Numeric		Make the average of all the non-null array values.
<code>[>]</code> or <code>[<]</code>	All		Return the greatest or least non-null value of the array.
<code>[#]</code>	All	N.A	Return the number of values in the array.
<code>[]</code>	All		Expand if under an expanded object. Otherwise sum if numeric, else concatenation separated by ", ".
	All		Between two separators, if an array, expand it if under an expanded object or take the first value of it.

Note 1: When the LIMIT restriction is applicable, only the first *m* array items are used, *m* being the value of the LIMIT option (to be specified in option_list). The LIMIT default value is 10.

Note 2: An alternative way to indicate what is to be expanded is to use the expand option in the option list, for instance:

```
OPTION_LIST='Expand=AUTHOR'
```

AUTHOR is here the key of the pair that has the array as a value (case sensitive). Expand is limited to only one branch (expanded arrays must be under the same object).

Let us take as an example the file `expense.json` ([found here](#)). The table `jexpall` expands all under and including the week array:

From Connect 1.07.0002

```
create table jexpall (  
  WHO char(12),  
  WEEK int(2) jpath='$.WEEK[*].NUMBER',  
  WHAT char(32) jpath='$.WEEK[*].EXPENSE[*].WHAT',  
  AMOUNT double(8,2) jpath='$.WEEK[*].EXPENSE[*].AMOUNT')  
engine=CONNECT table_type=JSON File_name='expense.json';
```

From Connect 1.6

```
create table jexpall (  
  WHO char(12),  
  WEEK int(2) field_format='$.WEEK[*].NUMBER',  
  WHAT char(32) field_format='$.WEEK[*].EXPENSE[*].WHAT',  
  AMOUNT double(8,2) field_format='$.WEEK[*].EXPENSE[*].AMOUNT')  
engine=CONNECT table_type=JSON File_name='expense.json';
```

Until Connect 1.5:

```
create table jexpall (  
  WHO char(12),  
  WEEK int(2) field_format='WEEK:[x]:NUMBER',  
  WHAT char(32) field_format='WEEK:[x]:EXPENSE:[x]:WHAT',  
  AMOUNT double(8,2) field_format='WEEK:[x]:EXPENSE:[x]:AMOUNT')  
engine=CONNECT table_type=JSON File_name='expense.json';
```

WHO	WEEK	WHAT	AMOUNT
Joe	3	Beer	18.00
Joe	3	Food	12.00
Joe	3	Food	19.00
Joe	3	Car	20.00
Joe	4	Beer	19.00
Joe	4	Beer	16.00
Joe	4	Food	17.00
Joe	4	Food	17.00
Joe	4	Beer	14.00
Joe	5	Beer	14.00
Joe	5	Food	12.00
Beth	3	Beer	16.00
Beth	4	Food	17.00
Beth	4	Beer	15.00
Beth	5	Food	12.00
Beth	5	Beer	20.00
Janet	3	Car	19.00
Janet	3	Food	18.00
Janet	3	Beer	18.00

Janet	4	Car	17.00
Janet	5	Beer	14.00
Janet	5	Car	12.00
Janet	5	Beer	19.00
Janet	5	Food	12.00

The table `jexpw` shows what was bought and the sum and average of amounts for each person and week:

From Connect 1.07.0002

```
create table jexpw (
  WHO char(12) not null,
  WEEK int(2) not null jpath='$.WEEK[*].NUMBER',
  WHAT char(32) not null jpath='$.WEEK[].EXPENSE["", "].WHAT',
  SUM double(8,2) not null jpath='$.WEEK[].EXPENSE[+].AMOUNT',
  AVERAGE double(8,2) not null jpath='$.WEEK[].EXPENSE[!].AMOUNT')
engine=CONNECT table_type=JSON File_name='expense.json';
```

From Connect 1.6:

```
create table jexpw (
  WHO char(12) not null,
  WEEK int(2) not null field_format='$.WEEK[*].NUMBER',
  WHAT char(32) not null field_format='$.WEEK[].EXPENSE["", "].WHAT',
  SUM double(8,2) not null field_format='$.WEEK[].EXPENSE[+].AMOUNT',
  AVERAGE double(8,2) not null field_format='$.WEEK[].EXPENSE[!].AMOUNT')
engine=CONNECT table_type=JSON File_name='expense.json';
```

Until Connect 1.5:

```
create table jexpw (
  WHO char(12) not null,
  WEEK int(2) not null field_format='WEEK:[x]:NUMBER',
  WHAT char(32) not null field_format='WEEK::EXPENSE:["", "]:WHAT',
  SUM double(8,2) not null field_format='WEEK::EXPENSE:[+]:AMOUNT',
  AVERAGE double(8,2) not null field_format='WEEK::EXPENSE[!]:AMOUNT')
engine=CONNECT table_type=JSON File_name='expense.json';
```

WHO	WEEK	WHAT	SUM	AVERAGE
Joe	3	Beer, Food, Food, Car	69.00	17.25
Joe	4	Beer, Beer, Food, Food, Beer	83.00	16.60
Joe	5	Beer, Food	26.00	13.00
Beth	3	Beer	16.00	16.00
Beth	4	Food, Beer	32.00	16.00
Beth	5	Food, Beer	32.00	16.00
Janet	3	Car, Food, Beer	55.00	18.33
Janet	4	Car	17.00	17.00
Janet	5	Beer, Car, Beer, Food	57.00	14.25

Let us see what the table `jexpz` does:

From Connect 1.6:

```

create table jexpz (
WHO char(12) not null,
WEEKS char(12) not null field_format='WEEK["", "].NUMBER',
SUMS char(64) not null field_format='WEEK["+"].EXPENSE[+].AMOUNT',
SUM double(8,2) not null field_format='WEEK[+].EXPENSE[+].AMOUNT',
AVGS char(64) not null field_format='WEEK["+"].EXPENSE[!].AMOUNT',
SUMAVG double(8,2) not null field_format='WEEK[+].EXPENSE[!].AMOUNT',
AVGSUM double(8,2) not null field_format='WEEK[!].EXPENSE[+].AMOUNT',
AVERAGE double(8,2) not null field_format='WEEK[!].EXPENSE[*].AMOUNT')
engine=CONNECT table_type=JSON File_name='expense.json';

```

From Connect 1.07.0002

```

create table jexpz (
WHO char(12) not null,
WEEKS char(12) not null jpath='WEEK["", "].NUMBER',
SUMS char(64) not null jpath='WEEK["+"].EXPENSE[+].AMOUNT',
SUM double(8,2) not null jpath='WEEK[+].EXPENSE[+].AMOUNT',
AVGS char(64) not null jpath='WEEK["+"].EXPENSE[!].AMOUNT',
SUMAVG double(8,2) not null jpath='WEEK[+].EXPENSE[!].AMOUNT',
AVGSUM double(8,2) not null jpath='WEEK[!].EXPENSE[+].AMOUNT',
AVERAGE double(8,2) not null jpath='WEEK[!].EXPENSE[*].AMOUNT')
engine=CONNECT table_type=JSON File_name='expense.json';

```

Until Connect 1.5:

```

create table jexpz (
WHO char(12) not null,
WEEKS char(12) not null field_format='WEEK:["", "]:NUMBER',
SUMS char(64) not null field_format='WEEK:["+"]:EXPENSE:[+]:AMOUNT',
SUM double(8,2) not null field_format='WEEK:[+]:EXPENSE:[+]:AMOUNT',
AVGS char(64) not null field_format='WEEK:["+"]:EXPENSE:[!]:AMOUNT',
SUMAVG double(8,2) not null field_format='WEEK:[+]:EXPENSE:[!]:AMOUNT',
AVGSUM double(8,2) not null field_format='WEEK:[!]:EXPENSE:[+]:AMOUNT',
AVERAGE double(8,2) not null field_format='WEEK:[!]:EXPENSE:[x]:AMOUNT')
engine=CONNECT table_type=JSON
File_name='E:/Data/Json/expense2.json';

```

WHO	WEEKS	SUMS	SUM	AVGS	SUMAVG	AVGSUM	AVERAGE
Joe	3, 4, 5	69.00+83.00+26.00	178.00	17.25+16.60+13.00	46.85	59.33	16.18
Beth	3, 4, 5	16.00+32.00+32.00	80.00	16.00+16.00+16.00	48.00	26.67	16.00
Janet	3, 4, 5	55.00+17.00+57.00	129.00	18.33+17.00+14.25	49.58	43.00	16.12

For all persons:

- Column 1 show the person name.
- Column 2 shows the weeks for which values are calculated.
- Column 3 lists the sums of expenses for each week.
- Column 4 calculates the sum of all expenses by person.
- Column 5 shows the week's expense averages.
- Column 6 calculates the sum of these averages.
- Column 7 calculates the average of the week's sum of expenses.
- Column 8 calculates the average expense by person.

It would be very difficult, if even possible, to obtain this result from table `jexpall` using an SQL query.

Handling of NULL Values

Json has a null explicit value that can be met in arrays or object key values. When regarding json as a relational table, a column value can be null because the corresponding json item is explicitly null, or implicitly because the corresponding item is missing in an array or object. CONNECT does not make any distinction between explicit and implicit nulls.

However, it is possible to specify how nulls are handled and represented. This is done by setting the string session variable `connect_json_null`. The default value of `connect_json_null` is "`<null>`"; it can be changed, for instance, by:

```

SET connect_json_null='NULL';

```

This changes its representation when a column displays the text of an object or the concatenation of the values of an array.

It is also possible to tell CONNECT to ignore nulls by:

```
SET connect_json_null=NULL;
```

When doing so, nulls do not appear in object text or array lists. However, this does not change the behavior of array calculation nor the result of array count.

Having Columns defined by Discovery

It is possible to let the MariaDB discovery process do the job of column specification. When columns are not defined in the create table statement, CONNECT endeavors to analyze the JSON file and to provide the column specifications. This is possible only for tables represented by an array of objects because CONNECT retrieves the column names from the object pair keys and their definition from the object pair values. For instance, the `jsample` table could be created saying:

```
create table jsample engine=connect table_type=JSON file_name='biblio3.json';
```

Let's check how it was actually specified using the show create table statement:

```
CREATE TABLE `jsample` (  
  `ISBN` char(13) NOT NULL,  
  `LANG` char(2) NOT NULL,  
  `SUBJECT` char(12) NOT NULL,  
  `AUTHOR` varchar(256) DEFAULT NULL,  
  `TITLE` char(30) NOT NULL,  
  `TRANSLATED` varchar(256) DEFAULT NULL,  
  `PUBLISHER` varchar(256) DEFAULT NULL,  
  `DATEPUB` int(4) NOT NULL  
) ENGINE=CONNECT DEFAULT CHARSET=latin1 `TABLE_TYPE`='JSON' `FILE_NAME`='biblio3.json';
```

It is equivalent except for the column sizes that have been calculated from the file as the maximum length of the corresponding column when it was a normal value. For columns that are json arrays or objects, the column is specified as a varchar string of length 256, supposedly big enough to contain the sub-object's concatenated values. Nullable is set to true if the column is null or missing in some rows or if its JPATH contains arrays.

If a more complex definition is desired, you can ask CONNECT to analyse the JPATH up to a given depth using the DEPTH or LEVEL option in the option list. Its default value is 0 but can be changed setting the `connect_default_depth` session variable (in future versions the default will be 5). The depth value is the number of sub-objects that are taken in the JPATH2 (this is different from what is defined and returned by the native `Json_Depth` function).

For instance:

```
create table jsampall2 engine=connect table_type=JSON  
file_name='biblio3.json' option_list='level=1';
```

This will define the table as:

From Connect 1.07.0002

```
CREATE TABLE `jsampall2` (  
  `ISBN` char(13) NOT NULL,  
  `LANG` char(2) NOT NULL,  
  `SUBJECT` char(12) NOT NULL,  
  `AUTHOR_FIRSTNAME` char(15) NOT NULL `JPATH`='$.AUTHOR.[0].FIRSTNAME',  
  `AUTHOR_LASTNAME` char(8) NOT NULL `JPATH`='$.AUTHOR.[0].LASTNAME',  
  `TITLE` char(30) NOT NULL,  
  `TRANSLATED_PREFIX` char(23) DEFAULT NULL `JPATH`='$.TRANSLATED.PREFIX',  
  `TRANSLATED_TRANSLATOR` varchar(256) DEFAULT NULL `JPATH`='$.TRANSLATED.TRANSLATOR',  
  `PUBLISHER_NAME` char(15) NOT NULL `JPATH`='$.PUBLISHER.NAME',  
  `PUBLISHER_PLACE` char(5) NOT NULL `JPATH`='$.PUBLISHER.PLACE',  
  `DATEPUB` int(4) NOT NULL  
) ENGINE=CONNECT DEFAULT CHARSET=latin1 `TABLE_TYPE`='JSON'  
  `FILE_NAME`='biblio3.json' `OPTION_LIST`='depth=1';
```

From Connect 1.6:

```
CREATE TABLE `jsampall2` (
  `ISBN` char(13) NOT NULL,
  `LANG` char(2) NOT NULL,
  `SUBJECT` char(12) NOT NULL,
  `AUTHOR_FIRSTNAME` char(15) NOT NULL `FIELD_FORMAT`='AUTHOR..FIRSTNAME',
  `AUTHOR_LASTNAME` char(8) NOT NULL `FIELD_FORMAT`='AUTHOR..LASTNAME',
  `TITLE` char(30) NOT NULL,
  `TRANSLATED_PREFIX` char(23) DEFAULT NULL `FIELD_FORMAT`='TRANSLATED.PREFIX',
  `TRANSLATED_TRANSLATOR` varchar(256) DEFAULT NULL `FIELD_FORMAT`='TRANSLATED.TRANSLATOR',
  `PUBLISHER_NAME` char(15) NOT NULL `FIELD_FORMAT`='PUBLISHER.NAME',
  `PUBLISHER_PLACE` char(5) NOT NULL `FIELD_FORMAT`='PUBLISHER.PLACE',
  `DATEPUB` int(4) NOT NULL
) ENGINE=CONNECT DEFAULT CHARSET=latin1 `TABLE_TYPE`='JSON'
  `FILE_NAME`='biblio3.json' `OPTION_LIST`='level=1';
```

Until Connect 1.5:

```
CREATE TABLE `jsampall2` (
  `ISBN` char(13) NOT NULL,
  `LANG` char(2) NOT NULL,
  `SUBJECT` char(12) NOT NULL,
  `AUTHOR_FIRSTNAME` char(15) NOT NULL `FIELD_FORMAT`='AUTHOR::FIRSTNAME',
  `AUTHOR_LASTNAME` char(8) NOT NULL `FIELD_FORMAT`='AUTHOR::LASTNAME',
  `TITLE` char(30) NOT NULL,
  `TRANSLATED_PREFIX` char(23) DEFAULT NULL `FIELD_FORMAT`='TRANSLATED:PREFIX',
  `TRANSLATED_TRANSLATOR` varchar(256) DEFAULT NULL `FIELD_FORMAT`='TRANSLATED:TRANSLATOR',
  `PUBLISHER_NAME` char(15) NOT NULL `FIELD_FORMAT`='PUBLISHER:NAME',
  `PUBLISHER_PLACE` char(5) NOT NULL `FIELD_FORMAT`='PUBLISHER:PLACE',
  `DATEPUB` int(4) NOT NULL
) ENGINE=CONNECT DEFAULT CHARSET=latin1 `TABLE_TYPE`='JSON'
  `FILE_NAME`='biblio3.json' `OPTION_LIST`='level=1';
```

For columns that are a simple value, the Json path is the column name. This is the default when the Jpath option is not specified, so it was not specified for such columns. However, you can force discovery to specify it by setting the `connect_all_path` variable to 1 or ON. This can be useful if you plan to change the name of such columns and relieves you of manually specifying the path (otherwise it would default to the new name and cause the column to not or wrongly be found).

Another problem is that CONNECT cannot guess what you want to do with arrays. Here the AUTHOR array is set to 0, which means that only its first value will be retrieved unless you also had specified “Expand=AUTHOR” in the option list. But of course, you can replace it with anything else.

This method can be used as a quick way to make a “template” table definition that can later be edited to make the desired definition. In particular, column names are constructed from all the object keys of their path in order to have distinct column names. This can be manually edited to have the desired names, provided their JPATH key names are not modified.

DEPTH can also be given the value -1 to create only columns that are simple values (no array or object). It normally defaults to 0 but this can be modified setting the `connect_default_depth` variable.

Note: Since version 1.6.4, CONNECT eliminates columns that are “void” or whose type cannot be determined. For instance given the file `sresto.json`:

```
{ "_id":1,"name":"Corner Social","cuisine":"American","grades":[{"grade":"A","score":6}] }
{ "_id":2,"name":"La Nueva Clasica Antillana","cuisine":"Spanish","grades":[] }
```

Previously, when using discovery, creating the table by:

```
create table sjr0
engine=connect table_type=JSON file_name='sresto.json'
option_list='Pretty=0,Depth=1' lrecl=128;
```

The table was previously created as:

```
CREATE TABLE `sjr0` (
  `id` bigint(1) NOT NULL,
  `name` char(26) NOT NULL,
  `cuisine` char(8) NOT NULL,
  `grades` char(1) DEFAULT NULL,
  `grades_grade` char(1) DEFAULT NULL `JPATH`='$.grades[0].grade',
  `grades_score` bigint(1) DEFAULT NULL `JPATH`='$.grades[0].score'
) ENGINE=CONNECT DEFAULT CHARSET=latin1 `TABLE_TYPE`='JSON'
  `FILE_NAME`='sresto.json'
  `OPTION_LIST`='Pretty=0,Depth=1,Accept=1' `LRECL`=128;
```

The column “grades” was added because of the void array in line 2. Now this column is skipped and does not appear anymore (unless the option `Accept=1` is added in the option list).

JSON Catalogue Tables

Another way to see JSON table column specifications is to use a catalogue table. For instance:

```
create table bibcol engine=connect table_type=JSON file_name='biblio3.json'
  option_list='level=2' catfunc=columns;
select column_name, type_name type, column_size size, jpath from bibcol;
```

which returns:

From Connect 1.07.0002:

column_name	type	size	jpath
ISBN	CHAR	13	\$.ISBN
LANG	CHAR	2	\$.LANG
SUBJECT	CHAR	12	\$.SUBJECT
AUTHOR_FIRSTNAME	CHAR	15	\$.AUTHOR[0].FIRSTNAME
AUTHOR_LASTNAME	CHAR	8	\$.AUTHOR[0].LASTNAME
TITLE	CHAR	30	\$.TITLE
TRANSLATED_PREFIX	CHAR	23	\$.TRANSLATED.PREFIX
TRANSLATED_TRANSLATOR_FIRSTNAME	CHAR	5	\$TRANSLATED.TRANSLATOR.FIRSTNAME
TRANSLATED_TRANSLATOR_LASTNAME	CHAR	6	\$.TRANSLATED.TRANSLATOR.LASTNAME
PUBLISHER_NAME	CHAR	15	\$.PUBLISHER.NAME
PUBLISHER_PLACE	CHAR	5	\$.PUBLISHER.PLACE
DATEPUB	INTEGER	4	\$.DATEPUB

From Connect 1.6:

column_name	type	size	jpath
ISBN	CHAR	13	
LANG	CHAR	2	
SUBJECT	CHAR	12	
AUTHOR_FIRSTNAME	CHAR	15	AUTHOR..FIRSTNAME
AUTHOR_LASTNAME	CHAR	8	AUTHOR..LASTNAME
TITLE	CHAR	30	
TRANSLATED_PREFIX	CHAR	23	TRANSLATED.PREFIX
TRANSLATED_TRANSLATOR_FIRSTNAME	CHAR	5	TRANSLATED.TRANSLATOR.FIRSTNAME
TRANSLATED_TRANSLATOR_LASTNAME	CHAR	6	TRANSLATED.TRANSLATOR.LASTNAME
PUBLISHER_NAME	CHAR	15	PUBLISHER.NAME
PUBLISHER_PLACE	CHAR	5	PUBLISHER.PLACE

DATEPUB	INTEGER	4	
---------	---------	---	--

Until Connect 1.5:

column_name	type	size	jpath
ISBN	CHAR	13	
LANG	CHAR	2	
SUBJECT	CHAR	12	
AUTHOR_FIRSTNAME	CHAR	15	AUTHOR::FIRSTNAME
AUTHOR_LASTNAME	CHAR	8	AUTHOR::LASTNAME
TITLE	CHAR	30	
TRANSLATED_PREFIX	CHAR	23	TRANSLATED:PREFIX
TRANSLATED_TRANSLATOR_FIRSTNAME	CHAR	5	TRANSLATED:TRANSLATOR:FIRSTNAME
TRANSLATED_TRANSLATOR_LASTNAME	CHAR	6	TRANSLATED:TRANSLATOR:LASTNAME
PUBLISHER_NAME	CHAR	15	PUBLISHER:NAME
PUBLISHER_PLACE	CHAR	5	PUBLISHER:PLACE
DATEPUB	INTEGER	4	

All this is mostly useful when creating a table on a remote file that you cannot easily see.

Finding the table within a JSON file

Given the file "facebook.json":

```

{
  "data": [
    {
      "id": "X999_Y999",
      "from": {
        "name": "Tom Brady", "id": "X12"
      },
      "message": "Looking forward to 2010!",
      "actions": [
        {
          "name": "Comment",
          "link": "http://www.facebook.com/X999/posts/Y999"
        },
        {
          "name": "Like",
          "link": "http://www.facebook.com/X999/posts/Y999"
        }
      ],
      "type": "status",
      "created_time": "2010-08-02T21:27:44+0000",
      "updated_time": "2010-08-02T21:27:44+0000"
    },
    {
      "id": "X998_Y998",
      "from": {
        "name": "Peyton Manning", "id": "X18"
      },
      "message": "Where's my contract?",
      "actions": [
        {
          "name": "Comment",
          "link": "http://www.facebook.com/X998/posts/Y998"
        },
        {
          "name": "Like",
          "link": "http://www.facebook.com/X998/posts/Y998"
        }
      ],
      "type": "status",
      "created_time": "2010-08-02T21:27:44+0000",
      "updated_time": "2010-08-02T21:27:44+0000"
    }
  ]
}

```

The table we want to analyze is represented by the array value of the "data" object. Here is how this is specified in the create table statement:

From Connect 1.07.0002:

```

create table jfacebook (
  `ID` char(10) jpath='id',
  `Name` char(32) jpath='from.name',
  `MyID` char(16) jpath='from.id',
  `Message` varchar(256) jpath='message',
  `Action` char(16) jpath='actions..name',
  `Link` varchar(256) jpath='actions..link',
  `Type` char(16) jpath='type',
  `Created` datetime date_format='YYYY-MM-DD\T\ 'hh:mm:ss' jpath='created_time',
  `Updated` datetime date_format='YYYY-MM-DD\T\ 'hh:mm:ss' jpath='updated_time')
engine=connect table_type=JSON file_name='facebook.json' option_list='Object=data,Expand=actions'

```

From Connect 1.6:

```

create table jfacebook (
`ID` char(10) field_format='id',
`Name` char(32) field_format='from.name',
`MyID` char(16) field_format='from.id',
`Message` varchar(256) field_format='message',
`Action` char(16) field_format='actions..name',
`Link` varchar(256) field_format='actions..link',
`Type` char(16) field_format='type',
`Created` datetime date_format='YYYY-MM-DD\T\N\hh:mm:ss' field_format='created_time',
`Updated` datetime date_format='YYYY-MM-DD\T\N\hh:mm:ss' field_format='updated_time')
engine=connect table_type=JSON file_name='facebook.json' option_list='Object=data,Expand=actions'

```

Until Connect 1.5:

```

create table jfacebook (
`ID` char(10) field_format='id',
`Name` char(32) field_format='from:name',
`MyID` char(16) field_format='from:id',
`Message` varchar(256) field_format='message',
`Action` char(16) field_format='actions::name',
`Link` varchar(256) field_format='actions::link',
`Type` char(16) field_format='type',
`Created` datetime date_format='YYYY-MM-DD\T\N\hh:mm:ss' field_format='created_time',
`Updated` datetime date_format='YYYY-MM-DD\T\N\hh:mm:ss' field_format='updated_time')
engine=connect table_type=JSON file_name='facebook.json' option_list='Object=data,Expand=actions'

```

This is the object option that gives the Jpath of the table. Note also an alternate way to declare the array to be expanded by the expand option of the option_list.

Because some string values contain a date representation, the corresponding columns are declared as datetime and the date format is specified for them.

The Jpath of the object option has the same syntax as the column Jpath but of course all array steps must be specified using the [n] (until Connect 1.5) or n (from Connect 1.6) format.

Note: This applies to the whole document for tables having `PRETTY = 2` (see below). Otherwise, it applies to the document objects of each file records.

JSON File Formats

The examples we have seen so far are files that, even they can be formatted in different ways (blanks, tabs, carriage return and line feed are ignored when parsing them), respect the JSON syntax and are made of only one item (Object or Array). Like for XML files, they are entirely parsed and a memory representation is made used to process them. This implies that they are of reasonable size to avoid an out of memory condition. Tables based on such files are recognized by the option `Pretty=2` that we did not specify above because this is the default.

An alternate format, which is the format of exported MongoDB files, is a file where each row is physically stored in one file record. For instance:

```

{ "_id" : "01001", "city" : "AGAWAM", "loc" : [ -72.622739, 42.070206 ], "pop" : 15338, "state" : "MA" }
{ "_id" : "01002", "city" : "CUSHMAN", "loc" : [ -72.51564999999999, 42.377017 ], "pop" : 36963, "state" : "MA" }
{ "_id" : "01005", "city" : "BARRE", "loc" : [ -72.1083540000001, 42.409698 ], "pop" : 4546, "state" : "MA" }
{ "_id" : "01007", "city" : "BELCHERTOWN", "loc" : [ -72.4109530000001, 42.275103 ], "pop" : 10579, "state" : "MA" }
...
{ "_id" : "99929", "city" : "WRANGELL", "loc" : [ -132.352918, 56.433524 ], "pop" : 2573, "state" : "AK" }
{ "_id" : "99950", "city" : "KETCHIKAN", "loc" : [ -133.18479, 55.942471 ], "pop" : 422, "state" : "AK" }

```

The original file, "cities.json", has 29352 records. To base a table on this file we must specify the option `Pretty=0` in the option list. For instance:

From Connect 1.07.0002:

```

create table cities (
  `_id` char(5) key,
  `city` char(32),
  `lat` double(12,6) jpath='loc.0',
  `long` double(12,6) jpath='loc.1',
  `pop` int(8),
  `state` char(2) distrib='clustered')
engine=CONNECT table_type=JSON file_name='cities.json' lrecl=128 option_list='pretty=0';

```

From Connect 1.6:

```

create table cities (
  `_id` char(5) key,
  `city` char(32),
  `lat` double(12,6) field_format='loc.0',
  `long` double(12,6) field_format='loc.1',
  `pop` int(8),
  `state` char(2) distrib='clustered')
engine=CONNECT table_type=JSON file_name='cities.json' lrecl=128 option_list='pretty=0';

```

Until Connect 1.5:

```

create table cities (
  `_id` char(5) key,
  `city` char(32),
  `long` double(12,6) field_format='loc:[0]',
  `lat` double(12,6) field_format='loc:[1]',
  `pop` int(8),
  `state` char(2) distrib='clustered')
engine=CONNECT table_type=JSON file_name='cities.json' lrecl=128 option_list='pretty=0';

```

Note the use of [n] (until Connect 1.5) or n (from Connect 1.6) array specifications for the longitude and latitude columns.

When using this format, the table is processed by CONNECT like a DOS, CSV or FMT table. Rows are retrieved and parsed by records and the table can be very large. Another advantage is that such a table can be indexed, which can be of great value for very large tables. The “distrib” option of the “state” column tells CONNECT to use block indexing when possible.

For such tables – as well as for *pretty=1* ones – the record size must be specified using the LRECL option. Be sure you don’t specify it too small as it is used to allocate the read/write buffers and the memory used for parsing the rows. If in doubt, be generous as it does not cost much in memory allocation.

Another format exists, noted by *Pretty=1*, which is similar to this one but has some additions to represent a JSON array. A header and a trailer records are added containing the opening and closing square bracket, and all records but the last are followed by a comma. It has the same advantages for reading and updating, but inserting and deleting are executed in the *pretty=2* way.

Alternate Table Arrangement

We have seen that the most natural way to represent a table in a JSON file is to make it on an array of objects. However, other possibilities exist. A table can be an array of arrays, a one column table can be an array of values, or a one row table can be just one object or one value. Single row tables are internally handled by adding a one value array around them.

Let us see how to handle, for instance, a table that is an array of arrays. The file:

```

[
  [56, "Coucou", 500.00],
  [2,0,1,4], "Hello World", 2.0316],
  ["1784", "John Doo", 32.4500],
  [1914, ["Nabucho","donosor"], 5.12],
  [7, "sept", [0.77,1.22,2.01]],
  [8, "huit", 13.0]
]

```

A table can be created on this file as:

From Connect 1.07.0002:

```

create table xjson (
`a` int(6) jpath='1',
`b` char(32) jpath='2',
`c` double(10,4) jpath='3')
engine=connect table_type=JSON file_name='test.json' option_list='Pretty=1,Jmode=1,Base=1' lrecl=

```

From Connect 1.6:

```

create table xjson (
`a` int(6) field_format='1',
`b` char(32) field_format='2',
`c` double(10,4) field_format='3')
engine=connect table_type=JSON file_name='test.json' option_list='Pretty=1,Jmode=1,Base=1' lrecl=

```

Until Connect 1.5:

```

create table xjson (
`a` int(6) field_format='[1]',
`b` char(32) field_format='[2]',
`c` double(10,4) field_format='[3]')
engine=connect table_type=JSON file_name='test.json'
option_list='Pretty=1,Jmode=1,Base=1' lrecl=128;

```

Columns are specified by their position in the row arrays. By default, this is zero-based but for this table the base was set to 1 by the *Base* option of the option list. Another new option in the option list is *Jmode=1*. It indicates what type of table this is. The *Jmode* values are:

1. An array of objects. This is the default.
2. An array of Array. Like this one.
3. An array of values.

When reading, this is not required as the type of the array items is specified for the columns; however, it is required when inserting new rows so CONNECT knows what to insert. For instance:

```
insert into xjson values(25, 'Breakfast', 1.414);
```

After this, it is displayed as:

a	b	c
56	Coucou	500.0000
2	Hello World	2.0316
1784	John Doo	32.4500
1914	Nabucho	5.1200
7	sept	0.7700
8	huit	13.0000
25	Breakfast	1.4140

Unspecified array values are represented by their first element.

Getting and Setting JSON Representation of a Column

We have seen that columns corresponding to a Json object or array are retrieved by default as the concatenation of all its values separated by a blank. It is also possible to retrieve and display such column contains as the full JSON string corresponding to it in the JSON file. This is specified in the *JPATH* by a *""* where the object or array would be specified.

Note: When having columns generated by discovery, this can be specified by adding the *STRINGIFY* option to *ON* or *1* in the option list.

For instance:

From Connect 1.07.0002:

```
create table jsample2 (
  ISBN char(15),
  Lng char(2) jpath='LANG',
  json_Author char(255) jpath='AUTHOR.*',
  Title char(32) jpath='TITLE',
  Year int(4) jpath='DATEPUB')
engine=CONNECT table_type=JSON file_name='biblio3.json';
```

From Connect 1.6:

```
create table jsample2 (
  ISBN char(15),
  Lng char(2) field_format='LANG',
  json_Author char(255) field_format='AUTHOR.*',
  Title char(32) field_format='TITLE',
  Year int(4) field_format='DATEPUB')
engine=CONNECT table_type=JSON file_name='biblio3.json';
```

Until Connect 1.5:

```
create table jsample2 (
  ISBN char(15),
  Lng char(2) field_format='LANG',
  json_Author char(255) field_format='AUTHOR:*',
  Title char(32) field_format='TITLE',
  Year int(4) field_format='DATEPUB')
engine=CONNECT table_type=JSON file_name='biblio3.json';
```

Now the query:

```
select json_Author from jsample2;
```

will return and display :

json_Author
[{"FIRSTNAME":"Jean-Christophe","LASTNAME":"Bernadac"}, {"FIRSTNAME":"François","LASTNAME":"Knab"}]
[{"FIRSTNAME":"William J.,"LASTNAME":"Pardi"}]

Note: Prefixing the column name by *json_* is optional but is useful when using the column as argument to Connect UDF functions, making it to be surely recognized as valid Json without aliasing.

This also works on input, a column specified so that it can be directly set to a valid JSON string.

This feature is of great value as we will see below.

Create, Read, Update and Delete Operations on JSON Tables

The SQL commands INSERT, UPDATE and DELETE are fully supported for JSON tables except those returned by REST queries. For INSERT and UPDATE, if the target values are simple values, there are no problems.

However, there are some issues when the added or modified values are objects or arrays.

Concerning objects, the same problems exist that we have already seen with the XML type. The added or modified object will have the format described in the table definition, which can be different from the one of the JSON file. Modifications should be done using a file specifying the full path of modified objects.

New problems are raised when trying to modify the values of an array. Only updates can be done on the original table. First of all, for the values of the array to be distinct values, all update operations concerning array values must be done using a table expanding this array.

For instance, to modify the authors of the `biblio.json` based table, the `jsampex` table must be used. Doing so, updating and deleting authors is possible using standard SQL commands. For example, to change the first name of Knab from François to John:

```
update jsampex set authorfn = 'John' where authorln = 'Knab';
```

However It would be wrong to do:

```
update jsampex set authorfn = 'John' where isbn = '9782212090819';
```

Because this would change the first name of both authors as they share the same ISBN.

Where things become more difficult is when trying to delete or insert an author of a book. Indeed, a delete command will delete the whole book and an insert command will add a new complete row instead of adding a new author in the same array. Here we are penalized by the SQL language that cannot give us a way to specify this. Something like:

```
update jsampex add authorfn = 'Charles', authorln = 'Dickens'
where title = 'XML en Action';
```

However this does not exist in SQL. Does this mean that it is impossible to do it? No, but it requires us to use a table specified on the same file but adapted to this task. One way to do it is to specify a table for which the authors are no more an expanded array. Supposing we want to add an author to the “XML en Action” book. We will do it on a table containing just the author(s) of that book, which is the second book of the table.

From Connect 1.6:

```
create table jauthor (
FIRSTNAME char(64),
LASTNAME char(64))
engine=CONNECT table_type=JSON File_name='biblio3.json' option_list='Object=1.AUTHOR';
```

Until Connect 1.5

```
create table jauthor (
FIRSTNAME char(64),
LASTNAME char(64))
engine=CONNECT table_type=JSON File_name='biblio3.json' option_list='Object=[1]:AUTHOR';
```

The command:

```
select * from jauthor;
```

replies:

FIRSTNAME	LASTNAME
William J.	Pardi

It is a standard JSON table that is an array of objects in which we can freely insert or delete rows.

```
insert into jauthor values ('Charles','Dickens');
```

We can check that this was done correctly by:

```
select * from jsampex;
```

This will display:

ISBN	Title	AuthorFN	AuthorLN	Year
9782212090819	Construire une application XML	Jean-Christophe	Bernadac	1999
9782212090819	Construire une application XML	John	Knab	1999
9782840825685	XML en Action	William J.	Pardi	1999
9782840825685	XML en Action	Charles	Dickens	1999

Note: If this table were a big table with many books, it would be difficult to know what the order of a specific book is in the table. This can be found by adding a special ROWID column in the table.

However, an alternate way to do it is by using direct JSON column representation as in the JSAMPLE2 table. This can be done by:

```

update jsample2 set json_Author =
' [{"FIRSTNAME": "William J.", "LASTNAME": "Pardi"},
  {"FIRSTNAME": "Charles", "LASTNAME": "Dickens"} ]'
where isbn = '9782840825685';

```

Here, we didn't have to find the index of the sub array to modify. However, this is not quite satisfying because we had to manually write the whole JSON value to set to the json_Author column.

Therefore we need specific functions to do so. They are introduced now.

JSON User Defined Functions

Although such functions written by other parties do exist,^[2] CONNECT provides its own UDFs that are specifically adapted to the JSON table type and easily available because, being inside the CONNECT library or DLL, they require no additional module to be loaded (see [CONNECT - Compiling JSON UDFs in a Separate Library](#) to make these functions in a separate library module).

In particular, [MariaDB 10.2](#) and [10.3](#) feature native JSON functions. In some cases, it is possible that these native functions can be used. However, mixing native and UDF JSON functions in the same query often does not work because the way they recognize their arguments is different and might even cause a server crash.

Here is the list of the CONNECT functions; more can be added if required.

Name	Type	Return	Description	Added
jbin_array	Function	STRING*	Make a JSON array containing its arguments.	MariaDB 10.1.9
jbin_array_add	Function	STRING*	Adds to its first array argument its second arguments.	MariaDB 10.1.9
jbin_array_add_values	Function	STRING*	Adds to its first array argument all following arguments.	
jbin_array_delete	Function	STRING*	Deletes the nth element of its first array argument.	MariaDB 10.1.9
jbin_file	Function	STRING*	Returns of a (json) file contain.	MariaDB 10.1.9
jbin_get_item	Function	STRING*	Access and returns a json item by a JPATH key.	MariaDB 10.1.9
jbin_insert_item	Function	STRING	Insert item values located to paths.	
jbin_item_merge	Function	STRING*	Merges two arrays or two objects.	MariaDB 10.1.9
jbin_object	Function	STRING*	Make a JSON object containing its arguments.	MariaDB 10.1.9
jbin_object_nonull	Function	STRING*	Make a JSON object containing its not null arguments.	MariaDB 10.1.9
jbin_object_add	Function	STRING*	Adds to its first object argument its second argument.	MariaDB 10.1.9
jbin_object_delete	Function	STRING*	Deletes the nth element of its first object argument.	MariaDB 10.1.9
jbin_object_key	Function	STRING*	Make a JSON object for key/value pairs.	
jbin_object_list	Function	STRING*	Returns the list of object keys as an array.	MariaDB 10.1.9
jbin_set_item	Function	STRING	Set item values located to paths.	
jbin_update_item	Function	STRING	Update item values located to paths.	
jfile_bjson	Function	STRING	Convert a pretty=0 file to another BJson file.	MariaDB 10.5.9 , MariaDB 10.4.18 , MariaDB 10.3.28 , MariaDB 10.2.36
jfile_convert	Function	STRING	Convert a Json file to another pretty=0 file.	MariaDB 10.5.9 , MariaDB 10.4.18 , MariaDB 10.3.28 , MariaDB 10.2.36
jfile_make	Function	STRING	Make a json file from its json item first argument.	MariaDB 10.1.9

json_array	Function	STRING	Make a JSON array containing its arguments.	MariaDB 10.0.17  until Connect 1.5
json_array_add	Function	STRING	Adds to its first array argument its second arguments (before MariaDB 10.1.9  , all following arguments).	
json_array_add_values	Function	STRING	Adds to its first array argument all following arguments.	MariaDB 10.1.9 
json_array_delete	Function	STRING	Deletes the nth element of its first array argument.	
json_array_grp	Aggregate	STRING	Makes JSON arrays from coming argument.	
json_file	Function	STRING	Returns the contains of (json) file.	MariaDB 10.1.9 
json_get_item	Function	STRING	Access and returns a json item by a JPATH key.	MariaDB 10.1.9 
json_insert_item	Function	STRING	Insert item values located to paths.	
json_item_merge	Function	STRING	Merges two arrays or two objects.	MariaDB 10.1.9 
json_locate_all	Function	STRING	Returns the JPATH's of all occurrences of an element.	MariaDB 10.1.9 
json_make_array	Function	STRING	Make a JSON array containing its arguments.	From Connect 1.6
json_make_object	Function	STRING	Make a JSON object containing its arguments.	From Connect 1.6
json_object	Function	STRING	Make a JSON object containing its arguments.	MariaDB 10.0.17  until Connect 1.5
json_object_delete	Function	STRING	Deletes the nth element of its first object argument.	MariaDB 10.1.9 
json_object_grp	Aggregate	STRING	Makes JSON objects from coming arguments.	
json_object_list	Function	STRING	Returns the list of object keys as an array.	MariaDB 10.1.9 
json_object_nonull	Function	STRING	Make a JSON object containing its not null arguments.	
json_serialize	Function	STRING	Serializes the return of a "Jbin" function.	MariaDB 10.1.9 
json_set_item	Function	STRING	Set item values located to paths.	
json_update_item	Function	STRING	Update item values located to paths.	
jsonvalue	Function	STRING	Make a JSON value from its unique argument. Called json_value until MariaDB 10.0.22  and MariaDB 10.1.8 	MariaDB 10.0.17 
jsoncontains	Function	INTEGER	Returns 0 or 1 if an element is contained in the document.	
jsoncontains_path	Function	INTEGER	Returns 0 or 1 if a JPATH is contained in the document.	
jsonget_string	Function	STRING	Access and returns a string element by a JPATH key.	MariaDB 10.1.9 
jsonget_int	Function	INTEGER	Access and returns an integer element by a JPATH key.	MariaDB 10.1.9 
jsonget_real	Function	REAL	Access and returns a real element by a JPATH key.	MariaDB 10.1.9 

jsonlocate	Function	STRING	Returns the JPATH to access one element.	MariaDB 10.1.9
------------	----------	--------	--	--------------------------------

String values are mapped to JSON strings. These strings are automatically escaped to conform to the JSON syntax. The automatic escaping is bypassed when the value has an alias beginning with 'json_'. This is automatically the case when a JSON UDF argument is another JSON UDF whose name begins with "json_" (not case sensitive). This is why all functions that do not return a Json item are not prefixed by "json_".

Argument string values, for some functions, can alternatively be json file names. When this is ambiguous, alias them as *jfile_*. Full path should be used because UDF functions has no means to know what the current database is. Apparently, when the file name path is not full, it is based on the MariaDB data directory but I am not sure it is always true.

Numeric values are (big) integers, double floating point values or decimal values. Decimal values are character strings containing a numeric representation and are treated as strings. Floating point values contain a decimal point and/or an exponent. Integers are written without decimal points.

To install these functions execute the following commands :^[3]

Note: Json function names are often written on this page with leading upper case letters for clarity. It is possible to do so in SQL queries because function names are case insensitive. However, when creating or dropping them, their names must match the case they are in the library module (lower case from [MariaDB 10.1.9](#)).

On Unix systems (from Connect 1.7.02):

```

create function jsonvalue returns string soname 'ha_connect.so';
create function json_make_array returns string soname 'ha_connect.so';
create function json_array_add_values returns string soname 'ha_connect.so';
create function json_array_add returns string soname 'ha_connect.so';
create function json_array_delete returns string soname 'ha_connect.so';
create function json_make_object returns string soname 'ha_connect.so';
create function json_object_nonnull returns string soname 'ha_connect.so';
create function json_object_key returns string soname 'ha_connect.so';
create function json_object_add returns string soname 'ha_connect.so';
create function json_object_delete returns string soname 'ha_connect.so';
create function json_object_list returns string soname 'ha_connect.so';
create function json_object_values returns string soname 'ha_connect.so';

create function jbin_insert_item returns string soname 'ha_connect';
create function jbin_update_item returns string soname 'ha_connect';
create function jbin_file returns string soname 'ha_connect';

```

On Windows (from Connect 1.6):

```

create function jsonvalue returns string soname 'ha_connect';
create function json_make_array returns string soname 'ha_connect';
create function json_array_add_values returns string soname 'ha_connect';
create function json_array_add returns string soname 'ha_connect';
create function json_array_delete returns string soname 'ha_connect';
create function json_make_object returns string soname 'ha_connect';
create function json_object_nonnull returns string soname 'ha_connect';
create function json_object_key returns string soname 'ha_connect';
create function json_object_add returns string soname 'ha_connect';
create function json_object_delete returns string soname 'ha_connect';
create function json_object_list returns string soname 'ha_connect';
create function jsonset_grp_size returns integer soname 'ha_connect';
create function jsonset_grp_size returns integer soname 'ha_connect';
create aggregate function json_array_grp returns string soname 'ha_connect';
create aggregate function json_object_grp returns string soname 'ha_connect';
create function jsonlocate returns string soname 'ha_connect';
create function json_locate_all returns string soname 'ha_connect';
create function jsoncontains returns integer soname 'ha_connect';
create function jsoncontains_path returns integer soname 'ha_connect';
create function json_item_merge returns string soname 'ha_connect';
create function json_get_item returns string soname 'ha_connect';
create function jsonset_string returns string soname 'ha_connect';
create function jsonset_int returns integer soname 'ha_connect';
create function jsonset_real returns real soname 'ha_connect';
create function json_set_item returns string soname 'ha_connect';
create function json_insert_item returns string soname 'ha_connect';
create function json_update_item returns string soname 'ha_connect';
create function json_file returns string soname 'ha_connect';
create function jfile_make returns string soname 'ha_connect';
create function json_serialize returns string soname 'ha_connect';
create function jbin_array returns string soname 'ha_connect';
create function jbin_array_add_values returns string soname 'ha_connect';
create function jbin_array_add returns string soname 'ha_connect';
create function jbin_array_delete returns string soname 'ha_connect';
create function jbin_object returns string soname 'ha_connect';
create function jbin_object_nonnull returns string soname 'ha_connect';
create function jbin_object_key returns string soname 'ha_connect';
create function jbin_object_add returns string soname 'ha_connect';
create function jbin_object_delete returns string soname 'ha_connect';
create function jbin_object_list returns string soname 'ha_connect';
create function jbin_item_merge returns string soname 'ha_connect';
create function jbin_get_item returns string soname 'ha_connect';
create function jbin_set_item returns string soname 'ha_connect';
create function jbin_insert_item returns string soname 'ha_connect';
create function jbin_update_item returns string soname 'ha_connect';
create function jbin_file returns string soname 'ha_connect';

```

On Windows (until Connect 1.5):

```

create function jsonvalue returns string soname 'ha_connect';
create function json_array returns string soname 'ha_connect';

create function jbin_update_item returns string soname 'ha_connect';
create function jbin_file returns string soname 'ha_connect';

```

Jfile_Bjson

MariaDB starting with [10.2.36](#)

JFile_Bjson was introduced in [MariaDB 10.5.9](#), [MariaDB 10.4.18](#), [MariaDB 10.3.28](#) and [MariaDB 10.2.36](#).

```
Jfile_Bjson(in_file_name, out_file_name, lrecl)
```

Converts the first argument `pretty=0` json file to Bjson file. B(binary)json is a pre-parsed json format. It is described below in the Performance chapter (available in next Connect versions).

Jfile_Convert

MariaDB starting with [10.2.36](#)

JFile_Convert was introduced in [MariaDB 10.5.9](#), [MariaDB 10.4.18](#), [MariaDB 10.3.28](#) and [MariaDB 10.2.36](#).

```
Jfile_Convert(in_file_name, out_file_name, lrecl)
```

Converts the first argument json file to another `pretty=0` json file. The third integer argument is the record length to use. This is often required to process huge json files that would be very slow if they were in `pretty=2` format.

This is done without completely parsing the file, is very fast and requires no big memory.

Jfile_Make

MariaDB starting with [10.1.9](#)

Jfile_Make was added in CONNECT 1.4 (from [MariaDB 10.1.9](#)).

```
Jfile_Make(arg1, arg2, [arg3], ...)
```

The first argument must be a json item (if it is just a string, Jfile_Make will try its best to see if it is a json item or an input file name). The following arguments are a string file name and an integer pretty value (defaulting to 2) in any order. This function creates a json file containing the first argument item.

The returned string value is the created file name. If not specified as an argument, the file name can in some cases be retrieved from the first argument; in such cases the file itself is modified.

This function can be used to create or format a json file. For instance, supposing we want to format the file tb.json, this can be done with the query:

```
select Jfile_Make('tb.json' jfile_, 2);
```

The tb.json file will be changed to:

```
[
  {
    "_id": 5,
    "type": "food",
    "ratings": [
      5,
      8,
      9
    ]
  },
  {
    "_id": 6,
    "type": "car",
    "ratings": [
      5,
      9
    ]
  }
]
```

Json_Array_Add

```
Json_Array_Add(arg1, arg2, [arg3][, arg4][, ...])
```

Note: In CONNECT version 1.3 (before [MariaDB 10.1.9](#)), this function behaved like the new `Json_Array_Add_Values` function. The following describes this function for CONNECT version 1.4 (from [MariaDB 10.1.9](#)) only. The first argument must be a JSON array. The second argument is added as member of this array. For example:

```
select Json_Array_Add(Json_Array(56,3.1416,'machin',NULL),
'One more') Array;
```

Array

```
[56,3.141600,"machin",null,"One more"]
```

Note: The first array is not escaped, its (alias) name beginning with 'json_'.

Now we can see how adding an author to the JSAMPLE2 table can alternatively be done:

```
update jsample2 set
  json_author = json_array_add(json_author, json_object('Charles' FIRSTNAME, 'Dickens' LASTNAME))
where isbn = '9782840825685';
```

Note: Calling a column returning JSON a name prefixed by json_ (like json_author here) is good practice and removes the need to give it an alias to prevent escaping when used as an argument.

Additional arguments: If a third integer argument is given, it specifies the position (zero based) of the added value:

```
select Json_Array_Add('[5,3,8,7,9]' json_, 4, 2) Array;
```

Array

```
[5,3,4,8,7,9]
```

If a string argument is added, it specifies the Json path to the array to be modified. For instance:

```
select Json_Array_Add('{"a":1,"b":2,"c":[3,4]}' json_, 5, 1, 'c');
```

Json_Array_Add('{"a":1,"b":2,"c":[3,4]}' json_, 5, 1, 'c')

```
{"a":1,"b":2,"c":[3,5,4]}
```

Json_Array_Add_Values

Json_Array_Add_Values added in CONNECT 1.4 replaces the function Json_Array_Add of CONNECT version 1.3 (before [MariaDB 10.1.9](#)).

```
Json_Array_Add_Values(arg, arglist)
```

The first argument must be a JSON array string. Then all other arguments are added as members of this array. For example:

```
select Json_Array_Add_Values
(Json_Array(56, 3.1416, 'machin', NULL), 'One more', 'Two more') Array;
```

Array

```
[56,3.141600,"machin",null,"One more","Two more"]
```

Json_Array_Delete

```
Json_Array_Delete(arg1, arg2 [,arg3] [...])
```

The first argument should be a JSON array. The second argument is an integer indicating the rank (0 based conforming to general json usage) of the element to delete. For example:

```
select Json_Array_Delete(Json_Array(56,3.1416, 'foo',NULL), 1) Array;
```

Array

```
[56,"foo",null]
```

Now we can see how to delete the second author from the JSAMPLE2 table:

```
update jsample2 set json_author = json_array_delete(json_author, 1)
where isbn = '9782840825685';
```

A Json path can be specified as a third string argument

Json_Array_Grp

```
Json_Array_Grp(arg)
```

This is an aggregate function that makes an array filled from values coming from the rows retrieved by a query. Let us suppose we have the pet table:

name	race	number
John	dog	2
Bill	cat	1
Mary	dog	1
Mary	cat	1
Lisbeth	rabbit	2
Kevin	cat	2
Kevin	bird	6
Donald	dog	1
Donald	fish	3

The query:

```
select name, json_array_grp(race) from pet group by name;
```

will return:

name	json_array_grp(race)
Bill	["cat"]
Donald	["dog","fish"]
John	["dog"]
Kevin	["cat","bird"]
Lisbeth	["rabbit"]
Mary	["dog","cat"]

One problem with the JSON aggregate functions is that they construct their result in memory and cannot know the needed amount of storage, not knowing the number of rows of the used table.

Therefore, the number of values for each group is limited. This limit is the value of `JsonGrpSize` whose default value is 10 but can be set using the `JsonSet_Grp_Size` function. Nevertheless, working on a larger table is possible, but only after setting `JsonGrpSize` to the ceiling of the number of rows per group for the table. Try not to set it to a very large value to avoid memory exhaustion.

JsonContains

```
JsonContains(json_doc, item [, int])<
```

This function can be used to check whether an item is contained in a document. Its arguments are the same than the ones of the `JsonLocate` function; only the return value changes. The integer returned value is 1 if the item is contained in the document or 0 otherwise.

JsonContains_Path

```
JsonContains_Path(json_doc, path)
```

This function can be used to check whether a JSON path is contained in the document. The integer returned value is 1 if the path is contained in the document or 0 otherwise.

Json_File

```
Json_File(arg1, [arg2, [arg3]], ...)
```

The first argument must be a file name. This function returns the text of the file that is supposed to be a JSON file. If only one argument is specified, the file text is returned without being parsed. Up to two additional arguments can be specified:

A string argument is the path to the sub-item to be returned. An integer argument specifies the pretty format value of the file.

This function is chiefly used to get the json item argument of other json functions from a json file. For instance, supposing the file tb.json is:

```
{ "_id" : 5, "type" : "food", "ratings" : [ 5, 8, 9 ] }
{ "_id" : 6, "type" : "car", "ratings" : [ 5, 9 ] }
```

Extracting a value from it can be done with a query such as:

```
select JsonGet_String(Json_File('tb.json', 0), '[1]:type') "Type";
```

or, from [MariaDB 10.2.8](#):

```
select JsonGet_String(Json_File('tb.json', 0), '$[1].type') "Type";
```

This query returns:

Type
car

However, we'll see that, most of the time, it is better to use Jbin_File or to directly specify the file name in queries. In particular this function should not be used for queries that must modify the json item because, even if the modified json is returned, the file itself would be unchanged.

Json_Get_Item

MariaDB starting with [10.1.9](#)

Json_Get_Item was added in CONNECT 1.4 (from [MariaDB 10.1.9](#)).

```
Json_Get_Item(arg1, arg2, ...)
```

This function returns a subset of the json document passed as first argument. The second argument is the json path of the item to be returned and should be one returning a json item (terminated by a '*'). If not, the function will try to make it right but this is not foolproof. For instance:

```
select Json_Get_Item(Json_Object('foo' as "first", Json_Array('a', 33)
as "json_second"), 'second') as "item";
```

The correct path should have been 'second:*' (or from [MariaDB 10.2.8](#), 'second.*'), but in this simple case the function was able to make it right. The returned item:

item
["a",33]

Note: The array is aliased "json_second" to indicate it is a json item and avoid escaping it. However, the "json_" prefix is skipped when making the object and must not be added to the path.

JsonGet_Grp_Size

```
JsonGet_Grp_Size(val)
```

This function returns the JsonGrpSize value.

JsonGet_String / JsonGet_Int / JsonGet_Real

MariaDB starting with [10.1.9](#)

JsonGet_String, JsonGet_Int and JsonGet_Real were added in CONNECT 1.4 (from [MariaDB 10.1.9](#)).

```
JsonGet_String(arg1, arg2, [arg3] ...)
JsonGet_Int(arg1, arg2, [arg3] ...)
JsonGet_Real(arg1, arg2, [arg3] ...)
```

The first argument should be a JSON item. If it is a string with no alias, it will be converted as a json item. The second argument is the path of the item to be located in the first argument and returned, eventually converted according to the used function. For example:

```
select
  JsonGet_String('{"qty":7,"price":29.50,"garanty":null}','price') "String",
  JsonGet_Int('{"qty":7,"price":29.50,"garanty":null}','price') "Int",
  JsonGet_Real('{"qty":7,"price":29.50,"garanty":null}','price') "Real";
```

This query returns:

String	Int	Real
29.50	29	29.5000000000000000

The function `JsonGet_Real` can be given a third argument to specify the number of decimal digits of the returned value. For instance:

```
select
  JsonGet_Real('{"qty":7,"price":29.50,"garanty":null}','price',4) "Real";
```

This query returns:

String
29.50

The given path can specify all operators for arrays except the “expand” [X] operator (or from [MariaDB 10.2.8](#), the “expand” [*] operator). For instance:

```
select
  JsonGet_Int(Json_Array(45,28,36,45,89), '[4]') "Rank",
  JsonGet_Int(Json_Array(45,28,36,45,89), '[#]') "Number",
  JsonGet_String(Json_Array(45,28,36,45,89), '[""]') "Concat",
  JsonGet_Int(Json_Array(45,28,36,45,89), '[+]') "Sum",
  JsonGet_Real(Json_Array(45,28,36,45,89), '[!]', 2) "Avg";
```

The result:

Rank	Number	Concat	Sum	Avg
89	5	45,28,36,45,89	243	48.60

Json_Item_Merge

```
Json_Item_Merge(arg1, arg2, ...)
```

This function merges two arrays or two objects. For arrays, this is done by adding to the first array all the values of the second array. For instance:

```
select Json_Item_Merge(Json_Array('a','b','c'), Json_Array('d','e','f')) as "Result";
```

The function returns:

Result
["a","b","c","d","e","f"]

For objects, the pairs of the second object are added to the first object if the key does not yet exist in it; otherwise the pair of the first object is set with the value of the matching pair of the second object. For instance:

```
select Json_Item_Merge(Json_Object(1 "a", 2 "b", 3 "c"), Json_Object(4 "d",5 "b",6 "f"))
as "Result";
```

The function returns:

Result
["a","b","c","d","e","f"]

```
{ "a":1, "b":5, "c":3, "d":4, "f":6 }
```

JsonLocate

```
JsonLocate(arg1, arg2, [arg3], ...):
```

The first argument must be a JSON tree. The second argument is the item to be located. The item to be located can be a constant or a json item. Constant values must be equal in type and value to be found. This is "shallow equality" – strings, integers and doubles won't match.

This function returns the json path to the located item or null if it is not found. For example:

```
select JsonLocate('{"AUTHORS":[{"FN":"Jules", "LN":"Verne"}, {"FN":"Jack", "LN":"London"}]}' json_, 'Jack') Path;
```

This query returns:

Path

```
AUTHORS:[1]:FN
```

or, from [MariaDB 10.2.8](#) ↗:

Path

```
$.AUTHORS[1].FN
```

The path syntax is the same used in JSON CONNECT tables.

By default, the path of the first occurrence of the item is returned. The third parameter can be used to specify the occurrence whose path is to be returned. For instance:

```
select
  JsonLocate('[45,28,[36,45],89]',45) first,
  JsonLocate('[45,28,[36,45],89]',45,2) second,
  JsonLocate('[45,28,[36,45],89]',45.0) `wrong type`,
  JsonLocate('[45,28,[36,45],89]', '[36,45]' json_) json;
```

first	second	wrong type	json
[0]	[2]:[1]	<null>	[2]

or, from [MariaDB 10.2.8](#) ↗:

first	second	wrong type	json
[\$0]	[\$2][1]	<null>	[\$2]

For string items, the comparison is case sensitive by default. However, it is possible to specify a string to be compared case insensitively by giving it an alias beginning by "ci":

```
select JsonLocate('{"AUTHORS":[{"FN":"Jules", "LN":"Verne"}, {"FN":"Jack", "LN":"London"}]}' json_, 'VERNE' ci) Path;
```

Path

```
AUTHORS:[0]:LN
```

or, from [MariaDB 10.2.8](#) ↗:

Path

```
$.AUTHORS[0].LN
```

Json_Locate_All

```
Json_Locate_All(arg1, arg2, [arg3], ...):
```

The first argument must be a JSON item. The second argument is the item to be located. This function returns the paths to all locations of the item as an array of strings. For example:

```
select Json_Locate_All('[[45,28],[[36,45],89]]',45);
```

This query returns:

All paths

```
["[0]:[0]","[1]:[0]:[1]"]
```

or, from [MariaDB 10.2.8](#):

All paths

```
["$[0][0]","$[1][0][1]"]
```

The returned array can be applied other functions. For instance, to get the number of occurrences of an item in a json tree, you can do:

```
select JsonGet_Int(Json_Locate_All('[[45,28],[[36,45],89]]',45), '#') "Nb of occurs";
```

or, from [MariaDB 10.2.8](#):

```
select JsonGet_Int(Json_Locate_All('[[45,28],[[36,45],89]]',45), '$[#]') "Nb of occurs";
```

The displayed result:

Nb of occurs

```
2
```

If specified, the third integer argument set the depth to search in the document. This means the maximum items in the paths (until [MariaDB 10.2.7](#), the number of ':' separator characters in them plus one). This value defaults to 10 but can be increased for complex documents or reduced to set the maximum wanted depth of the returned paths.

Json_Make_Array

```
Json_Make_Array(val1, ..., valn)
```

This function was named "Json_Array" in previous versions of CONNECT. It was renamed because [MariaDB 10.2](#) features native JSON functions including a [Json_Array](#) function. The native function does almost the same as the UDF one, but does not accept CONNECT-specific arguments such as the result from JBIN functions.

Json_Make_Array returns a string denoting a JSON array with all its arguments as members. For example:

```
select Json_Make_Array(56, 3.1416, 'My name is "Foo"', NULL);
```

Json_Make_Array(56, 3.1416, 'My name is "Foo"', NULL)

```
[56,3.141600,"My name is \"Foo\"",null]
```

Note: The argument list can be void. If so, a void array is returned.

This function was named "Json_Array" in previous versions of CONNECT. It was renamed because [MariaDB 10.2](#) features native JSON functions including a "Json_Array" function. The native function does almost the same as the UDF one but does not accept CONNECT specific arguments such as the result from JBIN functions.

Json_Make_Object

```
Json_Make_Object(arg1, ..., argn)
```

This function was named "Json_Object" in previous versions of CONNECT. It was renamed because [MariaDB 10.2](#) features native JSON functions including a [Json_Object](#) function. The native function does what the UDF [Json_Object_Key](#) does.

Json_Make_Object returns a string denoting a JSON object. For instance:

```
select Json_Make_Object(56, 3.1416, 'machin', NULL);
```

The object is filled with pairs corresponding to the given arguments. The key of each pair is made from the argument (default or specified) alias.

```
Json_Make_Object(56, 3.1416, 'machin', NULL)
```

```
{"56":56,"3.1416":3.141600,"machin":"machin","NULL":null}
```

When needed, it is possible to specify the keys by giving an alias to the arguments:

```
select Json_Make_Object(56 qty, 3.1416 price, 'machin' truc, NULL garanty);
```

```
Json_Make_Object(56 qty,3.1416 price,'machin' truc, NULL garanty)
```

```
{"qty":56,"price":3.141600,"truc":"machin","garanty":null}
```

If the alias is prefixed by 'json_' (to prevent escaping) the key name is stripped from that prefix.

This function is chiefly useful when entering values retrieved from a table, the key being by default the column name:

```
select Json_Make_Object(matricule, nom, titre, salaire) from connect.employe where nom = 'PANTIER'
```

```
Json_Make_Object(matricule, nom, titre, salaire)
```

```
{"matricule":40567,"nom":"PANTIER","titre":"DIRECTEUR","salaire":14000.000000}
```

This function was named "Json_Object" in previous versions of CONNECT. It was renamed because [MariaDB 10.2](#) features native JSON functions including a "Json_Object" function. The native function does what the UDF `Json_Object_Key` does.

Json_Object_Add

```
Json_Object_Add(arg1, arg2, [arg3] ...)
```

The first argument must be a JSON object. The second argument is added as a pair to this object. For example:

```
select Json_Object_Add  
( '{"item":"T-shirt","qty":27,"price":24.99}' json_old, 'blue' color) newobj;
```

```
newobj
```

```
{"item":"T-shirt","qty":27,"price":24.990000,"color":"blue"}
```

Note: If the specified key already exists in the object, its value is replaced by the new one.

The third string argument is a Json path to the target object.

Json_Object_Delete

```
Json_Object_Delete(arg1, arg2, [arg3] ...):
```

The first argument must be a JSON object. The second argument is the key of the pair to delete. For example:

```
select Json_Object_Delete('{"item":"T-shirt","qty":27,"price":24.99}' json_old, 'qty') newobj;
```

```
newobj
```

```
{"item":"T-shirt","price":24.99}
```

The third string argument is a Json path to the object to be the target of deletion.

Json_Object_Grp

```
Json_Object_Grp (arg1, arg2)
```

This function works like `Json_Array_Grp`. It makes a JSON object filled with value pairs whose keys are passed from its first argument and values are passed from its second argument.

This can be seen with the query:

```
select name, json_object_grp(number,race) from pet group by name;
```

This query returns:

name	json_object_grp(number,race)
Bill	{"cat":1}
Donald	{"dog":1,"fish":3}
John	{"dog":2}
Kevin	{"cat":2,"bird":6}
Lisbeth	{"rabbit":2}
Mary	{"dog":1,"cat":1}

Json_Object_Key

```
Json_Object_Key([key1, val1 [, ..., keyn, valn]])
```

Return a string denoting a JSON object. For instance:

```
select Json_Object_Key('qty', 56, 'price', 3.1416, 'truc', 'machin', 'garanty', NULL);
```

The object is filled with pairs made from each key/value arguments.

```
Json_Object_Key('qty', 56, 'price', 3.1416, 'truc', 'machin', 'garanty', NULL)
{"qty":56,"price":3.141600,"truc":"machin","garanty":null}
```

Json_Object_List

```
Json_Object_List(arg1, ...):
```

The first argument must be a JSON object. This function returns an array containing the list of all keys existing in the object. For example:

```
select Json_Object_List(Json_Object(56 qty,3.1416 price,'machin' truc, NULL garanty))
"Key List";
```

```
Key List
```

```
["qty","price","truc","garanty"]
```

Json_Object_Null

```
Json_Object_Null(arg1, ..., argn)
```

This function works like `Json_Make_Object` but "null" arguments are ignored and not inserted in the object. Arguments are regarded as "null" if they are JSON null values, void arrays or objects, or arrays or objects containing only null members.

It is mainly used to avoid constructing useless null items when converting tables (see later).

Json_Object_Values

```
Json_Object_Values(json_object)
```

The first argument must be a JSON object. This function returns an array containing the list of all values existing in the object. For example:

```
select Json_Object_Values('{"One":1,"Two":2,"Three":3}') "Value List";
```

Value List

```
[1,2,3]
```

JsonSet_Grp_Size

```
JsonSet_Grp_Size(val)
```

This function is used to set the JsonGrpSize value. This value is used by the following aggregate functions as a ceiling value of the number of items in each group. It returns the JsonGrpSize value that can be its default value when passed 0 as argument.

Json_Set_Item / Json_Insert_Item / Json_Update_Item

```
Json_{Set | Insert | Update}_Item(json_doc, [item, path [, val, path ...]])
```

These functions insert or update data in a JSON document and return the result. The value/path pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

- `Json_Set_Item` replaces existing values and adds non-existing values.
- `Json_Insert_Item` inserts values without replacing existing values.
- `Json_Update_Item` replaces only existing values.

Example:

```
set @j = Json_Array(1, 2, 3, Json_Object_Key('quatre', 4));
select Json_Set_Item(@j, 'foo', '[1]', 5, '[3]:cinq') as "Set",
       Json_Insert_Item(@j, 'foo', '[1]', 5, '[3]:cinq') as "Insert",
       Json_Update_Item(@j, 'foo', '[1]', 5, '[3]:cinq') as "Update";
```

or, from [MariaDB 10.2.8](#):

```
set @j = Json_Array(1, 2, 3, Json_Object_Key('quatre', 4));
select Json_Set_Item(@j, 'foo', '$[1]', 5, '$[3].cinq') as "Set",
       Json_Insert_Item(@j, 'foo', '$[1]', 5, '$[3].cinq') as "Insert",
       Json_Update_Item(@j, 'foo', '$[1]', 5, '$[3].cinq') as "Update";
```

This query returns:

Set	Insert	Update
[1,"foo",3,{"quatre":4,"cinq":5}]	[1,2,3,{"quatre":4,"cinq":5}]	[1,"foo",3,{"quatre":4}]

JsonValue

```
JsonValue (val)
```

Returns a JSON value as a string, for instance:

```
select JsonValue(3.1416);
```

JsonValue(3.1416)

```
3.141600
```

Before [MariaDB 10.1.9](#), this function was called `Json_Value`, but was renamed to avoid clashing with the `JSON_VALUE`

function.

The “JBIN” return type

Almost all functions returning a json string - whose name begins with *Json_* - have a counterpart with a name beginning with *Jbin_*. This is both for performance (speed and memory) as well as for better control of what the functions should do.

This is due to the way CONNECT UDFs work internally. The *Json* functions, when receiving json strings as parameters, parse them and construct a binary tree in memory. They work on this tree and before returning; serialize this tree to return a new json string.

If the json document is large, this can take up a large amount of time and storage space. It is all right when one simple json function is called – it must be done anyway – but is a waste of time and memory when json functions are used as parameters to other json functions.

To avoid multiple serializing and parsing, the *Jbin* functions should be used as parameters to other functions. Indeed, they do not serialize the memory document tree, but return a structure allowing the receiving function to have direct access to the memory tree. This saves the serialize-parse steps otherwise needed to pass the argument and removes the need to reallocate the memory of the binary tree, which by the way is 6 to 7 times the size of the json string. For instance:

```
select Json_Object(Jbin_Array_Add(Jbin_Array('a','b','c'), 'd') as "Jbin_foo") as "Result";
```

This query returns:

Result

```
{"foo":["a","b","c","d"]}
```

Here the binary json tree allocated by *Jbin_Array* is completed by *Jbin_Array_Add* and *Json_Object* and serialized only once to make the final result string. It would be serialized and parsed two more times if using “*Json*” functions.

Note that *Jbin* results are recognized as such because they are aliased beginning with “*Jbin_*”. This is why in the *Json_Object* function the alias is specified as “*Jbin_foo*”.

What happens if it is not recognized as such? These functions are declared as returning a string and to take care of this, the returned structure begins with a zero-terminated string. For instance:

```
select Jbin_Array('a','b','c');
```

This query replies:

Jbin_Array('a','b','c')

```
Binary Json array
```

Note: When testing, the tree returned by a “*Jbin*” function can be seen using the *Json_Serialize* function whose unique parameter must be a “*Jbin*” result. For instance:

```
select Json_Serialize(Jbin_Array('a','b','c'));
```

This query returns:

Json_Serialize(Jbin_Array('a','b','c'))

```
["a","b","c"]
```

Note: For this simple example, this is equivalent to using the *Json_Array* function.

Using a file as json UDF first argument

We have seen that many json UDFs can have an additional argument not yet described. This is in the case where the json item argument was referring to a file. Then the additional integer argument is the pretty value of the json file. It matters only when the first argument is just a file name (to make the UDF understand this argument is a file name, it should be aliased with a name beginning with *jfile_*) or if the function modifies the file, in which case it will be rewritten with this pretty format.

The json item is created by extracting the required part from the file. This can be the whole file but more often only some of it. There are two ways to specify the sub-item of the file to be used:

1. Specifying it in the *Json_File* or *Jbin_File* arguments.
2. Specifying it in the receiving function (not possible for all functions).

It doesn't make any difference when the *Jbin_File* is used but it does with *Json_File*. For instance:

```
select Jfile_Make('{ "a":1, "b":[44, 55]}' json_, 'test.json');
select Json_Array_Add(Json_File('test.json', 'b'), 66);
```

The second query returns:

```
Json_Array_Add(Json_File('test.json', 'b'), 66)
```

```
[44,55,66]
```

It just returns the – modified -- subset returned by the *Json_File* function, while the query:

```
select Json_Array_Add(Json_File('test.json'), 66, 'b');
```

returns what was received from *Json_File* with the modification made on the subset.

```
Json_Array_Add(Json_File('test.json'), 66, 'b')
```

```
{"a":1,"b":[44,55,66]}
```

Note that in both case the *test.json* file is not modified. This is because the *Json_File* function returns a string representing all or part of the file text but no information about the file name. This is all right to check what would be the effect of the modification to the file.

However, to have the file modified, use the *Jbin_File* function or directly give the file name. *Jbin_File* returns a structure containing the file name, a pointer to the file parsed tree and eventually a pointer to the subset when a path is given as a second argument:

```
select Json_Array_Add(Jbin_File('test.json', 'b'), 66);
```

This query returns:

```
Json_Array_Add(Jbin_File('test.json', 'b'), 66)
```

```
test.json
```

This time the file is modified. This can be checked with:

```
select Json_File('test.json', 3);
```

```
Json_File('test.json', 3)
```

```
{"a":1,"b":[44,55,66]}
```

The reason why the first argument is returned by such a query is because of tables such as:

```
create table tb (
n int key,
jfile_cols char(10) not null);
insert into tb values(1, 'test.json');
```

In this table, the *jfile_cols* column just contains a file name. If we update it by:

```
update tb set jfile_cols = select Json_Array_Add(Jbin_File('test.json', 'b'), 66)
where n = 1;
```

This is the *test.json* file that must be modified, not the *jfile_cols* column. This can be checked by:

```
select JsonGet_String(jfile_cols, '[1]:*') from tb;
```

```
JsonGet_String(jfile_cols, '[1]:*')
```

```
{"a":1,"b":[44,55,66]}
```

Note: It was an important facility to name the second column of the table beginning by "jfile_" so the json functions knew it was a file name without obliging to specify an alias in the queries.

Using “Jbin” to control what the query execution does

This is applying in particular when acting on json files. We have seen that a file was not modified when using the `Json_File` function as an argument to a modifying function because the modifying function just received a copy of the json file. This is not true when using the `Jbin_File` function that does not serialize the binary document and make it directly accessible. Also, as we have seen earlier, json functions that modify their first file parameter modify the file and return the file name. This is done by directly serializing the internal binary document as a file.

However, the “Jbin” counterpart of these functions does not serialize the binary document and thus does not modify the json file. For example let us compare these two queries:

`/* First query */`

```
select Json_Object(Jbin_Object_Add(Jbin_File('bt2.json'), 4 as "d") as "Jbin_bt1")
as "Result";
```

`/* Second query */`

```
select Json_Object(Json_Object_Add(Jbin_File('bt2.json'), 4 as "d") as "Jfile_bt1")
as "Result";
```

Both queries return:

Result

```
{"bt1":{"a":1,"b":2,"c":3,"d":4}}
```

In the first query `Jbin_Object_Add` does not serialize the document (no “Jbin” functions do) and `Json_Object` just returns a serialized modified tree. Consequently, the file `bt2.json` is not modified. This query is all right to copy a modified version of the json file without modifying it.

However, in the second query `Json_Object_Add` does modify the json file and returns the file name. The `Json_Object` function receives this file name, reads and parses the file, makes an object from it and returns the serialized result. This modification can be done willingly but can be an unwanted side effect of the query.

Therefore, using “Jbin” argument functions, in addition to being faster and using less memory, are also safer when dealing with json files that should not be modified.

Using JSON as Dynamic Columns

The JSON nosql language has all the features to be used as an alternative to dynamic columns. For instance, take the following example of dynamic columns:

```
create table assets (
  item_name varchar(32) primary key, /* A common attribute for all items */
  dynamic_cols blob /* Dynamic columns will be stored here */
);

INSERT INTO assets VALUES
('MariaDB T-shirt', COLUMN_CREATE('color', 'blue', 'size', 'XL'));

INSERT INTO assets VALUES
('Thinkpad Laptop', COLUMN_CREATE('color', 'black', 'price', 500));

SELECT item_name, COLUMN_GET(dynamic_cols, 'color' as char) AS color FROM assets;
+-----+-----+
| item_name | color |
+-----+-----+
| MariaDB T-shirt | blue |
| Thinkpad Laptop | black |
+-----+-----+
```

`/* Remove a column: */`

```
UPDATE assets SET dynamic_cols=COLUMN_DELETE(dynamic_cols, "price")
WHERE COLUMN_GET(dynamic_cols, 'color' as char)='black';
```

`/* Add a column: */`

```
UPDATE assets SET dynamic_cols=COLUMN_ADD(dynamic_cols, 'warranty', '3 years')
WHERE item_name='Thinkpad Laptop';
```

/* You can also list all columns, or get them together with their values in JSON format: */

```
SELECT item_name, column_list(dynamic_cols) FROM assets;
+-----+-----+
| item_name      | column_list(dynamic_cols) |
+-----+-----+
| MariaDB T-shirt | `size`,`color`           |
| Thinkpad Laptop | `color`,`warranty`       |
+-----+-----+

SELECT item_name, COLUMN_JSON(dynamic_cols) FROM assets;
+-----+-----+
| item_name      | COLUMN_JSON(dynamic_cols) |
+-----+-----+
| MariaDB T-shirt | {"size":"XL","color":"blue"}
| Thinkpad Laptop | {"color":"black","warranty":"3 years"}
+-----+-----+
```

The same result can be obtained with json columns using the json UDF's:

/* JSON equivalent */

```
create table jassets (
  item_name varchar(32) primary key, /* A common attribute for all items */
  json_cols varchar(512) /* Jason columns will be stored here */
);

INSERT INTO jassets VALUES
('MariaDB T-shirt', Json_Object('blue' color, 'XL' size));

INSERT INTO jassets VALUES
('Thinkpad Laptop', Json_Object('black' color, 500 price));

SELECT item_name, JsonGet_String(json_cols, 'color') AS color FROM jassets;
+-----+-----+
| item_name      | color |
+-----+-----+
| MariaDB T-shirt | blue  |
| Thinkpad Laptop | black |
+-----+-----+
```

/* Remove a column: */

```
UPDATE jassets SET json_cols=Json_Object_Delete(json_cols, 'price')
WHERE JsonGet_String(json_cols, 'color')='black';
```

/* Add a column */

```
UPDATE jassets SET json_cols=Json_Object_Add(json_cols, '3 years' warranty)
WHERE item_name='Thinkpad Laptop';
```

/* You can also list all columns, or get them together with their values in JSON format: */

```

SELECT item_name, Json_Object_List(json_cols) FROM jassets;
+-----+-----+
| item_name          | Json_Object_List(json_cols) |
+-----+-----+
| MariaDB T-shirt   | [{"color","size"}          |
| Thinkpad Laptop   | [{"color","warranty"}      |
+-----+-----+

SELECT item_name, json_cols FROM jassets;
+-----+-----+
| item_name          | json_cols                   |
+-----+-----+
| MariaDB T-shirt   | [{"color":"blue","size":"XL"}
| Thinkpad Laptop   | [{"color":"black","warranty":"3 years"}
+-----+-----+

```

However, using JSON brings features not existing in dynamic columns:

- Use of a language used by many implementation and developers.
- Full support of arrays, currently missing from dynamic columns.
- Access of subpart of json by JPATH that can include calculations on arrays.
- Possible references to json files.

With more experience, additional UDFs can be easily written to support new needs.

New Set of BSON Functions

All these functions have been rewritten using the new JSON handling way and are temporarily available changing the J starting name to B. Then `Json_Make_Array` new style is called using `Bson_Make_Array`. Some, such as `Bson_Item_Delete`, are new and some fix bugs found in their `Json` counterpart.

Converting Tables to JSON

The JSON UDF's and the direct Jpath "*" facility are powerful tools to convert table and files to the JSON format. For instance, the file `biblio3.json` we used previously can be obtained by converting the `xsample.xml` file. This can be done like this:

From Connect 1.07.0002

```

create table xj1 (row varchar(500) jpath='*') engine=connect table_type=JSON
file_name='biblio3.json' option_list='jmode=2';

```

Before Connect 1.07.0002

```

create table xj1 (row varchar(500) field_format='*')
engine=connect table_type=JSON file_name='biblio3.json' option_list='jmode=2';

```

And then :

```

insert into xj1
select json_object_nonnull(ISBN, language LANG, SUBJECT,
    json_array_grp(json_object(authorfn FIRSTNAME, authorln LASTNAME)) json_AUTHOR, TITLE,
    json_object(translated PREFIX, json_object(tranf FIRSTNAME, tranln LASTNAME) json_TRANSLATOR
    json_TRANSLATED, json_object(publisher NAME, location PLACE) json_PUBLISHER, date DATEPUB)
from xsampall2 group by isbn;

```

The `xj1` table rows will directly receive the `Json` object made by the `select` statement used in the `insert` statement and the table file will be made as shown (`xj1` is `pretty=2` by default) Its mode is `Jmode=2` because the values inserted are strings even if they denote `json` objects.

Another way to do this is to create a table describing the file format we want before the `biblio3.json` file existed:

From Connect 1.07.0002

```

create table jsampall3 (
  ISBN char(15),
  LANGUAGE char(2) jpath='LANG',
  SUBJECT char(32),
  AUTHORFN char(128) jpath='AUTHOR:[X]:FIRSTNAME',
  AUTHORLN char(128) jpath='AUTHOR:[X]:LASTNAME',
  TITLE char(32),
  TRANSLATED char(32) jpath='TRANSLATOR:PREFIX',
  TRANSLATORFN char(128) jpath='TRANSLATOR:FIRSTNAME',
  TRANSLATORLN char(128) jpath='TRANSLATOR:LASTNAME',
  PUBLISHER char(20) jpath='PUBLISHER:NAME',
  LOCATION char(20) jpath='PUBLISHER:PLACE',
  DATE int(4) jpath='DATEPUB')
engine=CONNECT table_type=JSON file_name='biblio3.json';

```

Before Connect 1.07.0002

```

create table jsampall3 (
  ISBN char(15),
  LANGUAGE char(2) field_format='LANG',
  SUBJECT char(32),
  AUTHORFN char(128) field_format='AUTHOR:[X]:FIRSTNAME',
  AUTHORLN char(128) field_format='AUTHOR:[X]:LASTNAME',
  TITLE char(32),
  TRANSLATED char(32) field_format='TRANSLATOR:PREFIX',
  TRANSLATORFN char(128) field_format='TRANSLATOR:FIRSTNAME',
  TRANSLATORLN char(128) field_format='TRANSLATOR:LASTNAME',
  PUBLISHER char(20) field_format='PUBLISHER:NAME',
  LOCATION char(20) field_format='PUBLISHER:PLACE',
  DATE int(4) field_format='DATEPUB')
engine=CONNECT table_type=JSON file_name='biblio3.json';

```

and to populate it by:

```

insert into jsampall3 select * from xsampall;

```

This is a simpler method. However, the issue is that this method cannot handle the multiple column values. This is why we inserted from `xsampall` not from `xsampall2`. How can we add the missing multiple authors in this table? Here again we must create a utility table able to handle JSON strings. From Connect 1.07.0002

```

create table xj2 (ISBN char(15), author varchar(150) jpath='AUTHOR:*') engine=connect
table_type=JSON file_name='biblio3.json' option_list='jmode=1';

```

Before Connect 1.07.0002

```

create table xj2 (ISBN char(15), author varchar(150) field_format='AUTHOR:*')
engine=connect table_type=JSON file_name='biblio3.json' option_list='jmode=1';

```

```

update xj2 set author =
(select json_array_grp(json_object(authorfn FIRSTNAME, authorln LASTNAME))
 from xsampall2 where isbn = xj2.isbn);

```

Voilà !

Converting json files

We have seen that json files can be formatted differently depending on the pretty option. In particular, big data files should be formatted with pretty equal to 0 when used by a CONNECT json table. The best and simplest way to convert a file from one format to another is to use the `Jfile_Make` function. Indeed this function makes a file of specified format using the syntax:

```

Jfile_Make(json_document, [file_name], [pretty]);

```

The file name is optional when the json document comes from a `Jbin_File` function because the returned structure makes it available. For instance, to convert back the json file `tb.json` to `pretty=0`, this can be simply done by:

```
select Jfile_Make(Jbin_File('tb.json'), 0);
```

Performance Consideration

MySQL and PostgreSQL have a JSON data type that is not just text but an internal encoding of JSON data. This is to save parsing time when executing JSON functions. Of course, the parse must be done anyway when creating the data and serializing must be done to output the result.

CONNECT directly works on character strings impersonating JSON values with the need of parsing them all the time but with the advantage of working easily on external data. Generally, this is not too penalizing because JSON data are often of some or reasonable size. The only case where it can be a serious problem is when working on a big JSON file.

Then, the file should be formatted or converted to *pretty=0*.

From Connect 1.7.002, this easily done using the `Jfile_Convert` function, for instance:

```
select jfile_convert('bibdoc.json','bibdoc0.json',350);
```

Such a json file should not be used directly by JSON UDFs because they parse the whole file, even when only a subset is used. Instead, it should be used by a JSON table created on it. Indeed, JSON tables do not parse the whole document but just the item corresponding to the row they are working on. In addition, indexing can be used by the table as explained previously on this page.

Generally speaking, the maximum flexibility offered by CONNECT is by using JSON tables and JSON UDFs together. Some things are better handled by tables, other by UDFs. The tools are there but it is up to you to discover the best way to resolve your problems.

Bjson files

Starting with Connect 1.7.002, *pretty=0* json files can be converted to a binary format that is a pre-parsed representation of json. This can be done with the `Jfile_Bjson` UDF function, for instance:

```
select jfile_bjson('bigfile.json','binfile.json',3500);
```

Here the third argument, the record length, must be 6 to 10 times larger than the `lrecl` of the initial json file because the parsed representation is bigger than the original json text representation.

Tables using such Bjson files must specify 'Pretty=-1' in the option list.

It is probably similar to the BSON used by MongoDB and PostgreSQL and permits to process queries up to 10 times faster than working on text json files. Indexing is also available for tables using this format making even more performance improvement. For instance, some queries on a json table of half a million rows, that were previously done in more than 10 seconds, took only 0.1 second when converted and indexed.

Here again, this has been remade to use the new way Json is handled. The files made using the `bfile_bjson` function are only from two to four times the size of the source files. This new representation is not compatible with the old one. Therefore, these files must be used with BSON tables only.

Specifying a JSON table Encoding

An important feature of JSON is that strings should be in UNICODE. As a matter of fact, all examples we have found on the Internet seemed to be just ASCII. This is because UNICODE is generally encoded in JSON files using UTF8 or UTF16 or UTF32.

To specify the required encoding, just use the `data_charset` CONNECT option or the native `DEFAULT CHARSET` option.

Retrieving JSON data from MongoDB

Classified as a NoSQL database program, MongoDB uses JSON-like documents (BSON) grouped in collections. The simplest way, and only method available before Connect 1.6, to access MongoDB data was to export a collection to a JSON file. This produces a file having the *pretty=0* format. Viewed as SQL, a collection is a table and documents are table rows.

Since CONNECT version 1.6, it is now possible to directly access MongoDB collections via their MongoDB C Driver. This is the purpose of the `MONGO` table type described later. However, JSON tables can also do it in a somewhat different way (providing `MONGO` support is installed as described for `MONGO` tables).

It is achieved by specifying the MongoDB connection URI while creating the table. For instance:

```
create or replace table jinvent (
  _id char(24) not null,
  item char(12) not null,
  instock varchar(300) not null jpath='instock.*')
engine=connect table_type=JSON tabname='inventory' lrecl=512
connection='mongodb://localhost:27017';
```

Before Connect 1.7.002

```
create or replace table jinvent (
  _id char(24) not null,
  item char(12) not null,
  instock varchar(300) not null field_format='instock.*')
engine=connect table_type=JSON tabname='inventory' lrecl=512
connection='mongodb://localhost:27017';
```

In this statement, the *file_name* option was replaced by the *connection* option. It is the URI enabling to retrieve data from a local or remote MongoDB server. The *tablename* option is the name of the MongoDB collection that will be used and the *dbname* option could have been used to indicate the database containing the collection (it defaults to the current database).

The way it works is that the documents retrieved from MongoDB are serialized and CONNECT uses them as if they were read from a file. This implies serializing by MongoDB and parsing by CONNECT and is not the best performance wise. CONNECT tries its best to reduce the data transfer when a query contains a reduced column list and/or a where clause. This way makes all the possibilities of the JSON table type available, such as calculated arrays.

However, to work on large JSON collations, using the MONGO table type is generally the normal way.

Note: JSON tables using the MongoDB access accept the specific MONGO options [colist](#), [filter](#) and [pipeline](#). They are described in the MONGO table chapter.

Summary of Options and Variables Used with Json Tables

Options and variables that can be used when creating Json tables are listed here:

Table Option	Type	Description
ENGINE	String	Must be specified as CONNECT.
TABLE_TYPE	String	Must be JSON or BSON.
FILE_NAME	String	The optional file (path) name of the Json file. Can be absolute or relative to the current data directory. If not specified, it defaults to the table name and json file type.
DATA_CHARSET	String	Set it to 'utf8' for most Unicode Json documents.
LRECL	Number	The file record size for pretty < 2 json files.
HTTP	String	The HTTP of the server of REST queries.
URI	String	THE URI of REST queries
CONNECTION*	String	Specifies a connection to MONGODB .
ZIPPED	Boolean	True if the json file(s) is/are zipped in one or several zip files.
MULTIPLE	Number	Used to specify a multiple file table.
SEP_CHAR	String	Set it to ':' for old tables using the old json path syntax.
CATFUNC	String	The catalog function (column) used when creating a catalog table.
OPTION_LIST	String	Used to specify all other options listed below.

(*) For Json tables connected to MongoDB, Mongo specific options can also be used.

Other options must be specified in the option list:

Table Option	Type	Description
--------------	------	-------------

DEPTH LEVEL	Number	Specifies the depth in the document CONNECT looks when defining columns by discovery or in catalog tables
PRETTY	Number	Specifies the format of the Json file (-1 for Bjson files)
EXPAND	String	The name of the column to expand.
OBJECT	String	The json path of the sub-document used for the table.
BASE	Number	The numbering base for arrays: 0 (the default) or 1.
LIMIT	Number	The maximum number of array values to use when concatenating, calculating or expanding arrays. Defaults to 50 (>= Connect 1.7.0003), 10 (<= Connect 1.7.0002).
FULLARRAY	Boolean	Used when creating with Discovery. Make a column for each value of arrays (up to LIMIT).
JMODE	Number	The Json mode (array of objects, array of arrays, or array of values) Only used when inserting new rows.
ACCEPT	Boolean	Keep null columns (for discovery).
AVGLEN	Number	An estimate average length of rows. This is used only when indexing and can be set if indexing fails by miscalculating the table max size.
STRINGIFY	String	Ask discovery to make a column to return the Json representation of this object.

Column options:

Column Option	Type	Description
JPATH FIELD_FORMAT	String	Defaults to the column name.
DATE_FORMAT	String	Specifies the date format into the Json file when defining a DATE, DATETIME or TIME column.

Variables used with Json tables are:

- [connect_default_depth](#)
- [connect_json_null](#)
- [connect_json_all_path](#)
- [connect_force_bson](#)

Notes

1. ↑ The value n can be 0 based or 1 based depending on the base table option. The default is 0 to match what is the current usage in the Json world but it can be set to 1 for tables created in old versions.
2. ↑ See for instance: [json-functions](#), https://github.com/mysqludf/lib_mysqludf_json#readme and https://blogs.oracle.com/svetasmirnova/entry/json_udf_functions_version_04
3. ↑ This will not work when CONNECT is compiled embedded

5.3.7.6.13 CONNECT XML Table Type

Overview

CONNECT supports tables represented by XML files. For these tables, the standard input/output functions of the operating

system are not used but the parsing and processing of the file is delegated to a specialized library. Currently two such systems are supported: libxml2, a part of the GNOME framework, but which does not require GNOME and, on Windows, MS-DOM (DOMDOC), the Microsoft standard support of XML documents.

DOMDOC is the default for the Windows version of CONNECT and libxml2 is always used on other systems. On Windows the choice can be specified using the XMLSUP [CREATE TABLE](#) list option, for instance specifying `option_list='xmlsup=libxml2'`.

Creating XML tables

First of all, it must be understood that XML is a very general language used to encode data having any structure. In particular, the tag hierarchy in an XML file describes a tree structure of the data. For instance, consider the file:

```
<?xml version="1.0" encoding="ISO-8859-1"?>
<BIBLIO SUBJECT="XML">
  <BOOK ISBN="9782212090819" LANG="fr" SUBJECT="applications">
    <AUTHOR>
      <FIRSTNAME>Jean-Christophe</FIRSTNAME>
      <LASTNAME>Bernadac</LASTNAME>
    </AUTHOR>
    <AUTHOR>
      <FIRSTNAME>François</FIRSTNAME>
      <LASTNAME>Knab</LASTNAME>
    </AUTHOR>

```

It represents data having the structure:

This structure seems at first view far from being tabular. However, modern database management systems, including

MariaDB, implement something close to the relational model and work on tables that are structurally not hierarchical but tabular with rows and columns.

Nevertheless, CONNECT can do it. Of course, it cannot guess what you want to extract from the XML structure, but gives you the possibility to specify it when you create the table^[1].

Let us take a first example. Suppose you want to make a table from the above document, displaying the node contents.

For this, you can define a table *xsamptag* as:

```
create table xsamptag (  
  AUTHOR char(50),  
  TITLE char(32),  
  TRANSLATOR char(40),  
  PUBLISHER char(40),  
  DATEPUB int(4))  
engine=CONNECT table_type=XML file_name='Xsample.xml';
```

It will be displayed as:

AUTHOR	TITLE	TRANSLATOR	PUBLISHER	DATEPUB
Jean-Christophe Bernadac	Construire une application XML	<null>	Eyrolles Paris	1999
William J. Pardi	XML en Action	James Guerin	Microsoft Press Paris	1999

Let us try to understand what happened. By default the column names correspond to tag names. Because this file is rather simple, CONNECT was able to default the top tag of the table as the root node `<BIBLIO>` of the file, and the row tags as the `<BOOK>` children of the table tag. In a more complex file, this should have been specified, as we will see later. Note that we didn't have to worry about the sub-tags such as `<FIRSTNAME>` or `<LASTNAME>` because CONNECT automatically retrieves the entire text contained in a tag and its sub-tags^[2].

Only the first author of the first book appears. This is because only the first occurrence of a column tag has been retrieved so the result has a proper tabular structure. We will see later what we can do about that.

How can we retrieve the values specified by attributes? By using a *Coltype* table option to specify the default column type. The value '@' means that column names match attribute names. Therefore, we can retrieve them by creating a table such as:

```
create table xsampattr (  
  ISBN char(15),  
  LANG char(2),  
  SUBJECT char(32))  
engine=CONNECT table_type=XML file_name='Xsample.xml'  
option_list='Coltype=@';
```

This table returns the following:

ISBN	LANG	SUBJECT
9782212090819	fr	applications
9782840825685	fr	applications

Now to define a table that will give us all the previous information, we must specify the column type for each column. Because in the next statement the column type defaults to Node, the *field_format* column parameter was used to indicate which columns are attributes:

From Connect 1.7.0002

```
create table xsamp (  
  ISBN char(15) xpath='@',  
  LANG char(2) xpath='@',  
  SUBJECT char(32) xpath='@',  
  AUTHOR char(50),  
  TITLE char(32),  
  TRANSLATOR char(40),  
  PUBLISHER char(40),  
  DATEPUB int(4))  
engine=CONNECT table_type=XML file_name='Xsample.xml'  
tablename='BIBLIO' option_list='rownode=BOOK';
```

Before Connect 1.7.0002

```
create table xsamp (
  ISBN char(15) field_format='@',
  LANG char(2) field_format='@',
  SUBJECT char(32) field_format='@',
  AUTHOR char(50),
  TITLE char(32),
  TRANSLATOR char(40),
  PUBLISHER char(40),
  DATEPUB int(4)
engine=CONNECT table_type=XML file_name='Xsample.xml'
tabname='BIBLIO' option_list='rownode=BOOK');
```

Once done, we can enter the query:

```
select subject, lang, title, author from xsamp;
```

This will return the following result:

SUBJECT	LANG	TITLE	AUTHOR
applications	fr	Construire une application XML	Jean-Christophe Bernadac
applications	fr	XML en Action	William J. Pardi

Note that we have been lucky. Because unlike SQL, XML is case sensitive and the column names have matched the node names only because the column names were given in upper case. Note also that the order of the columns in the table could have been different from the order in which the nodes appear in the XML file.

Using Xpaths with XML tables

Xpath is used by XML to locate and retrieve nodes. The table's main node Xpath is specified by the `tabname` option. If just the node name is given, CONNECT constructs an Xpath such as `'BIBLIO'` in the example above that should retrieve the `BIBLIO` node wherever it is within the XML file.

The row nodes are by default the children of the table node. However, for instance to eliminate some children nodes that are not real row nodes, the row node name can be specified using the `rownode` sub-option of the `option_list` option.

The `field_format` options we used above can be specified to locate more precisely where and what information to retrieve using an Xpath-like syntax. For instance:

From Connect 1.7.0002

```
create table xsampall (
  isbn char(15) xpath='@ISBN',
  language char(2) xpath='@LANG',
  subject char(32) xpath='@SUBJECT',
  authorfn char(20) xpath='AUTHOR/FIRSTNAME',
  authorln char(20) xpath='AUTHOR/LASTNAME',
  title char(32) xpath='TITLE',
  translated char(32) xpath='TRANSLATOR/@PREFIX',
  tranfn char(20) xpath='TRANSLATOR/FIRSTNAME',
  tranln char(20) xpath='TRANSLATOR/LASTNAME',
  publisher char(20) xpath='PUBLISHER/NAME',
  location char(20) xpath='PUBLISHER/PLACE',
  year int(4) xpath='DATEPUB'
engine=CONNECT table_type=XML file_name='Xsample.xml'
tabname='BIBLIO' option_list='rownode=BOOK');
```

Before Connect 1.7.0002

```

create table xsampall (
  isbn char(15) field_format='@ISBN',
  language char(2) field_format='@LANG',
  subject char(32) field_format='@SUBJECT',
  authorfn char(20) field_format='AUTHOR/FIRSTNAME',
  authorln char(20) field_format='AUTHOR/LASTNAME',
  title char(32) field_format='TITLE',
  translated char(32) field_format='TRANSLATOR/@PREFIX',
  tranfn char(20) field_format='TRANSLATOR/FIRSTNAME',
  tranln char(20) field_format='TRANSLATOR/LASTNAME',
  publisher char(20) field_format='PUBLISHER/NAME',
  location char(20) field_format='PUBLISHER/PLACE',
  year int(4) field_format='DATEPUB')
engine=CONNECT table_type=XML file_name='Xsample.xml'
tabname='BIBLIO' option_list='rownode=BOOK';

```

This very flexible column parameter serves several purposes:

- To specify the tag name, or the attribute name if different from the column name.
- To specify the type (tag or attribute) by a prefix of '@' for attributes.
- To specify the path for sub-tags using the '/' character.

This path is always relative to the current context (the column top node) and cannot be specified as an absolute path from the document root, therefore a leading '/' cannot be used. The path cannot be variable in node names or depth, therefore using '// ' is not allowed.

The query:

```

select isbn, title, translated, tranfn, tranln, location from
xsampall where translated is not null;

```

replies:

ISBN	TITLE	TRANSLATED	TRANFN	TRANLN	LOCATION
9782840825685	XML en Action	adapté de l'anglais par	James	Guerin	Paris

Libxml2 default name space issue

An issue with libxml2 is that some files can declare a default name space in their root node. Because Xpath only searches in that name space, the nodes will not be found if they are not prefixed. If this happens, specify the tabname option as an Xpath ignoring the current name space:

```
TABNAME="//*[local-name()='BIBLIO']"
```

This must also be done for the default of specified Xpath of the not attribute columns. For instance:

```
title char(32) field_format="*[local-name()='TITLE']",
```

Note: This raises an error (and is useless anyway) with DOMDOC.

Direct access on XML tables

Direct access is available on XML tables. This means that XML tables can be sorted and used in joins, even in the one-side of the join.

However, building a permanent index is not yet implemented. It is unclear whether this can be useful. Indeed, the DOM implementation that is used to access these tables firstly parses the whole file and constructs a node tree in memory. This may often be the longest part of the process, so the use of an index would not be of great value. Note also that this limits the XML files to a reasonable size. Anyway, when speed is important, this table type is not the best to use. Therefore, in these cases, it is probably better to convert the file to another type by inserting the XML table into another table of a more appropriate type for performance.

Accessing tags with namespaces

With the Windows DOMDOC support, this can be done using the prefix in the tabname column option and/or xpath column option. For instance, given the file gns.xml:

```
<?xml version="1.0" encoding="UTF-8"?>
<gpx xmlns:gns="http:dummy">
<gns:trkseg>
<trkpt lon="-121.9822235107421875" lat="37.3884925842285156">
<gns:ele>6.610851287841797</gns:ele>
<time>2014-04-01T14:54:05.000Z</time>
</trkpt>
<trkpt lon="-121.9821929931640625" lat="37.3885803222656250">
<ele>6.787827968597412</ele>
<time>2014-04-01T14:54:08.000Z</time>
</trkpt>
<trkpt lon="-121.9821624755859375" lat="37.3886299133300781">
<ele>6.771987438201904</ele>
<time>2014-04-01T14:54:10.000Z</time>
</trkpt>
</gns:trkseg>
</gpx>
```

and the defined CONNECT table:

```
CREATE TABLE xgns (
`lon` double(21,16) NOT NULL `xpath`='@',
`lat` double(20,16) NOT NULL `xpath`='@',
`ele` double(21,16) NOT NULL `xpath`='gns:ele',
`time` datetime date_format="YYYY-MM-DD 'T' hh:mm:ss '.000Z'"
)
ENGINE=CONNECT DEFAULT CHARSET=latin1 `table_type`=XML
`file_name`='gns.xml' tabname='gns:trkseg' option_list='xmlsup=domdoc';
```

```
select * from xgns;
```

Displays:

lon	lat	ele	time
-121,982223510742	37,3884925842285	6,6108512878418	01/04/2014 14:54:05
-121,982192993164	37,3885803222656	0	01/04/2014 14:54:08
-121,982162475586	37,3886299133301	0	01/04/2014 14:54:10

Only the prefixed 'ele' tag is recognized.

However, this does not work with the libxml2 support. The solution is then to use a function ignoring the name space:

```
CREATE TABLE xgns2 (
`lon` double(21,16) NOT NULL `xpath`='@',
`lat` double(20,16) NOT NULL `xpath`='@',
`ele` double(21,16) NOT NULL `xpath`="*[local-name()='ele']",
`time` datetime date_format="YYYY-MM-DD 'T' hh:mm:ss '.000Z'"
)
ENGINE=CONNECT DEFAULT CHARSET=latin1 `table_type`=XML
`file_name`='gns.xml' tabname="*[local-name()='trkseg']" option_list='xmlsup=libxml2';
```

Then :

```
select * from xgns2;
```

Displays:

lon	lat	ele	time
-121,982223510742	37,3884925842285	6,6108512878418	01/04/2014 14:54:05
-121,982192993164	37,3885803222656	6.7878279685974	01/04/2014 14:54:08
-121,982162475586	37,3886299133301	6.7719874382019	01/04/2014 14:54:10

This time, all 'ele' tags are recognized. This solution does not work with DOMDOC.

Having Columns defined by Discovery

It is possible to let the MariaDB discovery process do the job of column specification. When columns are not defined in the `CREATE TABLE` statement, `CONNECT` endeavours to analyze the XML file and to provide the column specifications. This is possible only for true XML tables, but not for HTML tables.

For instance, the `xsamp` table could have been created specifying:

```
create table xsamp
engine=CONNECT table_type=XML file_name='Xsample.xml'
tablename='BIBLIO' option_list='rownode=BOOK';
```

Let's check how it was actually specified using the `SHOW CREATE TABLE` statement:

```
CREATE TABLE `xsamp` (
  `ISBN` char(13) NOT NULL `FIELD_FORMAT`='@',
  `LANG` char(2) NOT NULL `FIELD_FORMAT`='@',
  `SUBJECT` char(12) NOT NULL `FIELD_FORMAT`='@',
  `AUTHOR` char(24) NOT NULL,
  `TRANSLATOR` char(12) DEFAULT NULL,
  `TITLE` char(30) NOT NULL,
  `PUBLISHER` char(21) NOT NULL,
  `DATEPUB` char(4) NOT NULL
) ENGINE=CONNECT DEFAULT CHARSET=latin1 `TABLE_TYPE`='XML'
`FILE_NAME`='E:/Data/Xml/Xsample.xml' `TABNAME`='BIBLIO' `OPTION_LIST`='rownode=BOOK';
```

It is equivalent except for the column sizes that have been calculated from the file as the maximum length of the corresponding column when it was a normal value. Also, all columns are specified as type `CHAR` because XML does not provide information about the node content data type. Nullable is set to true if the column is missing in some rows.

If a more complex definition is desired, you can ask `CONNECT` to analyse the `XPATH` up to a given level using the `level` option in the option list. The `level` value is the number of nodes that are taken in the `XPATH`. For instance:

```
create table xsampall
engine=CONNECT table_type=XML file_name='Xsample.xml'
tablename='BIBLIO' option_list='rownode=BOOK,Level=1';
```

This will define the table as:

From Connect 1.7.0002

```
CREATE TABLE `xsampall` (
  `ISBN` char(13) NOT NULL `XPATH`='@',
  `LANG` char(2) NOT NULL `XPATH`='@',
  `SUBJECT` char(12) NOT NULL `XPATH`='@',
  `AUTHOR_FIRSTNAME` char(15) NOT NULL `XPATH`='AUTHOR/FIRSTNAME',
  `AUTHOR_LASTNAME` char(8) NOT NULL `XPATH`='AUTHOR/LASTNAME',
  `TRANSLATOR_PREFIX` char(24) DEFAULT NULL `XPATH`='TRANSLATOR/@PREFIX',
  `TRANSLATOR_FIRSTNAME` char(7) DEFAULT NULL `XPATH`='TRANSLATOR/FIRSTNAME',
  `TRANSLATOR_LASTNAME` char(6) DEFAULT NULL `XPATH`='TRANSLATOR/LASTNAME',
  `TITLE` char(30) NOT NULL,
  `PUBLISHER_NAME` char(15) NOT NULL `XPATH`='PUBLISHER/NAME',
  `PUBLISHER_PLACE` char(5) NOT NULL `XPATH`='PUBLISHER/PLACE',
  `DATEPUB` char(4) NOT NULL
) ENGINE=CONNECT DEFAULT CHARSET=latin1 `TABLE_TYPE`='XML' `FILE_NAME`='Xsample.xml'
`TABNAME`='BIBLIO' `OPTION_LIST`='rownode=BOOK,Depth=1';
<</sql>>
```

Before Connect 1.7.0002

```
<<sql>>
CREATE TABLE `xsampall` (
  `ISBN` char(13) NOT NULL `FIELD_FORMAT`='@',
  `LANG` char(2) NOT NULL `FIELD_FORMAT`='@',
  `SUBJECT` char(12) NOT NULL `FIELD_FORMAT`='@',
  `AUTHOR_FIRSTNAME` char(15) NOT NULL `FIELD_FORMAT`='AUTHOR/FIRSTNAME',
  `AUTHOR_LASTNAME` char(8) NOT NULL `FIELD_FORMAT`='AUTHOR/LASTNAME',
  `TRANSLATOR_PREFIX` char(24) DEFAULT NULL `FIELD_FORMAT`='TRANSLATOR/@PREFIX',
  `TRANSLATOR_FIRSTNAME` char(7) DEFAULT NULL `FIELD_FORMAT`='TRANSLATOR/FIRSTNAME',
  `TRANSLATOR_LASTNAME` char(6) DEFAULT NULL `FIELD_FORMAT`='TRANSLATOR/LASTNAME',
  `TITLE` char(30) NOT NULL,
  `PUBLISHER_NAME` char(15) NOT NULL `FIELD_FORMAT`='PUBLISHER/NAME',
```

```

`PUBLISHER_PLACE` char(5) NOT NULL `FIELD_FORMAT`='PUBLISHER/PLACE',
`DATEPUB` char(4) NOT NULL
) ENGINE=CONNECT DEFAULT CHARSET=latin1 `TABLE_TYPE`='XML' `FILE_NAME`='Xsample.xml'
`TABNAME`='BIBLIO' `OPTION_LIST`='rownode=BOOK,Level=1';
<</sql>>

```

This **method** can be used **as** a quick way to make a **template** table definition that can later be edited to make the desired definition. In particular, **column names are constructed from all** the nodes of their path **in order to have distinct column names**. This can be manually edited to have the desired **names**, provided their XPATH **is not** modified.

To have a preview of how columns will be **defined**, you can use a **catalog table like this**:

```

<<sql>>
create table xsacol
engine=CONNECT table_type=XML file_name='Xsample.xml'
tabname='BIBLIO' option_list='rownode=BOOK,Level=1' catfunc=col;
<</sql>>

```

And when asking:

```

<<sql>>
select column_name Name, type_name Type, column_size Size, nullable, xpath from xsacol;
<</sql>>

```

You **get** the description of what the **table** columns will be:

```

<<style class="darkheader-nospace-borders">>
|= Name |= Type |= Size |= nullable |= xpath |
| ISBN | CHAR | 13 | 0 | @ |
| LANG | CHAR | 2 | 0 | @ |
| SUBJECT | CHAR | 12 | 0 | @ |
| AUTHOR_FIRSTNAME | CHAR | 15 | 0 | AUTHOR/FIRSTNAME |
| AUTHOR_LASTNAME | CHAR | 8 | 0 | AUTHOR/LASTNAME |
| TRANSLATOR_PREFIX | CHAR | 24 | 1 | TRANSLATOR/@PREFIX |
| TRANSLATOR_FIRSTNAME | CHAR | 7 | 1 | TRANSLATOR/FIRSTNAME |
| TRANSLATOR_LASTNAME | CHAR | 6 | 1 | TRANSLATOR/LASTNAME |
| TITLE | CHAR | 30 | 0 | |
| PUBLISHER_NAME | CHAR | 15 | 0 | PUBLISHER/NAME |
| PUBLISHER_PLACE | CHAR | 5 | 0 | PUBLISHER/PLACE |
| DATEPUB | CHAR | 4 | 0 | |
<</style>>

```

== **Write operations on XML tables**

You can freely use the **Update, Delete and Insert** commands with XML tables. However, you must understand that the format of the updated or inserted data follows the specifications of the **table** you created, **not** the ones of the original **source** file. For instance, let us suppose we **insert** a **new** book using the //xsamp// **table** (not the //xsampall// **table**) with the command:

```

<<code lang=mysql inline=false>>
insert into xsamp
(isbn, lang, subject, author, title, publisher,datepub)
values ('9782212090529','fr','général','Alain Michard',
'XML, Langage et Applications','Eyrolles Paris',1998);

```

Then if we ask:

```

select subject, author, title, translator, publisher from xsamp;

```

Everything seems correct when we get the result:

SUBJECT	AUTHOR	TITLE	TRANSLATOR	PUBLISHER
applications	Jean-Christophe Bernadac	Construire une application XML		Eyrolles Paris
applications	William J. Pardi	XML en Action	James Guerin	Microsoft Press Paris
général	Alain Michard	XML, Langage et Applications		Eyrolles Paris

However if we enter the apparently equivalent query on the *xsampall* table, based on the same file:

```
select subject,
concat(authorfn, ' ', authorln) author , title,
concat(tranfn, ' ', tranln) translator,
concat(publisher, ' ', location) publisher from xsampall;
```

this returns an apparently wrong answer:

SUBJECT	AUTHOR	TITLE	TRANSLATOR	PUBLISHER
applications	Jean-Christophe Bernadac	Construire une application XML		Eyrolles Paris
applications	William J. Pardi	XML en Action	James Guerin	Microsoft Press Paris
général		XML, Langage et Applications		

What happened here? Simply, because we used the *xsamp* table to do the Insert, what has been inserted within the XML file had the structure described for *xsamp*:

```
<BOOK ISBN="9782212090529" LANG="fr" SUBJECT="général">
  <AUTHOR>Alain Michard</AUTHOR>
  <TITLE>XML, Langage et Applications</TITLE>
  <TRANSLATOR></TRANSLATOR>
  <PUBLISHER>Eyrolles Paris</PUBLISHER>
  <DATEPUB>1998</DATEPUB>
</BOOK>
```

CONNECT cannot "invent" sub-tags that are not part of the *xsamp* table. Because these sub-tags do not exist, the *xsampall* table cannot retrieve the information that should be attached to them. If we want to be able to query the XML file by all the defined tables, the correct way to insert a new book to the file is to use the *xsampall* table, the only one that addresses all the components of the original document:

```
delete from xsamp where isbn = '9782212090529';

insert into xsampall (isbn, language, subject, authorfn, authorln,
title, publisher, location, year)
values ('9782212090529', 'fr', 'général', 'Alain', 'Michard',
'XML, Langage et Applications', 'Eyrolles', 'Paris', 1998);
```

Now the added book, in the XML file, will have the required structure:

```
<BOOK ISBN="9782212090529" LANG="fr" SUBJECT="général">
  <AUTHOR>
    <FIRSTNAME>Alain</FIRSTNAME>
    <LASTNAME>Michard</LASTNAME>
  </AUTHOR>
  <TITLE>XML, Langage et Applications</TITLE>
  <PUBLISHER>
    <NAME>Eyrolles</NAME>
    <PLACE>Paris</PLACE>
  </PUBLISHER>
  <DATEPUB>1998</DATEPUB>
</BOOK>
```

Note: We used a column list in the Insert statements when creating the table to avoid generating a `<TRANSLATOR>` node with sub-nodes, all containing null values (this works on Windows only).

Multiple nodes in the XML document

Let us come back to the above example XML file. We have seen that the author node can be "multiple" meaning that there can be more than one author of a book. What can we do to get the complete information fitting the relational model? CONNECT provides you with two possibilities, but is restricted to only one such multiple node per table.

The first and most challenging one is to return as many rows than there are authors, the other columns being repeated as if we had make a join between the author column and the rest of the table. To achieve this, simply specify the "multiple" node name and the "expand" option when creating the table. For instance, we can create the *xsamp2* table like this:

```

create table xsamp2 (
  ISBN char(15) field_format='@',
  LANG char(2) field_format='@',
  SUBJECT char(32) field_format='@',
  AUTHOR char(40),
  TITLE char(32),
  TRANSLATOR char(32),
  PUBLISHER char(32),
  DATEPUB int(4))
engine=CONNECT table_type=XML file_name='Xsample.xml'
tabname='BIBLIO'
option_list='rownode=BOOK,Expand=1,Mulnode=AUTHOR,Limit=2';

```

In this statement, the Limit option specifies the maximum number of values that will be expanded. If not specified, it defaults to 10. Any values above the limit will be ignored and a warning message issued^[3]. Now you can enter a query such as:

```
select isbn, subject, author, title from xsamp2;
```

This will retrieve and display the following result:

ISBN	SUBJECT	AUTHOR	TITLE
9782212090819	applications	Jean-Christophe Bernadac	Construire une application XML
9782212090819	applications	François Knab	Construire une application XML
9782840825685	applications	William J. Pardi	XML en Action
9782212090529	général	Alain Michard	XML, Langage et Applications

In this case, this is as if the table had four rows. However if we enter the query:

```
select isbn, subject, title, publisher from xsamp2;
```

this time the result will be:

ISBN	SUBJECT	TITLE	PUBLISHER
9782212090819	applications	Construire une application XML	Eyrolles Paris
9782840825685	applications	XML en Action	Microsoft Press Paris
9782212090529	général	XML, Langage et Applications	Eyrolles Paris

Because the author column does not appear in the query, the corresponding row was not expanded. This is somewhat strange because this would have been different if we had been working on a table of a different type. However, it is closer to the relational model for which there should not be two identical rows (tuples) in a table. Nevertheless, you should be aware of this somewhat erratic behavior. For instance:

```

select count(*) from xsamp2;           /* Replies 3 */
select count(author) from xsamp2;     /* Replies 4 */
select count(isbn) from xsamp2;       /* Replies 3 */
select isbn, subject, title, publisher from xsamp2 where author <> '';

```

This last query replies:

ISBN	SUBJECT	TITLE	PUBLISHER
9782212090819	applications	Construire une application XML	Eyrolles Paris
9782212090819	applications	Construire une application XML	Eyrolles Paris
9782840825685	applications	XML en Action	Microsoft Press Paris
9782212090529	général	XML, Langage et Applications	Eyrolles Paris

Even though the author column does not appear in the result, the corresponding row was expanded because the multiple column was used in the where clause.

Intermediate multiple node

The "multiple" node can be an intermediate node. If we want to do the same expanding with the `xsampall` table, there will be nothing more to do. The `xsampall2` table can be created with:

From Connect 1.7.0002

```
create table xsampall2 (
  isbn char(15) xpath='@ISBN',
  language char(2) xpath='@LANG',
  subject char(32) xpath='@SUBJECT',
  authorfn char(20) xpath='AUTHOR/FIRSTNAME',
  authorln char(20) xpath='AUTHOR/LASTNAME',
  title char(32) xpath='TITLE',
  translated char(32) xpath='TRANSLATOR/@PREFIX',
  tranfn char(20) xpath='TRANSLATOR/FIRSTNAME',
  tranln char(20) xpath='TRANSLATOR/LASTNAME',
  publisher char(20) xpath='PUBLISHER/NAME',
  location char(20) xpath='PUBLISHER/PLACE',
  year int(4) xpath='DATEPUB')
engine=CONNECT table_type=XML file_name='Xsample.xml'
tabname='BIBLIO' option_list='rownode=BOOK,Expand=1,Mulnode=AUTHOR,Limit=2';
```

Before Connect 1.7.0002

```
create table xsampall2 (
  isbn char(15) field_format='@ISBN',
  language char(2) field_format='@LANG',
  subject char(32) field_format='@SUBJECT',
  authorfn char(20) field_format='AUTHOR/FIRSTNAME',
  authorln char(20) field_format='AUTHOR/LASTNAME',
  title char(32) field_format='TITLE',
  translated char(32) field_format='TRANSLATOR/@PREFIX',
  tranfn char(20) field_format='TRANSLATOR/FIRSTNAME',
  tranln char(20) field_format='TRANSLATOR/LASTNAME',
  publisher char(20) field_format='PUBLISHER/NAME',
  location char(20) field_format='PUBLISHER/PLACE',
  year int(4) field_format='DATEPUB')
engine=CONNECT table_type=XML file_name='Xsample.xml'
tabname='BIBLIO'
option_list='rownode=BOOK,Expand=1,Mulnode=AUTHOR,Limit=2';
```

The only difference is that the "multiple" node is an intermediate node in the path. The resulting table can be seen with a query such as:

```
select subject, language lang, title, authorfn first, authorln
last, year from xsampall2;
```

This query displays:

SUBJECT	LANG	TITLE	FIRST	LAST	YEAR
applications	fr	Construire une application XML	Jean-Christophe	Bernadac	1999
applications	fr	Construire une application XML	François	Knab	1999
applications	fr	XML en Action	William J.	Pardi	1999
général	fr	XML, Langage et Applications	Alain	Michard	1998

These composite tables, half array half tree, reserve some surprises for us when updating, deleting from or inserting into them. Insert just cannot generate this structure; if two rows are inserted with just a different author, two book nodes will be generated in the XML file. Delete always deletes one book node and all its children nodes even if specified against only one author. Update is more complicated:

```
update xsampall2 set authorfn = 'Simon' where authorln = 'Knab';
update xsampall2 set year = 2002 where authorln = 'Bernadac';
update xsampall2 set authorln = 'Mercier' where year = 2002;
```

After these three updates, the first two responding "Affected rows: 1" and the last one responding "Affected rows: 2", the last query answers:

subject	lang	title	first	last	year
---------	------	-------	-------	------	------

applications	fr	Construire une application XML	Jean-Christophe	Mercier	2002
applications	fr	Construire une application XML	François	Knab	2002
applications	fr	XML en Action	William J.	Pardi	1999
général	fr	XML, Langage et Applications	Alain	Michard	1998

What must be understood here is that the Update modifies node values in the XML file, not cell values in the relational table. The first update worked normally. The second update changed the year value of the book and this shows for the two expanded rows because there is only one DATEPUB node for that book. Because the third update applies to a row having a certain date value, both author names were updated.

Making a List of Multiple Values

Another way to see multiple values is to ask CONNECT to make a comma separated list of the multiple node values. This time, it can only be done if the "multiple" node is not intermediate. For example, we can modify the *xsamp2* table definition by:

```
alter table xsamp2 option_list='rownode=BOOK,Mulnode=AUTHOR,Limit=3';
```

This time 'Expand' is not specified, and Limit gives the maximum number of items in the list. Now if we enter the query:

```
select isbn, subject, author "AUTHOR(S)", title from xsamp2;
```

We will get the following result:

ISBN	SUBJECT	AUTHOR(S)	TITLE
9782212090819	applications	Jean-Christophe Bernadac, François Knab	Construire une application XML
9782840825685	applications	William J. Pardi	XML en Action
9782212090529	général	Alain Michard	XML, Langage et Applications

Note that updating the "multiple" column is not possible because CONNECT does not know which of the nodes to update.

This could not have been done with the *xsampall2* table because the author node is intermediate in the path, and making two lists, one of first names and another one of last names would not make sense anyway.

What if a table contains several multiple nodes

This can be handled by creating several tables on the same file, each containing only one multiple node and constructing the desired result using joins.

Support of HTML Tables

Most tables included in HTML documents cannot be processed by CONNECT because the HTML language is often not compatible with the syntax of XML. In particular, XML requires all open tags to be matched by a closing tag while it is sometimes optional in HTML. This is often the case concerning column tags.

However, you can meet tables that respect the XML syntax but have some of the features of HTML tables. For instance:

```
<?xml version="1.0"?>
<Beers>
  <table>
    <th><td>Name</td><td>Origin</td><td>Description</td></th>
    <tr>
      <td><brandName>Huntsman</brandName></td>
      <td><origin>Bath, UK</origin></td>
      <td><details>Wonderful hop, light alcohol</details></td>
    </tr>
    <tr>
      <td><brandName>Tuborg</brandName></td>
      <td><origin>Danmark</origin></td>
      <td><details>In small bottles</details></td>
    </tr>
  </table>
</Beers>
```

Here the different column tags are included in `<td></td>` tags as for HTML tables. You cannot just add this tag in the Xpath of the columns, because the search is done on the first occurrence of each tag, and this would cause this search to fail for all columns except the first one. This case is handled by specifying the *Colnode* table option that gives the name of these column tags, for example:

From Connect 1.7.0002

```
create table beers (
  `Name` char(16) xpath='brandName',
  `Origin` char(16) xpath='origin',
  `Description` char(32) xpath='details')
engine=CONNECT table_type=XML file_name='beers.xml'
tabname='table' option_list='rownode=tr,colnode=td';
```

Before Connect 1.7.0002

```
create table beers (
  `Name` char(16) field_format='brandName',
  `Origin` char(16) field_format='origin',
  `Description` char(32) field_format='details')
engine=CONNECT table_type=XML file_name='beers.xml'
tabname='table' option_list='rownode=tr,colnode=td';
```

The table will be displayed as:

Name	Origin	Description
Huntsman	Bath, UK	Wonderful hop, light alcohol
Tuborg	Danmark	In small bottles

However, you can deal with tables even closer to the HTML model. For example the *coffee.htm* file:

```
<TABLE summary="This table charts the number of cups of coffee
consumed by each senator, the type of coffee (decaf
or regular), and whether taken with sugar.">
  <CAPTION>Cups of coffee consumed by each senator</CAPTION>
  <TR>
    <TH>Name</TH>
    <TH>Cups</TH>
    <TH>Type of Coffee</TH>
    <TH>Sugar?</TH>
  </TR>
  <TR>
    <TD>T. Sexton</TD>
    <TD>10</TD>
    <TD>Espresso</TD>
    <TD>No</TD>
  </TR>
  <TR>
    <TD>J. Dinnen</TD>
    <TD>5</TD>
    <TD>Decaf</TD>
    <TD>Yes</TD>
  </TR>
</TABLE>
```

Here column values are directly represented by the TD tag text. You cannot declare them as tags nor as attributes. In addition, they are not located using their name but by their position within the row. Here is how to declare such a table to CONNECT:

```
create table coffee (
  `Name` char(16),
  `Cups` int(8),
  `Type` char(16),
  `Sugar` char(4))
engine=connect table_type=XML file_name='coffee.htm'
tabname='TABLE' header=1 option_list='Coltype=HTML';
```

You specify the fact that columns are located by position by setting the *Coltype* option to 'HTML'. Each column position (0 based) will be the value of the *flag* column parameter that is set by default in sequence. Now we are able to display the

table:

Name	Cups	Type	Sugar
T. Sexton	10	Espresso	No
J. Dinnen	5	Decaf	Yes

Note 1: We specified 'header=n' in the create statement to indicate that the first n rows of the table are not data rows and should be skipped.

Note 2: In this last example, we did not specify the node names using the Rownode and Colnode options because when Coltype is set to 'HTML' they default to 'Rownode=TR' and 'Colnode=TD'.

Note 3: The Coltype option is a word only the first character of which is significant. Recognized values are:

T(ag) or N(ode) Column names match a tag name (the default).

A(tribute) or @ Column names match an attribute name.

H(tml) or C(ol) or P(os) Column are retrieved by their position.

New file setting

Some create options are used only when creating a table on a new file, i. e. when inserting into a file that does not exist yet. When specified, the 'Header' option will create a header row with the name of the table columns. This is chiefly useful for HTML tables to be displayed on a web browser.

Some new list-options are used in this context:

Encoding The encoding of the new document, defaulting to UTF-8.

Attribute A list of 'attname=attvalue' separated by ';' to add to the table node.

HeadAttr An attribute list to be added to the header row node.

Let us see for instance, the following create statement:

```
create table handlers (
  handler char(64),
  version char(20),
  author char(64),
  description char(255),
  maturity char(12))
engine=CONNECT table_type=XML file_name='handlers.htm'
tablename='TABLE' header=yes
option_list='coltype=HTML,encoding=ISO-8859-1,
attribute=border=1;cellpadding=5,headattr=bgcolor=yellow';
```

Supposing the table file does not exist yet, the first insert into that table, for instance by the following statement:

```
insert into handlers select plugin_name, plugin_version,
  plugin_author, plugin_description, plugin_maturity from
  information_schema.plugins where plugin_type = 'DAEMON';
```

will generate the following file:

```

<?xml version="1.0" encoding="ISO-8859-1"?>
<!-- Created by CONNECT Version 3.05.0005 August 17, 2012 -->
<TABLE border="1" cellpadding="5">
  <TR bgcolor="yellow">
    <TH>handler</TH>
    <TH>version</TH>
    <TH>author</TH>
    <TH>description</TH>
    <TH>maturity</TH>
  </TR>
  <TR>
    <TD>Maria</TD>
    <TD>1.5</TD>
    <TD>Monty Program Ab</TD>
    <TD>Compatibility aliases for the Aria engine</TD>
    <TD>Gamma</TD>
  </TR>
</TABLE>

```

This file can be used to display the table on a web browser (encoding should be ISO-8859-x)

handler	version	author	description	maturity
Maria	1.5	Monty Program Ab	Compatibility aliases for the Aria engine	Gamma

Note: The XML document encoding is generally specified in the XML header node and can be different from the DATA_CHARSET, which is always UTF-8 for XML tables. Therefore the table DATA_CHARSET character set should be unspecified, or specified as UTF8. The Encoding specification is useful only for new XML files and ignored for existing files having their encoding already specified in the header node.

Notes

- ↑ CONNECT does not claim to be able to deal with any XML document. Besides, those that can usefully be processed for data analysis are likely to have a structure that can easily be transformed into a table.
- ↑ With libxml2, sub tags text can be separated by 0 or several blanks depending on the structure and indentation of the data file.
- ↑ This may cause some rows to be lost because an eventual where clause on the “multiple” column is applied only on the limited number of retrieved rows.

5.3.7.6.14 CONNECT INI Table Type

Contents

- [1. Overview](#)
- [2. Column layout](#)
- [3. Row layout](#)

Overview

The INI type is one of the configuration or initialization files often found on Windows machines. For instance, let us suppose you have the following contact file *contact.ini*:

```
[BER]
name=Bertrand
forename=Olivier
address=21 rue Ferdinand Buisson
city=Issy-les-Mlx
zipcode=92130
tel=09.54.36.29.60
cell=06.70.06.04.16
```

```
[WEL]
name=Schmitt
forename=Bernard
hired=19/02/1985
address=64 tiergarten strasse
city=Berlin
zipcode=95013
tel=03.43.377.360
```

```
[UK1]
name=Smith
forename=Henry
hired=08/11/2003
address=143 Blum Rd.
city=London
zipcode=NW1 2BP
```

CONNECT lets you view it as a table in two different ways.

Column layout

The first way is to regard it as a table having one line per section, the columns being the keys you want to display. In this case, the CREATE statement could be:

```
create table contact (
  contact char(16) flag=1,
  name char(20),
  forename char(32),
  hired date date_format='DD/MM/YYYY',
  address char(64),
  city char(20),
  zipcode char(8),
  tel char(16))
engine=CONNECT table_type=INI file_name='contact.ini';
```

The column that will contain the section name can have any name but must specify `flag=1`. All other columns must have the names of the keys we want to display (case insensitive). The type can be character or numeric depending on the key value type, and the length is the maximum expected length for the key value. Once done, the statement:

```
select contact, name, hired, city, tel from contact;
```

This statement will display the file in tabular format.

contact	name	hired	city	tel
BER	Bertrand	1970-01-01	Issy-les-Mlx	09.54.36.29.60
WEL	Schmitt	1985-02-19	Berlin	03.43.377.360
UK1	Smith	2003-11-08	London	NULL

Only the keys defined in the create statements are visible; keys that do not exist in a section are displayed as null or pseudo null (blank for character, 1/1/70 for dates, and 0 for numeric) for columns declared NOT NULL.

All relational operations can be applied to this table. The table (and the file) can be updated, inserted and conditionally deleted. The only constraint is that when inserting values, the section name must be the first in the list of values.

Note 1: When inserting, if a section already exists, no new section will be created but the new values will be added or replace those of the existing section. Thus, the following two commands are equivalent:

```
update contact set forename = 'Harry' where contact = 'UK1';
insert into contact (contact,forename) values ('UK1','Harry');
```

Note 2: Because sections represent one line, a DELETE statement on a section key will delete the whole section.

Row layout

To be a good candidate for tabular representation, an INI file should have often the same keys in all sections. In practice, many files commonly found on computers, such as the *win.ini* file of the Windows directory or the *my.ini* file cannot be viewed that way because each section has different keys. In this case, a second way is to regard the file as a table having one row per section key and whose columns can be the section name, the key name, and the key value.

For instance, let us define the table:

```
create table xcont (
  section char(16) flag=1,
  keyname char(16) flag=2,
  value char(32))
engine=CONNECT table_type=INI file_name='contact.ini'
option_list='Layout=Row';
```

In this statement, the "Layout" option sets the display format, Column by default or anything else not beginning by 'C' for row layout display. The names of the three columns can be freely chosen. The Flag option gives the meaning of the column. Specify `flag=1` for the section name and `flag=2` for the key name. Otherwise, the column will contain the key value.

Once done, the command:

```
select * from xcont;
```

Will display the following result:

section	keyname	value
BER	name	Bertrand
BER	forename	Olivier
BER	address	21 rue Ferdinand Buisson
BER	city	Issy-les-Mlx
BER	zipcode	92130
BER	tel	09.54.36.29.60
BER	cell	06.70.06.04.16
WEL	name	Schmitt
WEL	forename	Bernard
WEL	hired	19/02/1985
WEL	address	64 tiergarten strasse
WEL	city	Berlin
WEL	zipcode	95013
WEL	tel	03.43.377.360
UK1	name	Smith
UK1	forename	Henry
UK1	hired	08/11/2003
UK1	address	143 Blum Rd.
UK1	city	London
UK1	zipcode	NW1 2BP

Note: When processing an INI table, all section names are retrieved in a buffer of 8K bytes (2048 bytes before 10.0.17). For a big file having many sections, this size can be increased using for example:

```
option_list='seclen=16K';
```

5.3.7.6.15 CONNECT - External Table Types

Because so many ODBC and JDBC drivers exist and only the main ones have been heavily tested, these table types cannot be ranked as stable. Use them with care in production applications.

These types can be used to access tables belonging to the current or another database server. Six types are currently provided:

ODBC: To be used to access tables from a database management system providing an ODBC connector. ODBC is a standard of Microsoft and is currently available on Windows. On Linux, it can also be used provided a specific application emulating ODBC is installed. Currently only unixODBC is supported.

JDBC: To be used to access tables from a database management system providing a JDBC connector. JDBC is an Oracle standard implemented in Java and principally meant to be used by Java applications. Using it directly from C or C++ application seems to be almost impossible due to an Oracle bug still not fixed. However, this can be achieved using a Java wrapper class used as an interface between C++ and JDBC. On another hand, JDBC is available on all platforms and operating systems.

Mongo: To access MongoDB collections as tables via their MongoDB C Driver. Because this requires both MongoDB and the C Driver to be installed and operational, this table type is not currently available in binary distributions but only when compiling MariaDB from source.

MySQL : This type is the preferred way to access tables belonging to another MySQL or MariaDB server. It uses the MySQL API to access the external table. Even though this can be obtained using the FEDERATED(X) plugin, this specific type is used internally by CONNECT because it also makes it possible to access tables belonging to the current server.

PROXY: Internally used by some table types to access other tables from one table.

External Table Specification

The four main external table types – odbc, jdbc, mongo and mysql – are specified giving the following information:

1. The data source. This is specified in the connection option.
2. The remote table or view to access. This can be specified within the connection string or using specific CONNECT options.
3. The column definitions. This can be also left to CONNECT to find them using the discovery MariaDB feature.
4. The optional Quoted option. Can be set to 1 to quote the identifiers in the query sent to the remote server. This is required if columns or table names can contain blanks.

The way this works is by establishing a connection to the external data source and by sending it an SQL statement (or its equivalent using API functions for MONGO) enabling it to execute the original query. To enhance performance, it is necessary to have the remote data source do the maximum processing. This is needed in particular to reduce the amount of data returned by the data source.

This is why, for SELECT queries, CONNECT uses the [cond_push](#) MariaDB feature to retrieve the maximum of the where clause of the original query that can be added to the query sent to the data source. This is automatic and does not require anything to be done by the user.

However, more can be done. In addition to accessing a remote table, CONNECT offers the possibility to specify what the remote server must do. This is done by specifying it as a view in the srcdef option. For example:

```
CREATE TABLE custnum ENGINE=CONNECT TABLE_TYPE=XXX
CONNECTION='connecton string'
SRCDEF='select pays as country, count(*) as customers from custnum group by pays';
```

Doing so, the group by clause will be done by the remote server considerably reducing the amount of data sent back on the connection.

This may even be increased by adding to the srcdef part of the “compatible” part of the query where clauses like this are done for table-based tables. Note that for MariaDB, this table has two columns, country and customers. Supposing the original query is:

```
SELECT * FROM custnum WHERE (country = 'UK' OR country = 'USA') AND customers > 5;
```

How can we make the where clause be added to the sent srcdef? There are many problems:

1. Where to include the additional information.
2. What about the use of alias.

3. How to know what will be a where clause or a having clause.

The first problem is solved by preparing the srcdef view to receive clauses. The above example srcdef becomes:

```
SRCDEF='select pays as country, count(*) as customers from custnum where %s group by pays having %s';
```

The %s in the srcdef are place holders for eventual compatible parts of the original query where clause. If the select query does not specify a where clause, or a gives an unacceptable where clause, place holders will be filled by dummy clauses (1=1).

The other problems must be solved by adding to the create table a list of columns that must be translated because they are aliases or/and aliases on aggregate functions that must become a having clause. For example, in this case:

```
CREATE TABLE custnum ENGINE=CONNECT TABLE_TYPE=XXX  
CONNECTION='connecton string'  
SRCDEF='select pays as country, count(*) as customers from custnum where %s group by pays having %s'  
OPTION_LIST='Alias=customers=*count(*);country=pays';
```

This is specified by the alias option, to be used in the option list. It is made of a semi-colon separated list of items containing:

1. The local column name (alias in the remote server)
2. An equal sign.
3. An eventual '*' indicating this is column correspond to an aggregate function.
4. The remote column name.

With this information, CONNECT will be able to make the query sent to the remote data source:

```
select pays as country, count(*) as customers from custnum where (pays = 'UK' OR pays = 'USA')  
group by country having count(*) > 5
```

Note: Some data sources, including MySQL and MariaDB, accept aliases in the having clause. In that case, the alias option could have been specified as:

```
OPTION_LIST='Alias=customers=*;country=pays';
```

Another option exists, phpos, enabling to specify what place holders are present and in what order. To be specified as "W", "WH", "H", or "HW". It is rarely used because by default CONNECT can set it from the srcdef content. The only cases it is needed is when the srcdef contains only a having place holder or when the having place holder occurs before the where place holder, which can occur on queries containing joins. CONNECT cannot handle more than one place holder of each type.

SRCDEF is not available for MONGO tables, but other ways of achieving this exist and are described in the MONGO table type chapter.

5.3.7.6.16 CONNECT ODBC Table Type: Accessing Tables From Another DBMS

Contents

1. Random Access of ODBC Tables
2. Retrieving data from a spreadsheet
3. Multiple ODBC tables
4. Performance consideration
5. Using ODBC Tables inside correlated sub-queries
6. Accessing specified views
7. Data Modifying Operations
 1. INSERT Command
 2. UPDATE and DELETE Commands
8. Sending commands to a Data Source
 1. Sending several commands together
9. Connecting to a Data Source
 1. Defining the Connection String
 2. ODBC Defined Connection Attributes
 3. Using a Predefined DSN
10. ODBC Tables on Linux/Unix
 1. SELinux
11. ODBC Catalog Information
 1. Table name case
12. Non-ASCII Character Sets with Oracle
 1. Using systemd
 2. Using Windows
13. OPTION_LIST Values Supported by the ODBC Tables

ODBC (Open Database Connectivity) is a standard API for accessing database management systems (DBMS). CONNECT uses this API to access data contained in other DBMS without having to implement a specific application for each one. An exception is the access to MySQL that should be done using the [MYSQL table type](#).

Note: On Linux, unixODBC must be installed.

These tables are given the type ODBC. For example, if a "Customers" table is contained in an Access™ database you can define it with a command such as:

```
create table Customer (  
  CustomerID varchar(5),  
  CompanyName varchar(40),  
  ContactName varchar(30),  
  ContactTitle varchar(30),  
  Address varchar(60),  
  City varchar(15),  
  Region varchar(15),  
  PostalCode varchar(10),  
  Country varchar(15),  
  Phone varchar(24),  
  Fax varchar(24))  
engine=connect table_type=ODBC block_size=10  
tabname='Customers'  
Connection='DSN=MS Access Database;DBQ=C:/Program  
Files/Microsoft Office/Office/1033/FPNWIND.MDB;';
```

Tabname option defaults to the table name. It is required if the source table name is different from the name of the CONNECT table. Note also that for some data sources this name is case sensitive.

Often, because CONNECT can retrieve the table description using ODBC catalog functions, the column definitions can be unspecified. For instance this table can be simply created as:

```
create table Customer engine=connect table_type=ODBC  
block_size=10 tabname='Customers'  
Connection='DSN=MS Access Database;DBQ=C:/Program Files/Microsoft Office/Office/1033/FPNWIND.MD
```

The `BLOCK_SIZE` specification will be used later to set the `RowsetSize` when retrieving rows from the ODBC table. A reasonably large `RowsetSize` can greatly accelerate the fetching process.

If you specify the column description, the column names of your table must exist in the data source table. However, you are not obliged to define all the data source columns and you can change the order of the columns. Some type conversion can also be done if appropriate. For instance, to access the FireBird sample table `EMPLOYEE`, you could define your table as:

```

create table empodbc (
  EMP_NO smallint(5) not null,
  FULL_NAME varchar(37) not null),
  PHONE_EXT varchar(4) not null,
  HIRE_DATE date,
  DEPT_NO smallint(3) not null,
  JOB_COUNTRY varchar(15),
  SALARY double(12,2) not null)
engine=CONNECT table_type=ODBC tabname='EMPLOYEE'
connection='DSN=firebird';

```

This definition ignores the FIRST_NAME, LAST_NAME, JOB_CODE, and JOB_GRADE columns. It places the FULL_NAME last column of the original table in second position. The type of the HIRE_DATE column was changed from *timestamp* to *date* and the type of the DEPT_NO column was changed from *char* to *integer*.

Currently, some restrictions apply to ODBC tables:

1. Cursor type is forward only (sequential reading).
2. No indexing of ODBC tables (do not specify any columns as key). However, because CONNECT can often add a where clause to the query sent to the data source, indexing will be used by the data source if it supports it. (Remote indexing is available with version 1.04, released with [MariaDB 10.1.6](#))
3. CONNECT ODBC supports [SELECT](#) and [INSERT](#). [UPDATE](#) and [DELETE](#) are also supported in a somewhat restricted way (see below). For other operations, use an ODBC table with the EXECSRC option (see below) to directly send proper commands to the data source.

Random Access of ODBC Tables

In CONNECT version 1.03 (until [MariaDB 10.1.5](#)) ODBC tables are not indexable. Version 1.04 (from [MariaDB 10.1.6](#)) adds remote indexing facility to the ODBC table type.

However, some queries require random access to an ODBC table; for instance when it is joined to another table or used in an order by queries applied to a long column or large tables.

There are several ways to enable random (position) access to a CONNECT ODBC table. They are dependant on the following table options:

Option	Type	Used For
Block_Size	Integer	Specifying the rowset size.
Memory*	Integer	Storing the result set in memory.
Scrollable*	Boolean	Using a scrollable cursor.

* - To be specified in the option_list.

When dealing with small tables, the simpler way to enable random access is to specify a rowset size equal or larger than the table size (or the result set size if a push down where clause is used). This means that the whole result is in memory on the first fetch and CONNECT will use it for further positional accesses.

Another way to have the result set in memory is to use the memory option. This option can be set to the following values:

0. No memory used (the default). Best when the table is read sequentially as in SELECT statements with only eventual WHERE clauses.
1. Memory size required is calculated during the first sequential table read. The allocated memory is filled during the second sequential read. Then the table rows are retrieved from the memory. This should be used when the table will be accessed several times randomly, such as in sub-selects or being the target table of a join.
2. A first query is executed to get the result set size and the needed memory is allocated. It is filled on the first sequential reading. Then random access of the table is possible. This can be used in the case of ORDER BY clauses, when MariaDB uses position reading.

Note that the best way to handle ORDER BY is to set the max_length_for_sort_data variable to a larger value (its default value is 1024 that is pretty small). Indeed, it requires less memory to be used, particularly when a WHERE clause limits the retrieved data set. This is because in the case of an order by query, MariaDB firstly retrieves the sequentially the result set and the position of each records. Often the sort can be done from the result set if it is not too big. But if too big, or if it implies some "long" columns, only the positions are sorted and MariaDB retrieves the final result from the table read in random order. If setting the max_length_for_sort_data variable is not feasible or does not work, to be able to retrieve table data from memory after the first sequential read, the memory option must be set to 2.

For tables too large to be stored in memory another possibility is to make your table to use a scrollable cursor. In this case each randomly accessed row can be retrieved from the data source specifying its cursor position, which is reasonably fast. However, scrollable cursors are not supported by all data sources.

With CONNECT version 1.04 (from [MariaDB 10.1.6](#)), another way to provide random access is to specify some columns to be indexed. This should be done only when the corresponding column of the source table is also indexed. This should be used for tables too large to be stored in memory and is similar to the remote indexing used by the [MYSQL table type](#) and by the [FEDERATED engine](#).

There remains the possibility to extract data from the external table and to construct another table of any file format from the data source. For instance to construct a fixed formatted DOS table containing the CUSTOMER table data, create the table as

```
create table Custfix engine=connect File_name='customer.txt'
table_type=fix block_size=20 as select * from customer;
```

Now you can use *custfix* for fast database operations on the copied *customer* table data.

Retrieving data from a spreadsheet

ODBC can also be used to create tables based on tabular data belonging to an Excel spreadsheet:

```
create table XLCONT
engine=CONNECT table_type=ODBC tabname='CONTACT'
Connection='DSN=Excel Files;DBQ=D:/Ber/Doc/Contact_BP.xls;';
```

This supposes that a tabular zone of the sheet including column headers is defined as a table named CONTACT or using a "named reference". Refer to the Excel documentation for how to specify tables inside sheets. Once done, you can ask:

```
select * from xlcont;
```

This will extract the data from Excel and display:

Nom	Fonction	Societe
Boisseau Frederic		9 Telecom
Martelliere Nicolas		Vidal SA (Groupe UBM)
Remy Agathe		Price Minister
Du Halgouet Tanguy		Danone
Vandamme Anna		GDF
Thomas Willy		Europ Assistance France
Thomas Dominique		Acooss (DG des URSSAF)
Thomas Berengere	Responsable SI Decisionnel	DEXIA Credit Local
Husy Frederic	Responsable Decisionnel	Neuf Cegetel
Lemonnier Nathalie	Directeur Marketing Client	Louis Vuitton
Louis Loic	Reporting International Decisionnel	Accor
Menseau Eric		Orange France

Here again, the columns description was left to CONNECT when creating the table.

Multiple ODBC tables

The concept of multiple tables can be extended to ODBC tables when they are physically represented by files, for instance to Excel or Access tables. The condition is that the connect string for the table must contain a field DBQ=*filename*, in which wildcard characters can be included as for multiple=1 tables in their filename. For instance, a table contained in several Excel files CA200401.xls, CA200402.xls, ...CA200412.xls can be created by a command such as:

```
create table ca04mul (Date char(19), Operation varchar(64),
Debit double(15,2), Credit double(15,2))
engine=CONNECT table_type=ODBC multiple=1
qchar= '' tabname='bank account'
connection='DSN=Excel Files;DBQ=D:/Ber/CA/CA2004*.xls;';
```

Providing that in each file the applying information is internally set for Excel as a table named "bank account". This

extension to ODBC does not support *multiple=2*. The *qchar* option was specified to make the identifiers quoted in the select statement sent to ODBC, in particular the when the table or column names contain blanks, to avoid SQL syntax errors.

Caution: Avoid accessing tables belonging to the currently running MariaDB server via the MySQL ODBC connector. This may not work and may cause the server to be restarted.

Performance consideration

To avoid extracting entire tables from an ODBC source, which can be a lengthy process, CONNECT extracts the "compatible" part of query WHERE clauses and adds it to the ODBC query. Compatible means that it must be understood by the data source. In particular, clauses involving scalar functions are not kept because the data source may have different functions than MariaDB or use a different syntax. Of course, clauses involving sub-select are also skipped. This will transfer eventual indexing to the data source.

Take care with clauses involving string items because you may not know whether they are treated by the data source as case sensitive or case insensitive. If in doubt, make your queries as if the data source was processing strings as case sensitive to avoid incomplete results.

Using ODBC Tables inside correlated sub-queries

Unlike not correlated subqueries that are executed only once, correlated subqueries are executed many times. It is what ODBC calls a "requery". Several methods can be used by CONNECT to deal with this depending on the setting of the MEMORY or SCROLLABLE Boolean options:

Option	Description
Default	Implementing "requery" by discarding the current result set and re submitting the query (as MFC does)
Memory=1 or 2	Storing the result set in memory as MYSQL tables do.
Scrollable=Yes	Using a scrollable cursor.

Note: the MEMORY and SCROLLABLE options must be specified in the OPTION _ LIST.

Because the table is accessed several times, this can make queries last very long except for small tables and is almost unacceptable for big tables. However, if it cannot be avoided, using the memory method is the best choice and can be more than four times faster than the default method. If it is supported by the driver, using a scrollable cursor is slightly slower than using memory but can be an alternative to avoid memory problems when the sub-query returns a huge result set.

If the result set is of reasonable size, it is also possible to specify the block_size option equal or slightly larger than the result set. The whole result set being read on the first fetch, can be accessed many times without having to do anything else.

Another good workaround is to replace within the correlated sub-query the ODBC table by a local copy of it because MariaDB is often able to optimize the query and to provide a very fast execution.

Accessing specified views

Instead of specifying a source table name via the TABNAME option, it is possible to retrieve data from a "view" whose definition is given in a new option SRCDEF. For instance:

```
CREATE TABLE custnum (  
  country varchar(15) NOT NULL,  
  customers int(6) NOT NULL)  
ENGINE=CONNECT TABLE_TYPE=ODBC BLOCK_SIZE=10  
CONNECTION='DSN=MS Access Database;DBQ=C:/Program Files/Microsoft Office/Office/1033/FPNWIND.MDB;  
SRCDEF='select country, count(*) as customers from customers group by country';
```

Or simply, because CONNECT can retrieve the returned column definition:

```
CREATE TABLE custnum ENGINE=CONNECT TABLE_TYPE=ODBC BLOCK_SIZE=10  
CONNECTION='DSN=MS Access Database;DBQ=C:/Program Files/Microsoft Office/Office/1033/FPNWIND.MDB;  
SRCDEF='select country, count(*) as customers from customers group by country';
```

Then, when executing for instance:

```
select * from custnum where customers > 3;
```

The processing of the group by is done by the data source, which returns only the generated result set on which only the where clause is performed locally. The result:

country	customers
Brazil	9
France	11
Germany	11
Mexico	5
Spain	5
UK	7
USA	13
Venezuela	4

This makes possible to let the data source do complicated operations, such as joining several tables or executing procedures returning a result set. This minimizes the data transfer through ODBC.

Data Modifying Operations

The only data modifying operations are the [INSERT](#), [UPDATE](#) and [DELETE](#) commands. They can be executed successfully only if the data source database or tables are not read/only.

INSERT Command

When inserting values to an ODBC table, local values are used and sent to the ODBC table. This does not make any difference when the values are constant but in a query such as:

```
insert into t1 select * from t2;
```

Where t1 is an ODBC table, t2 is a locally defined table that must exist on the local server. Besides, it is a good way to create a distant ODBC table from local data.

CONNECT does not directly support INSERT commands such as:

```
insert into t1 values(2,'Deux') on duplicate key update msg = 'Two';
```

Sure enough, the “on duplicate key update” part of it is ignored, and will result in error if the key value is duplicated.

UPDATE and DELETE Commands

Unlike the [INSERT](#) command, [UPDATE](#) and [DELETE](#) are supported in a simplified way. Only simple table commands are supported; CONNECT does not support multi-table commands, commands sent from a procedure, or issued via a trigger. These commands are just rephrased to correspond to the data source syntax and sent to the data source for execution. Let us suppose we created the table:

```
create table tolite (  
  id int(9) not null,  
  nom varchar(12) not null,  
  nais date default null,  
  rem varchar(32) default null)  
ENGINE=CONNECT TABLE_TYPE=ODBC tablename='lite'  
CONNECTION='DSN=SQLite3 Datasource;Database=test.sqlite3'  
CHARSET=utf8 DATA_CHARSET=utf8;
```

We can populate it by:

```
insert into tolite values(1,'Toto',now(),'First'),  
(2,'Foo', '2012-07-14', 'Second'), (4, 'Machin', '1968-05-30', 'Third');
```

The function `now()` will be executed by MariaDB and its returned value sent to the ODBC table.

Let us see what happens when updating the table. If we use the query:

```
update tolite set nom = 'Gillespie' where id = 10;
```

CONNECT will rephrase the command as:

```
update lite set nom = 'Gillespie' where id = 10;
```

What it did is just to replace the local table name with the remote table name and change all the back ticks to blanks or to the data source identifier quoting characters if QUOTED is specified. Then this command will be sent to the data source to be executed by it.

This is simpler and can be faster than doing a positional update using a cursor and commands such as “select ... for update of ...” that are not supported by all data sources. However, there are some restrictions that must be understood due to the way it is handled by MariaDB.

1. MariaDB does not know about all the above. The command will be parsed as if it were to be executed locally. Therefore, it must respect the MariaDB syntax.
2. Being executed by the data source, the (rephrased) command must also respect the data source syntax.
3. All data referenced in the SET and WHERE clause belongs to the data source.

This is possible because both MariaDB and the data source are using the SQL language. But you must use only the basic features that are part of the core SQL language. For instance, keywords like IGNORE or LOW_PRIORITY will cause syntax error with many data source.

Scalar function names also can be different, which severely restricts the use of them. For instance:

```
update tolite set nais = now() where id = 2;
```

This will not work with SQLite3, the data source returning an “unknown scalar function” error message. Note that in this particular case, you can rephrase it to:

```
update tolite set nais = date('now') where id = 2;
```

This is understood by both parsers, and even if this function would return NULL executed by MariaDB, it does return the current date when executed by SQLite3. But this begins to become too tricky so to overcome all these restrictions, and permit to have all types of commands executed by the data source, CONNECT provides a specific ODBC table subtype described now.

Sending commands to a Data Source

This can be done using a special subtype of ODBC table. Let us see this in an example:

```
create table crlite (  
  command varchar(128) not null,  
  number int(5) not null flag=1,  
  message varchar(255) flag=2  
engine=connect table_type=odbc  
connection='Driver=SQLite3 ODBC Driver;Database=test.sqlite3;NoWCHAR=yes'  
option_list='Execsrc=1';
```

The key points in this create statement are the EXECSRC option and the column definition.

The EXECSRC option tells that this table will be used to send a command to the data source. Most of the sent commands do not return result set. Therefore, the table columns are used to specify the command to be executed and to get the result of the execution. The name of these columns can be chosen arbitrarily, their function coming from the FLAG value:

Flag=0: The command to execute.

Flag=1: The affected rows, or -1 in case of error, or the result number of column if the command returns a result set.

Flag=2: The returned (eventually error) message.

How to use this table and specify the command to send? By executing a command such as:

```
select * from crlite where command = 'a command';
```

This will send the command specified in the WHERE clause to the data source and return the result of its execution. The syntax of the WHERE clause must be exactly as shown above. For instance:

```
select * from crlite where command =
'CREATE TABLE lite (
ID integer primary key autoincrement,
name char(12) not null,
birth date,
rem varchar(32)');
```

This command returns:

command	number	message
CREATE TABLE lite (ID integer primary key autoincrement, name...	0	Affected rows

Now we can create a standard ODBC table on the newly created table:

```
CREATE TABLE tlite
ENGINE=CONNECT TABLE_TYPE=ODBC tabname='lite'
CONNECTION='Driver=SQLite3 ODBC Driver;Database=test.sqlite3;NoWCHAR=yes'
CHARSET=utf8 DATA_CHARSET=utf8;
```

We can populate it directly using the supported INSERT statement:

```
insert into tlite(name,birth) values('Toto','2005-06-12');
insert into tlite(name,birth,rem) values('Foo',NULL,'No ID');
insert into tlite(name,birth) values('Truc','1998-10-27');
insert into tlite(name,birth,rem) values('John','1968-05-30','Last');
```

And see the result:

```
select * from tlite;
```

ID	name	birth	rem
1	Toto	2005-06-12	NULL
2	Foo	NULL	No ID
3	Truc	1998-10-27	NULL
4	John	1968-05-30	Last

Any command, for instance UPDATE, can be executed from the crlite table:

```
select * from crlite where command =
'update lite set birth = '2012-07-14' where ID = 2';
```

This command returns:

command	number	message
update lite set birth = '2012-07-15' where ID = 2	1	Affected rows

Let us verify it:

```
select * from tlite where ID = 2;
```

ID	name	birth	rem
2	Foo	2012-07-15	No ID

The syntax to send a command is rather strange and may seem unnatural. It is possible to use an easier syntax by defining a stored procedure such as:

```
create procedure send_cmd(cmd varchar(255))
MODIFIES SQL DATA
select * from crlite where command = cmd;
```

Now you can send commands like this:

```
call send_cmd('drop tlite');
```

This is possible only when sending one single command.

Sending several commands together

Grouping commands uses an easier syntax and is faster because only one connection is made for the all of them. To send several commands in one call, use the following syntax:

```
select * from crlite where command in (
'update lite set birth = '2012-07-14' where ID = 2',
'update lite set birth = '2009-08-10' where ID = 3');
```

When several commands are sent, the execution stops at the end of them or after a command that is in error. To continue after n errors, set the option `maxerr= n` (0 by default) in the option list.

Note 1: It is possible to specify the SRCDEF option when creating an EXECSRC table. It will be the command sent by default when a WHERE clause is not specified.

Note 2: Most data sources do not allow sending several commands separated by semi-colons.

Note 3: Quotes inside commands must be escaped. This can be avoided by using a different quoting character than the one used in the command

Note 4: The sent command must obey the data source syntax.

Note 5: Sent commands apply in the specified database. However, they can address any table within this database, or belonging to another database using the name syntax `schema.tabname`.

Connecting to a Data Source

There are two ways to establish a connection to a data source:

1. Using `SQLDriverConnect` and a Connection String
2. Using `SQLConnect` and a Data Source Name (DSN)

The first way uses a Connection String whose components describe what is needed to establish the connection. It is the most complete way to do it and by default `CONNECT` uses it.

The second way is a simplified way in which ODBC is just given the name of a DSN that must have been defined to ODBC or `UnixOdbc` and that contains the necessary information to establish the connection. Only the user name and password can be specified out of the DSN specification.

Defining the Connection String

Using the first way, the connection string must be specified. This is sometimes the most difficult task when creating ODBC tables because, depending on the operating system and the data source, this string can widely differ.

The format of the ODBC Connection String is:

```
connection-string ::= empty-string[;] | attribute[;] | attribute; connection-string
empty-string ::=
attribute ::= attribute-keyword=attribute-value | DRIVER=[{}attribute-value{}]
attribute-keyword ::= DSN | UID | PWD | driver-defined-attribute-keyword
attribute-value ::= character-string
driver-defined-attribute-keyword = identifier
```

Where `character-string` has zero or more characters; `identifier` has one or more characters; `attribute-keyword` is not case-sensitive; `attribute-value` may be case-sensitive; and the value of the DSN keyword does not consist solely of blanks. Due to the connection string grammar, keywords and attribute values that contain the characters `[] { } () , ; ? * = ! @` should be avoided. The value of the DSN keyword cannot consist only of blanks, and should not contain leading blanks. Because of the grammar of the system information, keywords and data source names cannot contain the backslash (`\`) character. Applications do not have to add braces around the attribute value after the `DRIVER` keyword unless the attribute contains a

semicolon (;), in which case the braces are required. If the attribute value that the driver receives includes the braces, the driver should not remove them, but they should be part of the returned connection string.

ODBC Defined Connection Attributes

The ODBC defined attributes are:

- DSN - the name of the data source to connect to. You must create this before attempting to refer to it. You create new DSNs through the ODBC Administrator (Windows), ODBCAdmin (unixODBC's GUI manager) or in the `odbc.ini` file.
- DRIVER - the name of the driver to connect to. You can use this in DSN-less connections.
- FILEDSN - the name of a file containing the connection attributes.
- UID/PWD - any username and password the database requires for authentication.
- SAVEFILE - request the DSN attributes are saved in this file.

Other attributes are DSN dependent attributes. The connection string can give the name of the driver in the DRIVER field or the data source in the DSN field (attention! meet the spelling and case) and has other fields that depend on the data source. When specifying a file, the DBQ field must give the **full** path and name of the file containing the table. Refer to the specific ODBC connector documentation for the exact syntax of the connection string.

Using a Predefined DSN

This is done by specifying in the option list the Boolean option "UseDSN" as yes or 1. In addition, string options "user" and "password" can be optionally specified in the option list.

When doing so, the connection string just contains the name of the predefined Data Source. For instance:

```
CREATE TABLE tlite ENGINE=CONNECT TABLE_TYPE=ODBC tablename='lite'  
CONNECTION='SQLite3 Datasource'  
OPTION_LIST='UseDSN=Yes,User=me,Password=myspass';
```

Note: the connection data source name (limited to 32 characters) should not be preceded by "DSN=".

ODBC Tables on Linux/Unix

In order to use ODBC tables, you will need to have unixODBC installed. Additionally, you will need the ODBC driver for your foreign server's protocol. For example, for MS SQL Server or Sybase, you will need to have FreeTDS installed.

Make sure the user running `mysqld` (usually the `mysql` user) has permission to the ODBC data source configuration and the ODBC drivers. If you get an error on Linux/Unix when using `TABLE_TYPE=ODBC`:

```
Error Code: 1105 [unixODBC][Driver Manager]Can't open lib  
'/usr/cachesys/bin/libcacheodbc.so' : file not found
```

You must make sure that the user running `mysqld` (usually "mysql") has enough permission to load the ODBC driver library. It can happen that the driver file does not have enough read privileges (use `chmod` to fix this), or loading is prevented by SELinux configuration (see below).

Try this command in a shell to check if the driver had enough permission:

```
sudo -u mysql ldd /usr/cachesys/bin/libcacheodbc.so
```

SELinux

SELinux can cause various problems. If you think SELinux is causing problems, check the system log (e.g. `/var/log/messages`) or the audit log (e.g. `/var/log/audit/audit.log`).

mysqld can't load some executable code, so it can't use the ODBC driver.

Example error:

```
Error Code: 1105 [unixODBC][Driver Manager]Can't open lib  
'/usr/cachesys/bin/libcacheodbc.so' : file not found
```

Audit log:

```
type=AVC msg=audit(1384890085.406:76): avc: denied { execute }
for pid=1433 comm="mysqld"
path="/usr/cachesys/bin/libcacheodbc.so" dev=dm-0 ino=3279212
scontext=unconfined_u:system_r:mysqld_t:s0
tcontext=unconfined_u:object_r:usr_t:s0 tclass=file
```

mysqld can't open TCP sockets on some ports, so it can't connect to the foreign server.

Example error:

```
ERROR 1296 (HY000): Got error 174 '[unixODBC][FreeTDS][SQL Server]Unable to connect to data
source' from CONNECT
```

Audit log:

```
type=AVC msg=audit(1423094175.109:433): avc: denied { name_connect } for pid=3193
comm="mysqld" dest=1433 scontext=system_u:system_r:mysqld_t:s0
tcontext=system_u:object_r:mssql_port_t:s0 tclass=tcp_socket
```

ODBC Catalog Information

Depending on the version of the used ODBC driver, some additional information on the tables are existing, such as table QUALIFIER or OWNER for old versions, now named CATALOG or SCHEMA since version 3.

CATALOG is apparently rarely used by most data sources, but SCHEMA (formerly OWNER) is and corresponds to the DATABASE information of MySQL.

The issue is that if no schema name is specified, some data sources return information for all schemas while some others only return the information of the "default" schema. In addition, the used "schema" or "database" is sometimes implied by the connection string and sometimes is not. Sometimes, it also can be included in a data source definition.

CONNECT offers two ways to specify this information:

1. When specified, the DBNAME create table option is regarded by ODBC tables as the SCHEMA name.
2. Table names can be specified as "*cat.sch.tab*" allowing to set the catalog and schema info.

When both are used, the qualified table name has precedence over DBNAME . For instance:

Tabname	DBname	Description
test.t1		The t1 table of the test schema.
test.t1	mydb	The t1 table of the test schema (test has precedence)
t1	mydb	The t1 table of the mydb schema
%.%.%		All tables in all catalogs and all schemas
t1		The t1 table in the default or all schema depending on the DSN
%.t1		The t1 table in all schemas for all DSN
test.%		All tables in the test schema

When creating a standard ODBC table, you should make sure only one source table is specified. Specifying more than one source table must be done only for CONNECT catalog tables (with CATFUNC=tables or columns).

In particular, when column definition is left to the Discovery feature, if tables with the same name are present in several schemas and the schema name is not specified, several columns with the same name will be generated. This will make the creation fail with a not very explicit error message.

Note: With some ODBC drivers, the DBNAME option or qualified table name is useless because the schema implied by the connection string or the definition of the data source has priority over the specified DBNAME .

Table name case

Another issue when dealing with ODBC tables is the way table and column names are handled regarding of the case.

For instance, Oracle follows to the SQL standard here. It converts non-quoted identifiers to upper case. This is correct and expected. PostgreSQL is not standard. It converts identifiers to lower case. MySQL/MariaDB is not standard. They preserve identifiers on Linux, and convert to lower case on Windows.

Think about that if you fail to see a table or a column on an ODBC data source.

Non-ASCII Character Sets with Oracle

When connecting through ODBC, the MariaDB Server operates as a client to the foreign database management system. As such, it requires that you configure MariaDB as you would configure native clients for the given database server.

In the case of connecting to Oracle, when using non-ASCII character sets, you need to properly set the NLS_LANG environment variable before starting the MariaDB Server.

For instance, to test this on Oracle, create a table that contains a series of special characters:

```
CREATE TABLE t1 (letter VARCHAR(4000));

INSERT INTO t1 VALUES
(UTL_RAW.CAST_TO_VARCHAR2 (HEXTORAW('C4'))),
(UTL_RAW.CAST_TO_VARCHAR2 (HEXTORAW('C5'))),
(UTL_RAW.CAST_TO_VARCHAR2 (HEXTORAW('C6')));
```

```
SELECT letter, RAWTOHEX(letter) FROM t1;
```

```
letter | RAWTOHEX(letter)
-----|-----
A      | C4
A      | C5
A      | C6
```

Then create a connecting table on MariaDB and attempt the same query:

```
CREATE TABLE t1 (
  letter VARCHAR(4000))
ENGINE=CONNECT
DEFAULT CHARSET=utf8mb4
CONNECTION='DSN=YOUR_DSN'
TABLE_TYPE = 'ODBC'
DATA_CHARSET = latin1
TABNAME = 'YOUR_SCHEMA.T1';
```

```
SELECT letter, HEX(letter) FROM t1;
```

```
+-----+-----+
| letter | HEX(letter) |
+-----+-----+
| A      | 41         |
| ?      | 3F         |
| ?      | 3F         |
+-----+-----+
```

While the character set is defined in a way that satisfies MariaDB, it has not been defined for Oracle, (that is, setting the NLS_LANG environment variable). As a result, Oracle is not providing the characters you want to MariaDB and Connect. The specific method of setting the NLS_LANG variable can vary depending on your operating system or distribution. If you're experiencing this issue, check your OS documentation for more details on how to properly set environment variables.

Using systemd

With Linux distributions that use [systemd](#), you need to set the environment variable in the service file, (systemd doesn't read from the /etc/environment file).

This is done by setting the Environment variable in the [Service] unit. For instance,

```
# systemctl edit mariadb.service

[Service]
Environment=NLS_LANG=GERMAN_GERMANY.WE8ISO8859P1
```

Then restart MariaDB,

```
# systemctl restart mariadb.service
```

You can now retrieve the appropriate characters from Oracle tables:

```
SELECT letter, HEX(letter) FROM t1;
```

```
+-----+  
| letter | HEX(letter) |  
+-----+  
| A     | C384      |  
| A     | C385      |  
| E     | C386      |  
+-----+
```

Using Windows

Microsoft Windows doesn't ignore environment variables the way systemd does on Linux, but it does require that you set the NLS_LANG environment variable on your system. In order to do so, you need to open an elevated command-prompt, (that is, Cmd.exe with administrative privileges).

From here, you can use the Setx command to set the variable. For instance,

```
Setx NLS_LANG GERMAN_GERMANY.WE8ISO8859P1 /m
```

Note: For more detail about this, see [MDEV-17501](#).

OPTION_LIST Values Supported by the ODBC Tables

The following options can be given as comma-separated string to the `OPTION_LIST` value in the `CREATE TABLE` statement.

Name	Default	Description
MaxRes	0	Maximum number of rows returned by catalog functions
ConnectTimeout	-1	Connection timeout in seconds, unlimited by default
QueryTimeout	-1	Query timeout in seconds, unlimited by default
UseDSN	false	Use pre-configured DSN

5.3.7.6.17 CONNECT JDBC Table Type: Accessing Tables from Another DBMS

10. [Fixing Problem With mariadb-dump](#)

The JDBC table type should be distributed with all recent versions of MariaDB. However, if the automatic compilation of it is possible after the java JDK was installed, the complete distribution of it is not fully implemented in older versions. The distributed `JdbcInterface.jar` file contains the `JdbcInterface` wrapper only. New versions distribute a `JavaWrappers.jar` that contains all currently existing wrappers.

This will require that:

1. The Java SDK is installed on your system.

2. The java wrapper class files are available on your system.
3. And of course, some JDBC drivers exist to be used with the matching DBMS.

Point 2 was made automatic in the newest versions of MariaDB.

Compiling From Source Distribution

Even when the Java JDK has been installed, CMake sometimes cannot find the location where it stands. For instance on Linux the Oracle Java JDK package might be installed in a path not known by the CMake lookup functions causing error message such as:

```
CMake Error at /usr/share/cmake/Modules/FindPackageHandleStandardArgs.cmake:148 (message):
  Could NOT find Java (missing: Java_JAR_EXECUTABLE Java_JAVAC_EXECUTABLE
  Java_JAVAH_EXECUTABLE Java_JAVADOC_EXECUTABLE)
```

When this happen, provide a Java prefix as a hint on where the package was loaded. For instance on Ubuntu I was obliged to enter:

```
export JAVA_HOME=/usr/lib/jvm/java-8-oracle
```

After that, the compilation of the CONNECT JDBC type was completed successfully.

Compiling the Java source files

They are the source of the java wrapper classes used to access JDBC drivers. In the source distribution, they are located in the CONNECT source directory.

The default wrapper, JdbcInterface, is the only one distributed with binary distribution. It uses the standard way to get a connection to the drivers via the DriverManager.getConnection method. Other wrappers, only available with source distribution, enable connection to a Data Source, eventually implementing pooling. However, they must be compiled and installed manually.

The available wrappers are:

Wrapper	Description
JdbcInterface	Used to make the connection with available drivers the standard way.
ApacheInterface	Based on the Apache common-DBC2 package this interface enables making connections to DBCP data sources with any JDBC drivers.
MariadbInterface	Makes connection to a MariaDB data source.
MysqlInterface	Makes connection to a Mysql data source. Must be used with a MySQL driver that implements data sources.
OracleInterface	Makes connection to an Oracle data source.
PostgresqlInterface	Makes connection to a Postgresql data source.

The wrapper used by default is specified by the `connect_java_wrapper` session variable and is initially set to `wrappers/JdbcInterface`. The wrapper to use for a table can also be specified in the option list as a wrapper option of the "create table" statements.

Note: Conforming java naming usage, class names are preceded by the java package name with a slash separator. However, this is not mandatory for CONNECT which adds the package name if it is missing.

The JdbcInterface wrapper is always usable when Java is present on your machine. Binary distributions have this wrapper already compiled as a JdbcInterface.jar file installed in the plugin directory whose path is automatically included in the class path of the JVM. Recent versions also add a JavaWrappers.jar that contains all these wrappers. Therefore there is no need to worry about its path.

Compiling the ApacheInterface wrapper requires that the Apache common-DBC2 package be installed. Other wrappers are to be used only with the matching JDBC drivers that must be available when compiling them.

Installing the jar file in the plugin directory is the best place because it is part of the class path. Depending on what is installed on your system, the source files can be reduced accordingly. To compile only the JdbcInterface.java file the CMAKE_JAVA_INCLUDE_PATH is not required. Here the paths are the ones existing on my Windows 7 machine and should be localized.

Setting the Required Information

Before any operation with a JDBC driver can be made, CONNECT must initialize the environment that will make working with Java possible. This will consist of:

1. Loading dynamically the JVM library module.
2. Creating the Java Virtual Machine.
3. Establishing contact with the java wrapper class.
4. Connecting to the used JDBC driver.

Indeed, the JVM library module is not statically linked to the CONNECT plugin. This is to make it possible to use a CONNECT plugin that has been compiled with the JDBC table type on a machine where the Java SDK is not installed. Otherwise, users not interested in the JDBC table type would be obliged to install the Java SDK on their machine to be able to load the CONNECT storage engine.

JVM Library Location

If the JVM library (jvm.dll on Windows, libjvm.so on Linux) was not placed in the standard library load path, CONNECT cannot find it and must be told where to search for it. This happens in particular on Linux when the Oracle Javapackage was installed in a private location.

If the JAVA_HOME variable was exported as explained above, CONNECT can sometimes find it using this information. Otherwise, its search path can be added to the LD_LIBRARY_PATH environment variable. But all this is complicated because making environment variables permanent on Linux is painful (many different methods must be used depending on the Linux version and the used shell).

This is why CONNECT introduced a new global variable connect_jvm_path to store this information. It can be set when starting the server as a command line option or even afterwards before the first use of the JDBC table type. For example:

```
set global connect_jvm_path="/usr/lib/jvm/java-8-oracle/jre/lib/i386/client"
```

or

```
set global connect_jvm_path="/usr/lib/jvm/java-8-oracle/jre/lib/i386/server"
```

The client library is smaller and faster for connection. The server library is more optimized and can be used in case of heavy load usage.

Note that this may not be required on Windows because the path to the JVM library can sometimes be found in the registry.

Once this library is loaded, CONNECT can create the required Java Virtual Machine.

Java Class Path

This is the list of paths Java searches when loading classes. With CONNECT, the classes to load will be the java wrapper classes used to communicate with the drivers, and the used JDBC driver classes that are grouped inside jar files. If the ApacheInterface wrapper must be used, the class path must also include all three jars used by the Apache package.

Caution: This class path is passed as a parameter to the Java Virtual Machine (JVM) when creating it and cannot be modified as it is a read only property. In addition, because MariaDB is a multi-threading application, this JVM cannot be destroyed and will be used throughout the entire life of the MariaDB server. Therefore, be sure it is correctly set before you use the JDBC table type for the first time. Otherwise, there will be practically no alternative than to shut down the server and restart it.

The path to the wrapper classes must point to the directory containing the wrappers sub-directory. If a JdbcInterface.jar file was made, its path is the directory where it is located followed by the jar file name. It is unclear where because this will depend on the installation process. If you start from a source distribution, it can be in the storage/connect directory where the CONNECT source files are or where you moved them or compiled the JdbcInterface.jar file.

For binary distributions, there is nothing to do because the jar file has been installed in the mysql share directory whose path is always automatically included in the class path available to the JVM.

Remaining are the paths of all the installed JDBC drivers that you intend to use. Remember that their path must include the jar file itself. Some applications use an environment variable CLASSPATH to contain them. Paths are separated by ':' on Linux and by ';' on Windows.

If the CLASSPATH variable actually exists and if it is available inside MariaDB, so far so good. You can check this using an UDF function provided by CONNECT that returns environment variable values:

```
create function envar returns string soname 'ha_connect.so';
select envar('CLASSPATH');
```

Most of the time, this will return null or some required files are missing. This is why CONNECT introduced a global variable to store this information. The paths specified in this variable will be added and have precedence to the ones, if any, of the CLASSPATH environment variable. As for the jvm path, this variable connect_class_path should be specified when starting the server but can also be set before using the JDBC table type for the first time.

The current directory (sql/data) is also placed by CONNECT at the beginning of the class path.

As an example, here is how I start MariaDB when doing tests on Linux:

```
olivier@olivier-Aspire-8920:~$ sudo /usr/local/mysql/bin/mysqld -u root --console --default-
storage-engine=myisam --skip-innodb --connect_jvm_path="/usr/lib/jvm/java-8-
oracle/jre/lib/i386/server" --
connect_class_path="/home/olivier/mariadb/10.1/storage/connect:/media/olivier/SOURCE/mysql-
connector-java-6.0.2/mysql-connector-java-6.0.2-bin.jar"
```

CONNECT JDBC Tables

These tables are given the type JDBC. For instance, supposing you want to access the boys table located on an external local or remote database management system providing a JDBC connector:

```
create table boys (
name char(12),
city char(12),
birth date,
hired date);
```

To access this table via JDBC you can create a table such as:

```
create table jboys engine=connect table_type=JDBC tabname=boys
connection='jdbc:mysql://localhost/dbname?user=root';
```

The CONNECTION option is the URL used to establish the connection with the remote server. Its syntax depends on the external DBMS and in this example is the one used to connect as root to a MySQL or MariaDB local database using the MySQL JDBC connector.

As for ODBC, the columns definition can be omitted and will be retrieved by the discovery process. The restrictions concerning column definitions are the same as for ODBC.

Note: The dbname indicated in the URL corresponds for many DBMS to the catalog information. For MySQL and MariaDB it is the schema (often called database) of the connection.

Using a Federated Server

Alternatively, a JDBC table can specify its connection options via a Federated server. For instance, supposing you have a table accessing an external PostgreSQL table defined as:

```
create table juuid engine=connect table_type=JDBC tabname=testuuid
connection='jdbc:postgresql:test?user=postgres&password=pwd';
```

You can create a Federated server:

```
create server 'post1' foreign data wrapper 'postgresql' options (
HOST 'localhost',
DATABASE 'test',
USER 'postgres',
PASSWORD 'pwd',
PORT 0,
SOCKET '',
OWNER 'postgres');
```

Now the JDBC table can be created by:

```
create table juuid engine=connect table_type=JDBC connection='post1' tabname=testuuid;
```

or by:

```
create table juuid engine=connect table_type=JDBC connection='post1/testuuid';
```

In any case, the location of the remote table can be changed in the Federated server without having to alter all the tables using this server.

JDBC needs a URL to establish a connection. CONNECT was able to construct that URL from the information contained in such Federated server definition when the URL syntax is similar to the one of MySQL, MariaDB or Postgresql. However, other DBMSs such as Oracle use a different URL syntax. In this case, simply replace the HOST information by the required URL in the Federated server definition. For instance:

```
create server 'oracle' foreign data wrapper 'oracle' options (  
HOST 'jdbc:oracle:thin:@localhost:1521:xe',  
DATABASE 'SYSTEM',  
USER 'system',  
PASSWORD 'manager',  
PORT 0,  
SOCKET '',  
OWNER 'SYSTEM');
```

Now you can create an Oracle table with something like this:

```
create table empour engine=connect table_type=JDBC connection='oracle/HR.EMPLOYEES';
```

Note: Oracle, as Postgresql, does not seem to understand the DATABASE setting as the table schema that must be specified in the Create Table statement.

Connecting to a JDBC driver

When the connection to the driver is established by the JdbcInterface wrapper class, it uses the options that are provided when creating the CONNECT JDBC tables. Inside the default Java wrapper, the driver's main class is loaded by the DriverManager.getConnection function that takes three arguments:

URL	That is the URL that you specified in the CONNECTION option.
User	As specified in the OPTION_LIST or NULL if not specified.
Password	As specified in the OPTION_LIST or NULL if not specified.

The URL varies depending on the connected DBMS. Refer to the documentation of the specific JDBC driver for a description of the syntax to use. User and password can also be specified in the option list.

Beware that the database name in the URL can be interpreted differently depending on the DBMS. For MySQL this is the schema in which the tables are found. However, for Postgresql, this is the catalog and the schema must be specified using the CONNECT dbname option.

For instance a table accessing a Postgresql table via JDBC can be created with a create statement such as:

```
create table jt1 engine=connect table_type=JDBC  
connection='jdbc:postgresql://localhost/mtr' dbname=public tabname=t1  
option_list='User=mtr,Password=mtr';
```

Note: In previous versions of JDBC, to obtain a connection, java first had to initialize the JDBC driver by calling the method Class.forName. In this case, see the documentation of your DBMS driver to obtain the name of the class that implements the interface java.sql.Driver. This name can be specified as an option DRIVER to be put in the option list. However, most modern JDBC drivers since version 4 are self-loading and do not require this option to be specified.

The wrapper class also creates some required items and, in particular, a statement class. Some characteristics of this statement will depend on the options specified when creating the table:

Scrollable	To be specified in the option list. Determines the cursor type: no= forward_only or yes=scroll_insensitive.
Block_size	Will be used to set the statement fetch size.

Fetch Size

The fetch size determines the number of rows that are internally retrieved by the driver on each interaction with the DBMS. Its default value depends on the JDBC driver. It is equal to 10 for some drivers but not for the MySQL or MariaDB

connectors.

The MySQL/MariaDB connectors retrieve all the rows returned by one query and keep them in a memory cache. This is generally fine in most cases, but not when retrieving a large result set that can make the query fail with a memory exhausted exception.

To avoid this, when accessing a big table and expecting large result sets, you should specify the `BLOCK_SIZE` option to 1 (the only acceptable value). However a problem remains:

Suppose you execute a query such as:

```
select id, name, phone from jbig limit 10;
```

Not knowing the limit clause, `CONNECT` sends to the remote DBMS the query:

```
SELECT id, name, phone FROM big;
```

In this query `big` can be a huge table having million rows. Having correctly specified the block size as 1 when creating the table, the wrapper just reads the 10 first rows and stops. However, when closing the statement, these MySQL/MariaDB drivers must still retrieve all the rows returned by the query. This is why, the wrapper class when closing the statement also cancels the query to stop that extra reading.

The bad news is that if it works all right for some previous versions of the MySQL driver, it does not work for new versions as well as for the MariaDB driver that apparently ignores the cancel command. The good news is that you can use an old MySQL driver to access MariaDB databases. It is also possible that this bug will be fixed in future versions of the drivers.

Connection to a Data Source

This is the java preferred way to establish a connection because a data source can keep a pool of connections that can be re-used when necessary. This makes establishing connections much faster once it was done for the first time.

`CONNECT` provide additional wrappers whose files are located in the `CONNECT` source directory. The wrapper to use can be specified in the global variable `connect_java_wrapper`, which defaults to `"JdbcInterface"`.

It can also be specified for a table in the option list by setting the option wrapper to its name. For instance:

```
create table jboys
engine=CONNECT table_type=JDBC tabname='boys'
connection='jdbc:mariadb://localhost/connect?user=root&useSSL=false'
option_list='Wrapper=MariadbInterface,Scrollable=1';
```

They can be used instead of the standard `JdbcInterface` and are using created data sources.

The Apache one uses data sources implemented by the `Apache-commons-dbc2` package and can be used with all drivers including those not implementing data sources. However, the Apache package must be installed and its three required jar files accessible via the class path.

1. `commons-dbc2-2.1.1.jar`
2. `commons-pool2-2.4.2.jar`
3. `commons-logging-1.2.jar`

Note: the versions numbers can be different on your installation.

The other ones use data sources provided by the matching JDBC driver. There are currently four wrappers to be used with `mysql-6.0.2`, `mariadb`, `oracle` and `postgresql`.

Unlike the class path, the used wrapper can be changed even after the JVM machine was created.

Random Access to JDBC Tables

The same methods described for ODBC tables can be used with JDBC tables.

Note that in the case of the MySQL or MariaDB connectors, because they internally read the whole result set in memory, using the `MEMORY` option would be a waste of memory. It is much better to specify the use of a scrollable cursor when needed.

Other Operations with JDBC Tables

Except for the way the connection string is specified and the table type set to JDBC, all operations with ODBC tables are done for JDBC tables the same way. Refer to the ODBC chapter to know about:

- Accessing specified views (SRCDEF)
- Data modifying operations.
- Sending commands to a data source.
- JDBC catalog information.

Note: Some JDBC drivers fail when the global `time_zone` variable is ambiguous, which sometimes happens when it is set to `SYSTEM`. If so, reset it to a not ambiguous value, for instance:

```
set global time_zone = '+2:00';
```

JDBC Specific Restrictions

Connecting via data sources created externally (for instance using Tomcat) is not supported yet.

Other restrictions are the same as for the ODBC table type.

Handling the UUID Data Type

PostgreSQL has a native UUID data type, internally stored as BIN(16). This is neither an SQL nor a MariaDB data type. The best we can do is to handle it by its character representation.

UUID will be translated to CHAR(36) when column definitions are set using discovery. Locally a PostgreSQL UUID column will be handled like a CHAR or VARCHAR column. Example:

Using the PostgreSQL table `testuuid` in the text database:

```
Table « public.testuuid »
Column | Type | Default
-----+-----+-----
id      | uuid | uuid_generate_v4()
msg     | text |
```

Its column definitions can be queried by:

```
create or replace table juuidcol engine=connect table_type=JDBC tabname=testuuid
catfunc=columns
connection='jdbc:postgresql:test?user=postgres&password=pwd';
```

```
select table_name "Table", column_name "Column", data_type "Type",
       type_name "Name", column_size "Size"
from juuidcol;
```

This query returns:

Table	Column	Type	Name	Size
testuuid	id	1111	uuid	2147483647
testuuid	msg	12	text	2147483647

Note: PostgreSQL, when a column size is undefined, returns 2147483647, which is not acceptable for MariaDB. `CONNECT` change it to the value of the `connect_conv_size` session variable. Also, for TEXT columns the data type returned is 12 (SQL_VARCHAR) instead of -1 the SQL_TEXT value.

Accessing this table via JDBC by:

```
CREATE TABLE juuid ENGINE=connect TABLE_TYPE=JDBC TABNAME=testuuid
CONNECTION='jdbc:postgresql:test?user=postgres&password=pwd';
```

it will be created by discovery as:

```
CREATE TABLE `juuid` (
  `id` char(36) DEFAULT NULL,
  `msg` varchar(8192) DEFAULT NULL
) ENGINE=CONNECT DEFAULT CHARSET=latin1 CONNECTION='jdbc:postgresql:test?
user=postgres&password=pwd' `TABLE_TYPE`='JDBC' `TABNAME`='testuuid';
```

Note: 8192 being here the `_connect_conv_size_value`.

Let's populate it:

```
insert into juuid(msg) values('First');
insert into juuid(msg) values('Second');
select * from juuid;
```

Result:

id	msg
4b173ee1-1488-4355-a7ed-62ba59c2b3e7	First
6859f850-94a7-4903-8d3c-fc3c874fc274	Second

Here the id column values come from the DEFAULT of the PostgreSQL column that was specified as uuid_generate_v4().

It can be set from MariaDB. For instance:

```
insert into juuid
  values ('2f835fb8-73b0-42f3-a1d3-8a532b38feca', 'inserted');
insert into juuid values (NULL, 'null');
insert into juuid values ('', 'random');
select * from juuid;
```

Result:

id	msg
4b173ee1-1488-4355-a7ed-62ba59c2b3e7	First
6859f850-94a7-4903-8d3c-fc3c874fc274	Second
2f835fb8-73b0-42f3-a1d3-8a532b38feca	inserted
<null>	null
8fc0a30e-dc66-4b95-ba57-497a161f4180	random

The first insert specifies a valid UUID character representation. The second one set it to NULL. The third one (a void string) generates a Java random UUID. UPDATE commands obey the same specification.

These commands both work:

```
select * from juuid where id = '2f835fb8-73b0-42f3-a1d3-8a532b38feca';
delete from juuid where id = '2f835fb8-73b0-42f3-a1d3-8a532b38feca';
```

However, this one fails:

```
select * from juuid where id like '%42f3%';
```

Returning:

1296: Got error 174 'ExecuteQuery: org.postgresql.util.PSQLException: ERROR: operator does not exist: uuid ~ unknown hint: no operator corresponds to the data name and to the argument types.

because CONNECT cond_push feature added the WHERE clause to the query sent to PostgreSQL:

```
SELECT id, msg FROM testuuid WHERE id LIKE '%42f3%'
```

and the LIKE operator does not apply to UUID in PostgreSQL.

To handle this, a new session variable was added to CONNECT: connect_cond_push. It permits to specify if cond_push is enabled or not for CONNECT and defaults to 1 (enabled). In this case, you can execute:

```
set connect_cond_push=0;
```

Doing so, the where clause will be executed by MariaDB only and the query will not fail anymore.

Executing the JDBC tests

Four tests exist but they are disabled because requiring some work to localized them according to the operating system and

available java package and JDBC drivers and DBMS.

Two of them, `jdbc.test` and `jdbc_new.test`, are accessing MariaDB via JDBC drivers that are contained in a fat jar file that is part of the test. They should be executable without anything to do on Windows; simply adding the option `--enable-disabled` when running the tests.

However, on Linux these tests can fail to locate the JVM library. Before executing them, you should export the `JAVA_HOME` environment variable set to the prefix of the java installation or export the `LD_LIBRARY_PATH` containing the path to the JVM lib.

Fixing Problem With mariadb-dump

In some case or some platform, when `CONNECT` is set up for use with JDBC table types, this causes `mariadb-dump` with the option `--all-databases` to fail.

This was reported by Robert Dyas who found the cause - see the discussion at [MDEV-11238](#).

5.3.7.6.18 CONNECT MONGO Table Type: Accessing Collections from MongoDB

Contents

1. [Accessing MongoDB from CONNECT](#)
 1. [Using the MongoDB C Driver](#)
 2. [Using the Mongo Java Driver](#)
 3. [Using JDBC](#)
 4. [Using JSON](#)
2. [CONNECT MONGO Tables](#)

 2. [Filter Option](#)
 3. [Pipeline Option](#)
 4. [Fullarray Option](#)
4. [Create, Read, Update and Delete Operations](#)
5. [Status of MONGO Table Type](#)
6. [Current Restrictions](#)

Classified as a NoSQL database program, MongoDB uses JSON-like documents (BSON) grouped in collections. The MONGO type is used to directly access MongoDB collections as tables.

Accessing MongoDB from CONNECT

Accessing MongoDB from CONNECT can be done in different ways:

1. As a MONGO table via the MongoDB C Driver.
2. As a MONGO table via the MongoDB Java Driver.
3. As a JDBC table using some commercially available MongoDB JDBC drivers.
4. As a JSON table via the MongoDB C or Java Driver.

Using the MongoDB C Driver

This is currently not available from binary distributions but only for versions compiled from source. The preferred version of the MongoDB C Driver is 1.7, because they provide package recognition. What must be done is:

1. Install `libbson` and the MongoDB C Driver 1.7.
2. Configure, compile and install MariaDB.

With earlier versions of the Mongo C Driver, the additional include directories and libraries will have to be specified manually when compiling.

When possible, this is the preferred means of access because it does not require all the Java path settings etc. and is faster than using the Java driver.

Using the Mongo Java Driver

This is possible with all distributions including JDBC support, or compiling from source. With a binary distribution that does

not enable the MONGO table type, it is possible to access MongoDB using an OEM module. See [CONNECT OEM Table Example](#) for details. The only additional things to do are:

1. Install the MongoDB Java Driver by downloading its jar file. Several versions are available. If possible use the latest version 3 one.
2. Add the path to it in the CLASSPATH environment variable or in the connect_class_path variable. This is like what is done to declare JDBC drivers.

Connection is established by new Java wrappers Mongo3Interface and Mongo2Interface. They are available in a JDBC distribution in the Mongo2.jar and Mongo3.jar files (previously JavaWrappers.jar). If version 2 of the Java Driver is used, specify "Version=2" in the option list when creating tables.

Using JDBC

See the documentation of the existing commercial JDBC Mongo drivers.

Using JSON

See the specific chapter of the JSON Table Type.

The following describes the MONGO table type.

CONNECT MONGO Tables

Creating and running MONGO tables requires a connection to a running local or remote MongoDB server.

A MONGO table is defined to access a MongoDB collection. The table rows will be the collection documents. For instance, to create a table based on the MongoDB sample collection restaurants, you can do something such as the following:

```
create table resto (
  _id varchar(24) not null,
  name varchar(64) not null,
  cuisine char(200) not null,
  borough char(16) not null,
  restaurant_id varchar(12) not null)
engine=connect table_type=MONGO tabname='restaurants'
data_charset=utf8 connection='mongodb://localhost:27017';
```

Note: The used driver is by default the C driver if only the MongoDB C Driver is installed and the Java driver if only the MongoDB Java Driver is installed. If both are available, it can be specified by the DRIVER option to be specified in the option list and defaults to C.

Here we did not define all the items of the collection documents but only those that are JSON values. The database is test by default. The connection value is the URI used to establish a connection to a local or remote MongoDB server. The value shown in this example corresponds to a local server started with its default port. It is the default connection value for MONGO tables so we could have omit specifying it.

Using discovery is available. This table could have been created by:

```
create table resto
engine=connect table_type=MONGO tabname='restaurants'
data_charset=utf8 option_list='level=-1';
```

Here "depth=-1" is used to create only columns that are simple values (no array or object). Without this, with the default value "depth=0" the table had been created as:

```
CREATE TABLE `resto` (
  `_id` char(24) NOT NULL,
  `address` varchar(136) NOT NULL,
  `borough` char(13) NOT NULL,
  `cuisine` char(64) NOT NULL,
  `grades` varchar(638) NOT NULL,
  `name` char(98) NOT NULL,
  `restaurant_id` char(8) NOT NULL
) ENGINE=CONNECT DEFAULT CHARSET=latin1 `TABLE_TYPE`='MONGO' `TABNAME`='restaurants'
`DATA_CHARSET`='utf8';
```

Fixing Problems With mariadb-dump

In some case or some platforms, when CONNECT is set up for use with JDBC table types, this causes `mariadb-dump` with the `--all-databases` option to fail.

This was reported by Robert Dyas who found the cause of it and how to fix it (see [MDEV-11238](#)).

This occurs when the Java JRE “Usage Tracker” is enabled. In that case, Java creates a directory `#mysql50#.oracle_jre_usage` in the mysql data directory that shows up as a database but cannot be accessed via MySQL Workbench nor apparently backed up by `mariadb-dump --all-databases`.

Per the Oracle documentation (<https://docs.oracle.com/javacomponents/usage-tracker/overview/>) the “Usage Tracker” is disabled by default. It is enabled only when creating the properties file `<JRE directory>/lib/management/usagetracker.properties`. This turns out to be WRONG on some platforms as the file does exist by default on a new installation, and the existence of this file enables the usage tracker.

The solution on CentOS 7 with the Oracle JVM is to rename or delete the `usagetracker.properties` file (to disable it) and then delete the bogus folder it created in the mysql database directory, then restart.

For example, the following works:

```
sudo mv /usr/java/default/jre/lib/management/management.properties
/usr/java/default/jre/lib/management/management.properties.TRACKER-OFF
sudo reboot
sudo rm -rf /var/lib/mysql/.oracle_jre_usage
sudo reboot
```

In this collection, the address column is a JSON object and the column grades is a JSON array. Unlike the JSON table, just specifying the column name with no Jpath result in displaying the JSON representation of them. For instance:

```
select name, address from resto limit 3;
```

name	address
Morris Park Bake Shop	{"building":"1007","coord":[-73.8561,40.8484], "street":"Morris ParkAve", "zipcode":"10462"}
Wendy'S	{"building":"469","coord":[-73.9617,40.6629], "street":"Flatbush Avenue", "zipcode":"11225"}
Reynolds Restaurant	{"building":"351","coord":[-73.9851,40.7677], "street":"West 57Street", "zipcode":"10019"}

MongoDB Dot Notation

To address the items inside object or arrays, specify the Jpath in MongoDB syntax (if using Discovery, specify the Depth option accordingly):

From Connect 1.7.0002

```
create table newresto (
_id varchar(24) not null,
name varchar(64) not null,
cuisine char(200) not null,
borough char(16) not null,
street varchar(65) jpath='address.street',
building char(16) jpath='address.building',
zipcode char(5) jpath='address.zipcode',
grade char(1) jpath='grades.0.grade',
score int(4) not null jpath='grades.0.score',
`date` date jpath='grades.0.date',
restaurant_id varchar(255) not null)
engine=connect table_type=MONGO tabname='restaurants'
data_charset=utf8 connection='mongodb://localhost:27017';
```

Before Connect 1.7.0002

```

create table newresto (
  _id varchar(24) not null,
  name varchar(64) not null,
  cuisine char(200) not null,
  borough char(16) not null,
  street varchar(65) field_format='address.street',
  building char(16) field_format='address.building',
  zipcode char(5) field_format='address.zipcode',
  grade char(1) field_format='grades.0.grade',
  score int(4) not null field_format='grades.0.score',
  `date` date field_format='grades.0.date',
  restaurant_id varchar(255) not null)
engine=connect table_type=MONGO tabname='restaurants'
data_charset=utf8 connection='mongodb://localhost:27017';

```

If this is not done, the Oracle JVM will start the usage tracker, which will create the hidden folder `.oracle_jre_usage` in the mysql home directory, which will cause a mariadb-dump of the server to fail.

```

select name, street, score, date from newresto limit 5;

```

name	street	score	date
Morris Park Bake Shop	Morris Park Ave	2	03/03/2014
Wendy'S	Flatbush Avenue	8	30/12/2014
Dj Reynolds Pub And Restaurant	West 57 Street	2	06/09/2014
Riviera Caterer	Stillwell Avenue	5	10/06/2014
Tov Kosher Kitchen	63 Road	20	24/11/2014

MONGO Specific Options

The MongoDB syntax for Jpath does not allow the CONNECT specific items on arrays. The same effect can still be obtained by a different way. For this, additional options are used when creating MONGO tables.

Option	Type	Description
Colist	String	Options to pass to the MongoDB cursor.
Filter	String	Query used by the MongoDB cursor.
Pipeline*	Boolean	If True, Colist is a pipeline.
Fullarray*	Boolean	Used when creating with Discovery.
Driver*	String	C or Java.
Version*	Integer	The Java Driver version (defaults to 3)

- : To be specified in the option list.

Note: For the content of these options, refer to the MongoDB documentation.

Colist Option

Used to pass different options when making the MongoDB cursor used to retrieve the collation documents. One of them is the projection, allowing to limit the items retrieved in documents. It is hardly useful because this limitation is made automatically by CONNECT. However, it can be used when using discovery to eliminate the `_id` (or another) column when you are not willing to keep it:

```

create table retest
engine=connect table_type=MONGO tabname='restaurants'
data_charset=utf8 option_list='depth=-1'
colist='{"projection":{"_id":0},"limit":5}';

```

In this example, we added another cursor option, the limit option that works like the limit SQL clause.

This additional option works only with the C driver. When using the Java driver, colist should be:

```
colist='{ "_id":0}';
```

And limit would be specified with select statements.

Note: When used with a JSON table, to specify the projection list (or 'all' to get all columns) makes JPATH to be Connect Json paths, not MongoDB ones, allowing JPATH options not available to MongoDB.

Filter Option

This option is used to specify a "filter" that works as a where clause on the table. Supposing we want to create a table restricted to the restaurant making English cuisine that are not located in the Manhattan borough, we can do it by:

```
create table english
engine=connect table_type=MONGO tabname='restaurants'
data_charset=utf8
colist='{ "projection": {"cuisine":0} }'
filter='{ "cuisine": "English", "borough": { "$ne": "Manhattan" } }'
option_list='Depth=-1';
```

And if we ask:

```
select * from english;
```

This query will return:

_id	borough	name	restaurant_id
58ada47de5a51ddfc5ee1f3	Brooklyn	The Park Slope Chipshop	40816202
58ada47de5a51ddfc5ee999	Brooklyn	Chip Shop	41076583
58ada47ee5a51ddfc5f13d5	Brooklyn	The Monro	41660253
58ada47ee5a51ddfc5f176e	Brooklyn	Dear Bushwick	41690534
58ada47ee5a51ddfc5f1e91	Queens	Snowdonia Pub	50000290

Pipeline Option

When this option is specified as true (by YES or 1) the Colist option contains a MongoDB pipeline applying to the table collation. This is a powerful mean for doing things such as expanding arrays like we do with JSON tables. For instance:

```
create table resto2 (
name varchar(64) not null,
borough char(16) not null,
date datetime not null,
grade char(1) not null,
score int(4) not null)
engine=connect table_type=MONGO tabname='restaurants' data_charset=utf8
colist='{ "pipeline": [ { "$match": { "cuisine": "French" } }, { "$unwind": "$grades" }, { "$project": {
"_id":0, "name":1, "borough":1, "date": "$grades.date", "grade": "$grades.grade", "score": "$grades.score" } } ] }'
option_list='Pipeline=1';
```

In this pipeline "\$match" is an early filter, "\$unwind" means that the grades array will be expanded (one Document for each array values) and "\$project" eliminates the _id and cuisine columns and gives the Jpath for the date, grade and score columns.

```
select name, grade, score, date from resto2
where borough = 'Bronx';
```

This query replies:

name	grade	score	date
Bistro Sk	A	10	21/11/2014 01:00:00
Bistro Sk	A	12	19/02/2014 01:00:00

Bistro Sk	B	18	12/06/2013 02:00:00
-----------	---	----	---------------------

This make possible to get things like we do with JSON tables:

```
select name, avg(score) average from resto2
group by name having average >= 25;
```

Can be used to get the average score inside the grades array.

name	average
Bouley Botanical	25,0000
Cheri	46,0000
Graine De Paris	30,0000
Le Pescadeux	29,7500

Fullarray Option

This option, like the Depth option, is only interpreted when creating a table with Discovery (meaning not specifying the columns). It tells CONNECT to generate a column for all existing values in the array. For instance, let us see the MongoDB collection tar by:

From Connect 1.7.0002

```
create table seetar (
Collection varchar(300) not null jpath='*')
engine=CONNECT table_type=MONGO tabname=tar;
```

Before Connect 1.7.0002

```
create table seetar (
Collection varchar(300) not null field_format='*')
engine=CONNECT table_type=MONGO tabname=tar;
```

The format "*" indicates we want to see the Json documents. This small collection is:

Collection
{"_id":{"_id":"58f63a5099b37d9c930f9f3b"},"item":"journal","prices":[87.0,45.0,63.0,12.0,78.0]}
{"_id":{"_id":"58f63a5099b37d9c930f9f3c"},"item":"notebook","prices":[123.0,456.0,789.0]}

The Fullarray option can be used here to generate enough columns to see all the prices of the document prices array.

```
create table tar
engine=connect table_type=MONGO
colist='{"projection":{"_id":0}}'
option_list='depth=1,Fullarray=YES';
```

The table has been created as:

From Connect 1.7.0002

```
CREATE TABLE `tar` (
`item` char(8) NOT NULL,
`prices_0` double(12,6) NOT NULL `JPATH`='prices.0',
`prices_1` double(12,6) NOT NULL `JPATH`='prices.1',
`prices_2` double(12,6) NOT NULL `JPATH`='prices.2',
`prices_3` double(12,6) DEFAULT NULL `JPATH`='prices.3',
`prices_4` double(12,6) DEFAULT NULL `JPATH`='prices.4'
) ENGINE=CONNECT DEFAULT CHARSET=latin1 `TABLE_TYPE`='MONGO' `COLIST`='{"projection":
{"_id":0}}' `OPTION_LIST`='depth=1,Fullarray=YES';
```

Before Connect 1.7.0002

```
CREATE TABLE `tar` (
  `item` char(8) NOT NULL,
  `prices_0` double(12,6) NOT NULL `FIELD_FORMAT`='prices.0',
  `prices_1` double(12,6) NOT NULL `FIELD_FORMAT`='prices.1',
  `prices_2` double(12,6) NOT NULL `FIELD_FORMAT`='prices.2',
  `prices_3` double(12,6) DEFAULT NULL `FIELD_FORMAT`='prices.3',
  `prices_4` double(12,6) DEFAULT NULL `FIELD_FORMAT`='prices.4'
) ENGINE=CONNECT DEFAULT CHARSET=latin1 `TABLE_TYPE`='MONGO' `COLLIST`='{ "projection":
{"_id":0}}' `OPTION_LIST`='level=1,Fullarray=YES';
```

And is displayed as:

item	prices_0	prices_1	prices_2	prices_3	prices_4
journal	87.00	45.00	63.00	12.00	78.00
notebook	123.00	456.00	789.00	NULL	NULL

Create, Read, Update and Delete Operations

All modifying operations are supported. However, inserting into arrays must be done in a specific way. Like with the Fullarray option, we must have enough columns to specify the array values. For instance, we can create a new table by:

From Connect 1.7.0002

```
create table testin (
n int not null,
m char(12) not null,
surname char(16) not null jpath='person.name.first',
name char(16) not null jpath='person.name.last',
age int(3) not null jpath='person.age',
price_1 double(8,2) jpath='d.0',
price_2 double(8,2) jpath='d.1',
price_3 double(8,2) jpath='d.2')
engine=connect table_type=MONGO tabname='tin'
connection='mongodb://localhost:27017';
```

Before Connect 1.7.0002

```
create table testin (
n int not null,
m char(12) not null,
surname char(16) not null field_format='person.name.first',
name char(16) not null field_format='person.name.last',
age int(3) not null field_format='person.age',
price_1 double(8,2) field_format='d.0',
price_2 double(8,2) field_format='d.1',
price_3 double(8,2) field_format='d.2')
engine=connect table_type=MONGO tabname='tin'
connection='mongodb://localhost:27017';
```

Now it is possible to populate it by:

```
insert into testin values
(1789, 'Welcome', 'Olivier', 'Bertrand', 56, 3.14, 2.36, 8.45),
(1515, 'Hello', 'John', 'Smith', 32, 65.17, 98.12, NULL),
(2014, 'Coucou', 'Foo', 'Bar', 20, -1.0, 74, 81356);
```

The result will be:

n	m	surname	name	age	price_1	price_2	price_3
1789	Welcome	Olivier	Bertrand	56	3,14	2,36	8,45
1515	Hello	John	Smith	32	65,17	98,12	NULL
2014	Coucou	Foo	Bar	20	-1	74	81356

Note: If the collection does not exist yet when creating the table and inserting in it, MongoDB creates it automatically.

It can be updated by queries such as:

```
update tintin set price_3 = 83.36 where n = 2014;
```

To look how the array is generated, let us create another table:

From Connect 1.7.0002

```
create table tintin (  
  n int not null,  
  name char(16) not null jpath='person.name.first',  
  prices varchar(255) jpath='d')  
engine=connect table_type=MONGO tabname='tin';
```

Before Connect 1.7.002

```
create table tintin (  
  n int not null,  
  name char(16) not null field_format='person.name.first',  
  prices varchar(255) field_format='d')  
engine=connect table_type=MONGO tabname='in';
```

This table is displayed as:

From Connect 1.7.0002

n	name	prices
1789	Olivier	[3.1400000000000001243,2.3599999999999998757,8.4499999999999992895]
1515	John	[65.170000000000001705,98.120000000000004547,null]
2014	Foo	[null,74.0,83.359999999999999432]

Before Connect 1.7.002

n	name	prices
1789	Olivier	[3.14, 2.36, 8.45]
1515	John	[65.17, 98.12]
2014	Foo	[<null>, 74.0, 83.36]

Note: This last table can be used to make array calculations like with JSON tables using the JSON UDF functions. For instance:

```
select name, jsonget_real(prices,'[+]') sum_prices, jsonget_real(prices,'[! ]') avg_prices from ti
```

This query returns:

name	sum_prices	avg_prices
Olivier	13.95	4.65
John	163.29	81.64
Foo	157,36	78.68

Note: When calculating on arrays, null values are ignored.

Status of MONGO Table Type

This table type is still under development. It has significant advantages over the JSON type to access MongoDB collections. Firstly, the access being direct, tables are always up to date whether the collection has been modified by another application. Performance wise, it can be faster than JSON, because most processing is done by MongoDB on BSON, its internal representation of JSON data, which is designed to optimize all operations. Note that using the MongoDB C Driver can be faster than using the MongoDB Java Driver.

Current Restrictions

- Option "CATFUNC=tables" is not implemented yet.

- Options SRCDEF and EXECSRC do not apply to MONGO tables.

5.3.7.6.19 CONNECT MYSQL Table Type: Accessing MySQL/MariaDB Tables

Contents

1. [Charset Specification](#)
2. [Indexing of MYSQL tables](#)
3. [Data Modifying Operations](#)
4. [Sending commands to a MariaDB Server](#)
 1. [Sending several commands in one call](#)
 2. [Retrieving Warnings and Notes](#)
5. [Connection Engine Limitations](#)
 1. [Data types](#)
 2. [SQL Limitations](#)
6. [CONNECT MYSQL versus FEDERATED](#)

This table type uses libmysql API to access a MySQL or MariaDB table or view. This table must be created on the current server or on another local or remote server. This is similar to what the [FederatedX](#) storage engine provides with some differences.

Currently the Federated-like syntax can be used to create such a table, for instance:

```
create table essai (
  num integer(4) not null,
  line char(15) not null)
engine=CONNECT table_type=MYSQL
connection='mysql://root@localhost/test/people';
```

The connection string can have the same syntax as that used by FEDERATED

```
scheme://username:password@hostname:port/database/tablename
scheme://username@hostname/database/tablename
scheme://username:password@hostname/database/tablename
scheme://username:password@hostname/database/tablename
```

However, it can also be mixed with connect standard options. For instance:

```
create table essai (
  num integer(4) not null,
  line char(15) not null)
engine=CONNECT table_type=MYSQL dbname=test tabname=people
connection='mysql://root@localhost';
```

It can also be specified as a reference to a federated server:

```
connection="connection_one"
connection="connection_one/table_foo"
```

The pure (deprecated) CONNECT syntax is also accepted:

```
create table essai (
  num integer(4) not null,
  line char(15) not null)
engine=CONNECT table_type=MYSQL dbname=test tabname=people
option_list='user=root,host=localhost';
```

The specific connection items are:

Option	Default value	Description
Table	The table name	The name of the table to access.
Database	The current DB name	The database where the table is located.
Host	localhost*	The host of the server, a name or an IP address.

User	The current user	The connection user name.
Password	No password	An optional user password.
Port	The currently used port	The port of the server.
Quoted	0	1 if remote Tabname must be quoted.

- When the host is specified as "localhost", the connection is established on Linux using Linux sockets. On Windows, the connection is established by default using shared memory if it is enabled. If not, the TCP protocol is used. An alternative is to specify the host as "." to use a named pipe connection (if it is enabled). This makes possible to use these table types with server skipping networking.

Caution: Take care not to refer to the MYSQL table itself to avoid an infinite loop!

MYSQL table can refer to the current server as well as to another server. Views can be referred by name or directly giving a source definition, for instance:

```
create table grp engine=connect table_type=mysql
CONNECTION='mysql://root@localhost/test/people'
SRCDEF='select title, count(*) as cnt from employees group by title';
```

When specified, the columns of the mysql table must exist in the accessed table with the same name, but can be only a subset of them and specified in a different order. Their type must be a type supported by CONNECT and, if it is not identical to the type of the accessed table matching column, a conversion can be done according to the rules given in [Data type conversion](#).

Note: For columns prone to be targeted by a where clause, keep the column type compatible with the source table column type (numeric or character) to have a correct rephrasing of the where clause.

If you do not want to restrict or change the column definition, do not provide it and leave CONNECT get the column definition from the remote server. For instance:

```
create table essai engine=CONNECT table_type=MYSQL
connection='mysql://root@localhost/test/people';
```

This will create the *essai* table with the same columns than the people table. If the target table contains CONNECT incompatible type columns, see [Data type conversion](#) to know how these columns can be converted or skipped.

Charset Specification

When accessing the remote table, CONNECT sets the connection charset set to the default local table charset as the FEDERATED engine does.

Do not specify a column character set if it is different from the table default character set even when it is the case on the remote table. This is because the remote column is translated to the local table character set when reading it. This is the default but it can be modified by the setting the [character_set_results](#) variable of the target server. If it must keep its setting, for instance to UTF8 when containing Unicode characters, specify the local default charset to its character set.

This means that it is not possible to correctly retrieve a remote table if it contains columns having different character sets. A solution is to retrieve it by several local tables, each accessing only columns with the same character set.

Indexing of MYSQL tables

Indexes are rarely useful with MYSQL tables. This is because CONNECT tries to access only the requested rows. For instance if you ask:

```
select * from essai where num = 23;
```

CONNECT will construct and send to the server the query:

```
SELECT num, line FROM people WHERE num = 23
```

If the *people* table is indexed on *num*, indexing will be used on the remote server. This, in all cases, will limit the amount of data to retrieve on the network.

However, an index can be specified for columns that are prone to be used to join another table to the MYSQL table. For

instance:

```
select d.id, d.name, f.dept, f.salary
from loc_tab d straight_join cnc_tab f on d.id = f.id
where f.salary > 10000;
```

If the *id* column of the remote table addressed by the *cnc_tab* MySQL table is indexed (which is likely if it is a key) you should also index the *id* column of the MySQL *cnc_tab* table. If so, using “remote” indexing as does FEDERATED, only the useful rows of the remote table will be retrieved during the join process. However, because these rows are retrieved by separate **SELECT** statements, this will be useful only when retrieving a few rows of a big table.

In particular, you should not specify an index for columns not used for joining and above all DO NOT index a joined column if it is not indexed in the remote table. This would cause multiple scans of the remote table to retrieve the joined rows one by one.

Data Modifying Operations

The CONNECT MySQL type supports **SELECT** and **INSERT** and a somewhat limited form of **UPDATE** and **DELETE**. These are described below.

The MySQL type uses similar methods than the ODBC type to implement the **INSERT**, **UPDATE** and **DELETE** commands. Refer to the ODBC chapter for the restrictions concerning them.

For the **UPDATE** and **DELETE** commands, there are fewer restrictions because the remote server being a MySQL server, the syntax of the command will be always acceptable by the remote server.

For instance, you can freely use keywords like **IGNORE** or **LOW_PRIORITY** as well as scalar functions in the **SET** and **WHERE** clauses.

However, there is still an issue on multi-table statements. Let us suppose you have a *t1* table on the remote server and want to execute a query such as:

```
update essai as x set line = (select msg from t1 where id = x.num)
where num = 2;
```

When parsed locally, you will have errors if no *t1* table exists or if it does not have the referenced columns. When *t1* does not exist, you can overcome this issue by creating a local dummy *t1* table:

```
create table t1 (id int, msg char(1)) engine=BLACKHOLE;
```

This will make the local parser happy and permit to execute the command on the remote server. Note however that having a local MySQL table defined on the remote *t1* table does not solve the problem unless it is also names *t1* locally.

This is why, to permit to have all types of commands executed by the data source without any restriction, **CONNECT** provides a specific MySQL table subtype described now.

Sending commands to a MariaDB Server

This can be done like for ODBC or JDBC tables by defining a specific table that will be used to send commands and get the result of their execution..

```
create table send (
  command varchar(128) not null,
  warnings int(4) not null flag=3,
  number int(5) not null flag=1,
  message varchar(255) flag=2)
engine=connect table_type=mysql
connection='mysql://user@host/database'
option_list='Execsrc=1,Maxerr=2';
```

The key points in this create statement are the **EXECSRC** option and the column definition.

The **EXECSRC** option tells that this table will be used to send commands to the MariaDB server. Most of the sent commands do not return result set. Therefore, the table columns are used to specify the command to be executed and to get the result of the execution. The name of these columns can be chosen arbitrarily, their function coming from the **FLAG** value:

Flag=0: The command to execute (the default)

Flag=1: The number of affected rows, or the result number of columns if the command would return a result set.

Flag=2: The returned (eventually error) message.

Flag=3: The number of warnings.

How to use this table and specify the command to send? By executing a command such as:

```
select * from send where command = 'a command';
```

This will send the command specified in the WHERE clause to the data source and return the result of its execution. The syntax of the WHERE clause must be exactly as shown above. For instance:

```
select * from send where command =  
'CREATE TABLE people (  
num integer(4) primary key autoincrement,  
line char(15) not null';
```

This command returns:

command	warnings	number	message
CREATE TABLE people (num integer(4) primary key aut...	0	0	Affected rows

Sending several commands in one call

It can be faster to execute because there will be only one connection for all of them. To send several commands in one call, use the following syntax:

```
select * from send where command in (  
"update people set line = 'Two' where id = 2",  
"update people set line = 'Three' where id = 3");
```

When several commands are sent, the execution stops at the end of them or after a command that is in error. To continue after n errors, set the option `maxerr= n` (0 by default) in the option list.

Note 1: It is possible to specify the SRCDEF option when creating an EXECSRC table. It will be the command sent by default when a WHERE clause is not specified.

Note 2: Backslashes inside commands must be escaped. Simple quotes must be escaped if the command is specified between simple quotes, and double quotes if it is specified between double quotes.

Note 3: Sent commands apply in the specified database. However, they can address any table within this database.

Note 4: Currently, all commands are executed in mode AUTOCOMMIT.

Retrieving Warnings and Notes

If a sent command causes warnings to be issued, it is useless to resend a “show warnings” command because the MariaDB server is opened and closed when sending commands. Therefore, getting warnings requires a specific (and tricky) way.

To indicate that warning text must be added to the returned result, you must send a multi-command query containing “pseudo” commands that are not sent to the server but directly interpreted by the EXECSRC table. These “pseudo” commands are:

Warning To get warnings

Note To get notes

Error To get errors returned as warnings (?)

Note that they must be spelled (case insensitive) exactly as above, no final “s”. For instance:

```

select * from send where command in ('Warning','Note',
'drop table if exists try',
'create table try (id int key auto_increment, msg varchar(32) not
null) engine=aria',
"insert into try(msg) values('One'),(NULL),('Three') ",
"insert into try values(2,'Deux') on duplicate key update msg =
'Two'",
"insert into try(message) values('Four'),('Five'),('Six')",
'insert into try(id) values(NULL)',
"update try set msg = 'Four' where id = 4",
'select * from try');

```

This can return something like this:

command	warnings	number	message
drop table if exists try	1	0	Affected rows
Note	0	1051	Unknown table 'try'
create table try (id int key auto_increment, msg...	0	0	Affected rows
insert into try(msg) values('One'),(NULL), (('Three'))	1	3	Affected rows
Warning	0	1048	Column 'msg' cannot be null
insert into try values(2,'Deux') on duplicate key...	0	2	Affected rows
insert into try(msge) values('Four'),('Five'), (('Six'))	0	1054	Unknown column 'msge' in 'field list'
insert into try(id) values(NULL)	1	1	Affected rows
Warning	0	1364	Field 'msg' doesn't have a default value
update try set msg = 'Four' where id = 4	0	1	Affected rows
select * from try	0	2	Result set columns

The execution continued after the command in error because of the MAXERR option. Normally this would have stopped the execution.

Of course, the last "select" command is useless here because it cannot return the table content. Another MySQL table without the EXECSRC option and with proper column definition should be used instead.

Connection Engine Limitations

Data types

There is a maximum key.index length of 255 bytes. You may be able to declare the table without an index and rely on the engine condition pushdown and remote schema.

The following types can't be used:

- BIT
- BINARY
- TINYBLOB, BLOB, MEDIUMBLOB, LONGBLOB
- TINYTEXT, MEDIUMTEXT, LONGTEXT
- ENUM
- SET
- Geometry types

Note: TEXT is allowed. However, the handling depends on the values given to the [connect_type_conv](#) and [connect_conv_size](#) system variables, and by default no conversion of TEXT columns is permitted.

SQL Limitations

The following SQL queries are not supported

- [REPLACE INTO](#)
- [INSERT ... ON DUPLICATE KEY UPDATE](#)

CONNECT MYSQL versus FEDERATED

The CONNECT MYSQL table type should not be regarded as a replacement for the [FEDERATED\(X\)](#) engine. The main use of the MYSQL type is to access other engine tables as if they were CONNECT tables. This was necessary when accessing tables from some CONNECT table types such as [TBL](#), [XCOL](#), [OCCUR](#), or [PIVOT](#) that are designed to access CONNECT tables only. When their target table is not a CONNECT table, these types are silently using internally an intermediate MYSQL table.

However, there are cases where you can use MYSQL CONNECT tables yourself, for instance:

1. When the table will be used by a [TBL](#) table. This enables you to specify the connection parameters for each sub-table and is more efficient than using a local FEDERATED sub-table.
2. When the desired returned data is directly specified by the SRCDEF option. This is great to let the remote server do most of the job, such as grouping and/or joining tables. This cannot be done with the FEDERATED engine.
3. To take advantage of the *push_cond* facility that adds a where clause to the command sent to the remote table. This restricts the size of the result set and can be crucial for big tables.
4. For tables with the EXEC SRC option on.
5. When doing tests. For instance to check a connection string.

If you need multi-table updating, deleting, or bulk inserting on a remote table, you can alternatively use the FEDERATED engine or a “send” table specifying the EXEC SRC option on.

5.3.7.6.20 CONNECT PROXY Table Type

Contents

1. [Proxy on non-CONNECT Tables](#)
2. [Using a PROXY Table as a View](#)
3. [Avoiding PROXY table loop](#)
4. [Modifying Operations](#)

A [PROXY](#) table is a table that accesses and reads the data of another table or view. For instance, to create a table based on the boys [FIX](#) table:

```
create table xboy engine=connect
table_type=PROXY tabname=boys;
```

Simply, [PROXY](#) being the default type when [TABNAME](#) is specified:

```
create table xboy engine=connect tabname=boys;
```

Because the boys table can be directly used, what can be the use of a proxy table? Well, its main use is to be internally used by other table types such as [TBL](#), [XCOL](#), [OCCUR](#), or [PIVOT](#). Sure enough, [PROXY](#) tables are [CONNECT](#) tables, meaning that they can be based on tables of any engines and accessed by table types that need to access [CONNECT](#) tables.

Proxy on non-CONNECT Tables

When the sub-table is a view or not a [CONNECT](#) table, [CONNECT](#) internally creates a temporary [CONNECT](#) table of [MYSQL](#) type to access it. This connection uses the same default parameters as for a [MYSQL](#) table. It is also possible to specify them to the [PROXY](#) table using in the [PROXY](#) declaration the same [OPTION_LIST](#) options as for a [MYSQL](#) table. Of course, it is simpler and more natural to use directly the [MYSQL](#) type in this case.

Normally, the default parameters should enable the [PROXY](#) table to reconnect the server. However, an issue is when the current user was logged using a password. The security protocol prevents [CONNECT](#) to retrieve this password and requires it to be given in the [PROXY](#) table create statement. For instance adding to it:

```
... option_list='Password=mypass';
```

However, it is often not advisable to write in clear a password that can be seen by all user able to see the table declaration by `show create table`, in particular, if the table is used when the current user is root. To avoid this, a specific user should be created on the local host that will be used by proxy tables to retrieve local tables. This user can have minimum grant options, for instance `SELECT` on desired directories, and needs no password. Supposing ‘proxy’ is such a user, the option list to add will be:

```
... option_list='user=proxy';
```

Using a PROXY Table as a View

A `PROXY` table can also be used by itself to modify the way a table is viewed. For instance, a proxy table does not use the indexes of the object table. It is also possible to define its columns with different names or type, to use only some of them or to changes their order. For instance:

```
create table city (
  city varchar(11),
  boy char(12) flag=1,
  birth date)
engine=CONNECT tabname=boys;
select * from city;
```

This will display:

city	boy	birth
Boston	John	1986-01-25
Boston	Henry	1987-06-07
San Jose	George	1981-08-10
Chicago	Sam	1979-11-22
Dallas	James	1992-05-13
Boston	Bill	1986-09-11

Here we did not have to specify column format or offset because data are retrieved from the boys table, not directly from the boys.txt file. The flag option of the `boy` column indicates that it correspond to the first column of the boys table, the `name` column.

Avoiding PROXY table loop

`CONNECT` is able to test whether a `PROXY`, or `PROXY`-based, table refers directly or indirectly to itself. If a direct reference can tested at table creation, an indirect reference can only be tested when executing a query on the table. However, this is possible only for local tables. When using remote tables or views, a problem can occur if the remote table or the view refers back to one of the local tables of the chain. The same caution should be used than when using `FEDERATEDX` tables.

Note: All `PROXY` or `PROXY`-based tables are read-only in this version.

Modifying Operations

All `INSERT` / `UPDATE` / `DELETE` operations can be used with proxy tables. However, the same restrictions applying to the source table also apply to the proxy table.

Note: All `PROXY` and `PROXY`-based table types are not indexable.

5.3.7.6.21 CONNECT XCOL Table Type

Contents

1. [Using Special Columns with XCOL](#)
2. [XCOL tables based on specified views](#)

`XCOL` tables are based on another table or view, like `PROXY` tables. This type can be used when the object table has a column that contains a list of values.

Suppose we have a `'children'` table that can be displayed as:

name	childlist
Sophie	Vivian, Antony

Lisbeth	Lucy,Charles,Diana
Corinne	
Claude	Marc
Janet	Arthur, Sandra, Peter, John

We can have a different view on these data, where each child will be associated with his/her mother by creating an `XCOL` table by:

```
CREATE TABLE xchild (
  mother char(12) NOT NULL,
  child char(12) DEFAULT NULL flag=2
) ENGINE=CONNECT table_type=XCOL tabname='chlist'
option_list='colname=child';
```

The `COLNAME` option specifies the name of the column receiving the list items. This will return from:

```
select * from xchild;
```

The requested view:

mother	child
Sophia	Vivian
Sophia	Antony
Lisbeth	Lucy
Lisbeth	Charles
Lisbeth	Diana
Corinne	NULL
Claude	Marc
Janet	Arthur
Janet	Sandra
Janet	Peter
Janet	John

Several things should be noted here:

- When the original *children* field is void, what happens depends on the NULL specification of the "multiple" column. If it is nullable, like here, a void string will generate a NULL value. However, if the column is not nullable, no row will be generated at all.
- Blanks after the separator are ignored.
- No copy of the original data was done. Both tables use the same source data.
- Specifying the column definitions in the `CREATE TABLE` statement is optional.

The "multiple" column *child* can be used as any other column. For instance:

```
select * from xchild where substr(child,1,1) = 'A';
```

This will return:

Mother	Child
Sophia	Antony
Janet	Arthur

If a query does not involve the "multiple" column, no row multiplication will be done. For instance:

```
select mother from xchild;
```

This will just return all the mothers:

mother
Sophia
Lisbeth
Corinne
Claude
Janet

The same occurs with other types of select statements, for instance:

```
select count(*) from xchild;      -- returns 5
select count(child) from xchild; -- returns 10
select count(mother) from xchild; -- returns 5
```

Grouping also gives different result:

```
select mother, count(*) from xchild group by mother;
```

Replies:

mother	count(*)
Claude	1
Corinne	1
Janet	1
Lisbeth	1
Sophia	1

While the query:

```
select mother, count(child) from xchild group by mother;
```

Gives the more interesting result:

mother	count(child)
Claude	1
Corinne	0
Janet	4
Lisbeth	3
Sophia	2

Some more options are available for this table type:

Option	Description
Sep_char	The separator character used in the "multiple" column, defaults to the comma.
Mult	Indicates the max number of multiple items. It is used to internally calculate the max size of the table and defaults to 10. (To be specified in <code>OPTION_LIST</code>).

Using Special Columns with XCOL

Special columns can be used in XCOL tables. The mostly useful one is ROWNUM that gives the rank of the value in the list of values. For instance:

```
CREATE TABLE xchild2 (
  rank int NOT NULL SPECIAL=ROWID,
  mother char(12) NOT NULL,
  child char(12) NOT NULL flag=2
) ENGINE=CONNECT table_type=XCOL tabname='chlist' option_list='colname=child';
```

This table will be displayed as:

rank	mother	child
1	Sophia	Vivian
2	Sophia	Antony
1	Lisbeth	Lucy
2	Lisbeth	Charles
3	Lisbeth	Diana
1	Claude	Marc
1	Janet	Arthur
2	Janet	Sandra
3	Janet	Peter
4	Janet	John

To list only the first child of each mother you can do:

```
SELECT mother, child FROM xchild2 where rank = 1 ;
```

returning:

mother	child
Sophia	Vivian
Lisbeth	Lucy
Claude	Marc
Janet	Arthur

However, note the following pitfall: trying to get the names of all mothers having more than 2 children cannot be done by:

```
SELECT mother FROM xchild2 where rank > 2;
```

This is because with no row multiplication being done, the rank value is always 1. The correct way to obtain this result is longer but cannot use the ROWNUM column:

```
SELECT mother FROM xchild2 group by mother having count(child) > 2;
```

XCOL tables based on specified views

Instead of specifying a source table name via the TABNAME option, it is possible to retrieve data from a "view" whose definition is given in a new option SRCDEF . For instance:

```
create table xsvars engine=connect table_type=XCOL
srcdef='show variables like "optimizer_switch"'
option_list='Colname=Value';
```

Then, for instance:

```
select value from xsvars limit 10;
```

This will display something like:

value
index_merge=on
index_merge_union=on
index_merge_sort_union=on
index_merge_intersection=on

index_merge_sort_intersection=off
engine_condition_pushdown=off
index_condition_pushdown=on
derived_merge=on
derived_with_keys=on
firstmatch=on

Note: All XCOL tables are read only.

5.3.7.6.22 CONNECT OCCUR Table Type

Similarly to the [XCOL](#) table type, [OCCUR](#) is an extension to the [PROXY](#) type when referring to a table or view having several columns containing the same kind of data. It enables having a different view of the table where the data from these columns are put in a single column, eventually causing several rows to be generated from one row of the object table. For example, supposing we have a *pets* table:

name	dog	cat	rabbit	bird	fish
John	2	0	0	0	0
Bill	0	1	0	0	0
Mary	1	1	0	0	0
Lisbeth	0	0	2	0	0
Kevin	0	2	0	6	0
Donald	1	0	0	0	3

We can create an occur table by:

```
create table xpet (
  name varchar(12) not null,
  race char(6) not null,
  number int not null)
engine=connect table_type=occur tabname=pets
option_list='OccurCol=number,RankCol=race'
Colist='dog,cat,rabbit,bird,fish';
```

When displaying it by

```
select * from xpet;
```

We will get the result:

name	race	number
John	dog	2
Bill	cat	1
Mary	dog	1
Mary	cat	1
Lisbeth	rabbit	2
Kevin	cat	2
Kevin	bird	6
Donald	dog	1
Donald	fish	3

First of all, the values of the column listed in the Colist option have been put in a unique column whose name is given by the OccurCol option. When several columns have non null (or pseudo-null) values, several rows are generated, with the other normal columns values repeated.

In addition, an optional special column was added whose name is given by the RankCol option. This column contains the

name of the source column from which the value of the OccurCol column comes from. It permits here to know the race of the pets whose number is given in *number*.

This table type permit to make queries that would be more complicated to make on the original tables. For instance to know who as more than 1 pet of a kind, you can simply ask:

```
select * from xpet where number > 1;
```

You will get the result:

name	race	number
John	dog	2
Lisbeth	rabbit	2
Kevin	cat	2
Kevin	bird	6
Donald	fish	3

Note 1: Like for [XCOLD tables](#), no row multiplication for queries not implying the Occur column.

Note 2: Because the OccurCol was declared "not null" no rows were generated for null or pseudo-null values of the column list. If the OccurCol is declared as nullable, rows are also generated for columns containing null or pseudo-null values.

Occur tables can be also defined from views or source definition. Also, CONNECT is able to generate the column definitions if not specified. For example:

```
create table ocsrc engine=connect table_type=occur
colist='january,february,march,april,may,june,july,august,september,
october,november,december' option_list='rankcol=month,occurcol=day'
srcdef='select ''Foo'' name, 8 january, 7 february, 2 march, 1 april,
      8 may, 14 june, 25 july, 10 august, 13 september, 22 october, 28
      november, 14 december';
```

This table is displayed as:

name	month	day
Foo	january	8
Foo	february	7
Foo	march	2
Foo	april	1
Foo	may	8
Foo	june	14
Foo	july	25
Foo	august	10
Foo	september	13
Foo	october	22
Foo	november	28
Foo	december	14

5.3.7.6.23 CONNECT PIVOT Table Type

Contents

1. Using the PIVOT Tables Type
2. Restricting the Columns in a Pivot Table
3. PIVOT Create Table Syntax
 1. Additional Access Options
4. Defining a Pivot Table
 1. Defining a Pivot Table from a Source Table
 2. Directly Defining the Source of a Pivot Table in SQL
5. Specifying the Columns Corresponding to the Pivot Column
6. Pivoting Big Source Tables

This table type can be used to transform the result of another table or view (called the source table) into a pivoted table along “pivot” and “facts” columns. A pivot table is a great reporting tool that sorts and sums (by default) independent of the original data layout in the source table.

For example, let us suppose you have the following “Expenses” table:

Who	Week	What	Amount
Joe	3	Beer	18.00
Beth	4	Food	17.00
Janet	5	Beer	14.00
Joe	3	Food	12.00
Joe	4	Beer	19.00
Janet	5	Car	12.00
Joe	3	Food	19.00
Beth	4	Beer	15.00
Janet	5	Beer	19.00
Joe	3	Car	20.00
Joe	4	Beer	16.00
Beth	5	Food	12.00
Beth	3	Beer	16.00
Joe	4	Food	17.00
Joe	5	Beer	14.00
Janet	3	Car	19.00
Joe	4	Food	17.00
Beth	5	Beer	20.00
Janet	3	Food	18.00
Joe	4	Beer	14.00
Joe	5	Food	12.00
Janet	3	Beer	18.00
Janet	4	Car	17.00
Janet	5	Food	12.00

Pivoting the table contents using the 'Who' and 'Week' fields for the left columns, and the 'What' field for the top heading and summing the 'Amount' fields for each cell in the new table, gives the following desired result:

Who	Week	Beer	Car	Food
Beth	3	16.00	0.00	0.00
Beth	4	15.00	0.00	17.00
Beth	5	20.00	0.00	12.00
Janet	3	18.00	19.00	18.00
Janet	4	0.00	17.00	0.00

Janet	5	33.00	12.00	12.00
Joe	3	18.00	20.00	31.00
Joe	4	49.00	0.00	34.00
Joe	5	14.00	0.00	12.00

Note that SQL enables you to get the same result presented differently by using the “group by” clause, namely:

```
select who, week, what, sum(amount) from expenses
      group by who, week, what;
```

However there is no way to get the pivoted layout shown above just using SQL. Even using embedded SQL programming for some DBMS is not quite simple and automatic.

The Pivot table type of CONNECT makes doing this much simpler.

Using the PIVOT Tables Type

To get the result shown in the example above, just define it as a new table with the statement:

```
create table pivex
engine=connect table_type=pivot tabname=expenses;
```

You can now use it as any other table, for instance to display the result shown above, just say:

```
select * from pivex;
```

The CONNECT implementation of the PIVOT table type does much of the work required to transform the source table:

1. Finding the “Facts” column, by default the last column of the source table. Finding “Facts” or “Pivot” columns work only for table based pivot tables. They do not for view or srcdef based pivot tables, for which they must be explicitly specified.
2. Finding the “Pivot” column, by default the last remaining column.
3. Choosing the aggregate function to use, “SUM” by default.
4. Constructing and executing the “Group By” on the “Facts” column, getting its result in memory.
5. Getting all the distinct values in the “Pivot” column and defining a “Data” column for each.
6. Spreading the result of the intermediate memory table into the final table.

The source table “Pivot” column must not be nullable (there are no such things as a “null” column) The creation will be refused even is this nullable column actually does not contain null values.

If a different result is desired, Create Table options are available to change the defaults used by Pivot. For instance if we want to display the average expense for each person and product, spread in columns for each week, use the following statement:

```
create table pivex2
engine=connect table_type=pivot tabname=expenses
option_list='PivotCol=Week,Function=AVG';
```

Now saying:

```
select * from pivex2;
```

Will display the resulting table:

Who	What	3	4	5
Beth	Beer	16.00	15.00	20.00
Beth	Food	0.00	17.00	12.00
Janet	Beer	18.00	0.00	16.50
Janet	Car	19.00	17.00	12.00
Janet	Food	18.00	0.00	12.00

Joe	Beer	18.00	16.33	14.00
Joe	Car	20.00	0.00	0.00
Joe	Food	15.50	17.00	12.00

Restricting the Columns in a Pivot Table

Let us suppose that we want a Pivot table from expenses summing the expenses for all people and products whatever week it was bought. We can do this just by removing from the pivex table the week column from the column list.

```
alter table pivex drop column week;
```

The result we get from the new table is:

Who	Beer	Car	Food
Beth	51.00	0.00	29.00
Janet	51.00	48.00	30.00
Joe	81.00	20.00	77.00

Note: Restricting columns is also needed when the source table contains extra columns that should not be part of the pivot table. This is true in particular for key columns that prevent a proper grouping.

PIVOT Create Table Syntax

The Create Table statement for PIVOT tables uses the following syntax:

```
create table pivot_table_name
[(column_definition)]
engine=CONNECT table_type=PIVOT
{tablename='source_table_name' | srcdef='source_table_def'}
[option_list='pivot_table_option_list'];
```

The column definition has two sets of columns:

1. A set of columns belonging to the source table, not including the “facts” and “pivot” columns.
2. “Data” columns receiving the values of the aggregated “facts” columns named from the values of the “pivot” column. They are indicated by the “flag” option.

The **options** and **sub-options** available for Pivot tables are:

Option	Type	Description
Tabname	<i>[DB.]Name</i>	The name of the table to “pivot”. If not set SrcDef must be specified.
SrcDef	<i>SQL_statement</i>	The statement used to generate the intermediate mysql table.
DBname	<i>name</i>	The name of the database containing the source table. Defaults to the current database.
Function*	<i>name</i>	The name of the aggregate function used for the data columns, SUM by default.
PivotCol*	<i>name</i>	Specifies the name of the Pivot column whose values are used to fill the “data” columns having the flag option.
FncCol*	<i>[func([name])]</i>	Specifies the name of the data “Facts” column. If the form func(name) is used, the aggregate function name is set to func.
Groupby*	<i>Boolean</i>	Set it to True (1 or Yes) if the table already has a GROUP BY format.
Accept*	<i>Boolean</i>	To accept non matching Pivot column values.

- : These options must be specified in the OPTION_LIST.

Additional Access Options

There are four cases where pivot must call the server containing the source table or on which the SrcDef statement must be executed:

1. The source table is not a CONNECT table.
2. The SrcDef option is specified.
3. The source table is on another server.
- 4.

The columns are not specified.

By default, pivot tries to call the currently used server using host=localhost, user=root not using password, and port=3306. However, this may not be what is needed, in particular if the local root user has a password in which case you can get an "access denied" error message when creating or using the pivot table.

Specify the host, user, password and/or port options in the option_list to override the default connection options used to access the source table, get column specifications, execute the generated group by or SrcDef query.

Defining a Pivot Table

There are principally two ways to define a PIVOT table:

1. From an existing table or view.
2. Directly giving the SQL statement returning the result to pivot.

Defining a Pivot Table from a Source Table

The **tablename** standard table option is used to give the name of the source table or view.

For tables, the internal Group By will be internally generated, except when the GROUPBY option is specified as true. Do it only when the table or view has a valid GROUP BY format.

Directly Defining the Source of a Pivot Table in SQL

Alternatively, the internal source can be directly defined using the **SrcDef** option that must have the proper group by format.

As we have seen above, a proper Pivot Table is made from an internal intermediate table resulting from the execution of a GROUP BY statement. In many cases, it is simpler or desirable to directly specify this when creating the pivot table. This may be because the source is the result of a complex process including filtering and/or joining tables.

To do this, use the **SrcDef** option, often replacing all other options. For instance, suppose that in the first example we are only interested in weeks 4 and 5. We could of course display it by:

```
select * from pivex where week in (4,5);
```

However, what if this table is a huge table? In this case, the correct way to do it is to define the pivot table as this:

```
create table pivex4
engine=connect table_type=pivot
option_list='PivotCol=what,FncCol=amount'
SrcDef='select who, week, what, sum(amount) from expenses
where week in (4,5) group by who, week, what';
```

If your source table has millions of records and you plan to pivot only a small subset of it, doing so will make a lot of a difference performance wise. In addition, you have entire liberty to use expressions, scalar functions, aliases, join, where and having clauses in your SQL statement. The only constraint is that you are responsible for the result of this statement to have the correct format for the pivot processing.

Using SrcDef also permits to use expressions and/or scalar functions. For instance:

```
create table xpivot (
Who char(10) not null,
What char(12) not null,
First double(8,2) flag=1,
Middle double(8,2) flag=1,
Last double(8,2) flag=1)
engine=connect table_type=PIVOT
option_list='PivotCol=wk,FncCol=amnt'
Srcdef='select who, what, case when week=3 then ''First'' when
week=5 then ''Last'' else ''Middle'' end as wk, sum(amount) *
6.56 as amnt from expenses group by who, what, wk';
```

Now the statement:

```
select * from xpivot;
```

Will display the result:

Who	What	First	Middle	Last
-----	------	-------	--------	------

Beth	Beer	104.96	98.40	131.20
Beth	Food	0.00	111.52	78.72
Janet	Beer	118.08	0.00	216.48
Janet	Car	124.64	111.52	78.72
Janet	Food	118.08	0.00	78.72
Joe	Beer	118.08	321.44	91.84
Joe	Car	131.20	0.00	0.00
Joe	Food	203.36	223.04	78.72

Note 1: to avoid multiple lines having the same fixed column values, it is mandatory in **SrcDef** to place the pivot column at the end of the group by list.

Note 2: in the create statement **SrcDef**, it is mandatory to give aliases **to** the columns containing expressions so they are recognized by the other options.

Note 3: in the **SrcDef** select statement, quotes must be escaped because the entire statement is passed to MariaDB between quotes. Alternatively, specify it between double quotes.

Note 4: We could have left **CONNECT** do the column definitions. However, because they are defined from the sorted names, the **Middle** column had been placed at the end of them.

Specifying the Columns Corresponding to the Pivot Column

These columns must be named from the values existing in the “pivot” column. For instance, supposing we have the following *pet* table:

name	race	number
John	dog	2
Bill	cat	1
Mary	dog	1
Mary	cat	1
Lisbeth	rabbit	2
Kevin	cat	2
Kevin	bird	6
Donald	dog	1
Donald	fish	3

Pivoting it using *race* as the pivot column is done with:

```
create table pivot
engine=connect table_type=pivot tabname=pet
option_list='PivotCol=race,groupby=1';
```

This gives the result:

name	dog	cat	rabbit	bird	fish
John	2	0	0	0	0
Bill	0	1	0	0	0
Mary	1	1	0	0	0
Lisbeth	0	0	2	0	0
Kevin	0	2	0	6	0
Donald	1	0	0	0	3

By the way, does this ring a bell? It shows that in a way **PIVOT** tables are doing the opposite of what **OCCUR** tables do.

We can alternatively define specifically the table columns but what happens if the Pivot column contains values that is not matching a “data” column? There are three cases depending on the specified options and flags.

First case: If no specific options are specified, this is an error an when trying to display the table. The query will abort with an error message stating that a non-matching value was met. Note that because the column list is established when creating the table, this is prone to occur if some rows containing new values for the pivot column are inserted in the source table. If this happens, you should re-create the table or manually add the new columns to the pivot table.

Second case: The accept option was specified. For instance:

```
create table xpivot2 (  
name varchar(12) not null,  
dog int not null default 0 flag=1,  
cat int not null default 0 flag=1)  
engine=connect table_type=pivot tabname=pet  
option_list='PivotCol=race,groupby=1,Accept=1';
```

No error will be raised and the non-matching values will be ignored. This table will be displayed as:

name	dog	cat
John	2	0
Bill	0	1
Mary	1	1
Lisbeth	0	0
Kevin	0	2
Donald	1	0

Third case: A “dump” column was specified with the flag value equal to 2. All non-matching values will be added in this column. For instance:

```
create table xpivot (  
name varchar(12) not null,  
dog int not null default 0 flag=1,  
cat int not null default 0 flag=1,  
other int not null default 0 flag=2)  
engine=connect table_type=pivot tabname=pet  
option_list='PivotCol=race,groupby=1';
```

This table will be displayed as:

name	dog	cat	other
John	2	0	0
Bill	0	1	0
Mary	1	1	0
Lisbeth	0	0	2
Kevin	0	2	6
Donald	1	0	3

It is a good idea to provide such a “dump” column if the source table is prone to be inserted new rows that can have a value for the pivot column that did not exist when the pivot table was created.

Pivoting Big Source Tables

This may sometimes be risky. If the pivot column contains too many distinct values, the resulting table may have too many columns. In all cases the process involved, finding distinct values when creating the table or doing the group by when using it, can be very long and sometimes can fail because of exhausted memory.

Restrictions by a where clause should be applied to the source table when creating the pivot table rather than to the pivot table itself. This can be done by creating an intermediate table or using as source a view or a srctdef option.

5.3.7.6.24 CONNECT TBL Table Type: Table List

Contents

1. [Sub-tables of not CONNECT engines](#)
2. [Using the TABID special column](#)
3. [Parallel Execution](#)

This type allows defining a table as a list of tables of any engine and type. This is more flexible than multiple tables that must be all of the same file type. This type does, but is more powerful than, what is done with the [MERGE](#) engine.

The list of the columns of the TBL table may not necessarily include all the columns of the tables of the list. If the name of some columns is different in the sub-tables, the column to use can be specified by its position given by the `FLAG` option of the column. If the `ACCEPT` option is set to true (Y or 1) columns that do not exist in some of the sub-tables are accepted and their value will be null or pseudo-null (this depends on the nullability of the column) for the tables not having this column. The column types can also be different and an automatic conversion will be done if necessary.

Note: If not specified, the column definitions are retrieved from the first table of the table list.

The default database of the sub-tables is the current database or if not, can be specified in the `DBNAME` option. For the tables that are not in the default database, this can be specified in the table list. For instance, to create a table based on the French table *employe* in the current database and on the English table *employee* of the *db2* database, the syntax of the create statement can be:

```
CREATE TABLE allemp (
  SERIALNO char(5) NOT NULL flag=1,
  NAME varchar(12) NOT NULL flag=2,
  SEX smallint(1),
  TITLE varchar(15) NOT NULL flag=3,
  MANAGER char(5) DEFAULT NULL flag=4,
  DEPARTMENT char(4) NOT NULL flag=5,
  SECRETARY char(5) DEFAULT NULL flag=6,
  SALARY double(8,2) NOT NULL flag=7)
ENGINE=CONNECT table_type=TBL
table_list='employe,db2.employee' option_list='Accept=1';
```

The search for columns in sub tables is done by name and, if they exist with a different name, by their position given by a not null `FLAG` option. Column `sex` exists only in the English table (`FLAG` is 0). Its values will null value for the French table.

For instance, the query:

```
select name, sex, title, salary from allemp where department = 318;
```

Can reply:

NAME	SEX	TITLE	SALARY
BARBOUD	NULL	VENDEUR	9700.00
MARCHANT	NULL	VENDEUR	8800.00
MINIARD	NULL	ADMINISTRATIF	7500.00
POUPIN	NULL	INGENIEUR	7450.00
ANTERPE	NULL	INGENIEUR	6850.00
LOULOUTE	NULL	SECRETAIRE	4900.00
TARTINE	NULL	OPERATRICE	2800.00
WERTHER	NULL	DIRECTEUR	14500.00
VOITURIN	NULL	VENDEUR	10130.00
BANCROFT	2	SALESMAN	9600.00

MERCHANT	1	SALESMAN	8700.00
SHRINKY	2	ADMINISTRATOR	7500.00
WALTER	1	ENGINEER	7400.00
TONGHO	1	ENGINEER	6800.00
HONEY	2	SECRETARY	4900.00
PLUMHEAD	2	TYPIST	2800.00
WERTHER	1	DIRECTOR	14500.00
WHEELFOR	1	SALESMAN	10030.00

The first 9 rows, coming from the French table, have a null for the sex value. They would have 0 if the sex column had been created NOT NULL.

Sub-tables of not CONNECT engines

Sub-tables are accessed as `PROXY` tables. For not CONNECT sub-tables that are accessed via the MySQL API, it is possible like with `PROXY` to change the MYSQL default options. Of course, this will apply to all not CONNECT tables of the list.

Using the TABID special column

The TABID special column can be used to see from which table the rows come from and to restrict the access to only some of the sub-tables.

Let us see the following example where t1 and t2 are MyISAM tables similar to the ones given in the `MERGE` description:

```
create table xt1 (
  a int(11) not null,
  message char(20))
engine=CONNECT table_type=MYSQL tabname='t1'
option_list='database=test,user=root';

create table xt2 (
  a int(11) not null,
  message char(20))
engine=CONNECT table_type=MYSQL tabname='t2'
option_list='database=test,user=root';

create table toto (
  tabname char(8) not null special='TABID',
  a int(11) not null,
  message char(20))
engine=CONNECT table_type=TBL table_list='xt1,xt2';

select * from total;
```

The result returned by the SELECT statement is:

tabname	a	message
xt1	1	Testing
xt1	2	table
xt1	3	t1
xt2	1	Testing
xt2	2	table
xt2	3	t2

Now if you send the query:

```
select * from total where tabname = 'xt2';
```

CONNECT will analyze the where clause and only read the `xt1` table. This can save time if you want to retrieve only a few

sub-tables from a TBL table containing many sub-tables.

Parallel Execution

Parallel Execution is currently unavailable until some bugs are fixed.

When the sub-tables are located on different servers, it is possible to execute the remote queries simultaneously instead of sequentially. To enable this, set the thread option to yes.

Additional options available for this table type:

Option	Description
Maxerr	The max number of missing tables in the table list before an error is raised. Defaults to 0.
Accept	If true, missing columns are accepted and return null values. Defaults to false.
Thread	If true, enables parallel execution of remote sub-tables.

These options can be specified in the `OPTION_LIST`.

5.3.7.6.25 CONNECT - Using the TBL and MYSQL Table Types Together

Contents

1. [Remotely executing complex queries](#)
2. [Providing a list of servers](#)

Used together, these types lift all the limitations of the [FEDERATED](#) and [MERGE](#) engines.

MERGE: Its limitation is obvious, the merged tables must be identical [MyISAM](#) tables, and MyISAM is not even the default engine for MariaDB. However, [TBL](#) accesses a collection of [CONNECT](#) tables, but because these tables can be user specified or internally created [MYSQL](#) tables, there is no limitation to the type of the tables that can be merged.

TBL is also much more flexible. The merged tables must not be "identical", they just should have the columns defined in the TBL table. If the type of one column in a merged table is not the one of the corresponding column of the TBL table, the column value will be converted. As we have seen, if one column of the TBL table of the TBL column does not exist in one of the merged table, the corresponding value will be set to null. If columns in a sub-table have a different name, they can be accessed by position using the FLAG column option of [CONNECT](#).

However, one limitation of the TBL type regarding [MERGE](#) is that TBL tables are currently read-only; [INSERT](#) is not supported by TBL. Also, keep using [MERGE](#) to access a list of identical [MyISAM](#) tables because it will be faster, not passing by the MySQL API.

FEDERATED(X): The main limitation of [FEDERATED](#) is to access only MySQL/MariaDB tables. The [MYSQL](#) table type of [CONNECT](#) has the same limitation but [CONNECT](#) provides the [ODBC table type](#) and [JDBC table type](#) that can access tables of any RDBS providing an ODBC or JDBC driver (including MySQL even it is not really useful!)

Another major limitation of [FEDERATED](#) is to access only one table. By combining TBL and [MYSQL](#) tables, [CONNECT](#) enables to access a collection of local or remote tables as one table. Of course the sub-tables can be on different servers. With one [SELECT](#) statement, a company manager will be able to interrogate results coming from all of his subsidiary computers. This is great for distribution, banking, and many other industries.

Remotely executing complex queries

Many companies or administrations must deal with distributed information. [CONNECT](#) enables to deal with it efficiently without having to copy it to a centralized database. Let us suppose we have on some remote network machines *m1*, *m2*, ... *mn* some information contained in two tables *t1* and *t2*.

Suppose we want to execute on all servers a query such as:

```
select c1, sum(c2) from t1 a, t2 b where a.id = b.id group by c1;
```

This raises many problems. Returning the column values of the *t1* and *t2* tables from all servers can be a lot of network traffic. The group by on the possibly huge resulting tables can be a long process. In addition, the join on the *t1* and *t2* tables may be relevant only if the joined tuples belong to the same machine, obliging to add a condition on an additional tabid or servid special column.

All this can be avoided and optimized by forcing the query to be locally executed on each server and retrieving only the small results of the group by queries. Here is how to do it. For each remote machine, create a table that will retrieve the locally executed query. For instance for m1:

```
create table rt1 engine=connect option_list='host=m1'
srcdef='select c1, sum(c2) as sc2 from t1 a, t2 b where a.id = b.id group by c1';
```

Note the alias for the functional column. An alias would be required for the c1 column if its name was different on some machines. The t1 and t2 table names can also be eventually different on the remote machines. The true names must be used in the SRCDEF parameter. This will create a set of tables with two columns named c1 and sc2^[1].

Then create the table that will retrieve the result of all these tables:

```
create table rtall engine=connect table_type=tbl
table_list='rt1,rt2,...,rtn' option_list='thread=yes';
```

Now you can retrieve the desired result by:

```
select c1, sum(sc2) from rtall;
```

Almost all the work will be done on the remote machines, simultaneously thanks to the thread option, making this query super-fast even on big tables placed on many remote machines.

Thread is currently experimental. Use it only for test and report any malfunction on [JIRA](#).

Providing a list of servers

An interesting case is when the query to run on remote machines is the same for all of them. It is then possible to avoid declaring all sub-tables. In this case, the table list option will be used to specify the list of servers the SRCDEF query must be sent. This will be a list of URL's and/or Federated server names.

For instance, supposing that federated servers srv1, srv2, ... srvn were created for all remote servers, it will be possible to create a tbl table allowing getting the result of a query executed on all of them by:

```
create table qall [column definition]
engine=connect table_type=TBL srcdef='a query'
table_list='srv1,srv2,...,srvn' [option_list='thread=yes'];
```

For instance:

```
create table verall engine=connect table_type=TBL srcdef='select @@version' table_list=',server_c
select * from verall;
```

This reply:

@@version
10.0.3-MariaDB-debug
10.0.2-MariaDB

Here the server list specifies a void server corresponding to the local running MariaDB and a federated server named *server_one*.

- ¹ To generate the columns from the SRCDEF query, CONNECT must execute it. This will make sure it is ok. However, if the remote server is not connected yet, or the remote table not existing yet, you can alternatively specify the columns in the create table statement.

5.3.7.6.26 CONNECT Table Types - Special "Virtual" Tables

Contents

1. [DIR Type](#)
 1. [The Subdir option](#)
 2. [The Nodir option \(Windows\)](#)
2. [Windows Management Instrumentation Table Type "WMI"](#)
 1. [Getting column information](#)
 2. [Performance Consideration](#)
 3. [Syntax of WMI queries](#)
3. [MAC Address Table Type "MAC"](#)

The special table types supported by CONNECT are the Virtual table type ([VIR](#) - introduced in [MariaDB 10.0.15](#)), Directory Listing table type (DIR), the Windows Management Instrumentation Table Type (WMI), and the "Mac Address" type (MAC).

These tables are "virtual tables", meaning they have no physical data but rather produce result data using specific algorithms. Note that this is close to what Views are, so they could be regarded as special views.

DIR Type

A table of type DIR returns a list of file name and description as a result set. To create a DIR table, use a Create Table statement such as:

```
create table source (  
  DRIVE char(2) NOT NULL,  
  PATH varchar(256) NOT NULL,  
  FNAME varchar(256) NOT NULL,  
  FTYPE char(4) NOT NULL,  
  SIZE double(12,0) NOT NULL flag=5,  
  MODIFIED datetime NOT NULL)  
engine=CONNECT table_type=DIR file_name='..\*\*.cc';
```

When used in a query, the table returns the same file information listing than the system "DIR *.cc" statement would return if executed in the same current directory (here supposedly ..)

For instance, the query:

```
select fname, size, modified from source  
where fname like '%handler%';
```

Displays:

fname	size	modified
handler	152177	2011-06-13 18:08:29
sql_handler	25321	2011-06-13 18:08:31

Note: the important item in this table is the flag option value (set sequentially from 0 by default) because it determines which particular information item is returned in the column:

Flag value	Information
0	The disk drive (Windows)
1	The file path
2	The file name
3	The file type
4	The file attribute
5	The file size
6	The last write access date
7	The last read access date
8	The file creation date

The Subdir option

When specified in the create table statement, the subdir option indicates to list, in addition to the files contained in the specified directory, all the files verifying the filename pattern that are contained in sub-directories of the specified directory. For instance, using:

```
create table data (
  PATH varchar(256) NOT NULL flag=1,
  FNAME varchar(256) NOT NULL,
  FTYPE char(4) NOT NULL,
  SIZE double(12,0) NOT NULL flag=5)
engine=CONNECT table_type=DIR file_name='*.frm'
option_list='subdir=1';

select path, count(*), sum(size) from data group by path;
```

You will get the following result set showing how many tables are created in the MariaDB databases and what is the total length of the FRM files:

path	count(*)	sum(size)
\\CommonSource\\mariadb-5.2.7\\sql\\data\\connect\\	30	264469
\\CommonSource\\mariadb-5.2.7\\sql\\data\\mysql\\	23	207168
\\CommonSource\\mariadb-5.2.7\\sql\\data\\test\\	22	196882

The Nodir option (Windows)

The Boolean Nodir option can be set to false (0 or no) to add directories that match the file name pattern from the listed files (it is true by default). This is an addition to CONNECT version 1.6. Previously, directory names matching pattern were listed on Windows. Directories were and are never listed on Linux.

Note: The way file names are retrieved makes positional access to them impossible. Therefore, DIR tables cannot be indexed or sorted when it is done using positions.

Be aware, in particular when using the subdir option, that queries on DIR tables are slow and can last almost forever if made on a directory that contains a great number of files in it and its sub-directories.

dir tables can be used to populate a list of files used to create a multiple=2 table. However, this is not as useful as it was when the multiple 3 did not exist.

Windows Management Instrumentation Table Type “WMI”

Note: This table type is available on Windows only.

WMI provides an operating system interface through which instrumented components provide information. Some Microsoft tools to retrieve information through WMI are the WMIC console command and the WMI CMI Studio application.

The CONNECT WMI table type enables administrators and operators not capable of scripting or programming on top of WMI to enjoy the benefit of WMI without even learning about it. It permits to present this information as tables that can be queried, transformed, copied in documents or other tables.

To create a WMI table displaying information coming from a WMI provider, you must provide the namespace and the class name that characterize the information you want to retrieve. The best way to find them is to use the WMI CIM Studio that have tools to browse namespaces and classes and that can display the names of the properties of that class.

The column names of the tables must be the names (case insensitive) of the properties you want to retrieve. For instance:

```
create table alias (
  friendlyname char(32) not null,
  target char(50) not null)
engine=CONNECT table_type='WMI'
option_list='Namespace=root\\cli,Class=Msft_CliAlias';
```

WMI tables returns one row for each instance of the related information. The above example is handy to get the class equivalent of the alias of the WMIC command and also to have a list of many classes commonly used.

Because most of the useful classes belong to the 'root\\cimv2' namespace, this is the default value for WMI tables when the namespace is not specified. Some classes have many properties whose name and type may not be known when creating the table. To find them, you can use the WMI CMI Studio application but his will be rarely required because CONNECT is

able to retrieve them.

Actually, the class specification also has default values for some namespaces. For the 'root\cli' namespace the class name defaults to 'Msft_CliAlias' and for the 'root_cimv2' namespace the class default value is 'Win32_ComputerSystemProduct'. Because many class names begin with 'Win32_' it is not necessary to say it and specifying the class as 'Product' will effectively use class 'Win32_Product'.

For example if you define a table as:

```
create table CSPROD engine=CONNECT table_type='WMI';
```

It will return the information on the current machine, using the class ComputerSystemProduct of the CIMV2 namespace. For instance:

```
select * from csprod;
```

Will return a result such as:

Column	Row 1
Caption	Computer system product
Description	Computer system product
IdentifyingNumber	LXAP50X32982327A922300
Name	Aspire 8920
SKUNumber	
UUID	00FC523D-B8F7-DC12-A70E-00B0D1A46136
Vendor	Acer
Version	Aspire 8920

Note: This is a transposed display that can be obtained with some GUI.

Getting column information

An issue, when creating a WMI table, is to make its column definition. Indeed, even when you know the namespace and the class for the wanted information, it is not easy to find what are the names and types of its properties. However, because CONNECT can retrieve this information from the WMI provider, you can simply omit defining columns and CONNECT will do the job.

Alternatively, you can get this information using a catalog table (see below).

Performance Consideration

Some WMI providers can be very slow to answer. This is not an issue for those that return few object instances, such as the ones returning computer, motherboard, or Bios information. They generally return only one row (instance). However, some can return many rows, in particular the "CIM_DataFile" class. This is why care must be taken about them.

Firstly, it is possible to limit the allocated result size by using the 'Estimate' create table option. To avoid result truncation, CONNECT allocates a result of 100 rows that is enough for almost all tables. The 'Estimate' option permits to reduce this size for all classes that return only a few rows, and in some rare case to increase it to avoid truncation.

However, it is not possible to limit the time taken by some WMI providers to answer, in particular the CIM_DATAFILE class. Indeed the Microsoft documentation says about it:

"Avoid enumerating or querying for all instances of CIM_DataFile on a computer because the volume of data is likely to either affect performance or cause the computer to stop responding."

Sure enough, even a simple query such as:

```
select count(*) from cim where drive = 'D:' and path like '\\MariaDB\\%';
```

is prone to last almost forever (probably due to the LIKE clause). This is why, when not asking for some specific items, you should consider using the DIR table type instead.

Syntax of WMI queries

Queries to WMI providers are done using the WQL language, not the SQL language. CONNECT does the job of making the WQL query. However, because of the restriction of the WQL syntax, the WHERE clause will be generated only when respecting the following restrictions:

1. No function.
2. No comparison between two columns.
3. No expression (currently a CONNECT restriction)
4. No BETWEEN and IN predicates.

Filtering with WHERE clauses not respecting these conditions will still be done by MariaDB only, except in the case of CIM_Datafile class for the reason given above.

However, there is one point that is not covered yet, the syntax used to specify dates in queries. WQL does not recognize dates as number items but translates them to its internal format dates specified as text. Many formats are recognized as described in the Microsoft documentation but only one is useful because common to WQL and MariaDB SQL. Here is an example of a query on a table named "cim" created by:

```
create table cim (  
  Name varchar(255) not null,  
  LastModified datetime not null)  
engine=CONNECT table_type='WMI'  
option_list='class=CIM_DataFile,estimate=5000';
```

The date must be specified with the format in which CIM DATETIME values are stored (WMI uses the date and time formats defined by the Distributed Management Task Force).

```
select * from cim where drive = 'D:' and path = '\\PlugDB\Bin\  
and lastmodified > '20120415000000.000000+120';
```

This syntax must be strictly respected. The text has the format:

```
yyyymmddHHMMSS.mmmmmmsUUU
```

It is: year, month, day, hour, minute, second, millisecond, and signed minute deviation from UTC [🌐](#). This format is locale-independent so you can write a query that runs on any machine.

Note 1: The WMI table type is available only in Windows versions of CONNECT.

Note 2: WMI tables are read only.

Note 3: WMI tables are not indexable.

Note 4: WMI consider all strings as case insensitive.

MAC Address Table Type “MAC”

Note: This table type is available on Windows only.

This type is used to display various general information about the computer and, in particular, about its network cards. To create such a table, the syntax to use is:

```
create table tabname (column definition)  
engine=CONNECT table_type=MAC;
```

Column names can be freely chosen because their signification, i.e. the values they will display, comes from the specified Flag option. The valid values for Flag are:

Flag	Valeur	Type
1	Host name	varchar(132)
2	Domain	varchar(132)
3	DNS address	varchar(24)
4	Node type	int(1)
5	Scope ID	varchar(256)
6	Routing	int(1)

7	Proxy	int(1)
8	DNS	int(1)
10	Name	varchar(260)
11	Description	varchar(132)
12	MAC address	char(24)
13	Type	int(3)
14	DHCP	int(1)
15	IP address	char(16)
16	SUBNET mask	char(16)
17	GATEWAY	char(16)
18	DHCP server	char(16)
19	Have WINS	int(1)
20	Primary WINS	char(16)
21	Secondary WINS	char(16)
22	Lease obtained	datetime
23	Lease expires	datetime

Note: The information of columns having a Flag value less than 10 are unique for the computer, the other ones are specific to the network cards of the computer.

For instance, you can define the table *macaddr* as:

```
create table macaddr (
  Host varchar(132) flag=1,
  Card varchar(132) flag=11,
  Address char(24) flag=12,
  IP char(16) flag=15,
  Gateway char(16) flag=17,
  Lease datetime flag=23)
engine=CONNECT table_type=MAC;
```

If you execute the query:

```
select host, address, ip, gateway, lease from macaddr;
```

It will return, for example:

Host	Address	IP	Gateway	Lease
OLIVIER	00-A0-D1-A4-61-36	0.0.0.0	0.0.0.0	1970-01-01 00:00:00
OLIVIER	00-1D-E0-9B-90-0B	192.168.0.10	192.168.0.254	2011-09-18 10:28:5

5.3.7.6.27 CONNECT Table Types - VIR

Contents

1. [VIR Type](#)
 1. [Displaying constants or expressions](#)
 2. [Generating a Table filled with constant values](#)
 3. [VIR tables vs. SEQUENCE tables](#)

VIR Type

A VIR table is a virtual table having only Special or Virtual columns. Its only property is its "size", or cardinality, meaning the number of virtual rows it contains. It is created using the syntax:

```
CREATE TABLE name [coldef] ENGINE=CONNECT TABLE_TYPE=VIR
[BLOCK_SIZE=n];
```

The optional `BLOCK_SIZE` option gives the size of the table, defaulting to 1 if not specified. When its columns are not specified, it is almost equivalent to a [SEQUENCE](#) table “seq_1_to_Size”.

Displaying constants or expressions

Many DBMS use a no-column one-line table to do this, often call “dual”. MySQL and MariaDB use syntax where no table is specified. With `CONNECT`, you can achieve the same purpose with a virtual table, with the noticeable advantage of being able to display several lines. For example:

```
create table virt engine=connect table_type=VIR block_size=10;
select concat('The square root of ', n, ' is') what,
round(sqrt(n),16) value from virt;
```

This will return:

what	value
The square root of 1 is	1.0000000000000000
The square root of 2 is	1.4142135623730951
The square root of 3 is	1.7320508075688772
The square root of 4 is	2.0000000000000000
The square root of 5 is	2.2360679774997898
The square root of 6 is	2.4494897427831779
The square root of 7 is	2.6457513110645907
The square root of 8 is	2.8284271247461903
The square root of 9 is	3.0000000000000000
The square root of 10 is	3.1622776601683795

What happened here? First of all, unlike Oracle “dual” tables that have no columns, a MariaDB table must have at least one column. By default, `CONNECT` creates `VIR` tables with one special column. This can be seen with the `SHOW CREATE TABLE` statement:

```
CREATE TABLE `virt` (
  `n` int(11) NOT NULL `SPECIAL`=ROWID,
  PRIMARY KEY (`n`)
) ENGINE=CONNECT DEFAULT CHARSET=latin1 `TABLE_TYPE`='VIR'
`BLOCK_SIZE`=10
```

This special column is called “n” and its value is the row number starting from 1. It is purely a virtual table and no data file exists corresponding to it and to its index. It is possible to specify the columns of a `VIR` table but they must be `CONNECT` special columns or virtual columns. For instance:

```
create table virt2 (
n int key not null special=rowid,
sig1 bigint as ((n*(n+1))/2) virtual,
sig2 bigint as (((2*n+1)*(n+1)*n)/6) virtual
engine=connect table_type=VIR block_size=10000000;
select * from virt2 limit 995, 5;
```

This table shows the sum and the sum of the square of the n first integers:

n	sig1	sig2
996	496506	329845486
997	497503	330839495
998	498501	331835499
999	499500	332833500

1000	500500	333833500
------	--------	-----------

Note that the size of the table can be made very big as there no physical data. However, the result should be limited in the queries. For instance:

```
select * from virt2 where n = 1664510;
```

Such a query could last very long if the rowid column were not indexed. Note that by default, CONNECT declares the “n” column as a primary key. Actually, VIR tables can be indexed but only on the ROWID (or ROWNUM) columns of the table. This is a virtual index for which no data is stored.

Generating a Table filled with constant values

An interesting use of virtual tables, which often cannot be achieved with a table of any other type, is to generate a table containing constant values. This is easily done with a virtual table. Let us define the table FILLER as:

```
create table filler engine=connect table_type=VIR block_size=5000000;
```

Here we choose a size larger than the biggest table we want to generate. Later if we need a table pre- filled with default and/or null values, we can do for example:

```
create table tp (
  id int(6) key not null,
  name char(16) not null,
  salary float(8,2));
insert into tp select n, 'unknown', NULL from filler where n <= 10000;
```

This will generate a table having 10000 rows that can be updated later when needed. Note that a [SEQUENCE](#) table could have been used here instead of FILLING .

VIR tables vs. SEQUENCE tables

With just its default column, a VIR table is almost equivalent to a [SEQUENCE](#) table. The syntax used is the main difference, for instance:

```
select * from seq_100_to_150_step_10;
```

can be obtained with a VIR table (of size ≥ 15) by:

```
select n*10 from vir where n between 10 and 15;
```

Therefore, the main difference is to be able to define the columns of VIR tables. Unfortunately, there are currently many limitations to virtual columns that hopefully should be removed in the future.

5.3.7.6.28 CONNECT Table Types - OEM: Implemented in an External LIB

Contents

1. [An OEM Table Example](#)
 1. [Some Currently Available OEM Table Modules and Subtypes](#)

Although CONNECT provides a rich set of table types, specific applications may need to access data organized in a way that is not handled by its existing foreign data wrappers (FDW). To handle these cases, CONNECT features an interface that enables developers to implement in C++ the required table wrapper and use it as if it were part of the standard CONNECT table type list. CONNECT can use these additional handlers providing the corresponding external module (dll or shared lib) be available.

To create such a table on an existing handler, use a Create Table statement as shown below.

```
create table xtab (column definitions)
engine=CONNECT table_type=OEM module='libname'
subtype='MYTYPE' [standard table options]
Option_list='Myopt=foo';
```

The option module gives the name of the DLL or shared library implementing the OEM wrapper for the table type. This library must be located in the plugin directory like all other plugins or UDF's.

This library must export a function *GetMYTYPE*. The option subtype enables CONNECT to have the name of the exported function and to use the new table type. Other options are interpreted by the OEM type and can also be specified within the *option_list* option.

Column definitions can be unspecified only if the external wrapper is able to return this information. For this it must export a function *ColMYTYPE* returning these definitions in a format acceptable by the CONNECT discovery function.

Which and how options must be specified and the way columns must be defined may vary depending on the OEM type used and should be documented by the OEM type implementer(s).

An OEM Table Example

The OEM table REST described in [Adding the REST Feature as a Library Called by an OEM Table](#) permits using REST-like tables with MariaDB binary distributions containing but not enabling the [REST table type](#)

Of course, the mongo (dll or so) exporting the GetREST and colREST functions must be available in the plugin directory for all this to work.

Some Currently Available OEM Table Modules and Subtypes

Module	Subtype	Description
libhello	HELLO	A sample OEM wrapper displaying a one line table saying "Hello world"
mongo	MONGO	Enables using tables based on MongoDB collections.
Tabfic	FIC	Handles files having the Windev HyperFile format.
Tabofx	OFC	Handles Open Financial Connectivity files.
Tabofx	QIF	Handles Quicken Interchange Format files.
Cirpack	CRPK	Handles CDR's from Cirpack UTP's.
Tabplg	PLG	Access tables from the PlugDB DBMS.

How to implement an OEM handler is out of the scope of this document.

5.3.7.6.29 CONNECT Table Types - Catalog Tables

A catalog table is one that returns information about another table, or data source. It is similar to what MariaDB commands such as *DESCRIBE* or *SHOW* do. Applied to local tables, this just duplicates what these commands do, with the noticeable difference that they are tables and can be used inside queries as joined tables or inside sub-selects.

But their main interest is to enable querying the structure of external tables that cannot be directly queried with description commands. Let's see an example:

Suppose we want to access the tables from a Microsoft Access database as an ODBC type table. The first information we must obtain is the list of tables existing in this data source. To get it, we will create a catalog table that will return it extracted from the result set of the SQLTables ODBC function:

```
create table tabinfo (
  table_name varchar(128) not null,
  table_type varchar(16) not null)
engine=connect table_type=ODBC catfunc=tables
Connection='DSN=MS Access Database;DBQ=C:/Program
Files/Microsoft Office/Office/1033/FPNWIND.MDB;';
```

The SQLTables function returns a result set having the following columns:

Field	Data Type	Null	Info Type	Flag Value
Table_Cat	char(128)	NO	FLD_CAT	17
Table_Name	char(128)	NO	FLD_SCHEM	18
Table_Name	char(128)	NO	FLD_NAME	1

Table_Type	char(16)	NO	FLD_TYPE	2
Remark	char(128)	NO	FLD_REM	5

Note: The Info Type and Flag Value are CONNECT interpretations of this result.

Here we could have omitted the column definitions of the catalog table or, as in the above example, chose the columns returning the name and type of the tables. If specified, the columns must have the exact name of the corresponding SQLTables result set, or be given a different name with the matching flag value specification.

(The Table_Type can be TABLE, SYSTEM TABLE, VIEW, etc.)

For instance, to get the tables we want to use we can ask:

```
select table_name from tabinfo where table_type = 'TABLE';
```

This will return:

table_name
Categories
Customers
Employees
Products
Shippers
Suppliers

Now we want to create the table to access the CUSTOMERS table. Because CONNECT can retrieve the column description of ODBC tables, it not necessary to specify them in the create table statement:

```
create table Customers engine=connect table_type=ODBC
Connection='DSN=MS Access Database;DBQ=C:/Program
Files/Microsoft Office/Office/1033/FPNWIND.MDB;';
```

However, if we prefer to specify them (to eventually modify them) we must know what the column definitions of that table are. We can get this information with a catalog table. This is how to do it:

```
create table custinfo engine=connect table_type=ODBC
tabname=customers catfunc=columns
Connection='DSN=MS Access Database;DBQ=C:/Program
Files/Microsoft Office/Office/1033/FPNWIND.MDB;';
```

Alternatively it is possible to specify what columns of the catalog table we want:

```
create table custinfo (
column_name char(128) not null,
type_name char(20) not null,
length int(10) not null flag=7,
prec smallint(6) not null flag=9)
engine=connect table_type=ODBC tabname=customers
catfunc=columns
Connection='DSN=MS Access Database;DBQ=C:/Program
Files/Microsoft Office/Office/1033/FPNWIND.MDB;';
```

To get the column info:

```
select * from custinfo;
```

which results in this table:

column_name	type_name	length	prec	nullable
CustomerID	VARCHAR	5	0	1
CompanyName	VARCHAR	40	0	1
ContactName	VARCHAR	30	0	1

ContactTitle	VARCHAR	30	0	1
Address	VARCHAR	60	0	1
City	VARCHAR	15	0	1
Region	VARCHAR	15	0	1
PostalCode	VARCHAR	10	0	1
Country	VARCHAR	15	0	1
Phone	VARCHAR	24	0	1
Fax	VARCHAR	24	0	1

Now you can create the CUSTOMERS table as:

```
create table Customers (
  CustomerID varchar(5),
  CompanyName varchar(40),
  ContactName varchar(30),
  ContactTitle varchar(30),
  Address varchar(60),
  City varchar(15),
  Region varchar(15),
  PostalCode varchar(10),
  Country varchar(15),
  Phone varchar(24),
  Fax varchar(24))
engine=connect table_type=ODBC block_size=10
Connection='DSN=MS Access Database;DBQ=C:/Program
Files/Microsoft Office/Office/1033/FPNWIND.MDB;';
```

Let us explain what we did here: First of all, the creation of the catalog table. This table returns the result set of an ODBC SQLColumns function sent to the ODBC data source. Columns functions always return a data set having some of the following columns, depending on the table type:

Field	Data Type	Null	Info Type	Flag Value	Returned by
Table_Cat*	char(128)	NO	FLD_CAT	17	ODBC, JDBC
Table_Schema*	char(128)	NO	FLD_SCEM	18	ODBC, JDBC
Table_Name	char(128)	NO	FLD_TABNAME	19	ODBC, JDBC
Column_Name	char(128)	NO	FLD_NAME	1	ALL
Data_Type	smallint(6)	NO	FLD_TYPE	2	ALL
Type_Name	char(30)	NO	FLD_TYPENAME	3	ALL
Column_Size*	int(10)	NO	FLD_PREC	4	ALL
Buffer_Length*	int(10)	NO	FLD_LENGTH	5	ALL
Decimal_Digits*	smallint(6)	NO	FLD_SCALE	6	ALL
Radix	smallint(6)	NO	FLD_RADIX	7	ODBC, JDBC, MYSQL
Nullable	smallint(6)	NO	FLD_NULL	8	ODBC, JDBC, MYSQL
Remarks	char(255)	NO	FLD_REM	9	ODBC, JDBC, MYSQL
Collation	char(32)	NO	FLD_CHARSET	10	MYSQL
Key	char(4)	NO	FLD_KEY	11	MYSQL
Default_value	N.A.		FLD_DEFAULT	12	
Privilege	N.A.		FLD_PRIV	13	
Date_fmt	char(32)	NO	FLD_DATEFMT	15	MYSQL
Xpath/Jpath	Varchar(256)	NO	FLD_FORMAT	16	XML/JSON

***: These names have changed since earlier versions of CONNECT.

Note: ALL includes the ODBC, JDBC, MYSQL, DBF, CSV, PROXY, TBL, XML, JSON, XCOL, and WMI table types. More could be added later.

We chose among these columns the ones that were useful for our create statement, using the flag value when we gave them a different name (case insensitive).

The options used in this definition are the same as the one used later for the actual CUSTOMERS data tables except that:

1. The `TABNAME` option is mandatory here to specify what the queried table name is.
2. The `CATFUNC` option was added both to indicate that this is a catalog table, and to specify that we want column information.

Note: If the `TABNAME` option had not been specified, this table would have returned the columns of all the tables defined in the connected data source.

Currently the available `CATFUNC` are:

Function	Specified as:	Applies to table types:
FNC_TAB	tables	ODBC, JDBC, MYSQL
FNC_COL	columns	ODBC, JDBC, MYSQL, DBF, CSV, PROXY, XCOL, TBL, WMI
FNC_DSN	datasources dsn sqldatasources	ODBC
FNC_DRIVER	drivers sqldrivers	ODBC, JDBC

Note: Only the bold part of the function name specification is required.

The `DATASOURCE` and `DRIVERS` functions respectively return the list of available data sources and ODBC drivers available on the system.

The `SQLDataSources` function returns a result set having the following columns:

Field	Data Type	Null	Info Type	Flag value
Name	varchar(256)	NO	FLD_NAME	1
Description	varchar(256)	NO	FLD_REM	9

To get the data source, you can do for instance:

```
create table datasources (
engine=CONNECT table_type=ODBC catfunc=DSN;
```

The `SQLDrivers` function returns a result set having the following columns:

Field	Type	Null	Info Type	Flag value
Description	varchar(128)	YES	FLD_NAME	1
Attributes	varchar(256)	YES	FLD_REM	9

You can get the driver list with:

```
create table drivers
engine=CONNECT table_type=ODBC catfunc=drivers;
```

Another example, WMI table

To create a catalog table returning the attribute names of a WMI class, use the same table options as the ones used with the normal WMI table plus the additional option 'catfunc=columns'. If specified, the columns of such a catalog table can be chosen among the following:

Name	Type	Flag	Description
Column_Name	CHAR	1	The name of the property
Data_Type	INT	2	The SQL data type
Type_Name	CHAR	3	The SQL type name
Column_Size	INT	4	The field length in characters

Buffer_Length	INT	5	Depends on the coding
Scale	INT	6	Depends on the type

If you wish to use a different name for a column, set the Flag column option.

For example, before creating the "csprod" table, you could have created the info table:

```
create table CSPRODCOL (
  Column_name char(64) not null,
  Data_Type int(3) not null,
  Type_name char(16) not null,
  Length int(6) not null,
  Prec int(2) not null flag=6)
engine=CONNECT table_type='WMI' catfunc=col;
```

Now the query:

```
select * from csprodcoll;
```

will display the result:

Column_name	Data_Type	Type_name	Length	Prec
Caption	1	CHAR	255	1
Description	1	CHAR	255	1
IdentifyingNumber	1	CHAR	255	1
Name	1	CHAR	255	1
SKUNumber	1	CHAR	255	1
UUID	1	CHAR	255	1
Vendor	1	CHAR	255	1
Version	1	CHAR	255	1

This can help to define the columns of the matching normal table.

Note 1: The column length, for the Info table as well as for the normal table, can be chosen arbitrarily, it just must be enough to contain the returned information.

Note 2: The Scale column returns 1 for text columns (meaning case insensitive); 2 for float and double columns; and 0 for other numeric columns.

Catalog Table result size limit

Because catalog tables are processed like the information retrieved by "Discovery" when table columns are not specified in a Create Table statement, their result set is entirely retrieved and memory allocated.

By default, this allocation is done for a maximum return line number of:

Catfunc	Max lines
Drivers	256
Data Sources	512
Columns	20,000
Tables	10,000

When the number of lines retrieved for a table is more than this maximum, a warning is issued by CONNECT. This is mainly prone to occur with columns (and also tables) with some data sources having many tables when the table name is not specified.

If this happens, it is possible to increase the default limit using the MAXRES option, for instance:

```
create table allcols engine=connect table_type=odbc
connection='DSN=ORACLE_TEST;UID=system;PWD=manager'
option_list='Maxres=110000' catfunc=columns;
```

Indeed, because the entire table result is memorized before the query is executed; the returned value would be limited even on a query such as:

```
select count(*) from allcols;
```

5.3.7.7 CONNECT - Security

The use of the CONNECT engine requires the `FILE` privilege for "outward" tables. This should not be an important restriction. The use of CONNECT "outward" tables on a remote server seems of limited interest without knowing the files existing on it and must be protected anyway. On the other hand, using it on the local client machine is not an issue because it is always possible to create locally a user with the `FILE` privilege.

5.3.7.8 CONNECT - OEM Table Example

This is an example showing how an OEM table can be implemented.

The header File `my_global.h`:

```
/*
 * Definitions needed by the included files.
 */
#ifndef MY_GLOBAL_H
#define MY_GLOBAL_H
typedef unsigned int uint;
typedef unsigned int uint32;
typedef unsigned short ushort;
typedef unsigned long ulong;
typedef unsigned long DWORD;
typedef char *LPSTR;
typedef const char *LPCSTR;
typedef int BOOL;
#ifdef __WIN__
typedef void *HANDLE;
#else
typedef int HANDLE;
#endif
typedef char *PSZ;
typedef const char *PCSZ;
typedef unsigned char BYTE;
typedef unsigned char uchar;
typedef long long longlong;
typedef unsigned long long ulonglong;
typedef char my_bool;
struct charset_info_st {};
typedef const charset_info_st CHARSET_INFO;
#define FALSE 0
#define TRUE 1
#define Item char
#define MY_MAX(a,b) ((a>b)?(a):(b))
#define MY_MIN(a,b) ((a<b)?(a):(b))
#endif // MY_GLOBAL_H
```

Note: This is a fake `my_global.h` that just contains what is useful for the `jmgomem.cpp` source file.

The source File `jmgomem.cpp`:

```
/*
 * jmgomem C++ Program Source Code File (.CPP)
 * PROGRAM NAME: jmgomem Version 1.0
 * (C) Copyright to the author Olivier BERTRAND 2017
 * This program is the Java MONGO OEM module definition.
 */
#include "my_global.h"

/*
 * Include application header files:
 */
```

```

/* global.h is header containing all global declarations. */
/* plgdbsem.h is header containing the DB application declarations. */
/* (x)table.h is header containing the TDBASE declarations. */
/* tabext.h is header containing the TDBEXT declarations. */
/* mongo.h is header containing the MONGO declarations. */
/*****/
#include "global.h"
#include "plgdbsem.h"
#if defined(HAVE_JMGO)
#include "csort.h"
#include "javaconn.h"
#endif // HAVE_JMGO
#include "xtable.h"
#include "tabext.h"
#include "mongo.h"

/*****/
/* These functions are exported from the MONGO library. */
/*****/
extern "C" {
    PTABDEF __stdcall GetMONGO(PGLOBAL, void*);
    PQRYRES __stdcall ColMONGO(PGLOBAL, PTOS, void*, char*, char*, bool);
} // extern "C"

/*****/
/* DB static variables. */
/*****/
int TDB::Tnum;
int DTVAL::Shift;
#if defined(HAVE_JMGO)
int CSORT::Limit = 0;
double CSORT::Lg2 = log(2.0);
size_t CSORT::Cpn[1000] = {0}; /* Precalculated cmpnum values */
#endif
char *JvmPath = NULL;
char *ClassPath = NULL;
char *GetPluginDir(void)
{return "C:/mongo-java-driver/mongo-java-driver-3.4.2.jar;"
    "C:/MariaDB-10.1/MariaDB/storage/connect/";}
char *GetJavaWrapper(void) {return (char*)"wrappers/Mongo3Interface";}
#else // !HAVE_JAVACONN

CRTJVM JAVAConn::CreateJavaVM;
GETJVM JAVAConn::GetCreatedJavaVMs;
#endif
#if defined(_DEBUG)
GETDEF JAVAConn::GetDefaultJavaVMInitArgs;
#endif // _DEBUG
#endif // !HAVE_JAVACONN
#endif // HAVE_JMGO

/*****/
/* This function returns a Mongo definition class. */
/*****/
PTABDEF __stdcall GetMONGO(PGLOBAL g, void *memp)
{
    return new(g, memp) MGODEF;
} // end of GetMONGO

#ifdef NOEXP
/*****/
/* Functions to be defined if not exported by the CONNECT version. */
/*****/
bool IsNum(PSZ s)
{
    for (char *p = s; *p; p++)
        if (*p == ']')
            break;
        else if (!isdigit(*p) || *p == '-')
            return false;

    return true;
} // end of IsNum
#endif

/*****/

```

```

/* Return the columns definition to MariaDB. */
/*****
PQRYRES __stdcall ColMONGO(PGLOBAL g, PTOS tp, char *tab,
                           char *db, bool info)
{
#ifdef NOMGOCOL
    // Cannot use discovery
    strcpy(g->Message, "No discovery, MGOColumns is not accessible");
    return NULL;
#else
    return MGOColumns(g, db, NULL, tp, info);
#endif
} // end of ColMONGO

```

The file `mongo.def` : (required only on Windows)

```

LIBRARY      MONGO
EXPORTS
    GetMONGO      @1
    ColMONGO      @2

```

Compiling this OEM

To compile this OEM module, first make the two or three required files by copy/pasting from the above listings.

Even if this module is to be used with a binary distribution, you need some source files in order to successfully compile it. At least the CONNECT header files that are included in `jmgoem.cpp` and the ones they can include. This can be obtained by downloading the MariaDB source file `tar.gz` and extracting from it the CONNECT sources files in a directory that will be added to the additional source directories if it is not the directory containing the above files.

The module must be linked to the `ha_connect.lib` of the binary version it will be used with. Recent distributions add this lib in the plugin directory.

The resulting module, for instance `mongo.so` or `mongo.dll`, must be placed in the plugin directory of the MariaDB server. Then, you will be able to use MONGO like tables simply replacing in the CREATE TABLE statement the option `TABLE_TYPE=MONGO` with `TABLE_TYPE=OEM SUBTYPE=MONGO MODULE='mongo.(so|dll)'`. Actually, the module name, here supposedly 'mongo', can be anything you like.

This will work with the last (not yet) distributed versions of [MariaDB 10.0](#) and 10.1 because, even if it is not enabled, the MONGO type is included in them. This is also the case for [MariaDB 10.2.9](#) but then, on Windows, you will have to define `NOEXP` and `NOMGOCOL` because these functions are not exported by this version.

To implement for older versions that do not contain the MONGO type, you can add the corresponding source files, namely `javaconn.cpp`, `jmgofam.cpp`, `jmgoconn.cpp`, `mongo.cpp` and `tabjmg.cpp` that you should find in the CONNECT extracted source files if you downloaded a recent version. As they include `my_global.h`, this is the reason why the included file was named this way. In addition, your compiling should define `HAVE_JMGO` and `HAVE_JAVACONN`. Of course, this is possible only if `ha_connect.lib` is available.

5.3.7.9.1 Using CONNECT - General Information

Contents

1. [Performance](#)
2. [Create Table statement](#)
3. [Drop Table statement](#)
4. [Alter Table statement](#)
5. [Update and Delete for File Tables](#)

The main characteristic of **CONNECT** is to enable accessing data scattered on a machine as if it was a centralized database. This, and the fact that locking is not used by connect (data files are open and closed for each query) makes **CONNECT** very useful for importing or exporting data into or from a MariaDB database and also for all types of Business Intelligence applications. However, it is not suited for transactional applications.

For instance, the index type used by **CONNECT** is closer to bitmap indexing than to B-trees. It is very fast for retrieving result but not when updating is done. In fact, even if only one indexed value is modified in a big table, the index is entirely remade (yet this being four to five times faster than for a b-tree index). But normally in Business Intelligence applications, files are not modified so often.

If you are using **CONNECT** to analyze files that can be modified by an external process, the indexes are of course not modified by it and become outdated. Use the **OPTIMIZE TABLE** command to update them before using the tables based on them.

This means also that **CONNECT** is not designed to be used by centralized servers, which are mostly used for transactions and often must run a long time without human intervening.

Performance

Performances vary a great deal depending on the table type. For instance, ODBC tables are only retrieved as fast as the other DBMS can do. If you have a lot of queries to execute, the best way to optimize your work can be sometime to translate the data from one type to another. Fortunately this is very simple with **CONNECT**. Fixed formats like **FIX**, **BIN** or **VEC** tables can be created from slower ones by commands such as:

```
Create table fastable table_specs select * from slowtable;
```

FIX and **BIN** are often the better choice because the I/O functions are done on blocks of **BLOCK_SIZE** rows. **VEC** tables can be very efficient for tables having many columns only a few being used in each query. Furthermore, for tables of reasonable size, the **MAPPED** option can very often speed up many queries.

Create Table statement

Be aware of the two broad kinds of **CONNECT** tables:

- Inward** They are table whose file name is not specified at create. An empty file will be given a default name (*tablename.tabtype*) and will be populated like for other engines. They do not require the **FILE** privilege and can be used for testing purpose.
- Outward** They are all other **CONNECT** tables and access external data sources or files. They are the true useful tables but require the **FILE** privilege.

Drop Table statement

For outward tables, the **DROP TABLE** statement just removes the table definition but does not erase the table data. However, dropping an inward tables also erase the table data as well.

Alter Table statement

Be careful using the [ALTER TABLE](#) statement. Currently the data compatibility is not tested and the modified definition can become incompatible with the data. In particular, Alter modifies the table definition only but does not modify the table data. Consequently, the table type should not be modified this way, except to correct an incorrect definition. Also adding, dropping or modifying columns may be wrong because the default offset values (when not explicitly given by the FLAG option) may be wrong when recompiled with missing columns.

Safe use of ALTER is for indexing, as we have seen earlier, and to change options such as MAPPED or HUGE those do not impact the data format but just the way the data file is accessed. Modifying the BLOCK_SIZE option is all right with FIX, BIN, DBF, split VEC tables; however it is unsafe for VEC tables that are not split (only one data file) because at their creation the estimate size has been made a multiple of the block size. This can cause errors if this estimate is not a multiple of the new value of the block size.

In all cases, it is safer to drop and re-create the table (outward tables) or to make another one from the table that must be modified.

Update and Delete for File Tables

CONNECT can execute these commands using two different algorithms:

- It can do it in place, directly modifying rows (update) or moving rows (delete) within the table file. This is a fast way to do it in particular when indexing is used.
- It can do it using a temporary file to make the changes. This is required when updating variable record length tables and is more secure in all cases.

The choice between these algorithms depends on the session variable [connect_use_tempfile](#).

5.3.7.9.2 Using CONNECT - Virtual and Special Columns

CONNECT supports MariaDB [virtual and persistent columns](#). It is also possible to declare a column as being a CONNECT special column. Let us see on an example how this can be done. The boys table we have seen previously can be recreated as:

```
create table boys (
  linenum int(6) not null default 0 special=rowid,
  name char(12) not null,
  city char(12) not null,
  birth date not null date_format='DD/MM/YYYY',
  hired date not null date_format='DD/MM/YYYY' flag=36,
  agehired int(3) as (floor(datediff(hired,birth)/365.25))
  virtual,
  fn char(100) not null default '' special=FILEID)
engine=CONNECT table_type=FIX file_name='boys.txt' mapped=YES lrecl=47;
```

We have defined two CONNECT special columns. You can give them any name; it is the field SPECIAL option that specifies the special column functional name.

Note: the default values specified for the special columns do not mean anything. They are specified just to prevent getting warning messages when inserting new rows.

For the definition of the *agehired* virtual column, no CONNECT options can be specified as it has no offset or length, not being stored in the file.

The command:

```
select * from boys where city = 'boston';
```

will return:

linenum	name	city	birth	hired	agehired	fn
1	John	Boston	1986-01-25	2010-06-02	24	d:\mariadb\sql\data\boys.txt
2	Henry	Boston	1987-06-07	2008-04-01	20	d:\mariadb\sql\data\boys.txt
6	Bill	Boston	1986-09-11	2008-02-10	21	d:\mariadb\sql\data\boys.txt

Existing special columns are listed in the following table:

Special Name	Type	Description of the column value
--------------	------	---------------------------------

ROWID	Integer	The row ordinal number in the table. This is not quite equivalent to a virtual column with an auto increment of 1 because rows are renumbered when deleting rows.
ROWNUM	Integer	The row ordinal number in the file. This is different from ROWID for multiple tables, TBL/XCOL/OCCUR/PIVOT tables, XML tables with a multiple column, and for DBF tables where ROWNUM includes soft deleted rows.
FILEID FDISK FPATH FNAME FTYPE	String	FILEID returns the full name of the file this row belongs to. Useful in particular for multiple tables represented by several files. The other special columns can be used to retrieve only one part of the full name.
TABID	String	The name of the table this row belongs to. Useful for TBL tables.
PARTID	String	The name of the partition this row belongs to. Specific to partitioned tables.
SERVID	String	The name of the federated server or server host used by a MYSQL table. "ODBC" for an ODBC table, "JDBC" for a JDBC table and "Current" for all other tables.

Note: CONNECT does not currently support auto incremented columns. However, a `ROWID` special column will do the job of a column auto incremented by 1.

5.3.7.9.3 Using CONNECT - Importing File Data Into MariaDB Tables

Directly using external (file) data has many advantages, such as to work on "fresh" data produced for instance by cash registers, telephone switches, or scientific apparatus. However, you may want in some case to import external data into your MariaDB database. This is extremely simple and flexible using the CONNECT handler. For instance, let us suppose you want to import the data of the `xsample.xml` XML file previously given in example into a [MyISAM](#) table called `biblio` belonging to the connect database. All you have to do is to create it by:

```
create table biblio engine=myisam select * from xsampall2;
```

This last statement creates the [MyISAM](#) table and inserts the original XML data, translated to tabular format by the `xsampall2` CONNECT table, into the MariaDB `biblio` table. Note that further transformation on the data could have been achieved by using a more elaborate Select statement in the Create statement, for instance using filters, alias or applying functions to the data. However, because the Create Table process copies table data, later modifications of the `xsample.xml` file will not change the `biblio` table and changes to the `biblio` table will not modify the `xsample.xml` file.

All these can be combined or transformed by further SQL operations. This makes working with CONNECT much more flexible than just using the [LOAD](#) statement.

5.3.7.9.4 Using CONNECT - Exporting Data From MariaDB

Exporting data from MariaDB is obviously possible with CONNECT in particular for all formats not supported by the [SELECT INTO OUTFILE](#) statement. Let us consider the query:

```
select plugin_name handler, plugin_version version, plugin_author
author, plugin_description description, plugin_maturity maturity
from information_schema.plugins where plugin_type = 'STORAGE ENGINE';
```

Supposing you want to get the result of this query into a file `handlers.htm` in XML/HTML format, allowing displaying it on an Internet browser, this is how you can do it:

Just create the CONNECT table that will be used to make the file:

```
create table handout
engine=CONNECT table_type=XML file_name='handout.htm' header=yes
option_list='name=TABLE,coltype=HTML,attribute=border=1;cellpadding=5
,headattr=bgcolor=yellow'
select plugin_name handler, plugin_version version, plugin_author
author, plugin_description description, plugin_maturity maturity
from information_schema.plugins where plugin_type = 'STORAGE ENGINE';
```

Here the column definition is not given and will come from the Select statement following the Create. The CONNECT options are the same we have seen previously. This will do both actions, creating the matching `handlers` CONNECT table and 'filling'

it with the query result.

Note 1: This could not be done in only one statement if the table type had required using explicit `CONNECT` column options. In this case, firstly create the table, and then populate it with an `Insert` statement.

Note 2: The source “plugins” table column “description” is a long text column, data type not supported for `CONNECT` tables. It has been silently internally replaced by `varchar(256)`.

5.3.7.9.5 Using `CONNECT` - Indexing

Contents

1. [Standard Indexing](#)
 1. [Handling index errors](#)
 2. [Index file mapping](#)
2. [Block Indexing](#)
 1. [Difference between standard indexing and block indexing](#)
 2. [Notes for this Release:](#)
3. [Remote Indexing](#)
4. [Dynamic Indexing](#)
5. [Virtual Indexing](#)

[Indexing](#) is one of the main ways to optimize queries. Key columns, in particular when they are used to join tables, should be indexed. But what should be done for columns that have only few distinct values? If they are randomly placed in the table they should not be indexed because reading many rows in random order can be slower than reading the entire table sequentially. However, if the values are sorted or clustered, indexing can be acceptable because `CONNECT` indexes store the values in the order they appear into the table and this will make retrieving them almost as fast as reading them sequentially.

`CONNECT` provides four indexing types:

1. Standard Indexing
2. Block Indexing
3. Remote Indexing
4. Dynamic Indexing

Standard Indexing

`CONNECT` standard indexes are created and used as the ones of other storage engines although they have a specific internal format. The `CONNECT` handler supports the use of standard indexes for most of the file based table types.

You can define them in the [CREATE TABLE](#) statement, or either using the `CREATE INDEX` statement or the [ALTER TABLE](#) statement. In all cases, the index files are automatically made. They can be dropped either using the [DROP INDEX](#) statement or the [ALTER TABLE](#) statement, and this erases the index files.

Indexes are automatically reconstructed when the table is created, modified by `INSERT`, `UPDATE` or `DELETE` commands, or when the `SEPINDEX` option is changed. If you have a lot of changes to do on a table at one moment, you can use table locking to prevent indexes to be reconstructed after each statement. The indexes will be reconstructed when unlocking the table. For instance:

```
lock table t1 write;
insert into t1 values (...);
insert into t1 values (...);
...
unlock tables;
```

If a table was modified by an external application that does not handle indexing, the indexes must be reconstructed to prevent returning false or incomplete results. To do this, use the [OPTIMIZE TABLE](#) command.

For outward tables, index files are not erased when dropping the table. This is the same as for the data file and preserves the possibility of several users using the same data file via different tables.

Unlike other storage engines, `CONNECT` constructs the indexes as files that are named by default from the data file name, not from the table name, and located in the data file directory. Depending on the `SEPINDEX` table option, indexes are saved in a unique file or in separate files (if `SEPINDEX` is true). For instance, if indexes are in separate files, the primary index of the table `dept.dat` of type `DOS` is a file named `dept_PRIMARY.dnx`. This makes possible to define several tables on the same data file, with eventual different options such as mapped or not mapped, and to share the index files as well.

If the index file should have a different name, for instance because several tables are created on the same data file with different indexes, specify the base index file name with the `XFILE_NAME` option.

Note 1: Indexed columns must be declared NOT NULL; CONNECT doesn't support indexes containing null values.

Note 2: MRR is used by standard indexing if it is enabled.

Note 3: Prefix indexing is not supported. If specified, the CONNECT engine ignores the prefix and builds a whole index.

Handling index errors

The way CONNECT handles indexing is very specific. All table modifications are done regardless of indexing. Only after a table has been modified, or when an `OPTIMIZE TABLE` command is sent are the indexes made. If an error occurs, the corresponding index is not made. However, CONNECT being a non-transactional engine, it is unable to roll back the changes made to the table. The main causes of indexing errors are:

- Trying to index a nullable column. In this case, you can alter the table to declare the column as not nullable or, if the column is nullable indeed, make it not indexed.
- Entering duplicate values in a column indexed by a unique index. In this case, if the index was wrongly declared as unique, alter its declaration to reflect this. If the column should really contain unique values, you must manually remove or update the duplicate values.

In both cases, after correcting the error, remake the indexes with the `OPTIMIZE TABLE` command.

Index file mapping

To accelerate the indexing process, CONNECT makes an index structure in memory from the index file. This can be done by reading the index file or using it as if it was in memory by "file mapping". On enabled versions, file mapping is used according to the boolean `connect_idx_map` system variable. Set it to 0 (file read) or 1 (file mapping).

Block Indexing

To accelerate input/output, CONNECT uses when possible a read/write mode by blocks of n rows, n being the value given in the `BLOCK _ SIZE` option of the Create Table, or a default value depending on the table type. This is automatic for fixed files (`FIX`, `BIN`, `DBF` or `VEC`), but must be specified for variable files (`DOS`, `CSV` or `FMT`).

For blocked tables, further optimization can be achieved if the data values for some columns are "clustered" meaning that they are not evenly scattered in the table but grouped in some consecutive rows. Block indexing permits to skip blocks in which no rows fulfill a conditional predicate without having even to read the block. This is true in particular for sorted columns.

You indicate this when creating the table by using the `DISTRIB =d` column option. The enum value `d` can be *scattered*, *clustered*, or *sorted*. In general only one column can be sorted. Block indexing is used only for clustered and sorted columns.

Difference between standard indexing and block indexing

- Block indexing is internally handled by CONNECT while reading sequentially a table data. This means in particular that when standard indexing is used on a table, block indexing is not used.
- In a query, only one standard index can be used. However, block indexing can combine the restrictions coming from a where clause implying several clustered/sorted columns.
- The block index files are faster to make and much smaller than standard index files.

Notes for this Release:

- On all operations that create or modify a table, CONNECT automatically calculates or recalculates and saves the mini/maxi or bitmap values for each block, enabling it to skip block containing no acceptable values. In the case where the optimize file does not correspond anymore to the table, because it has been accidentally destroyed, or because some column definitions have been altered, you can use the `OPTIMIZE TABLE` command to reconstruct the optimization file.
- Sorted column special processing is currently restricted to ascending sort. Column sorted in descending order must be flagged as clustered. Improper sorting is not checked in Update or Insert operations but is flagged when optimizing the table.
- Block indexing can be done in two ways. Keeping the min/max values existing for each block, or keeping a bitmap allowing knowing what column distinct values are met in each blocks. This second way often gives a better optimization, except for sorted columns for which both are equivalent. The bitmap approach can be done only on columns having not too many distinct values. This is estimated by the `MAX _ DIST` option value associated to the column when creating the table. ~~Bitmap block indexing will be used if this number is not greater than the `MAXBMP` setting for the database.~~
- CONNECT cannot perform block indexing on case insensitive character columns. To force block indexing on a

character column, specify its charset as not case insensitive, for instance as binary. However this will also apply to all other clauses, this column being now case sensitive.

Remote Indexing

Remote indexing is specific to the [MYSQL](#) table type. It is equivalent to what the [FEDERATED](#) storage does. A MYSQL table does not support indexes per se. Because access to the table is handled remotely, it is the remote table that supports the indexes. What the MYSQL table does is just to add a WHERE clause to the [SELECT](#) command sent to the remote server allowing the remote server to use indexing when applicable. Note however that because [CONNECT](#) adds when possible all or part of the where clause of the original query, this happens often even if the remote indexed column is not declared locally indexed. The only, but very important, case a column should be locally declared indexed is when it is used to join tables. Otherwise, the required where clause would not be added to the sent [SELECT](#) query.

See [Indexing of MYSQL tables](#) for more.

Dynamic Indexing

An indexed created as "dynamic" is a standard index which, in some cases, can be reconstructed for a specific query. This happens in particular for some queries where two tables are joined by an indexed key column. If the "from" table is big and the "to" big table reduced in size because of a where clause, it can be worthwhile to reconstruct the index on this reduced table.

Because of the time added by reconstructing the index, this will be valuable only if the time gained by reducing the index size is more than this reconstruction time. This is why this should not be done if the "from" table is small because there will not be enough row joining to compensate for the additional time. Otherwise, the gain of using a dynamic index is:

- Indexing time is a little faster if the index is smaller.
- The join process will return only the rows fulfilling the where clause.
- Because the table is read sequentially when reconstructing the index there is no need for MRR.
- Constructing the index can be faster if the table is reduced by block indexing.
- While constructing the index, [CONNECT](#) also stores in memory the values of other used columns.

This last point is particularly important. It means that after the index is reconstructed, the join is done on a temporary memory table.

Unfortunately, storage engines being called independently by MariaDB for each table, [CONNECT](#) has no global information to decide when it is good to use dynamic indexing. This is why you should use it only on cases where you see that some important join queries take a very long time and only on columns used for joining the table. How to declare an index to be dynamic is by using the Boolean [DYNAM](#) index option. For instance, the query:

```
select d.diag, count(*) cnt from diag d, patients p where d.pnb =
p.pnb and ageyears < 17 and county = 30 and drg <> 11 and d.diag
between 4296 and 9434 group by d.diag order by cnt desc;
```

Such a query joining the `diag` table to the `patients` table may last a very long time if the tables are big. To declare the primary key on the `pnb` column of the `patients` table to be dynamic:

```
alter table patients drop primary key;
alter table patients add primary key (pnb) comment 'DYNAMIC' dynam=1;
```

Note 1: The comment is not mandatory here but useful to see that the index is dynamic if you use the [SHOW INDEX](#) command.

Note 2: There is currently no way to just change the [DYNAM](#) option without dropping and adding the index. This is unfortunate because it takes time.

Virtual Indexing

It applies only to the virtual tables of type [VIR](#) and must be made on a column specifying `SPECIAL=ROWID` or `SPECIAL=ROWNUM`.

5.3.7.9.6 Using [CONNECT](#) - Condition Pushdown

The [ODBC](#), [JDBC](#), [MYSQL](#), [TBL](#) and [WMI](#) table types use engine condition pushdown in order to restrict the number of

rows returned by the RDBS source or the WMI component.

The `CONDITION_PUSHDOWN` argument used in old versions of `CONNECT` is no longer needed because `CONNECT` uses condition pushdown unconditionally.

5.3.7.9.7 USING CONNECT - Offline Documentation

Note: You can download a [PDF version of the CONNECT documentation](#) (1.7.0003).

`CONNECT` supports the MySQL/MariaDB partition specification. It is done similar to the way `MyISAM` or `InnoDB` do by using the `PARTITION` engine that must be enabled for this to work. This type of partitioning is sometimes referred as “horizontal partitioning”.

Partitioning enables you to distribute portions of individual tables across a file system according to rules which you can set largely as needed. In effect, different portions of a table are stored as separate tables in different locations. The user-selected rule by which the division of data is accomplished is known as a partitioning function, which in MariaDB can be the modulus, simple matching against a set of ranges or value lists, an internal hashing function, or a linear hashing function.

`CONNECT` takes this notion a step further, by providing two types of partitioning:

1. File partitioning. Each partition is stored in a separate file like in multiple tables.
2. Table partitioning. Each partition is stored in a separate table like in TBL tables.

Partition engine issues

Using partitions sometimes requires creating the tables in an unnatural way to avoid some error due to several partition engine bugs:

1. Engine specific column and index options are not recognized and cause a syntax error when the table is created. The workaround is to create the table in two steps, a `CREATE TABLE` statement followed by an `ALTER TABLE` statement.
2. The connection string, when specified for the table, is lost by the partition engine. The workaround is to specify the connection string in the `option_list`.
3. [MySQL upstream bug #71095](#). In case of list columns partitioning it sometimes causes a false “impossible where” clause to be raised. This makes a wrong void result returned when it should not be void. There is no workaround but this bug should be hopefully fixed.

The following examples are using the above workaround syntax to address these issues.

File Partitioning

File partitioning applies to file-based `CONNECT` table types. As with multiple tables, physical data is stored in several files instead of just one. The differences to multiple tables are:

1. Data is distributed amongst the different files following the partition rule.
2. Unlike multiple tables, partitioned tables are not read only.
3. Unlike multiple tables, partitioned tables can be indexable.
4. The file names are generated from the partition names.
5. Query pruning is automatically made by the partition engine.

The table file names are generated differently depending on whether the table is an inward or outward table. For inward tables, for which the file name is not specified, the partition file names are:

```
Data file name: table_name#P#partition_name.table_file_type
Index file name: table_name#P#partition_name.index_file_type
```

For instance for the table:

```
CREATE TABLE t1 (
  id INT KEY NOT NULL,
  msg VARCHAR(32))
ENGINE=CONNECT TABLE_TYPE=FIX
partition by range(id) (
  partition first values less than(10),
  partition middle values less than(50),
  partition last values less than(MAXVALUE));
```

CONNECT will generate in the current data directory the files:

```
| t1#P#first.fix
| t1#P#first.fnx
| t1#P#middle.fix
| t1#P#middle.fnx
| t1#P#last.fix
| t1#P#last.fnx
```

This is similar to what the partition engine does for other engines - CONNECT partitioned inward tables behave like other engines partition tables do. Just the data format is different.

Note: If sub-partitioning is used, inward table files and index files are named:

```
| table_name#P#partition_name#SP#subpartition_name.type
| table_name#P#partition_name#SP#subpartition_name.index_type
```

Outward Tables

The real problems occur with outward tables, in particular when they are created from already existing files. The first issue is to make the partition table use the correct existing file names. The second one, only for already existing not void tables, is to be sure the partitioning function match the distribution of the data already existing in the files.

The first issue is addressed by the way data file names are constructed. For instance let us suppose we want to make a table from the fixed formatted files:

```
E:\Data\part1.txt
E:\Data\part2.txt
E:\Data\part3.txt
```

This can be done by creating a table such as:

```
create table t2 (
  id int not null,
  msg varchar(32),
  index XID(id))
engine=connect table_type=FIX file_name='E:/Data/part%s.txt'
partition by range(id) (
  partition `1` values less than(10),
  partition `2` values less than(50),
  partition `3` values less than(MAXVALUE));
```

The rule is that for each partition the matching file name is internally generated by replacing in the given FILE _ NAME option value the "%s" part by the partition name.

If the table was initially void, further inserts will populate it according to the partition function. However, if the files did exist

and contained data, this is your responsibility to determine what partition function actually matches the data distribution in them. This means in particular that partitioning by key or by hash cannot be used (except in exceptional cases) because you have almost no control over what the used algorithm does.

In the example above, there is no problem if the table is initially void, but if it is not, serious problems can be met if the initial distribution does not match the table distribution. Supposing a row in which "id" as the value 12 was initially contained in the part1.txt file, it will be seen when selecting the whole table but if you ask:

```
select * from t2 where id = 12;
```

The result will have 0 rows. This is because according to the partition function query pruning will only look inside the second partition and will miss the row that is in the wrong partition.

One way to check for wrong distribution if for instance to compare the results from queries such as:

```
SELECT partition_name, table_rows FROM
information_schema.partitions WHERE table_name = 't2';
```

And

```
SELECT CASE WHEN id < 10 THEN 1 WHEN id < 50 THEN 2 ELSE 3 END
AS pn, COUNT(*) FROM part3 GROUP BY pn;
```

If they match, the distribution can be correct although this does not prove it. However, if they do not match, the distribution is surely wrong.

Partitioning on a Special Column

There are some cases where the files of a multiple table do not contain columns that can be used for range or list partitioning. For instance, let's suppose we have a multiple table based on the following files:

```
tmp/boston.txt
tmp/chicago.txt
tmp/atlanta.txt
```

Each of them containing the same kind of data:

```
ID: int
First_name: varchar(16)
Last_name: varchar(30)
Birth: date
Hired: date
Job: char(10)
Salary: double(8,2)
```

A multiple table can be created on them, for instance by:

```
create table mulemp (
id int NOT NULL,
first_name varchar(16) NOT NULL,
last_name varchar(30) NOT NULL,
birth date NOT NULL date_format='DD/MM/YYYY',
hired date NOT NULL date_format='DD/MM/YYYY',
job char(10) NOT NULL,
salary double(8,2) NOT NULL
) engine=CONNECT table_type=FIX file_name='tmp/*.txt' multiple=1;
```

The issue is that if we want to create a partitioned table on these files, there are no columns to use for defining a partition function. Each city file can have the same kind of column values and there is no way to distinguish them.

However, there is a solution. It is to add to the table a special column that will be used by the partition function. For instance, the new table creation can be done by:

```

create table partemp (
id int NOT NULL,
first_name varchar(16) NOT NULL,
last_name varchar(30) NOT NULL,
birth date NOT NULL date_format='DD/MM/YYYY',
hired date NOT NULL date_format='DD/MM/YYYY',
job char(16) NOT NULL,
salary double(10,2) NOT NULL,
city char(12) default 'boston' special=PARTID,
index XID(id)
) engine=CONNECT table_type=FIX file_name='E:/Data/Test/%s.txt';
alter table partemp
partition by list columns(city) (
partition `atlanta` values in('atlanta'),
partition `boston` values in('boston'),
partition `chicago` values in('chicago'));

```

Note 1: we had to do it in two steps because of the column CONNECT options.

Note 2: the special column PARTID returns the name of the partition in which the row is located.

Note 3: here we could have used the FNAME special column instead because the file name is specified as being the partition name.

This may seem rather stupid because it means for instance that a row will be in partition boston if it belongs to the partition boston! However, it works because the partition engine doesn't know about special columns and behaves as if the city column was a real column.

What happens if we populate it by?

```

insert into partemp(id,first_name,last_name,birth,hired,job,salary) values
(1205,'Harry','Cover','1982-10-07','2010-09-21','MANAGEMENT',125000.00);
insert into partemp values
(1524,'Jim','Beams','1985-06-18','2012-07-25','SALES',52000.00,'chicago'),
(1431,'Johnny','Walker','1988-03-12','2012-08-09','RESEARCH',46521.87,'boston'),
(1864,'Jack','Daniels','1991-12-01','2013-02-16','DEVELOPMENT',63540.50,'atlanta');

```

The value given for the city column (explicitly or by default) will be used by the partition engine to decide in which partition to insert the rows. It will be ignored by CONNECT (a special column cannot be given a value) but later will return the matching value. For instance:

```

select city, first_name, job from partemp where id in (1524,1431);

```

This query returns:

city	first_name	job
boston	Johnny	RESEARCH
chicago	Jim	SALES

Everything works as if the city column was a real column contained in the table data files.

Partitioning of zipped tables

Two cases are currently supported:

If a table is based on several zipped files, partitioning is done the standard way as above. This is the *file_name* option specifying the name of the zip files that shall contain the '%s' part used to generate the file names.

If a table is based on only one zip file containing several entries, this will be indicated by placing the '%s' part in the entry option value.

Note: If a table is based on several zipped files each containing several entries, only the first case is possible. Using sub-partitioning to make partitions on each entries is not supported yet.

Table Partitioning

With table partitioning, each partition is physically represented by a sub-table. Compared to standard partitioning, this brings the following features:

1. The partitions can be tables driven by different engines. This relieves the current existing limitation of the partition engine.

2. The partitions can be tables driven by engines not currently supporting partitioning.
3. Partition tables can be located on remote servers, enabling table sharding.
4. Like for TBL tables, the columns of the partition table do not necessarily match the columns of the sub-tables.

The way it is done is to create the partition table with a table type referring to other tables, [PROXY](#), [MYSQL ODBC](#) or [JDBC](#). Let us see how this is done on a simple example. Supposing we have created the following tables:

```
create table xt1 (
id int not null,
msg varchar(32))
engine=myisam;

create table xt2 (
id int not null,
msg varchar(32)); /* engine=innnoDB */

create table xt3 (
id int not null,
msg varchar(32))
engine=connect table_type=CSV;
```

We can for instance create a partition table using these tables as physical partitions by:

```
create table t3 (
id int not null,
msg varchar(32))
engine=connect table_type=PROXY tabname='xt%s'
partition by range columns(id) (
partition `1` values less than(10),
partition `2` values less than(50),
partition `3` values less than(MAXVALUE));
```

Here the name of each partition sub-table will be made by replacing the '%s' part of the tabname option value by the partition name. Now if we do:

```
insert into t3 values
(4, 'four'), (7, 'seven'), (10, 'ten'), (40, 'forty'),
(60, 'sixty'), (81, 'eighty one'), (72, 'seventy two'),
(11, 'eleven'), (1, 'one'), (35, 'thirty five'), (8, 'eight');
```

The rows will be distributed in the different sub-tables according to the partition function. This can be seen by executing the query:

```
select partition_name, table_rows from
information_schema.partitions where table_name = 't3';
```

This query replies:

partition_name	table_rows
1	4
2	4
3	3

Query pruning is of course automatic, for instance:

```
explain partitions select * from t3 where id = 81;
```

This query replies:

id	select_type	table	partitions	type	possible_keys	key	key_len	ref	rows	Extra
1	SIMPLE	part5	3	ALL	<null>	<null>	<null>	<null>	22	Using where

When executing this select query, only sub-table xt3 will be used.

Indexing with Table Partitioning

Using the [PROXY](#) table type seems natural. However, in this current version, the issue is that [PROXY](#) (and [ODBC](#)) tables are not indexable. This is why, if you want the table to be indexed, you must use the [MYSQL](#) table type. The CREATE TABLE statement will be almost the same:

```
create table t4 (
  id int key not null,
  msg varchar(32)
  engine=connect table_type=MYSQL tabname='xt%s'
  partition by range columns(id) (
    partition `1` values less than(10),
    partition `2` values less than(50),
    partition `3` values less than(MAXVALUE));
```

The column *id* is declared as a key, and the table type is now MYSQL. This makes Sub-tables accessed by calling a MariaDB server as MYSQL tables do. Note that this modifies only the way CONNECT sub-tables are accessed.

However, indexing just make the partitioned table use “remote indexing” the way FEDERATED tables do. This means that when sending the query to retrieve the table data, a where clause will be added to the query. For instance, let’s suppose you ask:

```
select * from t4 where id = 7;
```

The query sent to the server will be:

```
SELECT `id`, `msg` FROM `xt1` WHERE `id` = 7
```

On a query like this one, it does not change much because the where clause could have been added anyway by the `cond_push` function, but it does make a difference in case of joins. The main thing to understand is that real indexing is done by the called table and therefore that it should be indexed.

This also means that the `xt1`, `xt2`, and `xt3` table indexes should be made separately because creating the `t2` table as indexed does not make the indexes on the sub-tables.

Sharding with Table Partitioning

Using table partitioning can have one more advantage. Because the sub-tables can address a table located on another server, it is possible to shard a table on separate servers and hardware machines. This may be required to access as one table data already located on several remote machines, such as servers of a company branches. Or it can be just used to split a huge table for performance reason. For instance, supposing we have created the following tables:

```
create table rt1 (id int key not null, msg varchar(32))
engine=federated connection='mysql://root@host1/test/sales';

create table rt2 (id int key not null, msg varchar(32))
engine=federated connection='mysql://root@host2/test/sales';

create table rt3 (id int key not null, msg varchar(32))
engine=federated connection='mysql://root@host3/test/sales';
```

Creating the partition table accessing all these will be almost like what we did with the `t4` table:

```
create table t5 (
  id int key not null,
  msg varchar(32)
  engine=connect table_type=MYSQL tabname='rt%s'
  partition by range columns(id) (
    partition `1` values less than(10),
    partition `2` values less than(50),
    partition `3` values less than(MAXVALUE));
```

The only difference is the `tabname` option now referring to the `rt1`, `rt2`, and `rt3` tables. However, even if it works, this is not the best way to do it. This is because accessing a table via the MySQL API is done twice per table. Once by CONNECT to access the FEDERATED table on the local server, then a second time by FEDERATED engine to access the remote table.

The CONNECT MYSQL table type being used anyway, you’d rather use it to directly access the remote tables. Indeed, the partition names can also be used to modify the connection URL’s. For instance, in the case shown above, the partition table can be created as:

```

create table t6 (
id int key not null,
msg varchar(32))
engine=connect table_type=MYSQL
option_list='connect=mysql://root@host%s/test/sales'
partition by range columns(id) (
partition `1` values less than(10),
partition `2` values less than(50),
partition `3` values less than(MAXVALUE));

```

Several things can be noted here:

1. As we have seen before, the partition engine currently loses the connection string. This is why it was specified as “connect” in the option list.
2. For each partition sub-tables, the “%s” part of the connection string has been replaced by the partition name.
3. It is not needed anymore to define the rt1, rt2, and rt3 tables (even it does not harm) and the FEDERATED engine is no more used to access the remote tables.

This is a simple case where the connection string is almost the same for all the sub-tables. But what if the sub-tables are accessed by very different connection strings? For instance:

```

For rt1: connection='mysql://root:[email protected]:3307/test/xt1'
For rt2: connection='mysql://foo:foopass@denver/dbemp/xt2'
For rt3: connection='mysql://root@huston :5505/test/tabx'

```

There are two solutions. The first one is to use the parts of the connection string to differentiate as partition names:

```

create table t7 (
id int key not null,
msg varchar(32))
engine=connect table_type=MYSQL
option_list='connect=mysql://%s'
partition by range columns(id) (
partition `root:[email protected]:3307/test/xt1` values less than(10),
partition `foo:foopass@denver/dbemp/xt2` values less than(50),
partition `root@huston :5505/test/tabx` values less than(MAXVALUE));

```

The second one, allowing avoiding too complicated partition names, is to create federated servers to access the remote tables (if they do not already exist, else just use them). For instance the first one could be:

```

create server `server_one` foreign data wrapper 'mysql'
options
(host '127.0.0.1',
database 'test',
user 'root',
password 'tinono',
port 3307);

```

Similarly, “server_two” and “server_three” would be created and the final partition table would be created as:

```

create table t8 (
id int key not null,
msg varchar(32))
engine=connect table_type=MYSQL
option_list='connect=server_%s'
partition by range columns(id) (
partition `one/xt1` values less than(10),
partition `two/xt2` values less than(50),
partition `three/tabx` values less than(MAXVALUE));

```

It would be even simpler if all remote tables had the same name on the remote databases, for instance if they all were named xt1, the connection string could be set as “server_%s/xt1” and the partition names would be just “one”, “two”, and “three”.

Sharding on a Special Column

The technique we have seen above with file partitioning is also available with table partitioning. Companies willing to use as one table data sharded on the company branch servers can, as we have seen, add to the table create definition a special column. For instance:

```

create table t9 (
  id int not null,
  msg varchar(32),
  branch char(16) default 'main' special=PARTID,
  index XID(id)
engine=connect table_type=MYSQL
option_list='connect=server_%s/sales'
partition by range columns(id) (
  partition `main` values in('main'),
  partition `east` values in('east'),
  partition `west` values in('west'));

```

This example assumes that federated servers had been created named “server_main”, “server_east” and “server_west” and that all remote tables are named “sales”. Note also that in this example, the column id is no more a key.

Current Partition Limitations

Because the partition engine was written before some other engines were added to MariaDB, the way it works is sometime incompatible with these engines, in particular with CONNECT.

Update statement

With the sample tables above, you can do update statements such as:

```
update t2 set msg = 'quatre' where id = 4;
```

It works perfectly and is accepted by CONNECT. However, let us consider the statement:

```
update t2 set id = 41 where msg = 'four';
```

This statement is not accepted by CONNECT. The reason is that the column id being part of the partition function, changing its value may require the modified row to be moved to another partition. The way it is done by the partition engine is to delete the old row and to re-insert the new modified one. However, this is done in a way that is not currently compatible with CONNECT (remember that CONNECT supports UPDATE in a specific way, in particular for the table type MYSQL) This limitation could be temporary. Meanwhile the workaround is to manually do what is done above,

Deleting the row to modify and inserting the modified row:

```
delete from t2 where id = 4;
insert into t2 values(41, 'four');
```

Alter Table statement

For all CONNECT outward tables, the ALTER TABLE statement does not make any change in the table data. This is why ALTER TABLE should not be used; in particular to modify the partition definition, except of course to correct a wrong definition. Note that using ALTER TABLE to create a partition table in two steps because column options would be lost is valid as it applies to a table that is not yet partitioned.

As we have seen, it is also safe to use it to create or drop indexes. Otherwise, a simple rule of thumb is to avoid altering a table definition and better drop and re-create a table whose definition must be modified. Just remember that for outward CONNECT tables, dropping a table does not erase the data and that creating it does not modify existing data.

Rowid special column

Each partition being handled separately as one table, the ROWID special column returns the rank of the row in its partition, not in the whole table. This means that for partition tables ROWID and ROWNUM are equivalent.

5.3.7.10 CONNECT - Making the GetRest Library

To enable the REST feature with binary distributions of MariaDB, the function calling the cprestdk package is not included in CONNECT, thus allowing CONNECT normal operation when the cprestdk package is not installed. Therefore, it must be compiled separately as a library (so or dll) that will be loaded by CONNECT when needed.

This library will contain only one file shown here:

```
/* Restget C++ Program Source Code File (.CPP) */
/* Adapted from the sample program of the Casablanca tutorial. */
/* Copyright Olivier Bertrand 2019. */
/* */
#include <cpprest/filestream.h>
#include <cpprest/http_client.h>

using namespace utility::conversions; // String conversions utilities
using namespace web; // Common features like URIs.
using namespace web::http; // Common HTTP functionality
using namespace web::http::client; // HTTP client features
using namespace concurrency::streams; // Asynchronous streams

typedef const char* PCSZ;

extern "C" int restGetFile(char* m, bool xt, PCSZ http, PCSZ uri, PCSZ fn);

/* Make a local copy of the requested file. */
int restGetFile(char *m, bool xt, PCSZ http, PCSZ uri, PCSZ fn)
{
    int rc = 0;
    auto fileStream = std::make_shared<ostream>();

    if (!http || !fn) {
        strcpy(m, "Missing http or filename");
        return 2;
    } // endif

    if (xt)
        fprintf(stderr, "restGetFile: fn=%s\n", fn);

    // Open stream to output file.
    pplx::task<void> requestTask = fstream::open_ostream(to_string_t(fn))
        .then( [= ] (ostream outFile) {
            *fileStream= outFile;
        });

    if (xt)
        fprintf(stderr, "Outfile isopen=%d\n", outFile.is_open());

    // Create http_client to send the request.
    http_client client(to_string_t(http));

    if (uri) {
        // Build request URI and start the request.
        uri_builder builder(to_string_t(uri));
        return client.request(methods::GET, builder.to_string());
    } else
        return client.request(methods::GET);
})

// Handle response headers arriving.
.then( [= ] (http_response response) {
    if (xt)
        fprintf(stderr, "Received response status code:%u\n",
            response.status_code());

    // Write response body into the file.
    return response.body().read_to_end(fileStream->streambuf());
})

// Close the file stream.
.then( [= ] (size_t n) {
    if (xt)
        fprintf(stderr, "Return size=%zu\n", n);

    return fileStream->close();
});

// Wait for all the outstanding I/O to complete and handle any exceptions
try {
    if (xt)
```

```

    fprintf(stderr, "Waiting\n");

    requestTask.wait();
} catch (const std::exception &e) {
    if (xt)
        fprintf(stderr, "Error exception: %s\n", e.what());

    sprintf(m, "Error exception: %s", e.what());
    rc= 1;
} // end try/catch

if (xt)
    fprintf(stderr, "restget done: rc=%d\n", rc);

return rc;
} // end of restGetFile

```

This file exists in the source of CONNECT as `restget.cpp`. If you have no access to the source, use your favorite editor to make it by copy/pasting from the above.

Then, on Linux, compile the GetRest.so library:

```
g++ -o GetRest.so -O3 -Wall -std=c++11 -fPIC -shared restget.cpp -lcpprest
```

Note: You can replace `-O3` by `-g` to make a debug version.

This library should be placed where it can be accessed. A good place is the directory where the `libcpprest.so` is, for instance `/usr/lib64`. You can move or copy it there.

On windows, using Visual Studio, make an empty win32 dll project named GetRest and add it the above file. Also add it the module definition file `restget.def`:

```

LIBRARY REST
EXPORTS
    restGetFile    @1

```

Important: This file must be specified in the property linker input page.

Once compiled, the release or debug versions can be copied in the `cpprestsdk` corresponding directories, bin or debug\bin.

That is all. It is a once-off job. Once done, it will work with all new MariaDB versions featuring CONNECT version 1.07.

Note: the xt tracing variable is true when `connect_xtrace` setting includes the value "MONGO" (512).

Caution: If your server crashes when using this feature, this is likely because the GetRest lib is linked to the wrong `cpprestsdk` lib (this may only apply on Windows)

A Release version of GetRest must be linked to the release version of the `cpprestsdk` lib (`cpprest_2_10.dll`) but if you make a Debug version of GetRest, make sure it is linked to the Debug version of `cpprestsdk` lib (`cpprest_2_10d.dll`)

This may be automatic if you use Visual Studio to make the `GetRest.dll`.

5.3.7.11 CONNECT - Adding the REST Feature as a Library Called by an OEM Table

If you are using a version of MariaDB that does not support REST, this is how the REST feature can be added as a library called by an OEM table.

Before making the REST OEM module, the Microsoft Casablanca package must be installed as for compiling MariaDB from source.

Even if this module is to be used with a binary distribution, you need some CONNECT source files in order to successfully make it. It is made with four files existing in the version 1.06.0010 of CONNECT: `tabrest.cpp`, `restget.cpp`, `tabrest.h` and `mini-global.h`. It also needs the CONNECT header files that are included in `tabrest.cpp` and the ones they can include. This can be obtained by going to a recent download site of a version of MariaDB that includes the REST feature, downloading the MariaDB source file `tar.gz` and extracting from it the CONNECT sources files in a directory that will be added to the additional source directories if it is not the directory containing the above files.

On Windows, use a recent version of Visual Studio. Make a new empty DLL project and add the source files `tabrest.cpp` and `restget.cpp`. Visual studio should automatically generate all necessary connections to the `cpprest` SDK. Just edit the properties of the project to add the additional include directory (the one where the `CONNECT` source was downloaded) and the link to the `ha_connect.lib` of the binary version of MariaDB (in the same directory than `ha_connect.dll` in your binary distribution). Add the preprocessor definition `XML_SUPPORT`. Also set in the linker input page of the project property the Module definition File to the `rest.def` file (with its full path) also existing in the `CONNECT` source files. If you are making a debug configuration, make sure that in the C/C++ Code generation page the Runtime library line specifies Multi-threaded Debug DLL (/MDd) or your server will crash when using the feature.

This is not really simple but it is nothing compared with Linux! Someone having made an OEM module for its own application have written:

For whatever reason, `g++ / ld` on Linux are both extremely picky about what they will and won't consider a `""library""` for linking purposes. In order to get them to recognize and therefore find `ha_connect.so` as a "valid" linkable library, `ha_connect.so` must exist in a directory whose path is in `/etc/ld.so.conf` or `/etc/ld.so.conf.d/ha_connect.conf` *AND* its filename must begin with "lib".

On Fedora, you can make a link to `ha_connect.so` by:

```
$ sudo ln -s ../path to../ha_connect.so /usr/lib64/libconnect.so
```

This provides a library whose name begins with "lib". It was made in `/usr/lib64/` because it was the directory of the `libcpprest.so` Casablanca library. This solved the need of a file in `/etc/ld.so.conf.d` as this was already done for the `cpprest` library. Note that the `-s` parameter is a must, without it all sort of nasty errors are met when using the feature.

Then compile and install the OEM module with:

```
$ mkdir oem
$ cd oem
$ mkdir Release
$ make -f oemrest.mak
$ sudo cp rest.so /usr/local/mysql/lib/plugin
```

The `oemrest.mak` file:

```

#LINUX
CPP = g++
LD = g++
OD = ./Release/
SD = /home/olivier/MariaDB/server/storage/connect/
CD = /usr/lib64
# flags to compile object files that can be used in a dynamic library
CFLAGS= -Wall -c -O3 -std=c++11 -fPIC -fno-rtti -I$(SD) -DXML_SUPPORT
# Replace -O3 by -g for debug
LDFLAGS = -L$(CD) -lcpprest -lconnect

# Flags to create a dynamic library.
DYNLINKFLAGS = -shared
# on some platforms, use '-G' instead.

# REST library's archive file
OEMREST = rest.so

SRCS_CPP = $(SD)tabrest.cpp $(SD)restget.cpp
OBSJ_CPP = $(OD)tabrest.o $(OD)restget.o

# top-level rule
all: $(OEMREST)

$(OEMREST): $(OBSJ_CPP)
    $(LD) $(OBSJ_CPP) $(LDFLAGS) $(DYNLINKFLAGS) -o $@

#CPP Source files
$(OD)tabrest.o: $(SD)tabrest.cpp $(SD)mini-global.h $(SD)global.h $(SD)plgdbsem.h
$(SD)xtable.h $(SD)filamtxt.h $(SD)plgxml.h $(SD)tabdos.h $(SD)tabfmt.h $(SD)tabjson.h
$(SD)tabrest.h $(SD)tabxml.h
    $(CPP) $(CFLAGS) -o $@ $(SD)$(*F).cpp
$(OD)restget.o: $(SD)restget.cpp $(SD)mini-global.h $(SD)global.h
    $(CPP) $(CFLAGS) -o $@ $(SD)$(*F).cpp

# clean everything
clean:
    $(RM) $(OBSJ_CPP) $(OEMREST)

```

The SD and CD variables are the directories of the CONNECT source files and the one containing the libcpprest.so lib. They can be edited to match those on your machine OD is the directory that was made to contain the object files.

A very important flag is `-fno-rtti`. Without it you would be in big trouble.

The resulting module, for instance `rest.so` or `rest.dll`, must be placed in the plugin directory of the MariaDB server. Then, you will be able to use NoSQL tables simply replacing in the CREATE TABLE statement the `TABLE_TYPE` option `=JSON` or `XML` by `TABLE_TYPE=OEM SUBTYPE=REST MODULE='rest.(so|dll)'`. Actually, the module name, here supposedly 'rest', can be anything you like.

The file type is JSON by default. If not, it must be specified like this:

```
OPTION_LIST=' Ftype=XML'
```

To be added to the create table statement. For instance:

```

CREATE TABLE webw
ENGINE=CONNECT TABLE_TYPE=OEM MODULE='Rest.dll' SUBTYPE=REST
FILE_NAME='weatherdata.xml'
HTTP='https://samples.openweathermap.org/data/2.5/forecast?
q=London,us&mode=xml&appid=b6907d289e10d714a6e88b30761fae22'
OPTION_LIST=' Ftype=XML,Depth=3,Rownode=weatherdata';

```

Note: this last example returns an XML file whose format was not recognized by old CONNECT versions. It is here the reason of the option 'Rownode=weatherdata'.

If you have trouble making the module, you can post an issue on [JIRA](#).

5.3.7.12 CONNECT - Compiling JSON UDFs in a Separate Library

Although the JSON UDFs can be nicely included in the CONNECT library module, there are cases when you may need to have them in a separate library.

This is when CONNECT is compiled embedded, or if you want to test or use these UDFs with other MariaDB versions not including them.

To make it, you need to have access to the most recent MariaDB source code. Then, make a project containing these files:

1. jsonudf.cpp
2. json.cpp
3. value.cpp
4. osutil.c
5. plugutil.cpp
6. maputil.cpp
7. jsonutil.cpp

`jsonutil.cpp` is not distributed with the source code, you will have to make it from the following:

```

#include "my_global.h"
#include "mysqld.h"
#include "plugin.h"
#include <stdlib.h>
#include <string.h>
#include <stdio.h>
#include <errno.h>

#include "global.h"

extern "C" int GetTraceValue(void) { return 0; }
uint GetJsonGrpSize(void) { return 100; }

/*****
/* These replace missing function of the (not used) DTVAL class. */
*****/
typedef struct _datpar *PDTP;
PDTP MakeDateFormat(PGLOBAL, PSZ, bool, bool, int) { return NULL; }
int ExtractDate(char*, PDTP, int, int val[6]) { return 0; }

#ifdef __WIN__
my_bool CloseFileHandle(HANDLE h)
{
    return !CloseHandle(h);
} /* end of CloseFileHandle */

#else /* UNIX */
my_bool CloseFileHandle(HANDLE h)
{
    return (close(h)) ? TRUE : FALSE;
} /* end of CloseFileHandle */

int GetLastError()
{
    return errno;
} /* end of GetLastError */

#endif // UNIX

/*****
/* Program for sub-allocating one item in a storage area. */
/* Note: This function is equivalent to PlugSubAlloc except that in */
/* case of insufficient memory, it returns NULL instead of doing a */
/* long jump. The caller must test the return value for error. */
*****/
void *PlgDBSubAlloc(PGLOBAL g, void *memp, size_t size)
{
    PPOOLHEADER pph; // Points on area header.

    if (!memp) // Allocation is to be done in the Sarea
        memp = g->Sarea;

    size = ((size + 7) / 8) * 8; /* Round up size to multiple of 8 */
    pph = (PPOOLHEADER)memp;

    if ((uint)size > pph->FreeBlk) { /* Not enough memory left in pool */
        sprintf(g->Message,
            "Not enough memory in Work area for request of %d (used=%d free=%d)",
            (int)size, pph->To_Free, pph->FreeBlk);
        return NULL;
    } // endif size

    // Do the suballocation the simplest way
    memp = MakePtr(memp, pph->To_Free); // Points to sub_allocated block
    pph->To_Free += size; // New offset of pool free block
    pph->FreeBlk -= size; // New size of pool free block

    return (memp);
} // end of PlgDBSubAlloc

```

You can create the file by copy/paste from the above.

Set all the additional include directories to the MariaDB include directories used in plugin compiling plus the reference of the storage/connect directories, and compile like any other UDF giving any name to the made library module (I used `jsonudf.dll` on Windows).

Then you can create the functions using this name as the soname parameter.

There are some restrictions when using the UDFs this way:

- The `connect_json_grp_size` variable cannot be accessed. The group size is set and retrieved using the `jsonset_grp_size` and `jsonget_grp_size` functions (previously 100).
- In case of error, warnings are replaced by messages sent to `stderr`.
- No trace.

16. [connect_use_tempfile](#)
17. [connect_work_size](#)
18. [connect_xtrace](#)

This page documents system variables related to the [CONNECT storage engine](#). See [Server System Variables](#) for a complete list of system variables and instructions on setting them.

See also the [Full list of MariaDB options, system and status variables](#).

`connect_class_path`

- **Description:** Java class path
- **Commandline:** `--connect-class-path=value`
- **Scope:** Global
- **Dynamic:**
- **Data Type:** `string`
- **Default Value:**

`connect_cond_push`

- **Description:** Enable condition pushdown
- **Commandline:** `--connect-cond-push={0|1}`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `ON`

`connect_conv_size`

- **Description:** The size of the `VARCHAR` created when converting from a `TEXT` type. See [connect_type_conv](#).
- **Commandline:** `--connect-conv-size=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`

- **Default Value:**
 - `>= MariaDB 10.4.8`: 1024
 - `<= MariaDB 10.4.7`: 8192
 - **Range:** 0 to 65500
-

`connect_default_depth`

- **Description:** Default depth used by Json, XML and Mongo discovery.
 - **Commandline:** `--connect-default-depth=#`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** 5
 - **Range:** -1 to 16
 - **Introduced:** [MariaDB 10.5.7](#), [MariaDB 10.4.16](#)
-

`connect_default_prec`

- **Description:** Default precision used for doubles.
 - **Commandline:** `--connect-default-prec=#`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** 6
 - **Range:** 0 to 16
 - **Introduced:** [MariaDB 10.5.9](#), [MariaDB 10.4.18](#)
-

`connect_enable_mongo`

- **Description:** Enable the [Mongo table type](#).
 - **Commandline:** `--connect-enable-mongo={0|1}`
 - **Scope:** Global, Session
 - **Dynamic:**
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
 - **Introduced:** [MariaDB 10.3.2](#), [MariaDB 10.2.9](#)
 - **Removed:** [MariaDB 10.3.3](#)
-

`connect_exact_info`

- **Description:** Whether the CONNECT engine should return an exact record number value to information queries. It is OFF by default because this information can take a very long time for large variable record length tables or for remote tables, especially if the remote server is not available. It can be set to ON when exact values are desired, for instance when querying the repartition of rows in a partition table.
 - **Commandline:** `--connect-exact-info={0|1}`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
-

`connect_force_bson`

- **Description:** Force using BSON for JSON tables. Starting with these releases, the internal way JSON was parsed and handled was changed. The main advantage of the new way is to reduce the memory required to parse JSON (from 6 to 10 times the size of the JSON source to now only 2 to 4 times). However, this is in Beta mode and JSON tables are still handled using the old mode. To use the new mode, tables should be created with `TABLE_TYPE=BSON`, or by setting this session variable to 1 or ON. Then, all JSON tables will be handled as BSON. This is temporary until the new way replaces the old way by default.
 - **Commandline:** `--connect-force-bson={0|1}`
 - **Scope:** Global, Session
-

- **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
 - **Introduced:** [MariaDB 10.5.9](#), [MariaDB 10.4.18](#) 
-

`connect_indx_map`

- **Description:** Enable file mapping for index files. To accelerate the indexing process, CONNECT makes an index structure in memory from the index file. This can be done by reading the index file or using it as if it was in memory by “file mapping”. Set to 0 (file read, the default) or 1 (file mapping).
 - **Commandline:** `--connect-indx-map=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
-

`connect_java_wrapper`

- **Description:** Java wrapper.
 - **Commandline:** `--connect-java-wrapper=val`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `string`
 - **Default Value:** `wrappers/JdbcInterface`
-

`connect_json_all_path`

- **Description:** Discovery to generate json path for all columns if ON (the default) or do not when the path is the column name.
 - **Commandline:** `--connect-json-all-path={0|1}`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Data Type:** `boolean`
 - **Default Value:** `ON`
 - **Introduced:** [MariaDB 10.5.7](#), [MariaDB 10.4.16](#) 
-

`connect_json_grp_size`

- **Description:** Max number of rows for JSON aggregate functions.
 - **Commandline:** `--connect-json-grp-size=#`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `50` (\geq Connect 1.7.0003), `10` (\leq Connect 1.7.0002)
 - **Range:** `1` to `2147483647`
-

`connect_json_null`

- **Description:** Representation of JSON null values.
 - **Commandline:** `--connect-json-null=value`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `string`
 - **Default Value:** `<null>`
-

`connect_jvm_path`

- **Description:** Path to JVM library.

- **Commandline:** `--connect-jvm_path=value`
 - **Scope:** Global
 - **Dynamic:**
 - **Data Type:** `string`
 - **Default Value:**
-

`connect_type_conv`

- **Description:** Determines the handling of `TEXT` columns.
 - `NO` : The default until Connect 1.06.005, no conversion takes place, and a `TYPE_ERROR` is returned, resulting in a “not supported” message.
 - `YES` : The default from Connect 1.06.006. The column is internally converted to a column declared as `VARCHAR(n)`, `n` being the value of `connect_conv_size`.
 - `FORCE` (\geq Connect 1.06.006): Also convert ODBC blob columns to `TYPE_STRING`.
 - `SKIP` : No conversion. When the column declaration is provided via Discovery (meaning the `CONNECT` table is created without a column description), this column is not generated. Also applies to ODBC tables.
 - **Commandline:** `--connect-type-conv=#`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `enum`
 - **Valid Values:** `NO`, `YES`, `FORCE` or `SKIP`
 - **Default Value:** `YES`
-

`connect_use_tempfile`

- **Description:**
 - `NO` : The first algorithm is always used. Because it can cause errors when updating variable record length tables, this value should be set only for testing.
 - `AUTO` : This is the default value. It leaves `CONNECT` to choose the algorithm to use. Currently it is equivalent to `NO`, except when updating variable record length tables (`DOS`, `CSV` or `FMT`) with file mapping forced to `OFF`.
 - `YES` : Using a temporary file is chosen with some exceptions. These are when file mapping is `ON`, for `VEC` tables and when deleting from `DBF` tables (soft delete). For variable record length tables, file mapping is forced to `OFF`.
 - `FORCE` : Like `YES` but forces file mapping to be `OFF` for all table types.
 - `TEST` : Reserved for `CONNECT` development.
 - **Commandline:** `--connect-use-tempfile=#`
 - **Scope:** Session
 - **Dynamic:** Yes
 - **Data Type:** `enum`
 - **Default Value:** `AUTO`
-

`connect_work_size`

- **Description:** Size of the `CONNECT` work area used for memory allocation. Permits allocating a larger memory sub-allocation space when dealing with very large if sub-allocation fails. If the specified value is too big and memory allocation fails, the size of the work area remains but the variable value is not modified and should be reset.
 - **Commandline:** `--connect-work-size=#`
 - **Scope:** Global, Session (Session-only from `CONNECT` 1.03.005)
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `67108864`
 - **Range:** `4194304` upwards, depending on the physical memory size
-

`connect_xtrace`

- **Description:** Console trace value. Set to `0` (no trace), or to other values if a console tracing is desired. Note that to test this handler, MariaDB should be executed with the `--console` parameter because `CONNECT` prints some error and trace messages on the console. In some Linux versions, this is re-routed into the error log file. Console tracing can be set on the command line or later by names or values. Valid values (from Connect 1.06.006) include:
 - `0` : No trace

- YES or 1 : Basic trace
- MORE or 2 : More tracing
- INDEX or 4 : Index construction
- MEMORY or 8 : Allocating and freeing memory
- SUBALLOC or 16 : Sub-allocating in work area
- QUERY or 32 : Constructed query sent to external server
- STMT or 64 : Currently executing statement
- HANDLER or 128 : Creating and dropping CONNECT handlers
- BLOCK or 256 : Creating and dropping CONNECT objects
- MONGO or 512 : Mongo and REST (from [Connect 1.06.0010](#)) tracing
- For example:
 - `set global connect_xtrace=0;` *No trace*
 - `set global connect_xtrace='YES';` *By name*
 - `set global connect_xtrace=1;` *By value*
 - `set global connect_xtrace='QUERY,STMT';` *By name*
 - `set global connect_xtrace=96;` *By value*
 - `set global connect_xtrace=1023;` *Trace all*
- **Commandline:** `--connect-xtrace=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** set
- **Default Value:** 0
- **Valid Values:** See description

} // end of ReadColumn

```

tabfic.def

The file tabfic.def: (required only on Windows)

```

LIBRARY      TABFIC
DESCRIPTION  'FIC files'
EXPORTS
    GetFIC      @1

```

JSON UDFs in a separate library

Although the JSON UDF's can be nicely included in the CONNECT library module, there are cases when you may need to have them in a separate library.

This is when CONNECT is compiled embedded, or if you want to test or use these UDF's with other MariaDB versions not including them.

To make it, you need to have access to the last MariaDB source code. Then, make a project containing these files:

1. jsonudf.cpp
2. json.cpp
3. value.cpp
4. osutil.c
5. plugutil.c
6. maputil.cpp
7. jsonutil.cpp

jsonutil.cpp is not distributed with the source code, you will have to make it from the following:

```

#include "my_global.h"
#include "mysqld.h"
#include "plugin.h"
#include <stdlib.h>
#include <string.h>
#include <stdio.h>
#include <errno.h>

#include "global.h"

extern "C" int GetTraceValue(void) { return 0; }
uint GetJsonGrpSize(void) { return 100; }

/*****
/* These replace missing function of the (not used) DTVAL class. */
*****/
typedef struct _datpar *PDTP;
PDTP MakeDateFormat(PGLOBAL, PSZ, bool, bool, int) { return NULL; }
int ExtractDate(char*, PDTP, int, int val[6]) { return 0; }

#ifdef __WIN__
my_bool CloseFileHandle(HANDLE h)
{
    return !CloseHandle(h);
} /* end of CloseFileHandle */

#else /* UNIX */
my_bool CloseFileHandle(HANDLE h)
{
    return (close(h)) ? TRUE : FALSE;
} /* end of CloseFileHandle */

int GetLastError()
{
    return errno;
} /* end of GetLastError */

#endif // UNIX

/*****
/* Program for sub-allocating one item in a storage area. */
/* Note: This function is equivalent to PlugSubAlloc except that in */
/* case of insufficient memory, it returns NULL instead of doing a */
/* long jump. The caller must test the return value for error. */
*****/
void *PlgDBSubAlloc(PGLOBAL g, void *memp, size_t size)
{
    PPOOLHEADER pph; // Points on area header.

    if (!memp) // Allocation is to be done in the Sarea
        memp = g->Sarea;

    size = ((size + 7) / 8) * 8; /* Round up size to multiple of 8 */
    pph = (PPOOLHEADER)memp;

    if ((uint)size > pph->FreeBlk) { /* Not enough memory left in pool */
        sprintf(g->Message,
            "Not enough memory in Work area for request of %d (used=%d free=%d)",
            (int)size, pph->To_Free, pph->FreeBlk);
        return NULL;
    } // endif size

    // Do the suballocation the simplest way
    memp = MakePtr(memp, pph->To_Free); // Points to sub_allocated block
    pph->To_Free += size; // New offset of pool free block
    pph->FreeBlk -= size; // New size of pool free block

    return (memp);
} // end of PlgDBSubAlloc

```

You can create the file by copy/paste from the above.

Set all the additional include directories to the MariaDB include directories used in plugin compiling plus the reference of the storage/connect directories, and compile like any other UDF giving any name to the made library module (I used jsonudf.dll on Windows)

Then you can create the functions using this name as the soname parameter.

There are some restrictions when using the UDF's this way:

- The `connect_json_grp_size` variable cannot be accessed. The group size is set to 100.
- In case of error, warnings are replaced by messages sent to `stderr`.
- No trace.

5.3.8 CSV

The CSV storage engine

CSV Overview

Used to read and append to files stored in CSV (comma-separated-values) format.

Checking and Repairing CSV Tables

CSV tables support the `CHECK TABLE` and `REPAIR TABLE` statements.

5.3.8.1 CSV Overview

Contents

1. [The CSV storage engine and logging to tables](#)
2. [CSV Storage Engine files](#)
3. [Limitations](#)
4. [Examples](#)

The CSV Storage Engine can read and append to files stored in CSV (comma-separated-values) format.

However, since [MariaDB 10.0](#), a better storage engine is able to read and write such files: [CONNECT](#).

The CSV storage engine and logging to tables

The CSV storage engine is the default storage engine when using [logging of SQL queries](#) to tables.

```
mysqld --log-output=table
```

CSV Storage Engine files

When you create a table using the CSV storage engine, three files are created:

- `<table_name>.frm`
- `<table_name>.CSV`
- `<table_name>.CSM`

The `.frm` file is the table format file.

The `.CSV` file is a plain text file. Data you enter into the table is stored as plain text in comma-separated-values format.

The `.CSM` file stores metadata about the table such as the state and the number of rows in the table.

Limitations

- CSV tables do not support indexing.
- CSV tables cannot be partitioned.
- Columns in CSV tables must be declared as NOT NULL.
- No [transactions](#).
- The original CSV-format does not enable IETF-compatible parsing of embedded quote and comma characters. From [MariaDB 10.1.8](#), it is possible to do so by setting the [IETF_QUOTES](#) option when creating a table.

Examples

Forgetting to add NOT NULL:

```
CREATE TABLE csv_test (x INT, y DATE, z CHAR(10)) ENGINE=CSV;
ERROR 1178 (42000): The storage engine for the table doesn't support nullable columns
```

Creating, inserting and selecting:

```
CREATE TABLE csv_test (
  x INT NOT NULL, y DATE NOT NULL, z CHAR(10) NOT NULL
) ENGINE=CSV;
```

```
INSERT INTO csv_test VALUES
(1,CURDATE(),'one'),
(2,CURDATE(),'two'),
(3,CURDATE(),'three');
```

```
SELECT * FROM csv_test;
+---+-----+-----+
| x | y           | z     |
+---+-----+-----+
| 1 | 2011-11-16 | one   |
| 2 | 2011-11-16 | two   |
| 3 | 2011-11-16 | three |
+---+-----+-----+
```

Viewing in a text editor:

```
$ cat csv_test.CSV
1,"2011-11-16","one"
2,"2011-11-16","two"
3,"2011-11-16","three"
```

5.3.8.2 Checking and Repairing CSV Tables

CSV tables support the [CHECK TABLE](#) and [REPAIR TABLE](#) statements.

CHECK TABLE will mark the table as corrupt if it finds a problem, while REPAIR TABLE will restore rows until the first corrupted row, discarding the rest.

Examples

```
CREATE TABLE csv_test (
  x INT NOT NULL, y DATE NOT NULL, z CHAR(10) NOT NULL
) ENGINE=CSV;
```

```
INSERT INTO csv_test VALUES
(1,CURDATE(),'one'),
(2,CURDATE(),'two'),
(3,CURDATE(),'three');
```

```
SELECT * FROM csv_test;
+---+-----+-----+
| x | y           | z     |
+---+-----+-----+
| 1 | 2013-07-08 | one   |
| 2 | 2013-07-08 | two   |
| 3 | 2013-07-08 | three |
+---+-----+-----+
```

Using an editor, the actual file will look as follows

```
$ cat csv_test.CSV
1,"2013-07-08","one"
2,"2013-07-08","two"
3,"2013-07-08","three"
```

Let's introduce some corruption with an unwanted quote in the 2nd row:

```
1,"2013-07-08","one"
2","2013-07-08","two"
3,"2013-07-08","three"
```

```
CHECK TABLE csv_test;
+-----+-----+-----+-----+
| Table          | Op    | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.csv_test | check | error    | Corrupt  |
+-----+-----+-----+-----+
```

We can repair this, but all rows from the corrupt row onwards will be lost:

```
REPAIR TABLE csv_test;
+-----+-----+-----+-----+
| Table          | Op    | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.csv_test | repair | Warning  | Data truncated for column 'x' at row 2 |
| test.csv_test | repair | status   | OK       |
+-----+-----+-----+-----+

SELECT * FROM csv_test;
+---+-----+-----+
| x | y          | z |
+---+-----+-----+
| 1 | 2013-07-08 | one |
+---+-----+-----+
```

5.3.9 FederatedX

Information about the FederatedX Storage Engine

About FederatedX

Federated Storage Engine fork that uses libmysql to talk to the data source.

Differences Between FederatedX and Federated

Main differences between FederatedX and Federated.

5.3.9.1 About FederatedX

The FederatedX storage engine is a fork of MySQL's [Federated storage engine](#), which is no longer being developed by Oracle. The original purpose of FederatedX was to keep this storage engine's development progressing-- to both add new features as well as fix old bugs.

Since [MariaDB 10.0](#), the [CONNECT](#) storage engine also allows access to a remote database via MySQL or ODBC connection (table types: [MYSQL](#), [ODBC](#)). However, in the current implementation there are several limitations.

What is the FederatedX storage engine?

The FederatedX Storage Engine is a storage engine that works with both MariaDB and MySQL. Where other storage engines are built as interfaces to lower-level file-based data stores, FederatedX uses libmysql to talk to the data source, the data source being a remote RDBMS. Currently, since FederatedX only uses libmysql, it can only talk to another MariaDB or MySQL RDBMS. The plan is of course to be able to use other RDBMS systems as a data source. There is an existing project Federated ODBC which was able to use PostgreSQL as a remote data source, and it is this type of functionality which will be brought to FederatedX in subsequent versions.

History

The history of FederatedX is derived from the History of Federated. Cisco needed a MySQL storage engine that would allow them to consolidate remote tables on some sort of routing device, being able to interact with these remote tables as if they were local to the device, but not actually on the device, since the routing device had only so much storage space. The first prototype of the Federated Storage Engine was developed by JD (need to check on this- Brian Aker can verify) using the HANDLER interface. Brian handed the code to Patrick Galbraith and explained how it needed to work, and with Brian and Monty's tutelage and Patrick had a working Federated Storage Engine with MySQL 5.0. Eventually, Federated was released to the public in a MySQL 5.0 release.

When MySQL 5.1 became the production release of MySQL, Federated had more features and enhancements added to it, namely:

- New Federated SERVER added to the parser. This was something Cisco needed that made it possible to change the connection parameters for numerous Federated tables at once without having to alter or re-create the Federated tables.
- Basic Transactional support-- for supporting remote transactional tables
- Various bugs that needed to be fixed from MySQL 5.0
- Plugin capability

In [MariaDB 10.0.2](#) [FederatedX](#) got support for assisted [table discovery](#).

Installing the Plugin

Although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing `INSTALL SONAME` or `INSTALL PLUGIN`. For example:

```
INSTALL SONAME 'ha_federatedx';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the `--plugin-load` or the `--plugin-load-add` options. This can be specified as a command-line argument to `mariadb` or it can be specified in a relevant server [option group](#) in an [option file](#). For example:

```
[mariadb]
...
plugin_load_add = ha_federatedx
```

Uninstalling the Plugin

You can uninstall the plugin dynamically by executing `UNINSTALL SONAME` or `UNINSTALL PLUGIN`. For example:

```
UNINSTALL SONAME 'ha_federatedx';
```

If you installed the plugin by providing the `--plugin-load` or the `--plugin-load-add` options in a relevant server [option group](#) in an [option file](#), then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

How FederatedX works

Every storage engine has to implement derived standard handler class API methods for a storage engine to work. FederatedX is no different in that regard. The big difference is that FederatedX needs to implement these handler methods in such as to construct SQL statements to run on the remote server and if there is a result set, process that result set into the internal handler format so that the result is returned to the user.

Internal workings of FederatedX

Normal database files are local and as such: You create a table called 'users', a file such as 'users.MYD' is created. A handler reads, inserts, deletes, updates data in this file. The data is stored in particular format, so to read, that data has to be parsed into fields, to write, fields have to be stored in this format to write to this data file.

With the FederatedX storage engine, there will be no local files for each table's data (such as .MYD). A foreign database will store the data that would normally be in this file. This will necessitate the use of MySQL client API to read, delete, update, insert this data. The data will have to be retrieve via an SQL call "`SELECT * FROM users`". Then, to read this data, it will have to be retrieved via `mysql_fetch_row` one row at a time, then converted from the column in this select into the format that the handler expects.

The basic functionality of how FederatedX works is:

- The user issues an SQL statement against the local federatedX table. This statement is parsed into an item tree
- FederatedX uses the mysql handler API to implement the various methods required for a storage engine. It has access to the item tree for the SQL statement issued, as well as the Table object and each of its Field members. At
- With this information, FederatedX constructs an SQL statement
- The constructed SQL statement is sent to the Foreign data source through libmysql using the mysql client API
- The foreign database reads the SQL statement and sends the result back through the mysql client API to the origin
- If the original SQL statement has a result set from the foreign data source, the FederatedX storage engine iterates through the result set and converts each row and column to the internal handler format
- If the original SQL statement only returns the number of rows returned (`affected_rows`), that number is added to the table stats which results in the user seeing how many rows were affected.

FederatedX table creation

The create table will simply create the .frm file, and within the `CREATE TABLE` SQL statement, there SHALL be any of the following :

```
connection=scheme://username:password@hostname:port/database/tablename
connection=scheme://username@hostname/database/tablename
connection=scheme://username:password@hostname/database/tablename
connection=scheme://username:password@hostname/database/tablename
```

Or using the syntax introduced in MySQL versions 5.1 for a Federated server (SQL/MED Spec xxxx)

```
connection="connection_one"
connection="connection_one/table_foo"
```

An example of a connect string specifying all the connection parameters would be:

```
connection=mysql://username:password@hostname:port/database/tablename
```

Or, using a Federated server, first a server is created:

```
create server 'server_one' foreign data wrapper 'mysql' options
  (HOST '127.0.0.1',
  DATABASE 'db1',
  USER 'root',
  PASSWORD '',
  PORT 3306,
  SOCKET '',
  OWNER 'root');
```

MariaDB starting with [10.11.12](#)

You can also use 'mariadb' as a wrapper.

Then the FederatedX table is created specifying the newly created Federated server. The following statements creates a federated table, `federated.t1` against the table `db1.t1` on the remote server.

```
CREATE TABLE federated.t1 (
  `id` int(20) NOT NULL,
  `name` varchar(64) NOT NULL default ''
)
ENGINE="FEDERATED" DEFAULT CHARSET=latin1
CONNECTION='server_one';
```

(Note that in MariaDB, the original Federated storage engine is replaced with the new FederatedX storage engine. And for backward compatibility, the old name "FEDERATED" is used in create table. So in MariaDB, the engine type should be given as "FEDERATED" without an extra "X", not "FEDERATEDX").

The equivalent of above, if done specifying all the connection parameters

```
CONNECTION="mysql://[email protected]:3306/db1/t1"
```

You can also change the server to point to a new schema:

```
ALTER SERVER 'server_one' options (DATABASE 'db2');
```

All subsequent calls to any FederatedX table using the 'server_one' will now be against tables in `db2`! Guess what? You no longer have to perform an alter table in order to point one or more FederatedX tables to a new server!

This `connection="connection string"` is necessary for the handler to be able to connect to the foreign server, either by URL, or by server name.

Method calls

One way to see how the FederatedX storage engine works is to compile a debug build of MariaDB and turn on a trace log. Using a two column table, with one record, the following SQL statements shown below, can be analyzed for what internal methods they result in being called.

SELECT

If the query is for instance "`SELECT * FROM foo`", then the primary methods you would see with debug turned on would be first:

```
ha_federatedx::info
ha_federatedx::scan_time:
ha_federatedx::rnd_init: share->select_query SELECT * FROM foo
ha_federatedx::extra
```

Then for every row of data retrieved from the foreign database in the result set:

```
ha_federatedx::rnd_next
ha_federatedx::convert_row_to_internal_format
ha_federatedx::rnd_next
```

After all the rows of data that were retrieved, you would see:

```
ha_federatedx::rnd_end
ha_federatedx::extra
ha_federatedx::reset
```

INSERT

If the query was " **INSERT INTO** foo (id, ts) **VALUES** (2, now());", the trace would be:

```
ha_federatedx::write_row
ha_federatedx::reset
```

UPDATE

If the query was " **UPDATE** foo **SET** ts = now() **WHERE** id = 1;", the resultant trace would be:

```
ha_federatedx::index_init
ha_federatedx::index_read
ha_federatedx::index_read_idx
ha_federatedx::rnd_next
ha_federatedx::convert_row_to_internal_format
ha_federatedx::update_row

ha_federatedx::extra
ha_federatedx::extra
ha_federatedx::extra
ha_federatedx::external_lock
ha_federatedx::reset
```

FederatedX capabilities and limitations

- Tables MUST be created on the foreign server prior to any action on those tables via the handler, first version. IMPORTANT: IF you MUST use the FederatedX storage engine type on the REMOTE end, make sure that the table you connect to IS NOT a table pointing BACK to your ORIGINAL table! You know and have heard the screeching of audio feedback? You know putting two mirrors in front of each other how the reflection continues for eternity? Well, need I say more?!
- There is no way for the handler to know if the foreign database or table has changed. The reason for this is that this database has to work like a data file that would never be written to by anything other than the database. The integrity of the data in the local table could be breached if there was any change to the foreign database.
- Support for SELECT, INSERT, UPDATE, DELETE indexes.
- No ALTER TABLE, DROP TABLE or any other Data Definition Language calls.
- Prepared statements will not be used in the first implementation, it remains to to be seen whether the limited subset of the client API for the server supports this.
- This uses SELECT, INSERT, UPDATE, DELETE and not HANDLER for its implementation.
- This will not work with the query cache.
- FederatedX does not support [GEOMETRY](#) types. Such tables cannot be created explicitly, nor discovered.

How do you use FederatedX?

To use this handler, it's very simple. You must have two databases running, either both on the same host, or on different hosts.

First, on the foreign database you create a table, for example:

```
CREATE TABLE federated.test_table (
  id      int(20) NOT NULL auto_increment,
  name    varchar(32) NOT NULL default '',
  other   int(20) NOT NULL default '0',
  PRIMARY KEY (id),
  KEY name (name),
  KEY other_key (other))
DEFAULT CHARSET=latin1;
```

Then, on the server that will be connecting to the foreign host (client), you create a federated table without specifying the table structure:

```
CREATE TABLE federated_test_table ENGINE=FEDERATED
CONNECTION='mysql://[email protected]:9306/federated/test_table';
```

Notice the "ENGINE" and "CONNECTION" fields? This is where you respectively set the engine type, "FEDERATED" and foreign host information, this being the database your 'client' database will connect to and use as the "data file". Obviously, the foreign database is running on port 9306, so you want to start up your other database so that it is indeed on port 9306, and your FederatedX database on a port other than that. In my setup, I use port 5554 for FederatedX, and port 5555 for the foreign database.

Alternatively (or if you're using MariaDB before version 10.0.2) you specify the federated table structure explicitly:

```
CREATE TABLE federated_test_table (
  id      int(20) NOT NULL auto_increment,
  name    varchar(32) NOT NULL default '',
  other   int(20) NOT NULL default '0',
  PRIMARY KEY (id),
  KEY name (name),
  KEY other_key (other))
ENGINE=FEDERATED
DEFAULT CHARSET=latin1
CONNECTION='mysql://[email protected]:9306/federated/test_table';
```

In this case the table structure must match exactly the table on the foreign server.

How to see the storage engine in action

When developing this handler, I compiled the FederatedX database with debugging:

```
./configure --with-federatedx-storage-engine \
--prefix=/home/mysql/mysql-build/federatedx/ --with-debug
```

Once compiled, I did a 'make install' (not for the purpose of installing the binary, but to install all the files the binary expects to see in the directory I specified in the build with

```
--prefix=/home/code-dev/maria
```

Then, I started the foreign server:

```
/usr/local/mysql/bin/mysqld_safe \
--user=mysql --log=/tmp/mysqld.5555.log -P 5555
```

Then, I went back to the directory containing the newly compiled mysqld <builddir>/sql/ , started up gdb:

```
gdb ./mysqld
```

Then, within the (gdb) prompt:

```
(gdb) run --gdb --port=5554 --socket=/tmp/mysqld.5554 --skip-innodb --debug
```

Next, I open several windows for each:

1. Tail the debug trace: tail -f /tmp/mysqld.trace|grep ha_fed
2. Tail the SQL calls to the foreign database: tail -f /tmp/mysqld.5555.log
3. A window with a client open to the federatedx server on port 5554
4. A window with a client open to the federatedx server on port 5555

I would create a table on the client to the foreign server on port 5555, and then to the FederatedX server on port 5554. At this point, I would run whatever queries I wanted to on the FederatedX server, just always remembering that whatever changes I wanted to make on the table, or if I created new tables, that I would have to do that on the foreign server.

Another thing to look for is 'show variables' to show you that you have support for FederatedX handler support:

```
show variables like '%federat%'
```

and:

```
show storage engines;
```

Both should display the federatedx storage handler.

How do I create a federated server?

A federated server is a way to have a foreign data source defined-- with all connection parameters-- so that you don't have to specify explicitly the connection parameters in a string.

For instance, if you wanted to connect to a table, `first_db.test_table`, using this definition:

```
CREATE TABLE federated_test_table ENGINE=FEDERATED
CONNECTION='mysql://[email protected]/first_db/test_table';
```

You could instead create this with a server:

```
create server 'server_one' foreign data wrapper 'mysql' options
(HOST '192.168.1.123',
DATABASE 'first_db',
USER 'patg',
PASSWORD '',
PORT 3306,
SOCKET '',
OWNER 'root');
```

You could now specify the server instead of the full URL in the connection string:

```
CREATE TABLE federated_test_table ENGINE=FEDERATED
CONNECTION='server_one/test_table';
```

On the server where you create this `federated_test_table` you will now have access to the table `test_table` in the `first_db` database on the remote server found on 192.168.1.123.

How does FederatedX differ from the old Federated Engine?

FederatedX from a user point of view is the same for the most part. What is different with FederatedX and Federated is the following:

- Rewrite of the main Federated source code from one single `ha_federated.cc` file into three main abstracted components:
 - `ha_federatedx.cc` - Core implementation of FederatedX
 - `federated_io.cc` - Parent connection class to be over-ridden by derived classes for each RDBMS/client lib
 - `federated_io_<driver>.cc` - derived `federated_io` class for a given RDBMS
 - `federated_txn.cc` - New support for using transactional engines on the foreign server using a connection poll
- Various bugs fixed (need to look at opened bugs for Federated)

Where can I get FederatedX

FederatedX is part of [MariaDB 5.1](#) and later. MariaDB merged with the latest FederatedX when there is a need to get a bug fixed. You can get the latest code/follow/participate in the project from the [FederatedX home page](#).

What are the plans for FederatedX?

- Support for other RDBMS vendors using ODBC
- Support for pushdown conditions
- Ability to limit result set sizes

5.3.9.2 Differences Between FederatedX and Federated

The main differences are:

New features in FederatedX

- Transactions (beta feature)
- Supports partitions (alpha feature)
- New class structure which allows developers to write connection classes for other RDBMSs without having to modify base classes for FederatedX

Different behavior

- FederatedX is statically compiled into MariaDB by default.
- When you create a table with FederatedX, the connection will be tested. The `CREATE` will fail if MariaDB can't connect to the remote host or if the remote table doesn't exist.

5.3.10 MEMORY Storage Engine

Contents

1. [Memory Usage](#)
2. [Index Type](#)
3. [Replication](#)
4. [Example](#)

Contents of the MEMORY storage engine (previously known as HEAP) are stored in memory rather than on disk.

It is best-used for read-only caches of data from other tables, or for temporary work areas.

Since the data is stored in memory, it is highly vulnerable to power outages or hardware failure, and is unsuitable for permanent data storage. In fact, after a server restart, MEMORY tables will be recreated (because the definition file is stored on disk), but they will be empty. It is possible to re-populate them with a query using the `--init-file` server startup option.

Variable-length types like `VARCHAR` can be used in MEMORY tables. `BLOB` or `TEXT` columns are not supported for MEMORY tables.

Memory Usage

The maximum total size of MEMORY tables cannot exceed the `max_heap_table_size` system server variable. When a table is created this value applies to that table, and when the server is restarted this value applies to existing tables. Changing this value has no effect on existing tables. However, executing a `ALTER TABLE ... ENGINE=MEMORY` statement applies the current value of `max_heap_table_size` to the table. Also, it is possible to change the session value of `max_heap_table_size` before creating a table, to make sure that tables created by other sessions are not affected.

The `MAX_ROWS` table option provides a hint about the number of rows you plan to store in them. This is not a hard limit that cannot be exceeded, and does not allow to exceed `max_heap_table_size`. The storage engine uses `max_heap_table_size` and `MAX_ROWS` to calculate the maximum memory that could be allocated for the table.

Memory allocated to a MEMORY table is freed by running `DROP TABLE` or `TRUNCATE TABLE`, or rebuilding with `ALTER TABLE tbl_name ENGINE = MEMORY`. When rows are deleted, space is not automatically freed.

Index Type

The MEMORY storage engine permits indexes to be either B-tree or Hash. Hash is the default type for MEMORY. See [Storage Engine index types](#) for more on their characteristics.

A MEMORY table can have up to 64 indexes, 16 columns for each index and a maximum key length of 3072 bytes.

Replication

MEMORY tables are lost when a server restarts. In order to achieve this result in [replication](#), the first time a primary uses a MEMORY table after a restart, it writes a `DELETE` statement for that table to the binary log, so that replicas are also emptied.

Example

The following example shows how to create a `MEMORY` table with a given maximum size, as described above.

```
SET max_heap_table_size = 1024*516;

CREATE TABLE t (a VARCHAR(10), b INT) ENGINE = MEMORY;

SET max_heap_table_size = @@max_heap_table_size;
```

5.3.11 MERGE

Contents

1. [Description](#)
2. [Examples](#)

Description

The MERGE storage engine, also known as the MRG_MyISAM engine, is a collection of identical [MyISAM](#) tables that can be used as one. "Identical" means that all tables have identical column and index information. You cannot merge MyISAM tables in which the columns are listed in a different order, do not have exactly the same columns, or have the indexes in different order. However, any or all of the MyISAM tables can be compressed with [myisampack](#). Column names and index names can be different, as long as data types and NULL/NOT NULL clauses are the same. Differences in table options such as `AVG_ROW_LENGTH`, `MAX_ROWS`, or `PACK_KEYS` do not matter.

Each index in a MERGE table must match an index in underlying MyISAM tables, but the opposite is not true. Also, a MERGE table cannot have a PRIMARY KEY or UNIQUE indexes, because it cannot enforce uniqueness over all underlying tables.

The following options are meaningful for MERGE tables:

- `UNION`. This option specifies the list of the underlying MyISAM tables. The list is enclosed between parentheses and separated with commas.
- `INSERT_METHOD`. This option specifies whether, and how, INSERTs are allowed for the table. Allowed values are: `NO` (INSERTs are not allowed), `FIRST` (new rows will be written into the first table specified in the `UNION` list), `LAST` (new rows will be written into the last table specified in the `UNION` list). The default value is `NO`.

If you define a MERGE table with a definition which is different from the underlying MyISAM tables, or one of the underlying tables is not MyISAM, the CREATE TABLE statement will not return any error. But any statement which involves the table will produce an error like the following:

```
ERROR 1168 (HY000): Unable to open underlying table which is differently defined
or of non-MyISAM type or doesn't exist
```

A `CHECK TABLE` will show more information about the problem.

The error is also produced if the table is properly defined, but an underlying table's definition changes at some point in time.

If you try to insert a new row into a MERGE table with `INSERT_METHOD=NO`, you will get an error like the following:

```
ERROR 1036 (HY000): Table 'tbl_name' is read only
```

It is possible to build a MERGE table on MyISAM tables which have one or more [virtual columns](#). MERGE itself does not support virtual columns, thus such columns will be seen as regular columns. The data types and sizes will still need to be identical, and they cannot be NOT NULL.

Examples

```

CREATE TABLE t1 (
  a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  message CHAR(20)) ENGINE=MyISAM;

CREATE TABLE t2 (
  a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  message CHAR(20)) ENGINE=MyISAM;

INSERT INTO t1 (message) VALUES ('Testing'),('table'),('t1');

INSERT INTO t2 (message) VALUES ('Testing'),('table'),('t2');

CREATE TABLE total (
  a INT NOT NULL AUTO_INCREMENT,
  message CHAR(20), INDEX(a))
ENGINE=MERGE UNION=(t1,t2) INSERT_METHOD=LAST;

SELECT * FROM total;
+---+-----+
| a | message |
+---+-----+
| 1 | Testing |
| 2 | table   |
| 3 | t1      |
| 1 | Testing |
| 2 | table   |
| 3 | t2      |
+---+-----+

```

In the following example, we'll create three MyISAM tables, and then a MERGE table on them. However, one of them uses a different data type for the column b, so a SELECT will produce an error:

```

CREATE TABLE t1 (
  a INT,
  b INT
) ENGINE = MyISAM;

CREATE TABLE t2 (
  a INT,
  b INT
) ENGINE = MyISAM;

CREATE TABLE t3 (
  a INT,
  b TINYINT
) ENGINE = MyISAM;

CREATE TABLE t_mrg (
  a INT,
  b INT
) ENGINE = MERGE,UNION=(t1,t2,t3);

SELECT * FROM t_mrg;
ERROR 1168 (HY000): Unable to open underlying table which is differently defined
or of non-MyISAM type or doesn't exist

```

To find out what's wrong, we'll use a CHECK TABLE:

```

CHECK TABLE t_mrg\G
***** 1. row *****
  Table: test.t_mrg
  Op: check
Msg_type: Error
Msg_text: Table 'test.t3' is differently defined or of non-MyISAM type or doesn't exist
***** 2. row *****
  Table: test.t_mrg
  Op: check
Msg_type: Error
Msg_text: Unable to open underlying table which is differently defined or of non-MyISAM type or
doesn't exist
***** 3. row *****
  Table: test.t_mrg
  Op: check
Msg_type: error
Msg_text: Corrupt

```

Now, we know that the problem is in `t3`'s definition.

5.3.12 Mroonga

Mroonga (formerly named Groonga Storage Engine) is a storage engine that provides fast CJK-ready full text searching using column store.

About Mroonga

[Mroonga full text search storage engine.](#)

Mroonga Overview

[Basic Mroonga usage.](#)

Mroonga Status Variables

[Mroonga-related status variables.](#)

Mroonga System Variables

[Mroonga-related system variables.](#)

Mroonga User-Defined Functions

[Mroonga user-defined functions \(UDFs\).](#)

Information Schema MROONGA_STATS Table

[Mroonga activities statistics.](#)

5.3.12.1 About Mroonga

Contents

1. [How to Install](#)
2. [Limitations](#)
3. [Available Character Sets](#)
4. [More Information](#)

Mroonga Version	Introduced	Maturity
7.07	MariaDB 10.2.11 , MariaDB 10.1.29	Stable
5.04	MariaDB 10.1.6	Stable
5.02	MariaDB 10.0.18 , MariaDB 10.1.5	Stable
5.0	MariaDB 10.0.17	Stable
4.06	MariaDB 10.0.15	Stable

Mroonga is a full text search storage engine based on Groonga, which is an open-source CJK-ready (Chinese, Japanese, and Korean) fulltext search engine using column base. See <http://groonga.org> for more.

With Mroonga, you can have a CJK-ready full text search feature, and it is faster than the [MyISAM](#) and [InnoDB full text search](#) for both updating and searching.

Mroonga also supports Groonga's fast geolocation search by using MariaDB's geolocation SQL syntax.

Mroonga currently only supports Linux x86_64 (Intel64/AMD64).

How to Install

Enable Mroonga with the following statement:

```
INSTALL SONAME 'ha_mroonga';
```

On Debian and Ubuntu mroonga engine will be installed with

```
sudo apt-get install mariadb-plugin-mroonga
```

See [Plugin overview](#) for details on installing and uninstalling plugins.

SHOW ENGINES can be used to check whether Mroonga is installed correctly:

```
SHOW ENGINES;
...
***** 8. row *****
      Engine: Mroonga
      Support: YES
      Comment: CJK-ready fulltext search, column store
Transactions: NO
              XA: NO
      Savepoints: NO
...
```

Once the plugin is installed, add a UDF (User-Defined Function) named "last_insert_grn_id", that returns the record ID assigned by groonga in INSERT, by the following SQL.

```
CREATE FUNCTION last_insert_grn_id RETURNS INTEGER SONAME 'ha_mroonga.so';
```

Limitations

- The maximum size of a single key is 4096 bytes.
- The maximum size of all keys is 4GB.
- The maximum number of records in a fulltext index is 268,435,455
- The maximum number of distinct terms in a fulltext index is 268,435,455
- The maximum size of a fulltext index is 256GB

Note that the maximum sizes are not hard limits, and may vary according to circumstance.

For more details, see <http://mroonga.org/docs/reference/limitations.html>.

Available Character Sets

Mroonga supports a limited number of [character sets](#). These include:

- ASCII
- BINARY
- CP932
- EUCJPMS
- KOI8R
- LATIN1
- SJIS
- UJIS
- UTF8
- UTF8MB4

More Information

Further documentation for Mroonga can be found at <http://mroonga.org/docs/>

5.3.12.2 Mroonga Overview

Contents

1. [Score](#)
2. [Parser](#)
 1. [Examples](#)
 1. [TokenBigram vs TokenBigramSplitSymbol](#)
 2. [TokenBigram vs TokenBigramSplitSymbolAlpha](#)

Once Mroonga has been installed (see [About Mroonga](#)), its basic usage is similar to that of a [regular fulltext index](#).

For example:

```
CREATE TABLE ft_mroonga(copy TEXT,FULLTEXT(copy)) ENGINE=Mroonga;

INSERT INTO ft_mroonga(copy) VALUES ('Once upon a time'),
  ('There was a wicked witch'), ('Who ate everybody up');

SELECT * FROM ft_mroonga WHERE MATCH(copy) AGAINST('wicked');
+-----+
| copy          |
+-----+
| There was a wicked witch |
+-----+
```

Score

Mroonga can also order by weighting. For example, first add another record:

```
INSERT INTO ft_mroonga(copy) VALUES ('She met a wicked, wicked witch');
```

Records can be returned by weighting, for example, the newly added record has two occurrences of the word 'wicked' and a higher weighting:

```
SELECT *, MATCH(copy) AGAINST('wicked') AS score FROM ft_mroonga
  WHERE MATCH(copy) AGAINST('wicked') ORDER BY score DESC;
+-----+-----+
| copy          | score |
+-----+-----+
| She met a wicked, wicked witch | 299594 |
| There was a wicked witch      | 149797 |
+-----+-----+
```

Parser

Mroonga permits you to set a different parser for searching by specifying the parser in the `CREATE TABLE` statement as a comment or, in older versions, changing the value of the `mroonga_default_parser` system variable.

For example:

```
CREATE TABLE ft_mroonga(copy TEXT,FULLTEXT(copy) COMMENT 'parser "TokenDelimitNull"')
ENGINE=Mroonga;;
```

or

```
SET GLOBAL mroonga_default_parser = 'TokenBigramSplitSymbol';
```

The following parser settings are available:

Setting	Description
off	No tokenizing is performed.
TokenBigram	Default value. Continuous alphabetical characters, numbers or symbols are treated as a token.
TokenBigramIgnoreBlank	Same as <code>TokenBigram</code> except that white spaces are ignored.
TokenBigramIgnoreBlankSplitSymbol	Same as <code>TokenBigramSplitSymbol</code> . except that white spaces are ignore.
TokenBigramIgnoreBlankSplitSymbolAlpha	Same as <code>TokenBigramSplitSymbolAlpha</code> except that white spaces are ignored.
TokenBigramIgnoreBlankSplitSymbolAlphaDigit	Same as <code>TokenBigramSplitSymbolAlphaDigit</code> except that white spaces are ignored.
TokenBigramSplitSymbol	Same as <code>TokenBigram</code> except that continuous symbols are not treated as a token, but tokenised in bigram.
TokenBigramSplitSymbolAlpha	Same as <code>TokenBigram</code> except that continuous alphabetical characters are not treated as a token, but tokenised in bigram.
TokenDelimit	Tokenises by splitting on white spaces.
TokenDelimitNull	Tokenises by splitting on null characters (�).
TokenMecab	Tokenise using MeCab. Required Groonga to be built with MeCab support.
TokenTrigram	Tokenises in trigrams but continuous alphabetical characters, numbers or symbols are treated as a token.
TokenUnigram	Tokenises in unigrams but continuous alphabetical characters, numbers or symbols are treated as a token.

Examples

TokenBigram vs TokenBigramSplitSymbol

`TokenBigram` failing to match partial symbols which `TokenBigramSplitSymbol` matches, since `TokenBigramSplitSymbol` does not treat continuous symbols as a token.

```
DROP TABLE ft_mroonga;
CREATE TABLE ft_mroonga(copy TEXT,FULLTEXT(copy) COMMENT 'parser "TokenBigram"')
ENGINE=Mroonga;
INSERT INTO ft_mroonga(copy) VALUES ('Once upon a time'),
('There was a wicked witch'),
('Who ate everybody up'),
('She met a wicked, wicked witch'),
('A really wicked, wicked witch!?!?');
SELECT * FROM ft_mroonga WHERE MATCH(copy) AGAINST('!?!?');
Empty set (0.00 sec)

DROP TABLE ft_mroonga;
CREATE TABLE ft_mroonga(copy TEXT,FULLTEXT(copy) COMMENT 'parser "TokenBigramSplitSymbol"')
ENGINE=Mroonga;
INSERT INTO ft_mroonga(copy) VALUES ('Once upon a time'),
('There was a wicked witch'),
('Who ate everybody up'),
('She met a wicked, wicked witch'),
('A really wicked, wicked witch!?!?');
SELECT * FROM ft_mroonga WHERE MATCH(copy) AGAINST('!?!?');
+-----+
| copy          |
+-----+
| A really wicked, wicked witch!?!? |
+-----+
```

TokenBigram vs TokenBigramSplitSymbolAlpha

```

DROP TABLE ft_mroonga;
CREATE TABLE ft_mroonga(copy TEXT,FULLTEXT(copy) COMMENT 'parser "TokenBigram"')
ENGINE=Mroonga;
INSERT INTO ft_mroonga(copy) VALUES ('Once upon a time'),
('There was a wicked witch'),
('Who ate everybody up'),
('She met a wicked, wicked witch'),
('A really wicked, wicked witch!?!?');
SELECT * FROM ft_mroonga WHERE MATCH(copy) AGAINST('ick');
Empty set (0.00 sec)

DROP TABLE ft_mroonga;
CREATE TABLE ft_mroonga(copy TEXT,FULLTEXT(copy) COMMENT 'parser "TokenBigramSplitSymbolAlpha"')
ENGINE=Mroonga;
INSERT INTO ft_mroonga(copy) VALUES ('Once upon a time'),
('There was a wicked witch'),
('Who ate everybody up'),
('She met a wicked, wicked witch'),
('A really wicked, wicked witch!?!?');
SELECT * FROM ft_mroonga WHERE MATCH(copy) AGAINST('ick');
+-----+
| copy                                     |
+-----+
| There was a wicked witch                 |
| She met a wicked, wicked witch          |
| A really wicked, wicked witch!?!?      |
+-----+

```

5.3.12.3 Mroonga Status Variables

Contents

1. [Mroonga_count_skip](#)
2. [Mroonga_fast_order_limit](#)

This page documents status variables related to the [Mroonga storage engine](#). See [Server Status Variables](#) for a complete list of status variables that can be viewed with [SHOW STATUS](#).

Mroonga_count_skip

- **Description:** Incremented each time the 'fast line count feature' is used. Can be used to check if the feature is working after enabling it.
- **Data Type:** numeric

Mroonga_fast_order_limit

- **Description:** Incremented each time the 'fast ORDER BY LIMIT feature' is used. Can be used to check if the feature is working after enabling it.
- **Data Type:** numeric

5.3.12.4 Mroonga System Variables

Contents

5. [mroonga_default_tokenizer](#)
6. [mroonga_default_wrapper_engine](#)
7. [mroonga_dry_write](#)
8. [mroonga_enable_operations_recording](#)
9. [mroonga_enable_optimization](#)
10. [mroonga_libgroonga_embedded](#)
11. [mroonga_libgroonga_support_lz4](#)
12. [mroonga_libgroonga_support_zlib](#)
13. [mroonga_libgroonga_support_zstd](#)
14. [mroonga_libgroonga_version](#)
15. [mroonga_lock_timeout](#)
16. [mroonga_log_file](#)
17. [mroonga_log_level](#)
18. [mroonga_match_escalation_threshold](#)
19. [mroonga_max_n_records_for_estimate](#)
20. [mroonga_query_log_file](#)
21. [mroonga_vector_column_delimiter](#)
22. [mroonga_version](#)

This page documents system variables related to the [Mroonga storage engine](#). See [Server System Variables](#) for a complete list of system variables and instructions on setting them.

See also the [Full list of MariaDB options, system and status variables](#).

mroonga_action_on_fulltext_query_error

- **Description:** Action to take when encountering a Mroonga fulltext error.
 - `ERROR` : Report an error without logging.
 - `ERROR_AND_LOG` : Report an error with logging (the default)
 - `IGNORE` : No logging or reporting - the error is ignored.
 - `IGNORE_AND_LOG` : Log the error without reporting it.
- **Commandline:** `--mroonga-action-on-fulltext-query-error=value`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `enum`
- **Default Value:** `ERROR_AND_LOG`

mroonga_boolean_mode_syntax_flags

- **Description:** Flags to customize syntax in BOOLEAN MODE searches. Available flags:
 - `DEFAULT` : `(=SYNTAX_QUERY,ALLOW_LEADING_NOT)`
 - `ALLOW_COLUMN` : Allows `COLUMN:... syntax` in query syntax, an incompatible change to the regular BOOLEAN MODE syntax. Permits multiple indexes in one `MATCH () AGAINST ()` . Can be used in other operations besides full-text search, such as equal, and prefix search. See [Groonga query syntax](#) for more details.
 - `ALLOW_LEADING_NOT` Permits using the `NOT_INCLUDED_KEYWORD syntax` in the query syntax.
 - `ALLOW_UPDATE` : Permits updating values with the `COLUMN:=NEW_VALUE syntax` in the query syntax.
 - `SYNTAX_QUERY` : Mroonga will use Groonga's query syntax, compatible with MariaDB's BOOLEAN MODE syntax. Unless `SYNTAX_SCRIPT` is specified, this mode is always in use.
 - `SYNTAX_SCRIPT` : Mroonga will use Groonga's script syntax, a JavaScript-like syntax. If both `SYNTAX_QUERY` and `SYNTAX_SCRIPT` are specified, `SYNTAX_SCRIPT` will take precedence..
- **Commandline:** `--mroonga-boolean-mode-syntax-flags=value`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `enum`
- **Default Value:** `DEFAULT`

mroonga_database_path_prefix

- **Description:** The database path prefix.
 - **Commandline:** `--mroonga-database-path-prefix=value`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `string`
 - **Default Value:** (Empty)
-

`mroonga_default_parser`

- **Description:** The fulltext default parser, for example `TokenBigramSplitSymbolAlphaDigit` or `TokenBigram` (the default). See the list of options at [Mroonga Overview:Parser](#). Deprecated since Mroonga 5.04, use [mroonga_default_tokenizer](#) instead.
 - **Commandline:** `--mroonga-default-parser=value`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `string`
 - **Default Value:** `TokenBigram`
 - **Deprecated:** [MariaDB 10.1.6](#), Mroonga 5.0.4
-

`mroonga_default_tokenizer`

- **Description:** The fulltext default parser, for example `TokenBigramSplitSymbolAlphaDigit` or `TokenBigram` (the default). See the list of options at [Mroonga Overview:Parser](#).
 - **Commandline:** `--mroonga-default-tokenizer=value`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `string`
 - **Default Value:** `TokenBigram`
 - **Introduced:** [MariaDB 10.1.6](#), Mroonga 5.0.4
-

`mroonga_default_wrapper_engine`

- **Description:** The default engine for wrapper mode.
 - **Commandline:** `--mroonga-default-wrapper-engine=value`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `string`
 - **Default Value:** (Empty)
-

`mroonga_dry_write`

- **Description:** If set to `on`, (`off` is default), data is not actually written to the Groonga database. Only really useful to change for benchmarking.
 - **Commandline:** `--mroonga-dry-write[={0|1}]`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `off`
-

`mroonga_enable_operations_recording`

- **Description:** Whether recording operations for recovery to the Groonga database is enabled (default) or not. Requires reopening the database with [FLUSH TABLES](#) after changing the variable.
 - **Commandline:** `--mroonga-enable-operations-recording={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `ON`
 - **Introduced:** [MariaDB 10.2.11](#), [MariaDB 10.1.29](#)
-

mroonga_enable_optimization

- **Description:** If set to `on` (the default), optimization is enabled. Only really useful to change for benchmarking.
 - **Commandline:** `--mroonga-enable-optimization={0|1}`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `on`
-

mroonga_libgroonga_embedded

- **Description:** Whether libgroonga is embedded or not.
 - **Commandline:** None
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `ON`
 - **Introduced:** [MariaDB 10.1.6](#) 
-

mroonga_libgroonga_support_lz4

- **Description:** Whether libgroonga supports lz4 or not.
 - **Commandline:** None
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
-

mroonga_libgroonga_support_zlib

- **Description:** Whether libgroonga supports zlib or not.
 - **Commandline:** None
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `ON`
-

mroonga_libgroonga_support_zstd

- **Description:** Whether libgroonga supports Zstandard or not.
 - **Commandline:** None
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
 - **Introduced:** [MariaDB 10.2.11](#) , [MariaDB 10.1.29](#) 
-

mroonga_libgroonga_version

- **Description:** Groonga library version.
 - **Commandline:** None
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `string`
-

mroonga_lock_timeout

- **Description:** Lock timeout used in Groonga.
- **Commandline:** `--mroonga-lock-timeout=#`

- **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** numeric
 - **Default Value:** 900000
 - **Range:** -1 to 2147483647
-

mroonga_log_file

- **Description:** Name and path of the Mroonga log file.
 - **Commandline:** --mroonga-log-file=value
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** string
 - **Default Value:** groonga.log
-

mroonga_log_level

- **Description:** Mroonga log file output level, which determines what is logged. Valid levels include:
 - NONE : No output.
 - EMERG : Only emergency error messages, such as database corruption.
 - ALERT : Alert messages, such as internal errors.
 - CRIT : Critical error messages, such as deadlocks.
 - ERROR : Errors, such as API errors.
 - WARNING : Warnings, such as invalid arguments.
 - NOTICE : Notices, such as a change in configuration or a status change.
 - INFO : Information messages, such as file system operations.
 - DEBUG : Debug messages, suggested for developers or testers.
 - DUMP : Dump messages.
 - **Commandline:** --mroonga-log-level=value
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** enum
 - **Default Value:** NOTICE
-

mroonga_match_escalation_threshold

- **Description:** The threshold to determine whether the match method is escalated. -1 means never escalate.
 - **Commandline:** --mroonga-match-escalation-threshold=#
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** numeric
 - **Default Value:** 0
 - **Range:** -1 to 9223372036854775807
-

mroonga_max_n_records_for_estimate

- **Description:** The max number of records to estimate the number of matched records
 - **Commandline:** --mroonga-max-n-records-for-estimate=#
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** numeric
 - **Default Value:** 1000
 - **Range:** -1 to 2147483647
-

mroonga_query_log_file

- **Description:** Query log file for Mroonga.
 - **Commandline:** --mroonga-query-log-file=filename
 - **Scope:** Global
 - **Dynamic:** Yes
-

- **Data Type:** `string`
- **Default Value:** (Empty string)
- **Introduced:** [MariaDB 10.2.11](#) 

`mroonga_vector_column_delimiter`

- **Description:** Delimiter to use when outputting a vector column. The default is a white space.
- **Commandline:** `--mroonga-vector-column-delimiter=value`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `string`
- **Default Value:** (white space)

`mroonga_version`

- **Description:** Mroonga version
- **Commandline:** None
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `string`

5.3.12.5 Mroonga User-Defined Functions

Mroonga provides a number of User-defined functions (UDFs)

Creating Mroonga User-Defined Functions

How to install Mroonga's user-defined functions.

`last_insert_grn_id`

Returns the unique Groonga id of the last-inserted record.

`mroonga_command`

Pass a command to Groonga to execute.

`mroonga_escape`

Escaping a string.

`mroonga_highlight_html`

Highlights the specified keywords in the target text.

`mroonga_normalize`

Uses Groonga's normalizer to normalize text.

`mroonga_snippet`

A keyword with surrounding text, or the keyword in context.

`mroonga_snippet_html`

It provides a keyword with surrounding text, or the keyword in context.

5.3.12.5.1 Creating Mroonga User-Defined Functions

The [Mroonga storage engine](#) includes a number of [user-defined functions](#) that need to be created before they can be used. If these are not created already during Mroonga setup, you will need to do so yourself. The full list of available functions and the statements to create them are found in `share/mroonga/install.sql`, for example, as of Mroonga 7.07 ([MariaDB 10.2.11](#)  and [MariaDB 10.1.29](#) ) running on Linux:

```

DROP FUNCTION IF EXISTS last_insert_grn_id;
CREATE FUNCTION last_insert_grn_id RETURNS INTEGER
  SONAME 'ha_mroonga.so';

DROP FUNCTION IF EXISTS mroonga_snippet;
CREATE FUNCTION mroonga_snippet RETURNS STRING
  SONAME 'ha_mroonga.so';

DROP FUNCTION IF EXISTS mroonga_command;
CREATE FUNCTION mroonga_command RETURNS STRING
  SONAME 'ha_mroonga.so';

DROP FUNCTION IF EXISTS mroonga_escape;
CREATE FUNCTION mroonga_escape RETURNS STRING
  SONAME 'ha_mroonga.so';

DROP FUNCTION IF EXISTS mroonga_snippet_html;
CREATE FUNCTION mroonga_snippet_html RETURNS STRING
  SONAME 'ha_mroonga.so';

DROP FUNCTION IF EXISTS mroonga_normalize;
CREATE FUNCTION mroonga_normalize RETURNS STRING
  SONAME 'ha_mroonga.so';

DROP FUNCTION IF EXISTS mroonga_highlight_html;
CREATE FUNCTION mroonga_highlight_html RETURNS STRING
  SONAME 'ha_mroonga.so';

DROP FUNCTION IF EXISTS mroonga_query_expand;
CREATE FUNCTION mroonga_query_expand RETURNS STRING
  SONAME 'ha_mroonga.so';

```

5.3.12.5.2 last_insert_grn_id

Syntax

```
last_insert_grn_id()
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

Description

`last_insert_grn_id` is a [user-defined function](#) (UDF) included with the [Mroonga storage engine](#). It returns the unique Groonga id of the last-inserted record. See [Creating Mroonga User-Defined Functions](#) for details on creating this UDF if required.

Examples

```

SELECT last_insert_grn_id();
+-----+
| last_insert_grn_id() |
+-----+
|                    3 |
+-----+

```

5.3.12.5.3 mroonga_command

Contents

1. [Syntax](#)
2. [Description](#)
3. [Example](#)

Syntax

```
mroonga_command (command)
```

Description

`mroonga_command` is a [user-defined function](#) (UDF) included with the [Mroonga storage engine](#). It passes a command to Groonga for execution. See [Creating Mroonga User-Defined Functions](#) for details on creating this UDF if required.

- `command` - string, required parameter specifying the command to pass that will be executed by Groonga. See [the Groonga reference](#) [↗](#) for a list of commands.

Returns the result of the Groonga command.

Example

```
SELECT mroonga_command('status');
+-----+
| mroonga_command('status') |
+-----+
| { "alloc_count":593,"starttime":1512022368,"start_time":1512022368,"uptime":13510,"version":"7.0.7", "n_queries":0,"cache_hit_rate":0.0,"command_version":1,"default_command_version":1,"max_command_version":3} |
+-----+
```

5.3.12.5.4 mroonga_escape

Contents

1. [Syntax](#)
2. [Description](#)
3. [Example](#)

Syntax

```
mroonga_escape (string [,special_characters])
```

- `string` - required parameter specifying the text you want to escape
- `special_characters` - optional parameter specifying the characters to escape

Description

`mroonga_escape` is a [user-defined function](#) (UDF) included with the [Mroonga storage engine](#), used for escaping a string. See [Creating Mroonga User-Defined Functions](#) for details on creating this UDF if required.

If no `special_characters` parameter is provided, by default `+-<>*()"` are escaped.

Returns the escaped string.

Example

```
SELECT mroonga_escape("+-<>~*()\\"");
'\'+\|-\<\|>\|~\|\*\|(\|)\|\"':
```

5.3.12.5.5 mroonga_highlight_html

Syntax

```
mroonga_highlight_html(text[, query AS query])
mroonga_highlight_html(text[, keyword1, ..., keywordN])
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

Description

`mroonga_highlight_html` is a [user-defined function](#) (UDF) included with the [Mroonga storage engine](#). It highlights the specified keywords in the target text. See [Creating Mroonga User-Defined Functions](#) for details on creating this UDF if required.

The optional parameter can either be one or more *keywords*, or a Groonga *query*.

The function highlights the specified keywords in the target text by surrounding each keyword with `...`, and escaping special HTML characters such as `<` and `>`.

Returns highlighted HTML.

Examples

```
SELECT mroonga_highlight_html('<p>MariaDB includes the Mroonga storage engine</p>.')
  AS highlighted_html;
+-----+
| highlighted_html |
+-----+
| &lt;p&gt;MariaDB includes the Mroonga storage engine&lt;/p&gt;. |
+-----+
```

Highlighting the words `MariaDB` and `Mroonga` in a given text:

```
SELECT mroonga_highlight_html('MariaDB includes the Mroonga storage engine.', 'MariaDB',
'Mroonga')
  AS highlighted_html;
+-----+
| highlighted_html |
| |
+-----+
| <span class="keyword">MariaDB</span> includes the <span class="keyword">Mroonga</span>
storage engine. |
+-----+
+-----+
```

The same outcome, formulated as a Groonga query:

```

SELECT mroonga_highlight_html('MariaDB includes the Mroonga storage engine.', 'MariaDB OR
Mroonga'
  AS query) AS highlighted_text;
+-----+
| highlighted_text
|
+-----+
| <span class="keyword">MariaDB</span> includes the <span class="keyword">Mroonga</span>
storage engine. |
+-----+

```

5.3.12.5.6 mroonga_normalize

Syntax

```
mroonga_normalize(string[, normalizer_name])
```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

Description

`mroonga_normalize` is a [user-defined function](#) (UDF) included with the [Mroonga storage engine](#). It uses Groonga's normalizer to normalize text. See [Creating Mroonga User-Defined Functions](#) for details on creating this UDF if required.

Given a string, returns the normalized text.

See the [Groonga Normalizer Reference](#) [↗](#) for details on the Groonga normalizers. The default if no normalizer is provided is `NormalizerAuto`.

Examples

```

SELECT mroonga_normalize("ABいリットル");
+-----+
| mroonga_normalize("ABいリットル") |
+-----+
| abいリットル                        |
+-----+

```

5.3.12.5.7 mroonga_snippet

Syntax

```

mroonga_snippet document,
  max_length,
  max_count,
  encoding,
  skip_leading_spaces,
  html_escape,
  snippet_prefix,
  snippet_suffix,
  word1, word1_prefix, word1_suffix
  ...
[wordN wordN_prefix wordN_suffix]

```

Contents

1. [Syntax](#)
2. [Description](#)
3. [Example](#)

Description

`mroonga_snippet` is a [user-defined function](#) (UDF) included with the [Mroonga storage engine](#). It provides a keyword with surrounding text, or the keyword in context. See [Creating Mroonga User-Defined Functions](#) for details on creating this UDF if required.

The required parameters include:

- `document` - Column name or string value.
- `max_length` - Maximum length of the snippet, in bytes.
- `max_count` - Maximum snippet elements (N word).
- `encoding` - Encoding of the document, for example `cp932_japanese_ci`
- `skip_leading_spaces` - `1` to skip leading spaces, `0` to not skip.
- `html_escape` = `1` to enable HTML escape, `0` to disable.
- `prefix` - Snippet start text.
- `suffix` - Snippet end text.

The optional parameters include:

- `wordN` - A word.
- `wordN_prefix` - wordN start text.
- `wordN_suffix` - wordN end text

It can be used in both storage and wrapper mode.

Returns the snippet string.

Example

5.3.12.5.8 mroonga_snippet_html

Description

`mroonga_snippet_html` is a [user-defined function](#) (UDF) included with the [Mroonga storage engine](#). It provides a keyword with surrounding text, or the keyword in context. It is still considered experimental. See [Creating Mroonga User-Defined Functions](#) for details on creating this UDF if required.

1.1.1.2.9.1.1.29 Information Schema MROONGA_STATS Table

5.3.13 MyISAM

MyISAM was the default [storage engine](#) from MySQL 3.23 until it was replaced by [InnoDB](#) in MariaDB and MySQL 5.5. It's a light, non-transactional engine with great performance, is easy to copy between systems and has a small data footprint.

You're encouraged to rather use the [Aria](#) storage engine for new applications, which has even better performance and the goal of being crash-safe.

Until [MariaDB 10.4](#), [system tables](#) used the MyISAM storage engine.

5.3.13.1 MyISAM Overview

The MyISAM storage engine was the default storage engine from MySQL 3.23 until it was replaced as default by [InnoDB](#) in MariaDB and MySQL 5.5. Historically, MyISAM is a replacement for the older ISAM engine, removed in MySQL 4.1.

It's a light, non-transactional engine with great performance, is easy to copy between systems and has a small data footprint.

You're encouraged to rather use the [Aria](#) storage engine for new applications, which has even better performance in most cases and the goal of being crash-safe.

A MyISAM table is stored in three files on disk. There's a table definition file with an extension of `.frm`, a data file with the extension `.MYD`, and an index file with the extension `.MYI`.

MyISAM features

- Does not support [transactions](#).
- Does not support foreign keys.
- Supports [FULLTEXT indexes](#).
- Supports [GIS](#) data types.
- Storage limit of 256TB.
- Maximum of 64 indexes per table.
- Maximum of 32 columns per index.
- Maximum index length of 1000 bytes.
- Limit of $(2^{32})^2$ (1.844E+19) rows per table.
- Supports large files up to 63-bits in length where the underlying system supports this.
- All data is stored with the low byte first, so all files will still work if copied to other systems or other machines.
- The data file and the index file can be placed on different devices to improve speed.
- Supports table locking, not row locking.
- Supports a key buffer that is [segmented](#) in MariaDB.
- Supports [concurrent inserts](#).
- Supports fixed length, dynamic and compressed formats - see [MyISAM Storage Formats](#).
- Numeric index values are stored with the high byte first, which enables more efficient index compression.
- Data values are stored with the low byte first, making it mostly machine and operating system independent. The only exceptions are if a machine doesn't use two's-complement signed integers and the IEEE floating-point format.
- Can be copied between databases or systems with normal system tools, as long as the files are not open on either system. Use [FLUSH TABLES](#) to ensure files are not in use.
- There are a number of tools for working with MyISAM tables. These include:
 - [mariadb-check](#) for checking or repairing
 - [myisamchk](#) for checking or repairing
 - [myisampack](#) for compressing
- It is possible to build a [MERGE](#) table on the top of one or more MyISAM tables.

16. [myisam_use_mmap](#)

This page documents system variables related to the [MyISAM](#) storage engine. For options, see [MyISAM Options](#).

See [Server System Variables](#) for a complete list of system variables and instructions on setting them.

See also the [Full list of MariaDB options, system and status variables](#).

`key_buffer_size`

- **Description:** Size of the buffer for the index blocks used by MyISAM tables and shared for all threads. See [Optimizing key_buffer_size](#) for more on selecting the best value.
- **Commandline:** `--key-buffer-size=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `134217728`
- **Range:** 8 upwards (upper limit determined by operating system per process limit)

`key_cache_age_threshold`

- **Description:** The lower the setting, the more quickly buffers move from the hot key cache sublist to the warm sublist.
- **Commandline:** `--key-cache-age-threshold=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `300`
- **Range:** 100 to 4294967295

`key_cache_block_size`

- **Description:** [MyISAM](#) key cache block size in bytes .
- **Commandline:** `--key-cache-block-size=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `1024`
- **Range:** 512 to 16384

`key_cache_division_limit`

- **Description:** Percentage to use for the warm key cache buffer list (the remainder is allocated between the hot and cold caches).
- **Commandline:** `--key-cache-division-limit=#`
- **Scope:** Global

- **Dynamic:** Yes
 - **Data Type:** numeric
 - **Default Value:** 100
 - **Range:** 1 to 100
-

key_cache_file_hash_size

- **Description:** Number of hash buckets for open and changed files. If you have many MyISAM files open you should increase this for faster flushing of changes. A good value is probably 1/10th of the number of possible open MyISAM files.
 - **Commandline:** --key-cache-file-hash-size=#
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** numeric
 - **Default Value:** 512
 - **Range:** 128 to 16384
-

key_cache_segments

- **Description:** The number of segments in a key cache. See [Segmented Key Cache](#).
 - **Commandline:** --key-cache-segments=#
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Type:** numeric
 - **Default Value:** 0 (*non-segmented*)
 - **Range:** 0 to 64
-

myisam_block_size

- **Description:** Block size to be used for MyISAM index pages.
 - **Commandline:** --myisam-block-size=#
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** numeric
 - **Default Value:** 1024
-

myisam_data_pointer_size

- **Description:** Size in bytes of the default pointer, used in a [MyISAM CREATE TABLE](#) with no MAX_ROWS option.
 - **Commandline:** --myisam-data-pointer-size=#
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** numeric
 - **Default Value:** 6
 - **Range:** 2 to 7
-

myisam_max_extra_sort_file_size

- **Description:** Removed in MySQL 5.0.6, was used as a way to force long character keys in large tables to use the key cache method.
 - **Removed:** MySQL 5.0.6
-

myisam_max_sort_file_size

- **Description:** Maximum size in bytes of the temporary file used while recreating a MyISAM index. If the this size is exceeded, the slower process of using the key cache is done instead.
- **Commandline:** --myisam-max-sort-file-size=#
- **Scope:** Global
- **Dynamic:** Yes

- **Data Type:** numeric
 - **Default Value - 32 bit:** 2147483648
 - **Default Value - 64 bit:** 9223372036854775807
-

myisam_mmap_size

- **Description:** Maximum memory in bytes that can be used for memory mapping compressed MyISAM files. Too high a value may result in swapping if there are many compressed MyISAM tables.
 - **Commandline:** --myisam-mmap-size=#
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** numeric
 - **Default Value - 32 bit:** 4294967295
 - **Default Value - 64 bit:** 18446744073709547520
 - **Range - 32-bit:** 7 to 4294967295
 - **Range - 64-bit:** 7 to 18446744073709547520
-

myisam_recover_options

- **Description:** MyISAM recovery mode. Multiple options can be selected, comma-delimited. Using no argument is equivalent to specifying `DEFAULT`, while specifying "" is equivalent to `OFF`. If enabled each time the server opens a MyISAM table, it checks whether it has been marked as crashed, or wasn't closed properly. If so, mysqld will run a check and then attempt to repair the table, writing to the error log beforehand.
 - **OFF:** No recovery.
 - **BACKUP:** If the data file is changed while recovering, saves a backup of the .MYD data file. t.MYD will be saved as t.MYD-datetime.BAK.
 - **BACKUP_ALL:** Same as `BACKUP` but also backs up the .MYI index file. t.MYI will be saved as t.MYI-datetime.BAK.
 - **DEFAULT:** Recovers without backing up, forcing, or quick checking.
 - **FORCE:** Runs the recovery even if it determines that more than one row from the data file will be lost.
 - **QUICK:** Does not check rows in the table if there are no delete blocks.
 - **Commandline:** --myisam-recover-options[=name]
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** enumeration
 - **Default Value:**
 - `BACKUP,QUICK` ([>= MariaDB 10.2.4](#))
 - `DEFAULT` ([<= MariaDB 10.2.3](#))
 - `OFF`
 - **Valid Values:** `OFF`, `DEFAULT`, `BACKUP`, `BACKUP_ALL`, `FORCE` or `QUICK`
-

myisam_repair_threads

- **Description:** If set to more than 1, the default, MyISAM table indexes each have their own thread during repair and sorting. Increasing from the default will usually result in faster repair, but will use more CPU and memory.
 - **Commandline:** --myisam-repair-threads=#
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** numeric
 - **Default Value:** 1
 - **Range - 32-bit:** 1 to 4294967295
 - **Range - 64-bit:** 1 to 18446744073709547520
-

myisam_sort_buffer_size

- **Description:** Size in bytes of the buffer allocated when creating or sorting indexes on a MyISAM table. Increase for better `myisamchk -r, --recover` performance.
- **Commandline:** --myisam-sort-buffer-size=#
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** numeric

- **Default Value:** 134217720 (128MB)
- **Range:** 4096 to 18446744073709547520

mysam_stats_method

- **Description:** Determines how NULLs are treated for [MyISAM](#) index statistics purposes. If set to `nulls_equal`, the default, all NULL index values are treated as a single group. This is usually fine, but if you have large numbers of NULLs the average group size is slanted higher, and the optimizer may miss using the index for ref accesses when it would be useful. If set to `nulls_unequal`, the opposite approach is taken, with each NULL forming its own group of one. Conversely, the average group size is slanted lower, and the optimizer may use the index for ref accesses when not suitable. Setting to `nulls_ignored` ignores NULLs altogether from index group calculations. See also [Index Statistics](#), [aria_stats_method](#), [innodb_stats_method](#).
- **Commandline:** `--mysam-stats-method=name`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** enumeration
- **Default Value:** `nulls_equal`
- **Valid Values:** `nulls_equal`, `nulls_unequal`, `nulls_ignored`

mysam_use_mmap

- **Description:** If set to `1` (0 is default), memory mapping will be used to reading and writing MyISAM tables.
- **Commandline:** `--mysam-use-mmap`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** boolean
- **Default Value:** `OFF`

5.3.13.3 MyISAM Storage Formats

Contents

1. [Fixed-length](#)
2. [Dynamic](#)
3. [Compressed](#)

The [MyISAM](#) storage engine supports three different table storage formats.

These are `FIXED`, `DYNAMIC` and `COMPRESSED`. `FIXED` and `DYNAMIC` can be set with the `ROW FORMAT` option in the [CREATE TABLE](#) statement, or will be chosen automatically depending on the columns the table contains. `COMPRESSED` can only be set via the [mysampack](#) tool.

The [SHOW TABLE STATUS](#) statement can be used to see the storage format used by a table. Note that `COMPRESSED` tables are reported as `DYNAMIC` in that context.

Fixed-length

Fixed-length (or static) tables contain records of a fixed-length. Each column is the same length for all records, regardless of the actual contents. It is the default format if a table has no [BLOB](#), [TEXT](#), [VARCHAR](#) or [VARBINARY](#) fields, and no `ROW FORMAT` is provided. You can also specify a fixed table with `ROW_FORMAT=FIXED` in the table definition.

Tables containing `BLOB` or `TEXT` fields cannot be `FIXED`, as by design these are both dynamic fields. However, no error or warning will be raised if you specify `FIXED`.

Fixed-length tables have a number of characteristics

- fast, since MariaDB will always know where a record begins
- easy to repair: [mysamchk](#) is always able to recover all rows, except for the last one if it is not entirely written
- easy to cache
- take up more space than dynamic or compressed tables, as the maximum amount of storage space will be allocated to each record.
- reconstructing after a crash is uncomplicated due to the fixed positions

- no fragmentation or need to re-organize, unless records have been deleted and you want to free the space up.

Dynamic

Dynamic tables contain records of a variable length. It is the default format if a table has any BLOB, TEXT, VARCHAR or VARBINARY fields, and no ROW FORMAT is provided. You can also specify a DYNAMIC table with ROW_FORMAT=DYNAMIC in the table definition. If the table contains BLOB or TEXT columns, its format is always DYNAMIC, and the ROW FORMAT option is ignored.

Dynamic tables have a number of characteristics

- Each row contains a header indicating the length of the row.
- Rows tend to become fragmented easily. UPDATING a record to be longer will likely ensure it is stored in different places on the disk. Use [OPTIMIZE TABLE](#) when the fragmentation is too high.
- All string columns with a length of four or more are dynamic.
- They require much less space than fixed-length tables.
- Restoring after a crash is more complicated than with FIXED tables. Some fragments may be lost.

If a DYNAMIC table has some frequently-accessed fixed-length columns, it could be a good idea to move them into a separate FIXED table to avoid fragmentation.

Compressed

Compressed tables are a read-only format, created with the [myisampack](#) tool. This can be done while the server is running, but external lock must not be disabled. [myisamchk](#) is used to uncompress them.

Compressed tables have a number of characteristics:

- while the data is read-only, DDL statements such as [DROP TABLE](#) and [TRUNCATE TABLE](#) will still function.
- take much less space than fixed or dynamic tables. Each data has usually a 40-70% compression ratio
- rows are compressed separately, reducing access overhead.
- row headers will be from one to three bytes.
- rows can be compressed with different compression types, including
 - prefix space compression
 - suffix space compression
 - columns with small sets of values are converted to ENUM
 - numeric zeros are stored with only one bit
 - integer columns will be reduced to the smallest int type that can hold the contents

1.3.8 MyISAM Clients and Utilities

5.3.13.5 MyISAM Index Storage Space

Regular [MyISAM](#) tables make use of [B-tree indexes](#).

String indexes are space-compressed, which reduces the size of [VARCHARs](#) that don't use the full length, or a string that has trailing spaces. String indexes also make use of prefix-compression, where strings with identical prefixes are compressed.

Numeric indexes can also be prefix-compressed if the [PACK_KEYS=1](#) option is used. Regardless, the high byte is always stored first, which allows a reduced index size.

In the worst case, with no strings being space-compressed, the total index storage space will be $(\text{index_length}+4)/0.67$ per index.

5.3.13.6 MyISAM Log

The MyISAM log records all changes to [MyISAM](#) tables. It is not enabled by default. To enable it, start the server with the [--log-isam](#) option, for example:

```
--log-isam=myisam.log
```

The *isam* instead of *myisam* above is not a typo - it's a legacy from when the predecessor to the MyISAM format, called ISAM. The option can be used without specifying a filename, in which case the default, *myisam.log* is used.

To process the contents of the log file, use the [myisamlog](#) utility.

1.1.1.4.2.5 Concurrent Inserts

5.3.13.8 Segmented Key Cache

Contents

- [1. About Segmented Key Cache](#)
- [2. Segmented Key Cache Syntax](#)
- [3. Segmented Key Cache Statistics](#)

About Segmented Key Cache

A segmented key cache is a collection of structures for regular [MyISAM](#) key caches called key cache segments. Segmented key caches mitigate one of the major problems of the simple key cache: thread contention for key cache lock (mutex). With regular key caches, every call of a key cache interface function must acquire this lock. So threads compete for this lock even in the case when they have acquired shared locks for the file and the pages they want to read from are in the key cache buffers.

When working with a segmented key cache any key cache interface function that needs only one page has to acquire the key cache lock only for the segment the page is assigned to. This makes the chances for threads not having to compete for the same key cache lock better.

Any page from a file can be placed into a buffer of only one segment. The number of the segment is calculated from the file number and the position of the page in the file, and it's always the same for the page. Pages are evenly distributed among segments.

The idea and the original code of the segmented key cache was provided by Fredrik Nylander from Stardoll.com. The code was extensively reworked, improved, and eventually merged into MariaDB by Igor Babaev from Monty Program (now MariaDB Corporation).

You can find some benchmark results comparing various settings on the [Segmented Key Cache Performance](#) page.

Segmented Key Cache Syntax

New global variable: [key_cache_segments](#). This variable sets the number of segments in a key cache. Valid values for this variable are whole numbers between 0 and 64. If the number of segments is set to a number greater than 64 the number of segments will be truncated to 64 and a warning will be issued.

A value of 0 means the key cache is a regular (i.e. non-segmented) key cache. This is the default. If

`key_cache_segments` is 1 (or higher) then the new key cache segmentation code is used. In practice there is no practical use of a single-segment segmented key cache except for testing purposes, and setting `key_cache_segments = 1` should be slower than any other option and should not be used in production.

Other global variables used when working with regular key caches also apply to segmented key caches: [key_buffer_size](#), [key_cache_age_threshold](#), [key_cache_block_size](#), and [key_cache_division_limit](#).

Segmented Key Cache Statistics

Statistics about the key cache can be found by looking at the [KEY_CACHES](#) table in the [INFORMATION_SCHEMA](#) database. Columns in this table are:

Column Name	Description
<code>KEY_CACHE_NAME</code>	The name of the key cache
<code>SEGMENTS</code>	total number of segments (set to <code>NULL</code> for regular key caches)
<code>SEGMENT_NUMBER</code>	segment number (set to <code>NULL</code> for any regular key caches and for rows containing aggregation statistics for segmented key caches)
<code>FULL_SIZE</code>	memory for cache buffers/auxiliary structures
<code>BLOCK_SIZE</code>	size of the blocks
<code>USED_BLOCKS</code>	number of currently used blocks
<code>UNUSED_BLOCKS</code>	number of currently unused blocks
<code>DIRTY_BLOCKS</code>	number of currently dirty blocks

READ_REQUESTS	number of read requests
READS	number of actual reads from files into buffers
WRITE_REQUESTS	number of write requests
WRITES	number of actual writes from buffers into files

5.3.14 MyRocks

MyRocks is a storage engine that adds the RocksDB database to MariaDB. RocksDB is an LSM database with a great compression ratio that is optimized for flash storage.

MyRocks Version	Introduced	Maturity
MyRocks 1.0	MariaDB 10.3.7 , MariaDB 10.2.16	Stable
MyRocks 1.0	MariaDB 10.3.5 , MariaDB 10.2.14	Gamma
MyRocks 1.0	MariaDB 10.3.4 , MariaDB 10.2.13	Beta
MyRocks 1.0	MariaDB 10.2.5	Alpha

About MyRocks for MariaDB

Enables greater compression than InnoDB, and less write amplification.

Getting Started with MyRocks

Installing and getting started with MyRocks.

Building MyRocks in MariaDB

MariaDB compile process for MyRocks.

Loading Data Into MyRocks

MyRocks has ways to load data much faster than normal INSERTs

MyRocks Status Variables

MyRocks-related status variables.

MyRocks and Group Commit with Binary log

MyRocks supports group commit with the binary log

Optimizer Statistics in MyRocks

How MyRocks provides statistics to the query optimizer

Differences Between MyRocks Variants

Differences between Facebook's, MariaDB's and Percona Server's MyRocks.

MyRocks and Bloom Filters

Bloom filters are used to reduce read amplification.

MyRocks and CHECK TABLE

MyRocks supports the CHECK TABLE command.

MyRocks and Data Compression

MyRocks supports several compression algorithms.

MyRocks and Index-Only Scans

MyRocks and index-only scans on secondary indexes.

MyRocks and START TRANSACTION WITH CONSISTENT SNAPSHOT

FB/MySQL has added new syntax which returns the binlog coordinates pointing at the snapshot.

MyRocks Column Families

MyRocks stores data in column families, which are similar to tablespaces.

MyRocks in MariaDB 10.2 vs MariaDB 10.3

MyRocks storage engine in MariaDB 10.2 and MariaDB 10.3.

MyRocks Performance Troubleshooting

MyRocks exposes its performance metrics through several interfaces.

About MyRocks for MariaDB

MyRocks is an open source storage engine that was originally developed by Facebook.

MyRocks has been extended by the MariaDB engineering team to be a pluggable storage engine that you use in your MariaDB solutions. It works seamlessly with MariaDB features. This openness in the storage layer allows you to use the right storage engine to optimize your usage requirements, which provides optimum performance. Community contributions are one of MariaDB's greatest advantages over other databases. Under the lead of our developer Sergey Petrunia, MyRocks in MariaDB is occasionally being merged with upstream MyRocks from Facebook.

See more at: <https://mariadb.com/resources/blog/facebook-myrocks-mariadb#sthash.ZIEr7kNq.dpuf>

MyRocks, typically, gives greater performance for web scale type applications. It can be an ideal storage engine solution when you have workloads that require greater compression and IO efficiency. It uses a Log Structured Merge (LSM) architecture, which has advantages over B-Tree algorithms, to provide efficient data ingestion, like read-free replication slaves, or fast bulk data loading. MyRocks distinguishing features include:

- compaction filter
- merge operator
- backup
- column families
- bulk loading
- persistent cache

For more MyRocks features see: <https://github.com/facebook/rocksdb/wiki/Features-Not-in-LevelDB>

Benefits

On production workloads, MyRocks was tested to prove that it provides:

Greater Space Efficiency

- 2x more compression
MyRocks has 2x better compression compared to compressed InnoDB, 3-4x better compression compared to uncompressed InnoDB, meaning you use less space.

Greater Writing Efficiency

- 2x lower write rates to storage
MyRocks has a 10x less write amplification compared to InnoDB, giving you better endurance of flash storage and improving overall throughput.

Faster Data Loading

- faster database loads
MyRocks writes data directly onto the bottommost level, which avoids all compaction overheads when you enable faster data loading for a session.

Faster Replication

- No random reads for updating secondary keys, except for unique indexes. The Read-Free Replication option does away with random reads when updating primary keys, regardless of uniqueness, with a row-based binary logging format.

<http://myrocks.io> <https://mariadb.com/resources/blog/facebook-myrocks-mariadb>

Requirements and Limitations

- MyRocks is included from [MariaDB 10.2.5](#).
- MyRocks is available in the MariaDB Server packages for Linux and Windows.
- Maria DB optimistic parallel replication may not be supported.
- MyRocks is not available for 32-bit platforms
- [Galera Cluster](#) is tightly integrated into InnoDB storage engine (it also supports Percona's XtraDB which is a modified version of InnoDB). Galera Cluster does not work with any other storage engines, including MyRocks (or TokuDB for example).

MyRocks builds are available on platforms that support a sufficiently modern compiler, for example:

- Ubuntu Trusty, Xenial, (amd64 and ppc64el)
- Ubuntu Yakkety (amd64)
- Debian Jessie, stable (amd64, ppc64el)
- Debian Stretch, Sid (testing and unstable) (amd64)
- CentOS/RHEL 7 (amd64)
- Centos/RHEL 7.3 (amd64)
- Fedora 24 and 25 (amd64)
- OpenSUSE 42 (amd64)
- Windows 64 (zip and MSI)

5.3.14.2 Getting Started with MyRocks

MariaDB starting with [10.2.5](#)

The MyRocks storage engine was first released in [MariaDB 10.2.5](#).

MyRocks is a storage engine that adds the RocksDB database to MariaDB. RocksDB is an LSM database with a great compression ratio that is optimized for flash storage.

The storage engine must be installed before it can be used.

Contents

1. [Installing the Plugin's Package](#)
 1. [Installing on Linux](#)
 1. [Installing with a Package Manager](#)
 1. [Installing with yum/dnf](#)
 2. [Installing with apt-get](#)
 3. [Installing with zypper](#)
 2. [Installing on Windows](#)
 2. [Installing the Plugin](#)
 3. [Uninstalling the Plugin](#)
 4. [Verifying the Installation](#)
 5. [Compression](#)
 6. [System and Status Variables](#)

Installing the Plugin's Package

The MyRocks storage engine's shared library is included in MariaDB packages as the `ha_rocksdbs.so` or `ha_rocksdbs.dll` shared library on systems where it can be built. The plugin was first included in [MariaDB 10.2.5](#).

Installing on Linux

The MyRocks storage engine is included in [binary tarballs](#) on Linux.

Installing with a Package Manager

The MyRocks storage engine can also be installed via a package manager on Linux. In order to do so, your system needs to be configured to install from one of the MariaDB repositories.

You can configure your package manager to install it from MariaDB Corporation's MariaDB Package Repository by using the [MariaDB Package Repository setup script](#).

You can also configure your package manager to install it from MariaDB Foundation's MariaDB Repository by using the [MariaDB Repository Configuration Tool](#).

Installing with yum/dnf

On RHEL, CentOS, Fedora, and other similar Linux distributions, it is highly recommended to install the relevant [RPM package](#) from MariaDB's repository using `yum` or `dnf`. Starting with RHEL 8 and Fedora 22, `yum` has been replaced by `dnf`, which is the next major version of `yum`. However, `yum` commands still work on many systems that use `dnf`. For example:

```
sudo yum install MariaDB-rocksdbs-engine
```

Installing with apt-get

On Debian, Ubuntu, and other similar Linux distributions, it is highly recommended to install the relevant [DEB package](#) from MariaDB's repository using `apt-get`. For example:

```
sudo apt-get install mariadb-plugin-rocksdbs
```

Installing with zypper

On SLES, OpenSUSE, and other similar Linux distributions, it is highly recommended to install the relevant [RPM package](#) from MariaDB's repository using `zypper`. For example:

```
sudo zypper install MariaDB-rocksdbs-engine
```

Installing on Windows

The MyRocks storage engine is included in [MSI](#) and [ZIP](#) packages on Windows.

Installing the Plugin

Once the shared library is in place, the plugin is not actually installed by MariaDB by default. There are two methods that

can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing `INSTALL SONAME` or `INSTALL PLUGIN`. For example:

```
INSTALL SONAME 'ha_rocksdb';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the `--plugin-load` or the `--plugin-load-add` options. This can be specified as a command-line argument to `mysqld` or it can be specified in a relevant server `option group` in an `option file`. For example:

```
[mariadb]
...
plugin_load_add = ha_rocksdb
```

Note: When installed with a package manager, an option file that contains the `--plugin-load-add` option may also be installed. The RPM package installs it as `/etc/my.cnf.d/rocksdb.cnf`, and the DEB package installs it as `/etc/mysql/mariadb.conf.d/rocksdb.cnf`

Uninstalling the Plugin

You can uninstall the plugin dynamically by executing `UNINSTALL SONAME` or `UNINSTALL PLUGIN`. For example:

```
UNINSTALL SONAME 'ha_rocksdb';
```

If you installed the plugin by providing the `--plugin-load` or the `--plugin-load-add` options in a relevant server `option group` in an `option file`, then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

Verifying the Installation

After installing MyRocks you will see RocksDB in the list of plugins:

```
SHOW PLUGINS;
+-----+-----+-----+-----+-----+
| Name                | Status | Type                | Library      | License |
+-----+-----+-----+-----+-----+
...
| ROCKSDB              | ACTIVE | STORAGE ENGINE     | ha_rocksdb.so | GPL     |
| ROCKSDB_CFSTATS     | ACTIVE | INFORMATION SCHEMA | ha_rocksdb.so | GPL     |
| ROCKSDB_DBSTATS     | ACTIVE | INFORMATION SCHEMA | ha_rocksdb.so | GPL     |
| ROCKSDB_PERF_CONTEXT | ACTIVE | INFORMATION SCHEMA | ha_rocksdb.so | GPL     |
| ROCKSDB_PERF_CONTEXT_GLOBAL | ACTIVE | INFORMATION SCHEMA | ha_rocksdb.so | GPL     |
| ROCKSDB_CF_OPTIONS  | ACTIVE | INFORMATION SCHEMA | ha_rocksdb.so | GPL     |
| ROCKSDB_COMPACTION_STATS | ACTIVE | INFORMATION SCHEMA | ha_rocksdb.so | GPL     |
| ROCKSDB_GLOBAL_INFO | ACTIVE | INFORMATION SCHEMA | ha_rocksdb.so | GPL     |
| ROCKSDB_DDL         | ACTIVE | INFORMATION SCHEMA | ha_rocksdb.so | GPL     |
| ROCKSDB_INDEX_FILE_MAP | ACTIVE | INFORMATION SCHEMA | ha_rocksdb.so | GPL     |
| ROCKSDB_LOCKS       | ACTIVE | INFORMATION SCHEMA | ha_rocksdb.so | GPL     |
| ROCKSDB_TRX         | ACTIVE | INFORMATION SCHEMA | ha_rocksdb.so | GPL     |
...
+-----+-----+-----+-----+-----+
```

Compression

Supported compression types are listed in the `rocksdb_supported_compression_types` variable. For example:

```
SHOW VARIABLES LIKE 'rocksdb_supported_compression_types';
+-----+-----+
| Variable_name                | Value                |
+-----+-----+
| rocksdb_supported_compression_types | Snappy,Zlib         |
+-----+-----+
```

See [MyRocks and Data Compression](#) for more.

System and Status Variables

All MyRocks [system variables](#) and [status variables](#) are prefaced with "rocksdb", so you can query them with, for example:

```
SHOW VARIABLES LIKE 'rocksdb%';  
SHOW STATUS LIKE 'rocksdb%';
```

5.3.14.3 Building MyRocks in MariaDB

Contents

1. [Build Process and Requirements](#)
2. [Building on Ubuntu 16.04](#)
3. [Starting MyRocks](#)

This page describes how to get [MyRocks in MariaDB](#) when compiling MariaDB from source.

(See <https://github.com/facebook/mysql-5.6/wiki/Build-Steps> for instructions how to build the upstream)

Build Process and Requirements

MariaDB compile process will compile [MyRocks](#) into `ha_rocksdb.so` by default if the platform supports it (That is, no `WITH_ROCKSDB` switch is necessary).

Platform requirements:

- A 64-bit platform (due to some 32 bit compilers having difficulties with RocksDB)
- git installed (or git submodules fetched somehow)
- A sufficiently recent compiler:
 - gcc >= 4.8, or
 - clang >= 3.3, or
 - MS Visual Studio 2015 or newer

Building on Ubuntu 16.04

The steps were checked on a fresh install of Ubuntu 16.04.2 LTS Xenial.

```
sudo apt-get update  
sudo apt-get -y install g++ cmake libbz2-dev libaio-dev bison zlib1g-dev libsnappy-dev  
sudo apt-get -y install libgflags-dev libreadline6-dev libncurses5-dev libssl-dev liblz4-dev gdb  
;
```

```
git clone https://github.com/MariaDB/server.git mariadb-10.2  
cd mariadb-10.2  
git checkout 10.2  
git submodule init  
git submodule update  
cmake .  
make -j10
```

This should produce `storage/rocksdb/ha_rocksdb.so` which is MyRocks storage engine in the loadable form.

Starting MyRocks

MyRocks does not require any special way to initialize the data directory. Minimal `my.cnf` file:

```

cat > ~/my1.cnf <<EOF
[mysqld]

datadir=~/mysql-test/var/install.db
plugin-dir=~/storage/rocksdb
language=~/share/english
socket=/tmp/mysql.sock
port=3307

plugin-load=ha_rocksdb
default-storage-engine=rocksdb
EOF

```

Run the server like this

```

(cd mysql-test; ./mtr alias)
cp -r mysql-test/var/install.db ~/data1
cd ../sql
./mysqld --defaults-file=~/my1.cnf

```

Compression libraries. Supported compression libraries are listed in [rocksdb_supported_compression_types](#). Compiling like the above, I get:

```

Snappy, Zlib, LZ4, LZ4HC

```

5.3.14.4 Loading Data Into MyRocks

Being a write-optimized storage engine, MyRocks has special ways to load data much faster than normal INSERTs would.

See

- <http://myrocks.io/docs/getting-started/>; the section about "Migrating from InnoDB to MyRocks in production" has some clues.
- <https://github.com/facebook/mysql-5.6/wiki/Data-Loading> covers the topic in greater detail.

Note When one loads data with `rocksdb_bulk_load=1` and the data conflicts with the data already in the database, one may get non-trivial errors, for example:

```

ERROR 1105 (HY000): [./rocksdb/test.t1_PRIMARY_2_0.bulk_load.tmp] bulk load error:
  Invalid argument: External file requires flush

```

This page documents status variables related to the [MyRocks](#) storage engine. See [Server Status Variables](#) for a complete list of status variables that can be viewed with `SHOW STATUS`.

See also the [Full list of MariaDB options, system and status variables](#).

`Rocksdb_block_cache_add`

- **Description:** Number of blocks added to the Block Cache.
- **Scope:** Global, Session
- **Data Type:** `numeric`

`Rocksdb_block_cache_add_failures`

- **Description:** Number of failures when adding blocks to Block Cache.
- **Scope:** Global, Session
- **Data Type:** `numeric`
- **Introduced:** [MariaDB 10.2.15](#), [MariaDB 10.3.7](#)

`Rocksdb_block_cache_bytes_read`

- **Description:** Bytes read from Block Cache.
- **Scope:** Global, Session
- **Data Type:** `numeric`
- **Introduced:** [MariaDB 10.2.15](#), [MariaDB 10.3.7](#)

`Rocksdb_block_cache_bytes_write`

- **Description:** Bytes written to Block Cache.
- **Scope:** Global, Session
- **Data Type:** `numeric`
- **Introduced:** [MariaDB 10.2.15](#), [MariaDB 10.3.7](#)

`Rocksdb_block_cache_data_add`

- **Description:** Number of data blocks added to the Block Cache.
- **Scope:** Global, Session
- **Data Type:** `numeric`

- **Introduced:** [MariaDB 10.2.15](#), [MariaDB 10.3.7](#)
-

Rocksdb_block_cache_data_bytes_insert

- **Description:** Bytes added to the Block Cache.
 - **Scope:** Global, Session
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 10.2.15](#), [MariaDB 10.3.7](#)
-

Rocksdb_block_cache_data_hit

- **Description:** Number of hits when accessing the data block from the Block Cache.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_block_cache_data_miss

- **Description:** Number of misses when accessing the data block from the Block Cache.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_block_cache_filter_add

- **Description:** Number of bloom filter blocks added to the Block Cache.
 - **Scope:** Global, Session
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 10.2.15](#), [MariaDB 10.3.7](#)
-

Rocksdb_block_cache_filter_bytes_evict

- **Description:** Bytes of bloom filter blocks evicted from the Block Cache.
 - **Scope:** Global, Session
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 10.2.15](#), [MariaDB 10.3.7](#)
-

Rocksdb_block_cache_filter_bytes_insert

- **Description:** Bytes of bloom filter blocks added to the Block Cache.
 - **Scope:** Global, Session
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 10.2.15](#), [MariaDB 10.3.7](#)
-

Rocksdb_block_cache_filter_hit

- **Description:** Number of hits when accessing the filter block from the Block Cache.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_block_cache_filter_miss

- **Description:** Number of misses when accessing the filter block from the Block Cache.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_block_cache_hit

- **Description:** Total number of hits for the Block Cache.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_block_cache_index_add

- **Description:** Number of index blocks added to Block Cache index.
 - **Scope:** Global, Session
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 10.2.15](#), [MariaDB 10.3.7](#)
-

Rocksdb_block_cache_index_bytes_evict

- **Description:** Bytes of index blocks evicted from the Block Cache.
 - **Scope:** Global, Session
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 10.2.15](#), [MariaDB 10.3.7](#)
-

Rocksdb_block_cache_index_bytes_insert

- **Description:** Bytes of index blocks added to the Block Cache.
 - **Scope:** Global, Session
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 10.2.15](#), [MariaDB 10.3.7](#)
-

Rocksdb_block_cache_index_hit

- **Description:** Number of hits for the Block Cache index.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_block_cache_index_miss

- **Description:** Number of misses for the Block Cache index.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_block_cache_miss

- **Description:** Total number of misses for the Block Cache.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_block_cachecompressed_hit

- **Description:** Number of hits for the compressed Block Cache.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_block_cachecompressed_miss

- **Description:** Number of misses for the compressed Block Cache.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_bloom_filter_full_positive

- **Description:**
 - **Scope:** Global, Session
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 10.2.18](#), [MariaDB 10.3.10](#)
-

Rocksdb_bloom_filter_full_true_positive

- **Description:**
 - **Scope:** Global, Session
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 10.2.18](#), [MariaDB 10.3.10](#)
-

Rocksdb_bloom_filter_prefix_checked

- **Description:** Number of times the Bloom Filter checked before creating an iterator on a file.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_bloom_filter_prefix_useful

- **Description:** Number of times the Bloom Filter check used to avoid creating an iterator on a file.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_bloom_filter_useful

- **Description:** Number of times the Bloom Filter used instead of reading from file.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_bytes_read

- **Description:** Total number of uncompressed bytes read from memtables, cache or table files.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_bytes_written

- **Description:** Total number of uncompressed bytes written.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_compact_read_bytes

- **Description:** Number of bytes read during compaction.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_compact_write_bytes

- **Description:** Number of bytes written during compaction.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_compaction_key_drop_new

- **Description:** Number of keys dropped during compaction due their being overwritten by new values.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Rocksdb_compaction_key_drop_obsolete

- **Description:** Number of keys dropped during compaction due to their being obsolete.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Rocksdb_compaction_key_drop_user

- **Description:** Number of keys dropped during compaction due to user compaction.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Rocksdb_covered_secondary_key_lookups

- **Description:** Incremented when avoiding reading a record via a keyread. This indicates lookups that were performed via a secondary index containing a field that is only a prefix of the `VARCHAR` column, and that could return all requested fields directly from the secondary index.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Rocksdb_flush_write_bytes

- **Description:** Number of bytes written during flush.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Rocksdb_get_hit_l0

- **Description:** Number of times reads got data from the L0 compaction layer.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 10.2.15](#), [MariaDB 10.3.7](#)
-

Rocksdb_get_hit_l1

- **Description:** Number of times reads got data from the L1 compaction layer.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 10.2.15](#), [MariaDB 10.3.7](#)
-

Rocksdb_get_hit_l2_and_up

- **Description:** Number of times reads got data from the L2 and up compaction layer.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 10.2.15](#), [MariaDB 10.3.7](#)
-

Rocksdb_getupdatesince_calls

- **Description:** Number of calls to the `GetUpdatesSince` function. You may find this useful when monitoring refreshes of the transaction log.

- **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_iter_bytes_read

- **Description:** Total uncompressed bytes read from an iterator, including the size of both key and value.
 - **Scope:** Global, Session
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 10.2.15](#), [MariaDB 10.3.7](#)
-

Rocksdb_l0_num_files_stall_micros

- **Description:** Shows how long in microseconds throttled due to too many files in L0.
 - **Scope:** Global, Session
 - **Data Type:** numeric
 - **Removed:** [MariaDB 10.3.1](#), [MariaDB 10.2.8](#)
-

Rocksdb_l0_slowdown_micros

- **Description:** Total time spent waiting in microseconds while performing L0-L1 compactions.
 - **Scope:** Global, Session
 - **Data Type:** numeric
 - **Removed:** [MariaDB 10.3.1](#), [MariaDB 10.2.8](#)
-

Rocksdb_manual_compactions_processed

- **Description:**
 - **Scope:** Global, Session
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 10.2.18](#), [MariaDB 10.3.10](#)
-

Rocksdb_manual_compactions_running

- **Description:**
 - **Scope:** Global, Session
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 10.2.18](#), [MariaDB 10.3.10](#)
-

Rocksdb_memtable_compaction_micros

- **Description:**
 - **Scope:** Global, Session
 - **Data Type:** numeric
 - **Removed:** [MariaDB 10.3.1](#), [MariaDB 10.2.8](#)
-

Rocksdb_memtable_hit

- **Description:** Number of memtable hits.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_memtable_miss

- **Description:** Number of memtable misses.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_memtable_total

- **Description:** Memory used, in bytes, of all memtables.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Rocksdb_memtable_unflushed

- **Description:** Memory used, in bytes, of all unflushed memtables.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Rocksdb_no_file_closes

- **Description:** Number of times files were closed.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Rocksdb_no_file_errors

- **Description:** Number of errors encountered while trying to read data from an SST file.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Rocksdb_no_file_opens

- **Description:** Number of times files were opened.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Rocksdb_num_iterators

- **Description:** Number of iterators currently open.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Rocksdb_number_block_not_compressed

- **Description:** Number of uncompressed blocks.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Rocksdb_number_db_next

- **Description:** Number of `next` calls.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 10.2.15](#), [MariaDB 10.3.7](#)
-

Rocksdb_number_db_next_found

- **Description:** Number of `next` calls that returned data.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 10.2.15](#), [MariaDB 10.3.7](#)
-

Rocksdb_number_db_prev

- **Description:** Number of `prev` calls.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 10.2.15](#), [MariaDB 10.3.7](#)
-

Rocksdb_number_db_prev_found

- **Description:** Number of `prev` calls that returned data.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 10.2.15](#), [MariaDB 10.3.7](#)
-

Rocksdb_number_db_seek

- **Description:** Number of `seek` calls.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 10.2.15](#), [MariaDB 10.3.7](#)
-

Rocksdb_number_db_seek_found

- **Description:** Number of `seek` calls that returned data.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
 - **Introduced:** [MariaDB 10.2.15](#), [MariaDB 10.3.7](#)
-

Rocksdb_number_deletes_filtered

- **Description:** Number of deleted records were not written to storage due to a nonexistent key.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Rocksdb_number_keys_read

- **Description:** Number of keys have been read.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Rocksdb_number_keys_updated

- **Description:** Number of keys have been updated.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Rocksdb_number_keys_written

- **Description:** Number of keys have been written.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Rocksdb_number_merge_failures

- **Description:** Number of failures encountered while performing merge operator actions.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Rocksdb_number_multiget_bytes_read

- **Description:** Number of bytes read during RocksDB `MultiGet()` calls.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Rocksdb_number_multiget_get

- **Description:** Number of RocksDB `MultiGet()` requests made.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Rocksdb_number_multiget_keys_read

- **Description:** Number of keys read through RocksDB `MultiGet()` calls.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Rocksdb_number_reseeks_iteration

- **Description:** Number of reseeks that have occurred inside an iteration that skipped over a large number of keys with the same user key.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Rocksdb_number_sst_entry_delete

- **Description:** Number of delete markers written.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Rocksdb_number_sst_entry_merge

- **Description:** Number of merge keys written.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Rocksdb_number_sst_entry_other

- **Description:** Number of keys written that are not delete, merge or put keys.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Rocksdb_number_sst_entry_put

- **Description:** Number of put keys written.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Rocksdb_number_sst_entry_singledelete

- **Description:** Number of single-delete keys written.
 - **Scope:** Global, Session
 - **Data Type:** `numeric`
-

Rocksdb_number_superversion_acquires

- **Description:** Number of times the supervision structure acquired. This is useful when tracking files for the database.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_number_superversion_cleanups

- **Description:** Number of times the supervision structure performed cleanups.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_number_superversion_releases

- **Description:** Number of times the supervision structure released.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_queries_point

- **Description:** Number of single-row queries.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_queries_range

- **Description:** Number of multi-row queries.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_row_lock_deadlocks

- **Description:** Number of deadlocks.
 - **Scope:** Global, Session
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 10.2.15](#), [MariaDB 10.3.7](#)
-

Rocksdb_row_lock_wait_timeouts

- **Description:** Number of row lock wait timeouts.
 - **Scope:** Global, Session
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 10.2.15](#), [MariaDB 10.3.7](#)
-

Rocksdb_rows_deleted

- **Description:** Number of rows deleted.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_rows_deleted_blind

- **Description:**
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_rows_expired

- **Description:** Number of expired rows.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_rows_filtered

- **Description:** Number of TTL filtered rows.
 - **Scope:** Global, Session
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 10.2.15](#) [↗](#), [MariaDB 10.3.7](#) [↗](#)
-

Rocksdb_rows_inserted

- **Description:** Number of rows inserted.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_rows_read

- **Description:** Number of rows read.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_rows_updated

- **Description:** Number of rows updated.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_snapshot_conflict_errors

- **Description:** Number of snapshot conflict errors that have occurred during transactions that forced a rollback.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_stall_l0_file_count_limit_slowdowns

- **Description:** Write slowdowns due to L0 being near to full.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_stall_l0_file_count_limit_stops

- **Description:** Write stops due to L0 being to full.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_stall_locked_l0_file_count_limit_slowdowns

- **Description:** Write slowdowns due to L0 being near to full and L0 compaction in progress.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_stall_locked_l0_file_count_limit_stops

- **Description:** Write stops due to L0 being full and L0 compaction in progress.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_stall_memtable_limit_slowdowns

- **Description:** Write slowdowns due to approaching maximum permitted number of memtables.
 - **Scope:** Global, Session
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 10.2.10](#), [MariaDB 10.3.3](#)
-

Rocksdb_stall_memtable_limit_stops

- **Description:** * **Description:** Write stops due to reaching maximum permitted number of memtables.
 - **Scope:** Global, Session
 - **Data Type:** numeric
 - **Introduced:** [MariaDB 10.2.10](#), [MariaDB 10.3.3](#)
-

Rocksdb_stall_micros

- **Description:** Time in microseconds that the writer had to wait for the compaction or flush to complete.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_stall_pending_compaction_limit_slowdowns

- **Description:** Write slowdowns due to nearing the limit for the maximum number of pending compaction bytes.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_stall_pending_compaction_limit_stops

- **Description:** Write stops due to reaching the limit for the maximum number of pending compaction bytes.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_stall_total_slowdowns

- **Description:** Total number of write slowdowns.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_stall_total_stops

- **Description:** Total number of write stops.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_system_rows_deleted

- **Description:** Number of rows deleted from system tables.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_system_rows_inserted

- **Description:** Number of rows inserted into system tables.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_system_rows_read

- **Description:** Number of rows read from system tables.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_system_rows_updated

- **Description:** Number of rows updated for system tables.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_wal_bytes

- **Description:** Number of bytes written to WAL.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_wal_group_syncs

- **Description:** Number of group commit WAL file syncs have occurred. This is provided by MyRocks and is not a view of a RocksDB counter. Increased in `rocksdb_flush_wal()` when doing the `rdb->FlushWAL()` call.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_wal_synced

- **Description:** Number of syncs made on RocksDB WAL file.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_write_other

- **Description:** Number of writes processed by a thread other than the requesting thread.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_write_self

- **Description:** Number of writes processed by requesting thread.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

Rocksdb_write_timedout

- **Description:** Number of writes that timed out.
 - **Scope:** Global, Session
 - **Data Type:** numeric
-

- **Description:** Number of write calls that requested WAL.
- **Scope:** Global, Session
- **Data Type:** numeric

This page documents system variables related to the [MyRocks](#) storage engine. See [Server System Variables](#) for a complete list of system variables and instructions on setting them.

See also the [Full list of MariaDB options, system and status variables](#).

`rocksdb_access_hint_on_compaction_start`

- **Description:** `DBOptions::access_hint_on_compaction_start` for RocksDB. Specifies the file access pattern, applied to all input files, once a compaction starts.
- **Commandline:** `--rocksdb-access-hint-on-compaction-start=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `1`
- **Range:** `0` to `3`

`rocksdb_advise_random_on_open`

- **Description:** `DBOptions::advise_random_on_open` for RocksDB.
- **Commandline:** `--rocksdb-advise-random-on-open={0|1}`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `boolean`
- **Default Value:** `ON`

`rocksdb_allow_concurrent_memtable_write`

- **Description:** `DBOptions::allow_concurrent_memtable_write` for RocksDB.
- **Commandline:** `--rocksdb-allow-concurrent-memtable-write={0|1}`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `boolean`
- **Default Value:** `OFF`

rocksdb_allow_mmap_reads

- **Description:** DBOptions::allow_mmap_reads for RocksDB
 - **Commandline:** --rocksdb-allow-mmap-reads={0|1}
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** boolean
 - **Default Value:** OFF
-

rocksdb_allow_mmap_writes

- **Description:** DBOptions::allow_mmap_writes for RocksDB
 - **Commandline:** --rocksdb-allow-mmap-writes={0|1}
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** boolean
 - **Default Value:** OFF
-

rocksdb_allow_to_start_after_corruption

- **Description:** Allow server still to start successfully even if RocksDB corruption is detected.
 - **Commandline:** --rocksdb-allow-to-start-after-corruption={0|1}
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** boolean
 - **Default Value:** OFF
 - **Introduced:** [MariaDB 10.3.7](#), [MariaDB 10.2.15](#)
-

rocksdb_background_sync

- **Description:** Turns on background syncs for RocksDB
 - **Commandline:** --rocksdb-background-sync={0|1}
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** boolean
 - **Default Value:** OFF
 - **Removed:** [MariaDB 10.3.1](#), [MariaDB 10.2.8](#)
-

rocksdb_base_background_compactions

- **Description:** DBOptions::base_background_compactions for RocksDB
 - **Commandline:** --rocksdb-base-background-compactions=#
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** numeric
 - **Default Value:** 1
 - **Range:** -1 to 64
 - **Removed:** [MariaDB 10.3.1](#), [MariaDB 10.2.8](#)
-

rocksdb_blind_delete_primary_key

- **Description:** Deleting rows by primary key lookup, without reading rows (Blind Deletes). Blind delete is disabled if the table has secondary key.
 - **Commandline:** --rocksdb-blind-delete-primary-key={0|1}
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** boolean
 - **Default Value:** OFF
-

rocksdb_block_cache_size

- **Description:** Block_cache size for RocksDB (block size 1024)
- **Commandline:** --rocksdb-block-cache-size=#
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** numeric
- **Default Value:** 536870912
- **Range:** 1024 to 9223372036854775807

To see the statistics of block cache usage, check `SHOW ENGINE ROCKSDB STATUS` output (search for lines starting with `rocksdb.block.cache`).

One can check the size of data of the block cache in `DB_BLOCK_CACHE_USAGE` column of the `INFORMATION_SCHEMA.ROCKSDB_DBSTATS` table.

rocksdb_block_restart_interval

- **Description:** BlockBasedTableOptions::block_restart_interval for RocksDB
 - **Commandline:** --rocksdb-block-restart-interval=#
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** numeric
 - **Default Value:** 16
 - **Range:** 1 to 2147483647
-

rocksdb_block_size

- **Description:** BlockBasedTableOptions::block_size for RocksDB
 - **Commandline:** --rocksdb-block-size=#
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** numeric
 - **Default Value:** 4096
 - **Range:** 1 to 18446744073709551615
-

rocksdb_block_size_deviation

- **Description:** BlockBasedTableOptions::block_size_deviation for RocksDB
 - **Commandline:** --rocksdb-block-size-deviation=#
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** numeric
 - **Default Value:** 10
 - **Range:** 0 to 2147483647
-

rocksdb_bulk_load

- **Description:** Use bulk-load mode for inserts. This disables `unique_checks` and enables `rocksdb_commit_in_the_middle`.
 - **Commandline:** --rocksdb-bulk-load={0|1}
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** boolean
 - **Default Value:** OFF
-

rocksdb_bulk_load_allow_sk

- **Description:** Allow bulk loading of sk keys during bulk-load. Can be changed only when bulk load is disabled.
- **Commandline:** --rocksdb-bulk-load_allow_sk={0|1}
- **Scope:** Global, Session

- **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
 - **Introduced:** [MariaDB 10.3.10](#), [MariaDB 10.2.18](#)
-

`rocksdb_bulk_load_allow_unsorted`

- **Description:** Allow unsorted input during bulk-load. Can be changed only when bulk load is disabled.
 - **Commandline:** `--rocksdb-bulk-load-allow-unsorted={0|1}`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
-

`rocksdb_bulk_load_size`

- **Description:** Maximum number of records in a batch for bulk-load mode.
 - **Commandline:** `--rocksdb-bulk-load-size=#`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `1000`
 - **Range:** 1 to 1073741824
-

`rocksdb_bytes_per_sync`

- **Description:** `DBOptions::bytes_per_sync` for RocksDB.
 - **Commandline:** `--rocksdb-bytes-per-sync=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `0`
 - **Range:** 0 to 18446744073709551615
-

`rocksdb_cache_dump`

- **Description:** Include RocksDB block cache content in core dump.
 - **Commandline:** `--rocksdb-cache-dump={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `ON`
 - **Introduced:** [MariaDB 10.4.7](#), [MariaDB 10.3.17](#), [MariaDB 10.2.26](#)
-

`rocksdb_cache_high_pri_pool_ratio`

- **Description:** Specify the size of block cache high-pri pool.
 - **Commandline:** `--rocksdb-cache-high-pri-pool-ratio=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `double`
 - **Default Value:** `0.000000`
 - **Range:** 0 to 1
 - **Introduced:** [MariaDB 10.4.7](#), [MariaDB 10.3.17](#), [MariaDB 10.2.26](#)
-

`rocksdb_cache_index_and_filter_blocks`

- **Description:** `BlockBasedTableOptions::cache_index_and_filter_blocks` for RocksDB.
- **Commandline:** `--rocksdb-cache-index-and-filter-blocks={0|1}`

- **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `ON`
-

`rocksdb_cache_index_and_filter_with_high_priority`

- **Description:** `cache_index_and_filter_blocks_with_high_priority` for RocksDB.
 - **Commandline:** `--rocksdb-cache-index-and-filter-with-high-priority={0|1}`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `ON`
 - **Introduced:** [MariaDB 10.4.7](#), [MariaDB 10.3.17](#), [MariaDB 10.2.26](#)
-

`rocksdb_checksums_pct`

- **Description:** Percentage of rows to be checksummed.
 - **Commandline:** `--rocksdb-checksums-pct=#`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `100`
 - **Range:** `0` to `100`
-

`rocksdb_collect_sst_properties`

- **Description:** Enables collecting SST file properties on each flush.
 - **Commandline:** `--rocksdb-collect-sst-properties={0|1}`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `ON`
-

`rocksdb_commit_in_the_middle`

- **Description:** Commit rows implicitly every `rocksdb_bulk_load_size`, on bulk load/insert, update and delete.
 - **Commandline:** `--rocksdb-commit-in-the-middle={0|1}`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
-

`rocksdb_commit_time_batch_for_recovery`

- **Description:** `TransactionOptions::commit_time_batch_for_recovery` for RocksDB.
 - **Commandline:** `--rocksdb-commit-time-batch-for-recovery={0|1}`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
 - **Introduced:** [MariaDB 10.3.10](#), [MariaDB 10.2.18](#)
-

`rocksdb_compact_cf`

- **Description:** Compact column family.
- **Commandline:** `--rocksdb-compact-cf=value`
- **Scope:** Global
- **Dynamic:** Yes

- **Data Type:** `string`
 - **Default Value:** (Empty)
-

`rocksdb_compaction_readahead_size`

- **Description:** `DBOptions::compaction_readahead_size` for RocksDB.
 - **Commandline:** `--rocksdb-compaction-readahead-size=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** 0
 - **Range:** 0 to 18446744073709551615
-

`rocksdb_compaction_sequential_deletes`

- **Description:** RocksDB will trigger compaction for the file if it has more than this number sequential deletes per window.
 - **Commandline:** `--rocksdb-compaction-sequential-deletes=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** 0
 - **Range:** 0 to 2000000
-

`rocksdb_compaction_sequential_deletes_count_sd`

- **Description:** Counting `SingleDelete` as `rocksdb_compaction_sequential_deletes`.
 - **Commandline:** `--rocksdb-compaction-sequential-deletes-count-sd={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
-

`rocksdb_compaction_sequential_deletes_file_size`

- **Description:** Minimum file size required for `compaction_sequential_deletes`.
 - **Commandline:** `--rocksdb-compaction-sequential-deletes-file-size=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** 0
 - **Range:** -1 to 9223372036854775807
-

`rocksdb_compaction_sequential_deletes_window`

- **Description:** Size of the window for counting `rocksdb_compaction_sequential_deletes`.
 - **Commandline:** `--rocksdb-compaction-sequential-deletes-window=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** 0
 - **Range:** 0 to 2000000
-

`rocksdb_concurrent_prepare`

- **Description:** `DBOptions::concurrent_prepare` for RocksDB.
- **Commandline:** `--rocksdb-coconcurrent-prepare={0|1}`
- **Scope:** Global
- **Dynamic:** No

- **Data Type:** `boolean`
 - **Default Value:** `1`
 - **Removed:** [MariaDB 10.3.7](#) [MariaDB 10.2.15](#)
-

`rocksdb_create_checkpoint`

- **Description:** Checkpoint directory.
 - **Commandline:** `--rocksdb-create-checkpoint=value`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `string`
 - **Default Value:** (Empty)
-

`rocksdb_create_if_missing`

- **Description:** `DBOptions::create_if_missing` for RocksDB.
 - **Commandline:** `--rocksdb-create-if-missing={0|1}`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `ON`
-

`rocksdb_create_missing_column_families`

- **Description:** `DBOptions::create_missing_column_families` for RocksDB.
 - **Commandline:** `--rocksdb-create-missing-column-families={0|1}`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
-

`rocksdb_datadir`

- **Description:** RocksDB data directory.
 - **Commandline:** `--rocksdb-datadir[=value]`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `string`
 - **Default Value:** `./#rocksdb`
-

`rocksdb_db_write_buffer_size`

- **Description:** `DBOptions::db_write_buffer_size` for RocksDB.
 - **Commandline:** `--rocksdb-db-write-buffer-size=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:** `0`
 - **Range:** `0` to `18446744073709551615`
-

`rocksdb_deadlock_detect`

- **Description:** Enables deadlock detection.
 - **Commandline:** `--rocksdb-deadlock-detect={0|1}`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
-

rocksdb_deadlock_detect_depth

- **Description:** Number of transactions deadlock detection will traverse through before assuming deadlock.
 - **Commandline:** `--rocksdb-deadlock-detect-depth=#`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `50`
 - **Range:** `2` to `18446744073709551615`
-

rocksdb_debug_manual_compaction_delay

- **Description:** For debugging purposes only. Sleeping specified seconds for simulating long running compactions.
 - **Commandline:** `--rocksdb-debug_manual_compaction_delay=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `0`
 - **Range:** `0` to `4294967295`
 - **Introduced:** [MariaDB 10.3.10](#) , [MariaDB 10.2.18](#) 
-

rocksdb_debug_optimizer_no_zero_cardinality

- **Description:** If cardinality is zero, override it with some value.
 - **Commandline:** `--rocksdb-debug-optimizer-no-zero-cardinality={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `ON`
-

rocksdb_debug_ttl_ignore_pk

- **Description:** For debugging purposes only. If true, compaction filtering will not occur on PK TTL data. This variable is a no-op in non-debug builds.
 - **Commandline:** `--rocksdb-debug-ttl-ignore-pk={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
-

rocksdb_debug_ttl_read_filter_ts

- **Description:** For debugging purposes only. Overrides the TTL read filtering time to time + `debug_ttl_read_filter_ts`. A value of 0 denotes that the variable is not set. This variable is a no-op in non-debug builds.
 - **Commandline:** `--rocksdb-debug-ttl-read-filter-ts=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `0`
 - **Range:** `-3600` to `3600`
 - **Introduced:** [MariaDB 10.3.1](#) , [MariaDB 10.2.8](#) 
-

rocksdb_debug_ttl_rec_ts

- **Description:** For debugging purposes only. Overrides the TTL of records to `now() + debug_ttl_rec_ts`. The value can be +/- to simulate a record inserted in the past vs a record inserted in the 'future'. A value of 0 denotes that the variable is not set. This variable is a no-op in non-debug builds.
- **Commandline:** `--rocksdb-debug-ttl-read-filter-ts=#`
- **Scope:** Global
- **Dynamic:** Yes

- **Data Type:** numeric
 - **Default Value:** 0
 - **Range:** -3600 to 3600
 - **Introduced:** [MariaDB 10.3.1](#), [MariaDB 10.2.8](#)
-

rocksdb_debug_ttl_snapshot_ts

- **Description:** For debugging purposes only. Sets the snapshot during compaction to now() + debug_set_ttl_snapshot_ts. The value can be positive or negative to simulate a snapshot in the past vs a snapshot created in the 'future'. A value of 0 denotes that the variable is not set. This variable is a no-op in non-debug builds.
 - **Commandline:** --rocksdb-debug-ttl-snapshot-ts=#
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** numeric
 - **Default Value:** 0
 - **Range:** -3600 to 3600
 - **Introduced:** [MariaDB 10.3.1](#), [MariaDB 10.2.8](#)
-

rocksdb_default_cf_options

- **Description:** Default cf options for RocksDB.
 - **Commandline:** --rocksdb-default-cf-options=value
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** string
 - **Default Value:** (Empty)
-

rocksdb_delayed_write_rate

- **Description:** DBOptions::delayed_write_rate.
 - **Commandline:** --rocksdb-delayed-write-rate=#
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** numeric
 - **Default Value:** 0 (Previously 16777216)
 - **Range:** 0 to 18446744073709551615
-

rocksdb_delete_cf

- **Description:** Delete column family.
 - **Commandline:** --rocksdb-delete-cf=val
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** string
 - **Default Value:** (Empty string)
 - **Introduced:** [MariaDB 10.4.7](#), [MariaDB 10.3.17](#), [MariaDB 10.2.26](#)
-

rocksdb_delete_obsolete_files_period_micros

- **Description:** DBOptions::delete_obsolete_files_period_micros for RocksDB.
 - **Commandline:** --rocksdb-delete-obsolete-files-period-micros=#
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** numeric
 - **Default Value:** 21600000000
 - **Range:** 0 to 9223372036854775807
-

rocksdb_enable_2pc

- **Description:** Enable two phase commit for MyRocks. When set, MyRocks will keep its data consistent with the [binary log](#) (in other words, the server will be a crash-safe master). The consistency is achieved by doing two-phase XA commit with the binary log.
 - **Commandline:** `--rocksdb-enable-2pc={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `ON`
-

`rocksdb_enable_bulk_load_api`

- **Description:** Enables using `SstFileWriter` for bulk loading.
 - **Commandline:** `--rocksdb-enable-bulk-load-api={0|1}`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `ON`
-

`rocksdb_enable_insert_with_update_caching`

- **Description:** Whether to enable optimization where we cache the read from a failed insertion attempt in [INSERT ON DUPLICATE KEY UPDATE](#).
 - **Commandline:** `--rocksdb-enable-insert-with-update-caching={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `ON`
 - **Introduced:** [MariaDB 10.4.7](#), [MariaDB 10.3.17](#), [MariaDB 10.2.26](#)
-

`rocksdb_enable_thread_tracking`

- **Description:** `DBOptions::enable_thread_tracking` for RocksDB.
 - **Commandline:** `--rocksdb-enable-thread-tracking={0|1}`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
-

`rocksdb_enable_ttl`

- **Description:** Enable expired TTL records to be dropped during compaction.
 - **Commandline:** `--rocksdb-enable-ttl={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `ON`
 - **Introduced:** [MariaDB 10.3.1](#), [MariaDB 10.2.8](#)
-

`rocksdb_enable_ttl_read_filtering`

- **Description:** For tables with TTL, expired records are skipped/filtered out during processing and in query results. Disabling this will allow these records to be seen, but as a result rows may disappear in the middle of transactions as they are dropped during compaction. Use with caution.
 - **Commandline:** `--rocksdb-enable-ttl-read-filtering={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `ON`
 - **Introduced:** [MariaDB 10.3.1](#), [MariaDB 10.2.8](#)
-

rocksdb_enable_write_thread_adaptive_yield

- **Description:** DBOptions::enable_write_thread_adaptive_yield for RocksDB.
 - **Commandline:** --rocksdb-enable-write-thread-adaptive-yield={0|1}
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** boolean
 - **Default Value:** OFF
-

rocksdb_error_if_exists

- **Description:** DBOptions::error_if_exists for RocksDB.
 - **Commandline:** --rocksdb-error-if-exists={0|1}
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** boolean
 - **Default Value:** OFF
-

rocksdb_error_on_suboptimal_collation

- **Description:** Raise an error instead of warning if a sub-optimal collation is used.
 - **Commandline:** --rocksdb-error-on-suboptimal-collation={0|1}
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** boolean
 - **Default Value:** ON
 - **Introduced:** [MariaDB 10.3.10](#), [MariaDB 10.2.18](#)
-

rocksdb_flush_log_at_trx_commit

- **Description:** Sync on transaction commit. Similar to [innodb_flush_log_at_trx_commit](#). One can check the flushing by examining the [rocksdb_wal_synced](#) and [rocksdb_wal_bytes](#) status variables.
 - 1: Always sync on commit (the default).
 - 0: Never sync.
 - 2: Sync based on a timer controlled via rocksdb-background-sync.
 - **Commandline:** --rocksdb-flush-log-at-trx-commit=#
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** numeric
 - **Default Value:** 1
 - **Range:** 0 to 2
-

rocksdb_flush_memtable_on_analyze

- **Description:** Forces memtable flush on ANALYZE table to get accurate cardinality.
 - **Commandline:** --rocksdb-flush-memtable-on-analyze={0|1}
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** boolean
 - **Default Value:** ON
 - **Removed:** [MariaDB 10.3.7](#), [MariaDB 10.2.15](#)
-

rocksdb_force_compute_memtable_stats

- **Description:** Force to always compute memtable stats.
- **Commandline:** --rocksdb-force-compute-memtable-stats={0|1}
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** boolean
- **Default Value:** ON

rocksdb_force_compute_memtable_stats_cachetime

- **Description:** Time in usecs to cache memtable estimates.
 - **Commandline:** `--rocksdb-force-compute-memtable-stats-cachetime=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `60000000`
 - **Range:** 0 to 2147483647
-

rocksdb_force_flush_memtable_and_lzero_now

- **Description:** Acts similar to `force_flush_memtable_now`, but also compacts all L0 files.
 - **Commandline:** `--rocksdb-force-flush-memtable-and-lzero-now={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
 - **Introduced:** [MariaDB 10.3.1](#), [MariaDB 10.2.8](#)
-

rocksdb_force_flush_memtable_now

- **Description:** Forces memstore flush which may block all write requests so be careful.
 - **Commandline:** `--rocksdb-force-flush-memtable-now={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
-

rocksdb_force_index_records_in_range

- **Description:** Used to override the result of `records_in_range()` when **FORCE INDEX** is used.
 - **Commandline:** `--rocksdb-force-index-records-in-range=#`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `0`
 - **Range:** 0 to 2147483647
-

rocksdb_git_hash

- **Description:** Git revision of the RocksDB library used by MyRocks.
 - **Commandline:** `--rocksdb-git-hash=value=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `string`
 - **Default Value:** As per git revision.
-

rocksdb_hash_index_allow_collision

- **Description:** `BlockBasedTableOptions::hash_index_allow_collision` for RocksDB.
 - **Commandline:** `--rocksdb-hash-index-allow-collision={0|1}`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `ON`
-

rocksdb_ignore_unknown_options

- **Description:** Enable ignoring unknown options passed to RocksDB.
 - **Commandline:** `--rocksdb-ignore-unknown-options={0|1}`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `ON`
 - **Introduced:** [MariaDB 10.3.7](#), [MariaDB 10.2.15](#)
-

rocksdb_index_type

- **Description:** `BlockBasedTableOptions::index_type` for RocksDB.
 - **Commandline:** `--rocksdb-index-type=value`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `enum`
 - **Default Value:** `kBinarySearch`
 - **Valid Values:** `kBinarySearch`, `kHashSearch`
-

rocksdb_info_log_level

- **Description:** Filter level for info logs to be written mysqld error log. Valid values include 'debug_level', 'info_level', 'warn_level', 'error_level' and 'fatal_level'.
 - **Commandline:** `--rocksdb-info-log-level=value`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `enum`
 - **Default Value:** `error_level`
 - **Valid Values:** `error_level`, `debug_level`, `info_level`, `warn_level`, `fatal_level`
-

rocksdb_io_write_timeout

- **Description:** Timeout for experimental I/O watchdog.
 - **Commandline:** `--rocksdb-io-write-timeout=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `0`
 - **Valid Values:** `0` to `4294967295`
 - **Introduced:** [MariaDB 10.3.1](#), [MariaDB 10.2.8](#)
-

rocksdb_is_fd_close_on_exec

- **Description:** `DBOptions::is_fd_close_on_exec` for RocksDB.
 - **Commandline:** `--rocksdb-is-fd-close-on-exec={0|1}`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `ON`
-

rocksdb_keep_log_file_num

- **Description:** `DBOptions::keep_log_file_num` for RocksDB.
 - **Commandline:** `--rocksdb-keep-log-file-num=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:** `1000`
 - **Range:** `0` to `18446744073709551615`
-

rocksdb_large_prefix

- **Description:** Support large index prefix length of 3072 bytes. If off, the maximum index prefix length is 767.
 - **Commandline:** `--rocksdb-large_prefix={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
-

rocksdb_lock_scanned_rows

- **Description:** Take and hold locks on rows that are scanned but not updated.
 - **Commandline:** `--rocksdb-lock-scanned-rows={0|1}`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
-

rocksdb_lock_wait_timeout

- **Description:** Number of seconds to wait for lock.
 - **Commandline:** `--rocksdb-lock-wait-timeout=#`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `1`
 - **Range:** `1 to 1073741824`
-

rocksdb_log_dir

- **Description:** `DBOptions::log_dir` for RocksDB. Where the log files are stored. An empty value implies `rocksdb_datadir` is used as the directory.
 - **Commandline:** `--rocksdb-log-dir=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `string`
 - **Default Value:** (Empty)
 - **Introduced:** [MariaDB 10.9.1](#) 
-

rocksdb_log_file_time_to_roll

- **Description:** `DBOptions::log_file_time_to_roll` for RocksDB.
 - **Commandline:** `--rocksdb-log-file-time-to_roll=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:** `0`
 - **Range:** `0 to 18446744073709551615`
-

rocksdb_manifest_preallocation_size

- **Description:** `DBOptions::manifest_preallocation_size` for RocksDB.
 - **Commandline:** `--rocksdb-manifest-preallocation-size=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:** `4194304`
 - **Range:** `0 to 18446744073709551615`
-

rocksdb_manual_compaction_threads

- **Description:** How many rocksdb threads to run for manual compactions.
 - **Commandline:** `--rocksdb-manual-compaction-threads=#`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `0`
 - **Range:** `0` to `128`
 - **Introduced:** [MariaDB 10.3.10](#), [MariaDB 10.2.18](#)
-

rocksdb_manual_wal_flush

- **Description:** `DBOptions::manual_wal_flush` for RocksDB.
 - **Commandline:** `--rocksdb-manual-wal-flush={0|1}`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `ON`
-

rocksdb_master_skip_tx_api

- **Description:** Skipping holding any lock on row access. Not effective on slave.
 - **Commandline:** `--rocksdb-master-skip-tx-api={0|1}`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
-

rocksdb_max_background_compactions

- **Description:** `DBOptions::max_background_compactions` for RocksDB.
 - **Commandline:** `--rocksdb-max-background-compactions=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `1`
 - **Range:** `1` to `64`
 - **Removed:** [MariaDB 10.3.1](#), [MariaDB 10.2.8](#)
-

rocksdb_max_background_flushes

- **Description:** `DBOptions::max_background_flushes` for RocksDB.
 - **Commandline:** `--rocksdb-max-background-flushes=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:** `1`
 - **Range:** `1` to `64`
 - **Removed:** [MariaDB 10.3.1](#), [MariaDB 10.2.8](#)
-

rocksdb_max_background_jobs

- **Description:** `DBOptions::max_background_jobs` for RocksDB.
- **Commandline:** `--rocksdb-max-background-jobs=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `2`
- **Range:** `-1` to `64`

- **Introduced:** [MariaDB 10.3.1](#), [MariaDB 10.2.8](#)

rocksdb_max_latest_deadlocks

- **Description:** Maximum number of recent deadlocks to store.
- **Commandline:** `--rocksdb-max-latest-deadlocks=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** 5
- **Range:** 0 to 4294967295

rocksdb_max_log_file_size

- **Description:** `DBOptions::max_log_file_size` for RocksDB.
- **Commandline:** `--rocksdb-max-log-file-size=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** 0
- **Range:** 0 to 18446744073709551615

rocksdb_max_manifest_file_size

- **Description:** `DBOptions::max_manifest_file_size` for RocksDB.
- **Commandline:** `--rocksdb-manifest-log-file-size=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** 1073741824
- **Range:** 0 to 18446744073709551615

rocksdb_max_manual_compactions

- **Description:** Maximum number of pending + ongoing number of manual compactions..
- **Commandline:** `--rocksdb-manual_compactions=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** 10
- **Range:** 0 to 4294967295
- **Introduced:** [MariaDB 10.3.10](#), [MariaDB 10.2.18](#)

rocksdb_max_open_files

- **Description:** `DBOptions::max_open_files` for RocksDB.
- **Commandline:** `--rocksdb-max-open-files=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** -2
- **Range:** -2 to 2147483647

rocksdb_max_row_locks

- **Description:** Maximum number of locks a transaction can have.
- **Commandline:** `--rocksdb-max-row-locks=#`
- **Scope:** Global, Session
- **Dynamic:** Yes

- **Data Type:** numeric
 - **Default Value:** 1048576
 - **Range:**
 - 1 to 1073741824 ([>= MariaDB 10.3.10](#), [MariaDB 10.2.18](#))
 - 1 to 1048576 ([<= MariaDB 10.3.9](#), [MariaDB 10.2.17](#))
-

rocksdb_max_subcompactions

- **Description:** DBOptions::max_subcompactions for RocksDB.
 - **Commandline:** --rocksdb-max-subcompactions=#
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** numeric
 - **Default Value:** 1
 - **Range:** 1 to 64
-

rocksdb_max_total_wal_size

- **Description:** DBOptions::max_total_wal_size for RocksDB. The maximum size limit for write-ahead-log files. Once this limit is reached, RocksDB forces the flushing of memtables.
 - **Commandline:** --rocksdb-max-total-wal-size=#
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** numeric
 - **Default Value:** 0
 - **Range:** 0 to 9223372036854775807
-

rocksdb_merge_buf_size

- **Description:** Size to allocate for merge sort buffers written out to disk during inplace index creation.
 - **Commandline:** --rocksdb-merge-buf-size=#
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** numeric
 - **Default Value:** 67108864
 - **Range:** 100 to 18446744073709551615
-

rocksdb_merge_combine_read_size

- **Description:** Size that we have to work with during combine (reading from disk) phase of external sort during fast index creation.
 - **Commandline:** --rocksdb-merge-combine-read-size=#
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** numeric
 - **Default Value:** 1073741824
 - **Range:** 100 to 18446744073709551615
-

rocksdb_merge_tmp_file_removal_delay_ms

- **Description:** Fast index creation creates a large tmp file on disk during index creation. Removing this large file all at once when index creation is complete can cause trim stalls on Flash. This variable specifies a duration to sleep (in milliseconds) between calling chsize() to truncate the file in chunks. The chunk size is the same as merge_buf_size.
 - **Commandline:** --rocksdb-merge-tmp-file-removal-delay-ms=#
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** numeric
 - **Default Value:** 0
 - **Range:** 0 to 18446744073709551615
-

rocksdb_new_table_reader_for_compaction_inputs

- **Description:** DBOptions::new_table_reader_for_compaction_inputs for RocksDB.
 - **Commandline:** `--rocksdb-new-table-reader-for-compaction-inputs={0|1}`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
-

rocksdb_no_block_cache

- **Description:** BlockBasedTableOptions::no_block_cache for RocksDB.
 - **Commandline:** `--rocksdb-no-block-cache={0|1}`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
-

rocksdb_override_cf_options

- **Description:** Option overrides per cf for RocksDB. Note that the `rocksdb-override-cf-options` syntax is quite strict, and any typos will result in a parse error, and the MyRocks plugin will not be loaded. Depending on your configuration, the server may still start. If it does start, you can use this command to check if the plugin is loaded:
`select * from information_schema.plugins where plugin_name='ROCKSDB'` (note that you need the "ROCKSDB" plugin. Other auxiliary plugins like "ROCKSDB_TRX" might still get loaded). Another way is to detect the error is check the error log.
 - **Commandline:** `--rocksdb-override-cf-options=value`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `string`
 - **Default Value:** (Empty)
-

rocksdb_paranoid_checks

- **Description:** DBOptions::paranoid_checks for RocksDB.
 - **Commandline:** `--rocksdb-paranoid-checks={0|1}`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `ON`
-

rocksdb_pause_background_work

- **Description:** Disable all rocksdb background operations.
 - **Commandline:** `--rocksdb-pause-background-work={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
-

rocksdb_perf_context_level

- **Description:** Perf Context Level for rocksdb internal timer stat collection.
 - **Commandline:** `--rocksdb-perf-context-level=#`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `0`
 - **Range:** `0 to 5`
-

rocksdb_persistent_cache_path

- **Description:** Path for BlockBasedTableOptions::persistent_cache for RocksDB.
 - **Commandline:** --rocksdb-persistent-cache-path=value
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** string
 - **Default Value:** (Empty)
-

rocksdb_persistent_cache_size_mb

- **Description:** Size of cache in MB for BlockBasedTableOptions::persistent_cache for RocksDB.
 - **Commandline:** --rocksdb-persistent-cache-size-mb=#
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** numeric
 - **Default Value:** 0
 - **Range:** 0 to 18446744073709551615
-

rocksdb_pin_l0_filter_and_index_blocks_in_cache

- **Description:** pin_l0_filter_and_index_blocks_in_cache for RocksDB.
 - **Commandline:** --rocksdb-pin-l0-filter-and-index-blocks-in-cache={0|1}
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** boolean
 - **Default Value:** ON
-

rocksdb_print_snapshot_conflict_queries

- **Description:** Logging queries that got snapshot conflict errors into *.err log.
 - **Commandline:** --rocksdb-print-snapshot-conflict-queries={0|1}
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** boolean
 - **Default Value:** OFF
-

rocksdb_rate_limiter_bytes_per_sec

- **Description:** DBOptions::rate_limiter bytes_per_sec for RocksDB.
 - **Commandline:** --rocksdb-rate-limiter-bytes-per-sec=#
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** numeric
 - **Default Value:** 0
 - **Range:** 0 to 9223372036854775807
-

rocksdb_read_free_rpl_tables

- **Description:** List of tables that will use read-free replication on the slave (i.e. not lookup a row during replication).
 - **Commandline:** --rocksdb-read-free-rpl-tables=value
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** string
 - **Default Value:** (Empty)
 - **Removed:** [MariaDB 10.4.7](#), [MariaDB 10.3.17](#), [MariaDB 10.2.26](#)
-

rocksdb_records_in_range

- **Description:** Used to override the result of `records_in_range()`. Set to a positive number to override.
 - **Commandline:** `--rocksdb-records-in-range=#`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `0`
 - **Range:** `0` to `2147483647`
-

`rocksdb_remove_mariabackup_checkpoint`

- **Description:** Remove [mariabackup](#) checkpoint.
 - **Commandline:** `--rocksdb-remove-mariabackup-checkpoint={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
 - **Introduced:** [MariaDB 10.3.8](#), [MariaDB 10.2.16](#)
-

`rocksdb_reset_stats`

- **Description:** Reset the RocksDB internal statistics without restarting the DB.
 - **Commandline:** `--rocksdb-reset-stats={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
 - **Introduced:** [MariaDB 10.3.1](#), [MariaDB 10.2.8](#)
-

`rocksdb_rollback_on_timeout`

- **Description:** Whether to roll back the complete transaction or a single statement on lock wait timeout (a single statement by default).
 - **Commandline:** `--rocksdb-rollback-on-timeout={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
 - **Introduced:** [MariaDB 10.4.7](#), [MariaDB 10.3.17](#), [MariaDB 10.2.26](#)
-

`rocksdb_seconds_between_stat_computes`

- **Description:** Sets a number of seconds to wait between optimizer stats recomputation. Only changed indexes will be refreshed.
 - **Commandline:** `--rocksdb-seconds-between-stat-computes=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `3600`
 - **Range:** `0` to `4294967295`
-

`rocksdb_signal_drop_index_thread`

- **Description:** Wake up drop index thread.
 - **Commandline:** `--rocksdb-signal-drop-index-thread={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
-

rocksdb_sim_cache_size

- **Description:** Simulated cache size for RocksDB.
 - **Commandline:** `--rocksdb-sim-cache-size=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:** `0`
 - **Range:** `0` to `9223372036854775807`
-

rocksdb_skip_bloom_filter_on_read

- **Description:** Skip using bloom filter for reads.
 - **Commandline:** `--rocksdb-skip-bloom-filter-on_read={0|1}`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
-

rocksdb_skip_fill_cache

- **Description:** Skip filling block cache on read requests.
 - **Commandline:** `--rocksdb-skip-fill-cache={0|1}`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
-

rocksdb_skip_unique_check_tables

- **Description:** Skip unique constraint checking for the specified tables.
 - **Commandline:** `--rocksdb-skip-unique-check-tables=value`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `string`
 - **Default Value:** `.*`
-

rocksdb_sst_mgr_rate_bytes_per_sec

- **Description:** `DBOptions::sst_file_manager rate_bytes_per_sec` for RocksDB
 - **Commandline:** `--rocksdb-sst-mgr-rate-bytes-per-sec=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `0`
 - **Range:** `0` to `18446744073709551615`
-

rocksdb_stats_dump_period_sec

- **Description:** `DBOptions::stats_dump_period_sec` for RocksDB.
 - **Commandline:** `--rocksdb-stats-dump-period-sec=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:** `600`
 - **Range:** `0` to `2147483647`
-

rocksdb_stats_level

- **Description:** Statistics Level for RocksDB. Default is 0 (kExceptHistogramOrTimers).
 - **Commandline:** `--rocksdb-stats-level=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** 0
 - **Range:** 0 to 4
 - **Introduced:** [MariaDB 10.4.7](#), [MariaDB 10.3.17](#), [MariaDB 10.2.26](#)
-

`rocksdb_stats_recalc_rate`

- **Description:** The number of indexes per second to recalculate statistics for. 0 to disable background recalculation.
 - **Commandline:** `--rocksdb-stats-recalc_rate=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** 0
 - **Range:** 0 to 4294967295
 - **Introduced:** [MariaDB 10.3.10](#), [MariaDB 10.2.18](#)
-

`rocksdb_store_row_debug_checksums`

- **Description:** Include checksums when writing index/table records.
 - **Commandline:** `--rocksdb-store-row-debug-checksums={0|1}`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** OFF
-

`rocksdb_strict_collation_check`

- **Description:** Enforce case sensitive collation for MyRocks indexes.
 - **Commandline:** `--rocksdb-strict-collation-check={0|1}`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** ON
-

`rocksdb_strict_collation_exceptions`

- **Description:** List of tables (using regex) that are excluded from the case sensitive collation enforcement.
 - **Commandline:** `--rocksdb-strict-collation-exceptions=value`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `string`
 - **Default Value:** (Empty)
-

`rocksdb_supported_compression_types`

- **Description:** Compression algorithms supported by RocksDB. Note that RocksDB does not make use of [MariaDB 10.7 compression-plugins](#).
 - **Commandline:** `--rocksdb-supported-compression-types=value`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `string`
 - **Default Value:** Snappy, Zlib, ZSTDNotFinal
-

`rocksdb_table_cache_numshardbits`

- **Description:** DBOptions::table_cache_numshardbits for RocksDB.
 - **Commandline:** `--rocksdb-table-cache-numshardbits=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:** `6`
 - **Range:** `0` to `19`
-

`rocksdb_table_stats_sampling_pct`

- **Description:** Percentage of entries to sample when collecting statistics about table properties. Specify either 0 to sample everything or percentage [1..100]. By default 10% of entries are sampled.
 - **Commandline:** `--rocksdb-table-stats-sampling-pct=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `10`
 - **Range:** `0` to `100`
-

`rocksdb_tmpdir`

- **Description:** Directory for temporary files during DDL operations.
 - **Commandline:** `--rocksdb-tmpdir[=value]`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `string`
 - **Default Value:** (Empty)
-

`rocksdb_trace_sst_api`

- **Description:** Generate trace output in the log for each call to the SstFileWriter.
 - **Commandline:** `--rocksdb-trace-sst-api={0|1}`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
-

`rocksdb_two_write_queues`

- **Description:** DBOptions::two_write_queues for RocksDB.
 - **Commandline:** `--rocksdb-two-write-queues={0|1}`
 - **Scope:** Global,
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `ON`
 - **Introduced:** [MariaDB 10.3.7](#) , [MariaDB 10.2.15](#) 
-

`rocksdb_unsafe_for_binlog`

- **Description:** Allowing statement based binary logging which may break consistency.
 - **Commandline:** `--rocksdb-unsafe-for-binlog={0|1}`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
-

`rocksdb_update_cf_options`

- **Description:** Option updates per column family for RocksDB.

- **Commandline:** `--rocksdb-update-cf-options=value`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `varchar`
 - **Default Value:** (Empty)
 - **Introduced:** [MariaDB 10.3.1](#), [MariaDB 10.2.8](#)
-

`rocksdb_use_adaptive_mutex`

- **Description:** `DBOptions::use_adaptive_mutex` for RocksDB.
 - **Commandline:** `--rocksdb-use-adaptive-mutex={0|1}`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
-

`rocksdb_use_clock_cache`

- **Description:** Use `ClockCache` instead of default `LRUCache` for RocksDB.
 - **Commandline:** `--rocksdb-use-clock-cache={0|1}`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
-

`rocksdb_use_direct_io_for_flush_and_compaction`

- **Description:** `DBOptions::use_direct_io_for_flush_and_compaction` for RocksDB.
 - **Commandline:** `--rocksdb-use-direct-io-for-flush-and-compaction={0|1}`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
 - **Introduced:** [MariaDB 10.3.1](#), [MariaDB 10.2.8](#)
-

`rocksdb_use_direct_reads`

- **Description:** `DBOptions::use_direct_reads` for RocksDB.
 - **Commandline:** `--rocksdb-use-direct-reads={0|1}`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
-

`rocksdb_use_direct_writes`

- **Description:** `DBOptions::use_direct_writes` for RocksDB.
 - **Commandline:** `--rocksdb-use-direct-reads={0|1}`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
 - **Removed:** [MariaDB 10.3.1](#), [MariaDB 10.2.8](#)
-

`rocksdb_use_fsync`

- **Description:** `DBOptions::use_fsync` for RocksDB.
- **Commandline:** `--rocksdb-use-fsync={0|1}`
- **Scope:** Global

- **Dynamic:** No
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
-

`rocksdb_validate_tables`

- **Description:** Verify all `.frm` files match all RocksDB tables (0 means no verification, 1 means verify and fail on error, and 2 means verify but continue).
 - **Commandline:** `--rocksdb-validate-tables=#`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `numeric`
 - **Default Value:** `1`
 - **Range:** 0 to 2
-

`rocksdb_verify_row_debug_checksums`

- **Description:** Verify checksums when reading index/table records.
 - **Commandline:** `--rocksdb-verify-row-debug-checksums={0|1}`
 - **Scope:** Global, Session
 - **Dynamic:** Yes
 - **Data Type:** `boolean`
 - **Default Value:** `OFF`
-

`rocksdb_wal_bytes_per_sync`

- **Description:** `DBOptions::wal_bytes_per_sync` for RocksDB.
 - **Commandline:** `--rocksdb-wal-bytes-per-sync=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `0`
 - **Range:** 0 to 18446744073709551615
-

`rocksdb_wal_dir`

- **Description:** `DBOptions::wal_dir` for RocksDB. Directory where the write-ahead-log files are stored.
 - **Commandline:** `--rocksdb-wal-dir=value`
 - **Scope:** Global
 - **Dynamic:** No
 - **Data Type:** `string`
 - **Default Value:** (Empty)
-

`rocksdb_wal_recovery_mode`

- **Description:** `DBOptions::wal_recovery_mode` for RocksDB. Default is `kAbsoluteConsistency`. Records that are not yet committed are stored in the Write-Ahead-Log (WAL). If the server is not cleanly shut down, the recovery mode will determine the WAL recovery behavior.
 - **1:** `kAbsoluteConsistency`. Will not start if any corrupted entries (including incomplete writes) are detected (the default).
 - **0:** `kTolerateCorruptedTailRecords`. Ignores any errors found at the end of the WAL
 - **2:** `kPointInTimeRecovery`. Replay of the WAL is halted after finding an error. The system will be recovered to the latest consistent point-in-time. Data from a replica can used to replay past the point-in-time.
 - **3:** `kSkipAnyCorruptedRecords`. A risky option where any corrupted entries are skipped while subsequent healthy WAL entries are applied.
 - **Commandline:** `--rocksdb-wal-recovery-mode=#`
 - **Scope:** Global
 - **Dynamic:** Yes
 - **Data Type:** `numeric`
 - **Default Value:** `1`
-

- **Range:** 0 to 3

rocksdb_wal_size_limit_mb

- **Description:** DBOptions::WAL_size_limit_MB for RocksDB. Write-ahead-log files are moved to an archive directory once their memtables are flushed. This variable specifies the largest size, in MB, that the archive can be.
- **Commandline:** `--rocksdb-wal-size-limit-mb=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** 0
- **Range:** 0 to 9223372036854775807

rocksdb_wal_ttl_seconds

- **Description:** DBOptions::WAL_ttl_seconds for RocksDB. Oldest time, in seconds, that a write-ahead-log file should exist.
- **Commandline:** `--rocksdb-wal-ttl-seconds=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** 0
- **Range:** 0 to 9223372036854775807

rocksdb_whole_key_filtering

- **Description:** BlockBasedTableOptions::whole_key_filtering for RocksDB. If set (the default), the bloomfilter to use the whole key (rather than only the prefix) for filtering is enabled. Lookups should use the whole key for matching to make best use of this setting.
- **Commandline:** `--rocksdb-whole-key-filtering={0|1}`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `boolean`
- **Default Value:** ON

rocksdb_write_batch_max_bytes

- **Description:** Maximum size of write batch in bytes. 0 means no limit.
- **Commandline:** `--rocksdb-write-batch-max-bytes=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** 0
- **Range:** 0 to 18446744073709551615

rocksdb_write_disable_wal

- **Description:** WriteOptions::disableWAL for RocksDB.
- **Commandline:** `--rocksdb-write-disable-wal={0|1}`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** OFF

rocksdb_write_ignore_missing_column_families

- **Description:** WriteOptions::ignore_missing_column_families for RocksDB.
- **Commandline:** `--rocksdb-write-ignore-missing-column-families={0|1}`
- **Scope:** Global, Session

- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `OFF`

`rocksdb_write_policy`

- **Description:** `DBOptions::write_policy` for RocksDB.
- **Commandline:** `--rocksdb-write-policy=val`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `enum`
- **Default Value:** `write_committed`
- **Valid Values:** `write_committed`, `write_prepared`, `write_unprepared`
- **Introduced:** [MariaDB 10.3.10](#) , [MariaDB 10.2.18](#) 

5.3.14.7 MyRocks Transactional Isolation

TODO:

- MyRocks uses snapshot isolation
- Support `do READ-COMMITTED` and `REPEATABLE-READ`
- `SERIALIZABLE` is not supported
 - There is no "Gap Locking" which makes Statement Based Replication unsafe (See MyRocks and Replication).

5.3.14.8 MyRocks and Replication

Contents

1. [MyRocks and Statement-Based Replication](#)
 1. [Can One Still Use SBR with MyRocks?](#)
2. [Read-Free Slave](#)
3. [Differences From Upstream MyRocks](#)

Details about how MyRocks works with [replication](#).

MyRocks and Statement-Based Replication

[Statement-based](#) replication (SBR) works as follows: SQL statements are executed on the master (possibly concurrently). They are written into the binlog (this fixes their ordering, "a serialization"). The slave then reads the binlog and executes the statements in their binlog order.

In order to prevent data drift, serial execution of statements on the slave must have the same effect as concurrent execution of these statements on the master. In other words, transaction isolation on the master must be close to `SERIALIZABLE` transaction isolation level (This is not a strict mathematical proof but shows the idea).

InnoDB achieves this by (almost) supporting `SERIALIZABLE` transactional isolation level. It does so by supporting "Gap Locks". MyRocks doesn't support `SERIALIZABLE` isolation, and it doesn't support gap locks.

Because of that, generally one cannot use MyRocks and statement-based replication.

Updating a MyRocks table while having SBR on, will result in an error as follow:

```
ERROR 4056 (HY000): Can't execute updates on master with binlog_format != ROW.
```

Can One Still Use SBR with MyRocks?

Yes. In many cases, database applications run a restricted set of SQL statements, and it's possible to prove that lack of Gap Lock support is not a problem and data skew will not occur.

In that case, one can set `@@rocksdb_unsafe_for_binlog=1` and MyRocks will work with SBR. The user is however responsible for making sure their queries are not causing a data skew.

Read-Free Slave

Differences From Upstream MyRocks

MyRocks upstream (that is, Facebook's MySQL branch) has a number of unique replication enhancements. These are available in upstream's version of MyRocks but not in MariaDB's version of MyRocks.

- Read-Free Replication (see <https://github.com/facebook/mysql-5.6/wiki/Read-Free-Replication>) TODO
- `<<unique_check_lag_threshold>>` . This is FB/MySQL-5.6 feature where unique checks are disabled if replication lag exceeds a certain threshold.
- `<<slave_gtid_info=OPTIMIZED>>` . This is said to be:

```
<<quote>>
"Whether SQL threads update mysql.slave_gtid_info table. If this value "
"is OPTIMIZED, updating the table is done inside storage engines to "
"avoid MySQL layer's performance overhead",
<</quote>>
```

5.3.14.9 MyRocks and Group Commit with Binary log

Contents

1. [Counter Values to Watch](#)
2. [On the Value of rocksdb_wal_group_syncs](#)
3. [Examples](#)

MyRocks supports group commit with the [binary log \(MDEV-11934\)](#).

Counter Values to Watch

(The following is only necessary if you are studying MyRocks internals)

MariaDB's group commit counters are:

[Binlog_commits](#) - how many transactions were written to the binary log

[Binlog_group_commits](#) - how many group commits happened. (e.g. if each group had two transactions, this will be twice as small as [Binlog_commits](#))

On the RocksDB side, there is one relevant counter: [Rocksdb_wal_synced](#) - How many times RocksDB's WAL file was synced. (TODO: this is after group commit happened, right?)

On the Value of rocksdb_wal_group_syncs

FB/MySQL-5.6 has a [rocksdb_wal_group_syncs](#) counter (The counter is provided by MyRocks, it is not a view of a RocksDB counter). It is increased in `rocksdb_flush_wal()` when doing the `rd->FlushWAL()` call.

`rocksdb_flush_wal()` is called by MySQL's Group Commit when it wants to make the effect of several `rocksdb_prepare()` calls persistent.

So, the value of [rocksdb_wal_group_syncs](#) in FB/MySQL-5.6 is similar to [Binlog_group_commits](#) in MariaDB.

MariaDB doesn't have that call, each `rocksdb_prepare()` call takes care of being persistent on its own.

Because of that, [rocksdb_wal_group_syncs](#) is zero for MariaDB. (Currently, it is only incremented when the binlog is rotated).

Examples

So for a workload with `concurrency=50, n_queries=10K`, one gets

- `Binlog_commits=10K`
- `Binlog_group_commits=794`
- `Rocksdb_wal_synced=8362`

This is on a RAM disk

For a workload with concurrency=50, n_queries=10K, rotating laptop hdd, one gets

- Binlog_commits= 10K
- Binlog_group_commits=1403
- Rocksdb_wal_synced=400

The test took 38 seconds, Number of syncs was 1400+400=1800, which gives 45 syncs/sec which looks normal for this slow rotating desktop hdd.

Note that the WAL was synced fewer times than there were binlog commit groups (?)

5.3.14.10 Optimizer Statistics in MyRocks

Contents

1. [How MyRocks computes statistics](#)
 1. [Are index statistics predictable?](#)
 2. [Records-in-range estimates](#)
2. [ANALYZE TABLE](#)
3. [Debugging helper variables](#)

This article describes how MyRocks storage engine provides statistics to the query optimizer.

There are three kinds of statistics:

- Table statistics (number of rows in the table, average row size)
- Index cardinality (how distinct values are in the index)
- records-in-range estimates (how many rows are in a certain range "const1 < tbl.key < const2").

How MyRocks computes statistics

MyRocks (actually RocksDB) uses LSM files which are written once and never updated. When an LSM file is written, MyRocks will compute index cardinalities and number-of-rows for the data in the file. (The file generally has rows, index records and/or tombstones for multiple tables/indexes).

For performance reasons, statistics are computed based on a fraction of rows in the LSM file. The percentage of rows used is controlled by `rocksdb_table_stats_sampling_pct`; the default value is 10%.

Before the data is dumped into LSM file, it is stored in the MemTable. MemTable doesn't allow computing index cardinalities, but it can provide an approximate number of rows in the table. Use of MemTable data for statistics is controlled by `rocksdb_force_compute_memtable_stats`; the default value is `ON`.

Are index statistics predictable?

Those who create/run MTR tests, need to know whether EXPLAIN output is deterministic. For MyRocks tables, the answer is NO (just like for InnoDB).

Statistics are computed using sampling and `GetApproximateMemTableStats()` which means that the `#rows` column in the EXPLAIN output may vary slightly.

Records-in-range estimates

MyRocks uses RocksDB's `GetApproximateSizes()` call to produce an estimate for the number of rows in the certain range. The data in MemTable is also taken into account by issuing a `GetApproximateMemTableStats` call.

ANALYZE TABLE

ANALYZE TABLE will possibly flush the MemTable (depending on the `rocksdb_flush_memtable_on_analyze` and `rocksdb_pause_background_work` settings).

After that, it will re-read statistics from the SST files and re-compute the summary numbers (TODO: and if the data was already on disk, the result should not be different from the one we had before ANALYZE?)

Debugging helper variables

There are a few variables that will cause MyRocks to report certain pre-defined estimate numbers to the optimizer:

- `@@rocksdb_records_in_range` - if not 0, report that any range has this many rows
- `@@rocksdb_force_index_records_in_range` - if not 0, and FORCE INDEX hint is used, report that any range has this

many rows.

- `@@rocksdb_debug_optimizer_n_rows` - if not 0, report that any MyRocks table has this many rows.

5.3.14.11 Differences Between MyRocks Variants

MyRocks is available in

- Facebook's (FB) MySQL branch (originally based on MySQL 5.6)
- MariaDB (from 10.2 and 10.3)
- Percona Server from 5.7

This page lists differences between these variants.

This is a work in progress. The contents are not final

Contents

1. [RocksDB Data Location](#)
2. [Compression Algorithms](#)
3. [RocksDB Version Information](#)
4. [RocksDB Version](#)
5. [Binlog Position in `information_schema.rocksdb_global_info`](#)
6. [Gap Lock Detector](#)
7. [Generated Columns](#)
8. [`rpl_skip_tx_api`](#)
9. [Details](#)

RocksDB Data Location

FB and Percona store RocksDB files in `$datadir/.rocksdb`. MariaDB puts them in `$datadir/#rocksdb`. This is more friendly for packaging and OS scripts.

Compression Algorithms

- FB's branch doesn't provide binaries. One needs to compile it with appropriate compression libraries.
- In MariaDB, available compression algorithms can be seen in the `rocksdb_supported_compression_types` variable. From [MariaDB 10.7](#), algorithms can be [installed as a plugin](#). In earlier versions, the set of supported compression algorithms depends on the platform.
 - On Ubuntu 16.04 (current LTS) it is `Snappy, Zlib, LZ4, LZ4HC`.
 - On CentOS 7.4 it is `Snappy, Zlib`.
 - In the bintar tarball it is `Snappy, Zlib`.
- Percona Server supports: `Zlib, ZSTD, LZ4` (the default), `LZ4HC`. **Unsupported algorithms:** `Snappy, BZip2, XPress`.

RocksDB Version Information

- FB's branch provides the `rocksdb_git_hash` `*status*` variable.
- MariaDB provides the `@@rocksdb_git_hash` `*system*` variable.
- Percona Server doesn't provide either.

RocksDB Version

- Facebook's branch uses RocksDB 5.10.0 (the version number can be found in `include/rocksdb/version.h`)

```
commit ba295cda29daee3ffe58549542804efdfd969784
Author: Andrew Kryczka <[email protected]>
Date: Fri Jan 12 11:03:55 2018 -0800
```

- MariaDB currently uses 5.8.0

```
commit 9a970c81af9807071bd690f4c808c5045866291a
Author: Yi Wu <[email protected]>
Date: Wed Sep 13 17:21:35 2017 -0700
```

- Percona Server uses 5.8.0

```
commit ab0542f5ec6e7c7e405267eaa2e2a603a77d570b
Author: Maysam Yabandeh <[email protected]>
Date: Fri Sep 29 07:55:22 2017 -0700
```

Binlog Position in information_schema.rocksdb_global_info

- FB branch provides information_schema.rocksdb_global_info type=BINLOG, NAME={FILE, POS, GTID}.
- Percona Server doesn't provide it.
- MariaDB doesn't provide it.

One use of that information is to take the output of `myrocks_hotbackup` and make it a new master.

Gap Lock Detector

- FB branch has a "Gap Lock Detector" feature. It is at the SQL layer. It can be controlled with `gap_lock_XXX` variables and is disabled by default (`gap-lock-raise-error=false`, `gap-lock-write-lock=false`).
- Percona Server has gap lock checking ON but doesn't seem to have any way to control it? Queries that use Gap Lock on MyRocks fail with an error like this:

```
insert into tbl2 select * from tbl1;
ERROR 1105 (HY000): Using Gap Lock without full unique key in multi-table or multi-statement
transactions
is not allowed. You need to either rewrite queries to use all unique key columns in WHERE equal
conditions,
or rewrite to single-table, single-statement transaction. Query: insert into tbl2 select *
from tbl1
```

- MariaDB doesn't include the Gap Lock Detector.

Generated Columns

- Both MariaDB and Percona Server support [generated columns](#), but neither one supports them for the MyRocks storage engine (attempts to create a table will produce an error).
- [Invisible columns](#) in [MariaDB 10.3](#) are supported (as they are an SQL layer feature).

rpl_skip_tx_api

Facebook's branch has a performance feature for replication slaves, `rpl_skip_tx_api`. It is not available in MariaDB or in Percona Server.

Details

The above comparison was made using

- FB/MySQL 5.6.35
- Percona Server 5.7.20-19-log
- [MariaDB 10.2.13](#) [↗](#) (MyRocks is beta)

5.3.14.12 MyRocks and Bloom Filters

Contents

1. Bloom Filter Parameters
 1. Computing Prefix Length
2. Configuring Bloom Filter
3. Checking if Bloom Filter is Useful

Bloom filters are used to reduce read amplification. Bloom filters can be set on a per-column family basis (see [myrocks-column-families](#)).

Bloom Filter Parameters

- How many bits to use
- `whole_key_filtering=true/false`
- Whether the bloom filter is for the entire key or for the prefix. In case of a prefix, you need to look at the index definition and compute the desired prefix length.

Computing Prefix Length

- It's 4 bytes for `index_nr`
- Then, for fixed-size columns (integer, date[time], decimal) it is `key_length` as shown by `EXPLAIN`. For VARCHAR columns, determining the length is tricky (It depends on the values stored in the table. Note that MyRocks encodes VARCHARs with "Variable-Length Space-Padded Encoding" format).

Configuring Bloom Filter

To enable 10-bit bloom filter for 8-byte prefix length for column family "cf1", put this into `my.cnf`:

```
rocksdb_override_cf_options='cfl={block_based_table_factory=
{filter_policy=bloomfilter:10:false;whole_key_filtering=0};prefix_extractor=capped:8};'
```

and restart the server.

Check if the column family actually uses the bloom filter:

```
select *
from information_schema.rocksdb_cf_options
where
  cf_name='cf1' and
  option_type IN ('TABLE_FACTORY::FILTER_POLICY', 'PREFIX_EXTRACTOR');
```

```
+-----+-----+-----+
| CF_NAME | OPTION_TYPE | VALUE |
+-----+-----+-----+
| cf1     | PREFIX_EXTRACTOR | rocksdb.CappedPrefix.8 |
| cf1     | TABLE_FACTORY::FILTER_POLICY | rocksdb.BuiltinBloomFilter |
+-----+-----+-----+
```

Checking if Bloom Filter is Useful

Watch these status variables:

```
show status like '%bloom%';
+-----+-----+-----+
| Variable_name | Value |
+-----+-----+-----+
| Rocksdb_bloom_filter_prefix_checked | 1 |
| Rocksdb_bloom_filter_prefix_useful | 0 |
| Rocksdb_bloom_filter_useful | 0 |
+-----+-----+-----+
```

Other useful variables are:

- `rocksdb_force_flush_memtable_now` - bloom filter is only used when reading data from disk. If you are doing testing, flush the data to disk first.

- `rocksdb_skip_bloom_filter_on_read` - skip using the bloom filter (default is FALSE).

5.3.14.13 MyRocks and CHECK TABLE

MyRocks supports the `CHECK TABLE` command.

The command will do a number of checks to verify that the table data is self-consistent.

The details about the errors are printed into the `error log`. If `log_warnings > 2`, the error log will also have some informational messages which can help with troubleshooting.

Besides this, RocksDB has its own (low-level) log in `#rocksdb/LOG` file.

5.3.14.14 MyRocks and Data Compression

Contents

1. [Supported Compression Algorithms](#)
2. [Compression Settings](#)
 1. [Checking Compression Settings](#)
 2. [Modifying Compression Settings](#)
 3. [Caveat: Syntax Errors](#)
3. [Checking How the Data is Compressed](#)

MyRocks supports several compression algorithms.

Supported Compression Algorithms

Supported compression algorithms can be checked like so:

```
show variables like 'rocksdb%compress%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| rocksdb_supported_compression_types | Snappy,Zlib,LZ4,LZ4HC,ZSTDNotFinal |
+-----+-----+
```

Another way to make the check is to look into `#rocksdb/LOG` file in the data directory. It should have lines like:

```
2019/04/12-14:08:23.869919 7f839188b540 Compression algorithms supported:
2019/04/12-14:08:23.869920 7f839188b540 kZSTDNotFinalCompression supported: 1
2019/04/12-14:08:23.869922 7f839188b540 kZSTD supported: 1
2019/04/12-14:08:23.869923 7f839188b540 kXpressCompression supported: 0
2019/04/12-14:08:23.869924 7f839188b540 kLZ4HCCompression supported: 1
2019/04/12-14:08:23.869924 7f839188b540 kLZ4Compression supported: 1
2019/04/12-14:08:23.869925 7f839188b540 kBZip2Compression supported: 0
2019/04/12-14:08:23.869926 7f839188b540 kZlibCompression supported: 1
2019/04/12-14:08:23.869927 7f839188b540 kSnappyCompression supported: 1
```

Compression Settings

Compression is set on a per-Column Family basis. See [MyRocks Column Families](#).

Checking Compression Settings

To check current compression settings for a column family one can use a query like so:

```
select * from information_schema.rocksdb_cf_options
where option_type like '%compression%' and cf_name='default';
```

The output will be like:

CF_NAME	OPTION_TYPE	VALUE
default	COMPRESSION_TYPE	kSnappyCompression
default	COMPRESSION_PER_LEVEL	NUL
default	COMPRESSION_OPTS	-14:32767:0
default	BOTTOMMOST_COMPRESSION	kDisableCompressionOption
default	TABLE_FACTORY::VERIFY_COMPRESSION	0
default	TABLE_FACTORY::ENABLE_INDEX_COMPRESSION	1

Current column family settings will be used for the new SST files.

Modifying Compression Settings

Compression settings are not dynamic parameters, one cannot change them by setting [rocksdb_update_cf_options](#).

The procedure to change compression settings is as follows:

- Edit `my.cnf` to set [rocksdb_override_cf_options](#).

Example:

```
rocksdb-override-cf-options='cfl={compression=kZSTD;bottommost_compression=kZSTD;}'
```

- Restart the server.

The data will not be re-compressed immediately. However, all new SST files will use the new compression settings, so as data gets inserted/updated the column family will gradually start using the new option.

Caveat: Syntax Errors

Please note that `rocksdb-override-cf-options` syntax is quite strict. Any typos will result in the parse error, and MyRocks plugin will not be loaded. Depending on your configuration, the server may still start. If it does start, you can use this command to check if the plugin is loaded:

```
select * from information_schema.plugins where plugin_name='ROCKSDB'
```

(note that you need the "ROCKSDB" plugin. Other auxiliary plugins like "ROCKSDB_TRX" might still get loaded).

Another way is to detect the error is check the error log. When option parsing fails, it will contain messages like so:

```
2019-04-16 11:07:57 140283675678016 [Warning] Invalid cf config for cfl in override options
(options: cfl={compression=kLZ4Compression;bottommost_compression=kZSTDCompression;})
2019-04-16 11:07:57 140283675678016 [ERROR] RocksDB: Failed to initialize CF options map.
2019-04-16 11:07:57 140283675678016 [ERROR] Plugin 'ROCKSDB' init function returned error.
2019-04-16 11:07:57 140283675678016 [ERROR] Plugin 'ROCKSDB' registration as a STORAGE ENGINE
failed.
```

Checking How the Data is Compressed

A query to check what compression is used in the SST files that store the data for a given table (test.t1):

```
select
  SP.sst_name, SP.compression_algo
from
  information_schema.rocksdb_sst_props SP,
  information_schema.rocksdb_ddl D,
  information_schema.rocksdb_index_file_map IFM
where
  D.table_schema='test' and D.table_name='t1' and
  D.index_number= IFM.index_number and
  IFM.sst_name=SP.sst_name;
```

Example output:

```

+-----+-----+
| sst_name | compression_algo |
+-----+-----+
| 000028.sst | Snappy |
| 000028.sst | Snappy |
| 000026.sst | Snappy |
| 000026.sst | Snappy |
+-----+-----+

```

5.3.14.15 MyRocks and Index-Only Scans

Contents

1. [Secondary Keys Only](#)
2. [Background: Mem-Comparable Keys](#)
3. [Index-Only Support for Various Datatypes](#)
4. [Index-Only Support for Various Collations](#)
 1. [1. Binary \(Reversible\) Collations](#)
 2. [2. Restorable Collations](#)
 3. [3. All Other Collations](#)
5. [Covering Secondary Key Lookups for VARCHARs](#)

This article is about [MyRocks](#) and index-only scans on secondary indexes. It applies to MariaDB's MyRocks, Facebook's MyRocks, and other variants.

Secondary Keys Only

The primary key in MyRocks is always the clustered key, that is, the index record is THE table record and so it's not possible to do "index only" because there isn't anything that is not in the primary key's (Key,Value) pair.

Secondary keys may or may not support index-only scans, depending on the datatypes of the columns that the query is trying to read.

Background: Mem-Comparable Keys

MyRocks indexes store "mem-comparable keys" (that is, the key values are compared with `memcmp`). For some datatypes, it is easily possible to convert between the column value and its mem-comparable form, while for others the conversion is one-way.

For example, in case-insensitive collations capital and regular letters are considered identical, i.e. 'c'='C'. For some datatypes, MyRocks stores some extra data which allows it to restore the original value back. (For the `latin1_general_ci` collation and character 'c', for example, it will store one bit which says whether the original value was a small 'c' or a capital letter 'C'). This doesn't work for all datatypes, though.

Index-Only Support for Various Datatypes

Index-only scans are supported for numeric and date/time datatypes. For CHAR and VAR[CHAR], it depends on which collation is used, see below for details.

Index-only scans are currently not supported for less frequently used datatypes, like

- `BIT(n)`
- `SET(...)`
- `ENUM(...)` *It is actually possible to add support for those, feel free to write a patch or at least make a case why a particular datatype is important*

Index-Only Support for Various Collations

As far as Index-only support is concerned, MyRocks distinguishes three kinds of collations:

- 1. Binary (Reversible) Collations

These are `binary`, `latin1_bin`, and `utf8_bin`.

For these collations, it is possible to convert a value back from its mem-comparable form. Hence, one can restore the

original value back from its index record, and index-only scans are supported.

- 2. Restorable Collations

These are collations where one can store some extra information which helps to restore the original value.

Criteria (from storage/rocksdb/rdb_datadic.cc, rdb_is_collation_supported()) are:

- The charset should use 1-byte characters (so, unicode-based collations are not included)
- `strxfrm(1 byte) = {one 1-byte weight value always}`
- no binary sorting
- PAD attribute

The examples are: `latin1_general_ci`, `latin1_general_cs`, `latin1_swedish_ci`, etc.

Index-only scans are supported for these collations.

- 3. All Other Collations

For these collations, there is no known way to restore the value from its mem-comparable form, and so index-only scans are not supported.

MyRocks needs to fetch the clustered PK record to get the field value.

Covering Secondary Key Lookups for VARCHARs

TODO: there is also this optimization:

<https://github.com/facebook/mysql-5.6/issues/303> <https://github.com/facebook/mysql-5.6/commit/f349c95848e92b5b27b44f0e57194100eb0997e7>

document it.

5.3.14.16 MyRocks and START TRANSACTION WITH CONSISTENT SNAPSHOT

FB/MySQL has added new syntax:

```
START TRANSACTION WITH CONSISTENT ROCKSDB | INNODB SNAPSHOT;
```

The statement returns the binlog coordinates pointing at the snapshot.

MariaDB (and Percona Server) support extension to the regular

```
START TRANSACTION WITH CONSISTENT SNAPSHOT;
```

syntax as documented in [Enhancements for START TRANSACTION WITH CONSISTENT SNAPSHOT](#).

After issuing the statement, one can examine the `binlog_snapshot_file` and `binlog_snapshot_position` status variables to see the binlog position that corresponds to the snapshot.

5.3.14.17 MyRocks Column Families

MyRocks stores data in column families. These are similar to tablespaces. By default, the data is stored in the `default` column family.

One can specify which column family the data goes to by using index comments:

```
INDEX index_name (col1, col2, ...) COMMENT 'column_family_name'
```

Contents

1. [Reasons for Column Families](#)
2. [Creating a Column Family](#)
3. [Dropping a Column Family](#)
4. [Setting Column Family Parameters](#)
 1. [rocksdb_override_cf_options](#)
5. [Examining Column Family Parameters](#)

If the column name starts with `rev:`, the column family is reverse-ordered.

Reasons for Column Families

Storage parameters like

- Bloom filter settings
- Compression settings
- Whether the data is stored in reverse order

are specified on a per-column family basis.

Creating a Column Family

When creating a table or index, you can specify the name of the column family for it. If the column family doesn't exist, it will be automatically created.

Dropping a Column Family

There is currently no way to drop a column family. RocksDB supports this internally but MyRocks doesn't provide any way to do it.

Setting Column Family Parameters

Use these variables:

- [rocksdb_default_cf_options](#) - a my.cnf parameter specifying default options for all column families.
- [rocksdb_override_cf_options](#) - a my.cnf parameter specifying per-column family option overrides.
- [rocksdb_update_cf_options](#) - a dynamically-settable variable which allows to change parameters online. Not all parameters can be changed.

rocksdb_override_cf_options

This parameter allows one to override column family options for specific column families. Here is an example of how to set `option1=value1` and `option2=value` for column family `cf1`, and `option3=value3` for column family `cf3`:

```
rocksdb_override_cf_options='cf1={option1=value1;option2=value2};cf2={option3=value3}'
```

One can check the contents of `INFORMATION_SCHEMA.ROCKSDB_CF_OPTIONS` to see what options are available.

Options that are frequently configured are:

- Data compression. See [myrocks-and-data-compression](#).
- Bloom Filters. See [myrocks-and-bloom-filters](#).

Examining Column Family Parameters

See the `INFORMATION_SCHEMA.ROCKSDB_CF_OPTIONS` table.

5.3.14.18 MyRocks in MariaDB 10.2 vs MariaDB 10.3

MyRocks storage engine itself is identical in [MariaDB 10.2](#) and [MariaDB 10.3](#).

[MariaDB 10.3](#) has a feature that should be interesting for MyRocks users. It is the `gtid_pos_auto_engines` option ([MDEV-](#)

12179 [🔗](#)). This is a performance feature for replication slaves that use multiple transactional storage engines.

For further information, see [mysql.gtid_slave_pos table](#).

5.3.14.19 MyRocks Performance Troubleshooting

Contents

- 1. [Status Variables](#)
- 2. [SHOW ENGINE ROCKSDB STATUS](#)
- 3. [Performance Context](#)

MyRocks exposes its performance metrics through several interfaces:

- Status variables
- SHOW ENGINE ROCKSDB STATUS
- RocksDB's perf context

the contents slightly overlap, but each source has its own unique information, so be sure to check all three.

Status Variables

Check the output of

```
SHOW STATUS like 'Rocksdb%'
```

See [MyRocks Status Variables](#) for more information.

SHOW ENGINE ROCKSDB STATUS

This produces a lot of information.

One particularly interesting part is compaction statistics. It shows the amount of data on each SST level and other details:

```
***** 4. row *****
Type: CF_COMPACTIION
Name: default
Status:
** Compaction Stats [default] **
Level   Files   Size      Score Read(GB)  Rn(GB) Rnp1(GB) Write(GB) Wnew(GB) Moved(GB) W-Amp
Rd(MB/s) Wr(MB/s) Comp(sec) Comp(cnt) Avg(sec) KeyIn KeyDrop
-----

Performance Context

RocksDB has an internal mechanism called "perf context". The counter values are exposed through two tables:

- [INFORMATION_SCHEMA.ROCKSDB_PERF_CONTEXT_GLOBAL](#) - global counters
- [INFORMATION_SCHEMA.ROCKSDB_PERF_CONTEXT](#) - Per-table/partition counters

By default statistics are NOT collected. One needs to set [rocksdb_perf_context_level](#) to some value (e.g. 3) to enable collection.

5.3.15 OQGRAPH

The Open Query GRAPH computation engine, or OQGRAPH as the engine itself is called, allows you to handle hierarchies (tree structures) and complex graphs (nodes having many connections in several directions).

OQGRAPH Version	Introduced	Maturity
3.0	MariaDB 10.0.25	Gamma
3.0	MariaDB 10.0.7	Beta
2.0	MariaDB 5.2.1	

Installing OQGRAPH

5.3.15.1 Installing OQGRAPH

Contents

- [Installation](#)
 - [Debian and Ubuntu](#)
 - [Fedora/Red Hat/CentOS](#)
 - [Installing the Plugin](#)

The Open Query GRAPH computation engine, or OQGRAPH as the engine itself is called, allows you to handle hierarchies (tree structures) and complex graphs (nodes having many connections in several directions).

Installation

The OQGRAPH storage engine exists as a separate package in the repositories for [MariaDB 10.0.7](#) and later. On Ubuntu and Debian the package is called `mariadb-oqgraph-engine-10.0` or `mariadb-plugin-oqgraph`. On Red Hat, CentOS, and Fedora the package is called `MariaDB-oqgraph-engine`. To install the plugin, first install the appropriate package and then install the plugin using the `INSTALL SONAME` or `INSTALL PLUGIN` commands.

Debian and Ubuntu

On Debian and Ubuntu, install the package as follows:

```
sudo apt-get install mariadb-plugin-oqgraph
```

or (for [MariaDB 10.0](#))

```
sudo apt-get install mariadb-oqgraph-engine-10.0
```

Fedora/Red Hat/CentOS

Note that OQGRAPH v3 requires libjudy, which is not in the official Red Hat/Fedora repositories. This needs to be installed first, for example:

```
wget http://dl.fedoraproject.org/pub/epel/6/x86_64/epel-release-6-8.noarch.rpm
rpm -Uvh epel-release-6-8.noarch.rpm
```

Then install the package, as follows:

```
sudo yum install MariaDB-oqgraph-engine
```

Installing the Plugin

On either system you can then launch the `mysql` command-line client and install the plugin in MariaDB as follows:

```
INSTALL SONAME 'ha_oqgraph';
```

5.3.15.2 OQGRAPH Overview

Contents

1. [Installing](#)
2. [Creating a Table](#)
3. [Example with origin and destination nodes only](#)
4. [Manipulating Weight](#)

The Open Query GRAPH computation engine, or OQGRAPH as the engine itself is called, allows you to handle hierarchies (tree structures) and complex graphs (nodes having many connections in several directions).

OQGRAPH is unlike other storage engines, consisting of an entirely different architecture to a regular storage engine such as Aria, MyISAM or InnoDB.

It is intended to be used for retrieving hierarchical information, such as those used for graphs, routes or social relationships, in plain SQL.

Installing

See [Installing OQGRAPH](#). Note that if the [query cache](#) is enabled, OQGRAPH will not use it.

Creating a Table

The following documentation is based upon [MariaDB 10.0.7](#) and OQGRAPH v3.

Example with origin and destination nodes only

To create an OQGRAPH v3 table, a backing table must first be created. This backing table will store the actual data, and will be used for all INSERTs, UPDATEs and so on. It must be a regular table, not a view. Here's a simple example to start with:

```
CREATE TABLE oq_backing (
  origid INT UNSIGNED NOT NULL,
  destid INT UNSIGNED NOT NULL,
  PRIMARY KEY (origid, destid),
  KEY (destid)
);
```

Some data can be inserted into the backing table to test with later:

```
INSERT INTO oq_backing(origid, destid)
VALUES (1,2), (2,3), (3,4), (4,5), (2,6), (5,6);
```

Now the read-only OQGRAPH table is created. The CREATE statement must match the format below - any difference will

result in an error.

```
CREATE TABLE oq_graph (
  latch VARCHAR(32) NULL,
  origid BIGINT UNSIGNED NULL,
  destid BIGINT UNSIGNED NULL,
  weight DOUBLE NULL,
  seq BIGINT UNSIGNED NULL,
  linkid BIGINT UNSIGNED NULL,
  KEY (latch, origid, destid) USING HASH,
  KEY (latch, destid, origid) USING HASH
)
ENGINE=OQGRAPH
data_table='oq_backing' origid='origid' destid='destid';
```

An older format (prior to [MariaDB 10.0.7](#)) has the latch field as a SMALLINT rather than a VARCHAR. The format gives an error:

```
CREATE TABLE oq_old (
  latch SMALLINT UNSIGNED NULL,
  origid BIGINT UNSIGNED NULL,
  destid BIGINT UNSIGNED NULL,
  weight DOUBLE NULL,
  seq BIGINT UNSIGNED NULL,
  linkid BIGINT UNSIGNED NULL,
  KEY (latch, origid, destid) USING HASH,
  KEY (latch, destid, origid) USING HASH
)
ENGINE=OQGRAPH
data_table='oq_backing' origid='origid' destid='destid';

ERROR 1005 (HY000): Can't create table `test`.`oq_old` (errno: 140 "Wrong create options")
```

The old, deprecated format can still be used prior to [MariaDB 11.5](#) if the value of the `oqgraph_allow_create_integer_latch` system variable is changed from its default, `FALSE`, to `TRUE`.

```
SET GLOBAL oqgraph_allow_create_integer_latch=1;

CREATE TABLE oq_old (
  latch SMALLINT UNSIGNED NULL,
  origid BIGINT UNSIGNED NULL,
  destid BIGINT UNSIGNED NULL,
  weight DOUBLE NULL,
  seq BIGINT UNSIGNED NULL,
  linkid BIGINT UNSIGNED NULL,
  KEY (latch, origid, destid) USING HASH,
  KEY (latch, destid, origid) USING HASH
)
ENGINE=OQGRAPH
data_table='oq_backing' origid='origid' destid='destid';
Query OK, 0 rows affected, 1 warning (0.19 sec)

SHOW WARNINGS;
+-----+-----+-----+
| Level  | Code | Message
|
+-----+-----+-----+
| Warning | 1287 | 'latch SMALLINT UNSIGNED NULL' is deprecated and will be removed in a future
release. Please use 'latch VARCHAR(32) NULL' instead |
+-----+-----+-----+
```

Data is only inserted into the backing table, not the OQGRAPH table.

Now, having created the `oq_graph` table linked to a backing table, it is now possible to query the `oq_graph` table directly. The `weight` field, since it was not specified in this example, defaults to `1`.

```
SELECT * FROM oq_graph;
+-----+-----+-----+-----+-----+-----+
| latch | origid | destid | weight | seq | linkid |
+-----+-----+-----+-----+-----+-----+
| NULL  | 1      | 2      | 1      | NULL | NULL    |
| NULL  | 2      | 3      | 1      | NULL | NULL    |
| NULL  | 2      | 6      | 1      | NULL | NULL    |
| NULL  | 3      | 4      | 1      | NULL | NULL    |
| NULL  | 4      | 5      | 1      | NULL | NULL    |
| NULL  | 5      | 6      | 1      | NULL | NULL    |
+-----+-----+-----+-----+-----+-----+
```

The data here represents one-directional starting and ending nodes. So node 2 has paths to node 3 and node 6, while node 6 has no paths to any other node.

Manipulating Weight

There are three fields which can be manipulated: `origid`, `destid` (the example above uses these two), as well as `weight`. To create a backing table with a `weight` field as well, the following syntax can be used:

```
CREATE TABLE oq2_backing (
  origid INT UNSIGNED NOT NULL,
  destid INT UNSIGNED NOT NULL,
  weight DOUBLE NOT NULL,
  PRIMARY KEY (origid, destid),
  KEY (destid)
);
```

```
INSERT INTO oq2_backing(origid, destid, weight)
VALUES (1,2,1), (2,3,1), (3,4,3), (4,5,1), (2,6,10), (5,6,2);
```

```
CREATE TABLE oq2_graph (
  latch VARCHAR(32) NULL,
  origid BIGINT UNSIGNED NULL,
  destid BIGINT UNSIGNED NULL,
  weight DOUBLE NULL,
  seq BIGINT UNSIGNED NULL,
  linkid BIGINT UNSIGNED NULL,
  KEY (latch, origid, destid) USING HASH,
  KEY (latch, destid, origid) USING HASH
)
ENGINE=OQGRAPH
data_table='oq2_backing' origid='origid' destid='destid' weight='weight';
```

```
SELECT * FROM oq2_graph;
+-----+-----+-----+-----+-----+-----+
| latch | origid | destid | weight | seq | linkid |
+-----+-----+-----+-----+-----+-----+
| NULL  | 1      | 2      | 1      | NULL | NULL    |
| NULL  | 2      | 3      | 1      | NULL | NULL    |
| NULL  | 2      | 6      | 10     | NULL | NULL    |
| NULL  | 3      | 4      | 3      | NULL | NULL    |
| NULL  | 4      | 5      | 1      | NULL | NULL    |
| NULL  | 5      | 6      | 2      | NULL | NULL    |
+-----+-----+-----+-----+-----+-----+
```

See [OQGRAPH Examples](#) for OQGRAPH usage examples.

5.3.15.3 OQGRAPH Examples

Contents

- [1. Creating a Table with origid, destid Only](#)
- [2. Creating a Table with Weight](#)
- [3. Shortest Path](#)
- [4. Possible Destinations](#)
- [5. Leaf Nodes](#)
- [6. Summary of Implemented Latch Commands](#)

Creating a Table with origid, destid Only

```
CREATE TABLE oq_backing (  
  origid INT UNSIGNED NOT NULL,  
  destid INT UNSIGNED NOT NULL,  
  PRIMARY KEY (origid, destid),  
  KEY (destid)  
);
```

Some data can be inserted into the backing table to test with later:

```
INSERT INTO oq_backing(origid, destid)  
VALUES (1,2), (2,3), (3,4), (4,5), (2,6), (5,6);
```

Now the read-only **OQGRAPH** table is created.

From [MariaDB 10.1.2](#) onwards you can use the following syntax:

```
CREATE TABLE oq_graph  
ENGINE=OQGRAPH  
data_table='oq_backing' origid='origid' destid='destid';
```

Prior to [MariaDB 10.1.2](#), the **CREATE** statement must match the format below - any difference will result in an error.

```
CREATE TABLE oq_graph (  
  latch VARCHAR(32) NULL,  
  origid BIGINT UNSIGNED NULL,  
  destid BIGINT UNSIGNED NULL,  
  weight DOUBLE NULL,  
  seq BIGINT UNSIGNED NULL,  
  linkid BIGINT UNSIGNED NULL,  
  KEY (latch, origid, destid) USING HASH,  
  KEY (latch, destid, origid) USING HASH  
)  
ENGINE=OQGRAPH  
data_table='oq_backing' origid='origid' destid='destid';
```

Creating a Table with Weight

For the examples on this page, we'll create a second OQGRAPH table and backing table, this time with `weight` as well.

```
CREATE TABLE oq2_backing (  
  origid INT UNSIGNED NOT NULL,  
  destid INT UNSIGNED NOT NULL,  
  weight DOUBLE NOT NULL,  
  PRIMARY KEY (origid, destid),  
  KEY (destid)  
);
```

```
INSERT INTO oq2_backing(origid, destid, weight)  
VALUES (1,2,1), (2,3,1), (3,4,3), (4,5,1), (2,6,10), (5,6,2);
```

```
CREATE TABLE oq2_graph (
  latch VARCHAR(32) NULL,
  origid BIGINT UNSIGNED NULL,
  destid BIGINT UNSIGNED NULL,
  weight DOUBLE NULL,
  seq BIGINT UNSIGNED NULL,
  linkid BIGINT UNSIGNED NULL,
  KEY (latch, origid, destid) USING HASH,
  KEY (latch, destid, origid) USING HASH
)
ENGINE=OQGRAPH
data_table='oq2_backing' origid='origid' destid='destid' weight='weight';
```

Shortest Path

A `latch` value of `'dijkstras'` and an `origid` and `destid` is used for finding the shortest path between two nodes, for example:

```
SELECT * FROM oq_graph WHERE latch='breadth_first' AND origid=1 AND destid=6;
+-----+-----+-----+-----+-----+
| latch  | origid | destid | weight | seq  | linkid |
+-----+-----+-----+-----+-----+
| dijkstras|      1 |      6 |  NULL  |    0 |      1 |
| dijkstras|      1 |      6 |    1   |    1 |      2 |
| dijkstras|      1 |      6 |    1   |    2 |      6 |
+-----+-----+-----+-----+-----+
```

Note that nodes are uni-directional, so there is no path from node 6 to node 1:

```
SELECT * FROM oq_graph WHERE latch='dijkstras' AND origid=6 AND destid=1;
Empty set (0.00 sec)
```

Using the [GROUP_CONCAT](#) function can produce more readable results, for example:

```
SELECT GROUP_CONCAT(linkid ORDER BY seq) AS path FROM oq_graph
WHERE latch='dijkstras' AND origid=1 AND destid=6;
+-----+
| path  |
+-----+
| 1,2,6 |
+-----+
```

Using the table `oq2_graph`, the shortest path is different:

```
SELECT GROUP_CONCAT(linkid ORDER BY seq) AS path FROM oq2_graph
WHERE latch='dijkstras' AND origid=1 AND destid=6;
+-----+
| path  |
+-----+
| 1,2,3,4,5,6 |
+-----+
```

The reason is the weight between nodes 2 and 6 is 10 in `oq_graph2`, so the shortest path taking into account `weight` is now across more nodes.

Possible Destinations

```
SELECT GROUP_CONCAT(linkid) AS dests FROM oq_graph WHERE latch='dijkstras' AND origid=2;
+-----+
| dests  |
+-----+
| 5,4,6,3,2 |
+-----+
```

Note that this returns all possible destinations along the path, not just immediate links.

Leaf Nodes

MariaDB 10.3.3 [↗](#)

Support for the `leaves` latch value was introduced in [MariaDB 10.3.3](#) [↗](#).

A `latch` value of `'leaves'` and either `origid` or `destid` is used for finding leaf nodes at the beginning or end of a graph.

```
INSERT INTO oq_backing(origid, destid)
VALUES (1,2), (2,3), (3,5), (4,5), (5,6), (6,7), (6,8), (2,8);
```

For example, to find all reachable nodes from `origid` that only have incoming edges:

```
SELECT * FROM oq_graph WHERE latch='leaves' AND origid=2;
+-----+-----+-----+-----+-----+-----+
| latch | origid | destid | weight | seq | linkid |
+-----+-----+-----+-----+-----+-----+
| leaves | 2 | NULL | 4 | 2 | 7 |
| leaves | 2 | NULL | 1 | 1 | 8 |
+-----+-----+-----+-----+-----+-----+
```

And to find all nodes from which a path can be found to `destid` that only have outgoing edges:

```
SELECT * FROM oq_graph WHERE latch='leaves' AND destid=5;
+-----+-----+-----+-----+-----+-----+
| latch | origid | destid | weight | seq | linkid |
+-----+-----+-----+-----+-----+-----+
| leaves | NULL | 5 | 3 | 2 | 1 |
| leaves | NULL | 5 | 1 | 1 | 4 |
+-----+-----+-----+-----+-----+-----+
```

Summary of Implemented Latch Commands

Latch	Alternative	additional where clause fields	Graph operation
NULL	(unspecified)	(none)	List original data
(empty string)	0	(none extra)	List all vertices in linkid column
(empty string)	0	origid	List all first hop vertices from origid in linkid column
dijkstras	1	origid, destid	Find shortest path using Dijkstras algorithm between origid and destid, with traversed vertex ids in linkid column
dijkstras	1	origid	Find all vertices reachable from origid, listed in linkid column, and report sum of weights of vertices on path to given vertex in weight
dijkstras	1	destid	Find all vertices from which a path can be found to destid, listed in linkid column, and report sum of weights of vertices on path to given vertex in weight
breadth_first	2	origid	List vertices reachable from origid in linkid column
breadth_first	2	destid	List vertices from which a path can be found to destid in linkid column
breadth_first	2	origid, destid	Find shortest path between origid and destid, report in linkid column
leaves	4	origid	List vertices reachable from origid, that only have incoming edges (from MariaDB 10.3.3 ↗)
leaves	4	destid	List vertices from which a path can be found to destid, that only have outgoing edges (from MariaDB 10.3.3 ↗)
leaves	4	origid, destid	Not supported, will return an empty result

Note: the use of integer latch commands is deprecated and may be phased out in a future release. Currently, numeric values in the strings are interpreted as aliases, and use of an integer column can be optionally allowed, for the latch commands column.

The use of integer latches is controlled using the [oqgraph_allow_create_integer_latch](#) system variable.

5.3.15.4 Compiling OQGRAPH

To compile OQGraph v2 you need to have the boost library with the versions not earlier than 1.40 and not later than 1.55 and gcc version not earlier than 4.5.

MariaDB starting with [10.0.7](#)

OQGraph v3 compiles fine with the newer boost libraries, but it additionally needs the Judy library installed.

When all build prerequisites are met, OQGraph is enabled and compiled automatically. To enable or disable OQGRAPH explicitly, see the generic [plugin build instructions](#).

Finding Out Why OQGRAPH Didn't Compile

If OQGRAPH gets compiled properly, there should be a file like:

```
storage/oqgraph/ha_oqgraph.so
```

If this is not the case, then you can find out if there is any modules missing that are required by OQGRAPH by doing:

```
cmake . -LAH | grep -i oqgraph
```

5.3.15.5 Building OQGRAPH Under Windows

OQGRAPH v3 can be built on Windows.

MariaDB starting with [10.0.11](#)

This has been tested using Windows 7, Microsoft Visual Studio Express 2010 (32-bit), Microsoft Windows 64-bit Platform SDK 7.1 (64-bit), the Boost library >= 1.55 and Judy 1.0.5. Probably other recent versions of Boost, Judy or MSVC may work but these combinations have not been tested.

- Download the source package for Boost 1.55 from the Boost project website, <http://www.boost.org>
- Download the source package for Judy 1.05 via <http://judy.sourceforge.net/>
- Follow the documented instructions for building under Windows from the command line:
[Building_MariaDB_on_Windows](#)
 - Ensure that the following variable is set to CMAKE: `JUDY_ROOT=path\to\judy\unzipped`
 - See also comments in `storage/oqgraph/cmake/FindJudy.cmake`

5.3.15.6 OQGRAPH System and Status Variables

Contents

1. [System Variables](#)
 1. [oqgraph_allow_create_integer_latch](#)
2. [Status Variables](#)
 1. [Oqgraph_boost_version](#)
 2. [Oqgraph_compat_mode](#)
 3. [Oqgraph_verbose_debug](#)

This page documents system and status variables related to the [OQGRAPH storage engine](#). See [Server Status Variables](#) and [Server System Variables](#) for complete list of all system and status variables.

System Variables

- **Description:** Created when the [OQGRAPH](#) storage engine is installed, if set to `1` (`0` is default), permits the `latch` field to be an integer (see [OQGRAPH Overview](#)). This deprecated feature was removed in [MariaDB 11.5](#).
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `0`
- **Removed:** [MariaDB 11.5](#).

Status Variables

`Oqgraph_boost_version`

- **Description:** [OQGRAPH](#) boost version.
- **Scope:** Global, Session
- **Data Type:** `string`

`Oqgraph_compat_mode`

- **Description:** Whether or not legacy tables with integer latches are supported.
- **Scope:** Global, Session
- **Data Type:** `string`

`Oqgraph_verbose_debug`

- **Description:** Whether or not verbose debugging is enabled. If it is, performance may be adversely impacted
- **Scope:** Global, Session
- **Data Type:** `string`

5.3.16 S3 Storage Engine

MariaDB starting with [10.5](#)
The [S3 storage engine](#) has been available since [MariaDB 10.5.4](#).

S3 is a read-only storage engine that stores its data in Amazon S3.

The [S3 storage engine](#) is read only and allows one to archive MariaDB tables in Amazon S3, or any third-party public or private cloud that implements S3 API (of which there are many), but still have them accessible for reading in MariaDB.

Installing the Plugin

As of [MariaDB 10.5.7](#), the S3 storage engine is currently [gamma maturity](#), so the following step can be omitted.

On earlier releases, when it was [alpha maturity](#), it will not load by default on a stable release of the server due to the default value of the [plugin_maturity](#) variable. Set to `alpha` (or below) in your config file to permit installation of the plugin:

```
[mariadb]
plugin-maturity = alpha
```

and restart the server.

Now [install the plugin library](#), for example:

```
INSTALL SONAME 'ha_s3';
```

If the library is not available, for example:

```
INSTALL SONAME 'ha_s3';
ERROR 1126 (HY000): Can't open shared library '/var/lib/mysql/lib64/mysql/plugin/ha_s3.so'
(errno: 13, cannot open shared object file: No such file or directory)
```

you may need to install a separate package for the S3 storage engine, for example:

```
shell> yum install MariaDB-s3-engine
```

or for Debian/Ubuntu

```
shell> apt install mariadb-plugin-s3
```

Creating an S3 table.

As S3 tables are read only, one cannot create a S3 table with `CREATE TABLE`. One should use instead use `ALTER TABLE old_table ENGINE=S3` to convert an existing table to be stored on S3.

Moving Data to S3

To move data from an existing table to S3, one can run:

```
ALTER TABLE old_table ENGINE=S3 COMPRESSION_ALGORITHM=zlib
```

To get data back to a 'normal' table one can do:

```
ALTER TABLE s3_table ENGINE=INNODB
```

New Options for `ALTER TABLE`

- `S3_BLOCK_SIZE` : Set to 4M as default. This is the block size for all index and data pages stored in S3.
- `COMPRESSION_ALGORITHM` : Set to 'none' as default. Which compression algorithm to use for block stored in S3. Options are: `none` or `zlib`.

`ALTER TABLE` can be used on S3 tables as normal to add columns or change column definitions.

mariadb Startup Options for S3

To be able to use S3 for storage one ***must*** define how to access S3 and where data are stored in S3:

- `s3_access_key`: The AWS access key to access your data
- `s3_secret_key`: The AWS secret key to access your data
- `s3_bucket`: The AWS bucket where your data should be stored. All MariaDB table data is stored in this bucket.
- `s3_region`: The AWS region where your data should be stored.

For compatibility tweaks with different providers:

- `s3_provider`: Enable S3 provider specific compatibility tweaks. "Default", "Amazon", or "Huawei". From [MariaDB 11.6.2](#).

If you are using an S3 service that is using HTTP to connect (like <https://min.io/>) you also need to set the following variables:

- `s3_port`: Port number to connect to (0 means use default)
- `s3_use_http`: If true, force use of HTTP protocol

If you are going to use a primary-replica setup, you should look at the following variables:

- `s3_replicate_alter_as_create_select`: When converting an S3 table to local table, log all rows in binary log. Defaults to `TRUE`. This allows the replica to replicate `CREATE TABLE .. SELECT FROM s3_table` even if the replica doesn't have access to the original `s3_table`.
- `s3_slave_ignore_updates`: Should be set if primary and replica share the same S3 instance. This tells the replica that it can ignore any updates to the S3 tables as they are already applied on the primary. Defaults to `FALSE`.

The above defaults assume that the primary and replica don't share the same S3 instance.

Other, less critical options, are:

- `s3_host_name`: Hostname for the S3 service. "s3.amazonaws.com", Amazon S3 service, by default.
- `s3_protocol_version`: Protocol used to communication with S3. One of "Auto", "Amazon" or "Original" where "Auto" is the default. If you get errors like "8 Access Denied" when you are connecting to another service provider, then try to change this option. The reason for this variable is that Amazon has changed some parts of the S3 protocol since they originally introduced it but other service providers are still using the original protocol.
- `s3_block_size`: Set to 4M as default. This is the default block size for a table, if not specified in `CREATE TABLE`.
- `s3_pagecache_buffer_size`: Default 128M. The size of the buffer used for data and index blocks for S3 tables. Increase this to get better index handling (for all reads and multiple writes) to as much as you can afford.
- `s3_ssl_no_verify`: If true, SSL certificate verification for the S3 endpoint is disabled. From [MariaDB 11.6.2](#).
- `ss3_no_content_type`: If true (false is default), disables the Content-Type header, required for some providers. From [MariaDB 11.6.2](#).

Last some options you probably don't have to ever touch:

- **s3_pagecache_age_threshold** : Default 300: This characterizes the number of hits a hot block has to be untouched until it is considered aged enough to be downgraded to a warm block. This specifies the percentage ratio of that number of hits to the total number of blocks in the page cache.
- **s3_pagecache_division_limit**: Default 100. The minimum percentage of warm blocks in key cache.
- **s3_pagecache_file_hash_size**: Default 512. Number of hash buckets for open files. If you have a lot of S3 files open you should increase this for faster flush of changes. A good value is probably 1/10 of number of possible open S3 files.
- **s3_debug**: Default 0. Generates a trace file from libmarias3 on stderr (mysqld.err) for debugging the S3 protocol.

Typical my.cnf Entry for connecting to Amazon S3 service

```
[mariadb]
s3=ON
s3-bucket=mariadb
s3-access-key=xxxx
s3-secret-key=xxx
s3-region=eu-north-1
s3-host-name=s3.amazonaws.com
# The following is useful if you want to use minio as a S3 server. (https://min.io/)
#s3-port=9000
#s3-use-http=ON

# Primary and replica share same S3 tables.
s3-slave-ignore-updates=1

[aria_s3_copy]
s3-bucket=mariadb
s3-access-key=xxxx
s3-secret-key=xxx
s3-region=eu-north-1
s3-host-name=s3.amazonaws.com
# The following is useful if you want to use minio as a S3 server. (https://min.io/)
#s3-port=9000
#s3-use-http=ON
```

Typical my.cnf entry for connecting to a [minio](#) S3 server

```
[mariadb]
s3=ON
s3-host-name="127.0.0.1"
s3-bucket=storage-engine
s3-access-key=minio
s3-secret-key=minioadmin
s3-port=9000
s3-use-http=ON

[aria_s3_copy]
s3=ON
s3-host-name="127.0.0.1"
s3-bucket=storage-engine
s3-access-key=minio
s3-secret-key=minioadmin
s3-port=9000
s3-use-http=ON
```

Typical Usage Case for S3 Tables

The typical use case would be that there exists tables that after some time would become fairly inactive, but are still important so that they can not be removed. In that case, an option is to move such a table to an archiving service, which is accessible through an S3 API.

Notice that S3 means the Cloud Object Storage API defined by Amazon AWS. Often the whole of Amazon's Cloud Object Storage is referred to as S3. In the context of the S3 archive storage engine, it refers to the API itself that defines how to store objects in a cloud service, being it Amazon's or someone else's. OpenStack for example provides an S3 API for storing objects.

The main benefit of storing things in an S3 compatible storage is that the cost of storage is much cheaper than many other alternatives. Many S3 implementations also provide reliable long-term storage.

Operations Allowed on S3 Tables

- **ALTER TABLE** S3 supports all types, keys and other options that are supported by the [Aria](#) engine. One can also perform **ALTER TABLE** on an S3 table to add or modify columns etc.
- **DROP TABLE**
- **SELECT** Any SELECT operations you can perform on a normal table should work with an S3 table.
- **SHOW TABLES** will show all tables that exist in the current defined S3 location.
- S3 tables can be part of [partitions](#). See Discovery below.

Discovery

The S3 storage engine supports full [MariaDB discovery](#). This means that if you have the S3 storage engine enabled and properly configured, the table stored in S3 will automatically be discovered when it's accessed with **SHOW TABLES**, **SELECT** or any other operation that tries to access it. In the case of SELECT, the .frm file from S3 will be copied to the local storage to speed up future accesses.

When an S3 table is opened for the first time (it's not in the table cache) and there is a local .frm file, the S3 engine will check if it's still relevant, and if not, update or delete the .frm file.

This means that if the table definition changes on S3 and it's in the local cache, one has to execute **FLUSH TABLES** to get MariaDB to notice the change and update the .frm file.

If partitioning S3 tables are used, the partition definitions will also be stored on S3 storage and will be discovered by other servers.

Discovery of S3 tables is not done for tables in the [mysql databases](#) to make mariadb boot faster and more securely.

Replication

S3 works with [replication](#). One can use replication in two different scenarios:

- The primary and replica share the same S3 storage. In this case the primary will make all changes to the S3 data and the replica will ignore any changes in the replication stream to S3 data. This scenario is achieved by setting [s3_slave_ignore_updates](#) to 1.
- The primary and replica don't share the same S3 storage or the replica uses another storage engine for the S3 tables. This scenario is achieved by setting [s3_slave_ignore_updates](#) to 0.

aria_s3_copy

[aria_s3_copy](#) is an external tool that one can use to copy [Aria](#) tables to and from S3. Use `aria_s3_copy --help` to get the options of how to use it.

mariadb-dump

- [mariadb-dump](#) will by default ignore S3 tables. If `mariadb-dump` is run with the `--copy-s3-tables` option, the resulting file will contain a CREATE statement for a similar [Aria](#) table, followed by the table data and ending with an `ALTER TABLE xxx ENGINE=S3.`

ANALYZE TABLE

As of [MariaDB 10.5.14](#), **ANALYZE TABLE** is supported for S3 tables. As the S3 tables are read-only, a normal `ANALYZE TABLE` will not do anything. However using `ANALYZE TABLE table_name PERSISTENT FOR...` will now work.

CHECK TABLE

As of [MariaDB 10.5.14](#), **CHECK TABLE** will work. As S3 tables are read only it is very unlikely that they can become corrupted. The only known way an S3 table could be corrupted if either the original table copied to S3 was corrupted or the process of copying the original table to S3 was somehow interrupted.

Current Limitations

- [mysql-test-run](#) doesn't by default test the S3 engine as we can't embed AWS keys into mysql-test-run.
- Replicas should not access S3 tables while they are ALTERed! This is because there is no locking implemented to S3

between servers. However, after a table (either the original S3 table or the partitioned S3 table) is changed on the primary, the replica will notice this on the next access and update its local definition.

Limitations in `ALTER .. PARTITION`

All `ALTER PARTITION` operations are supported on S3 partitioning tables except:

- REBUILD PARTITION
- TRUNCATE PARTITION
- REORGANIZE PARTITION

Performance Considerations

Depending on your connection speed to your S3 provider, there can be some notable slowdowns in some operations.

Discovery

As S3 is supporting discovery (automatically making tables available that are in S3) this can cause some small performance problems if the S3 engine is enabled. Partitioning S3 tables also support discovery.

- CREATE TABLE is a bit slower as the S3 engine has to check if the to-be-created table is already S3.
- Queries on information_schema tables are slower as S3 has to check if there is new tables in S3.
- DROP of non existing tables are slower as S3 has to check if the table is in S3.
